The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

NOTE

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Legacy Rx FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "Legacy FIFO Overflow" flag; bit 6 becomes the "Legacy FIFO Warning" flag, bit 5 becomes the "Frames Available in Legacy FIFO" flag and bits 4-0 are unused. See the description of Interrupt Flags 1 Register (IFLAG1) for more information.

If both Legacy Rx FIFO and DMA are enabled (MCR[RFEN] and MCR[DMA] = 1) the FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in Legacy FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register.

72.3.14 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table 459 in Supervisor Mode or with S only) results in an access error.
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.

- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  1. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  2. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0h, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0080h, and the space 0080h–008Fh is used by the one MB. The memory space 0090h–017Fh is available. The space 0180h–087Fh is reserved. The space 0880h–0883h is used by the one individual mask and the available memory in the mask registers space would be 0884h–08BFh. From 08C0h–09DFh there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.
  3. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

Table 457. Access permissions

1. Access in low power is only possible if RAM_clk and ipg_clk are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules below.

3. Write operation has no effect.
4. Enhanced Rx FIFO must not be accessed if MCR[RFEN] is set.

72.3.15 Detection and correction of memory errors

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, ranging from 080h–ADFh and from C20h–31FFh. The RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK registers need to be initialized as well. MCR[RFEN] and ERF[ERFEN] must not be set during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to five parity bits that ensure a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in two bits can be detected but not corrected (non-correctable errors). Errors in more than two bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

FlexCAN detects a noncorrectable error in the event either an all-zeros or an all-ones read occurs. See description of Error Report Syndrome Register (RERRSYNR).

Memory errors are indicated to the host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address register (RERRAR), Error Report Data register (RERRDR) and Error Report Syndrome register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by MECR[ECCDIS]. When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated with the data.

To avoid accidentally changing the critical error correction configuration, this protocol must be followed to enable the update of the Memory Error Control register (MECR):

1. By default, CTRL2[ECRWRE] is zero and MECR[ECRWRDIS] is one.
2. Set CTRL2[ECRWRE].
3. Clear MECR[ECRWRDIS].
4. All writes to Memory Error Control register (MECR) must keep MECR[ECRWRDIS] cleared.
5. After configuration is done, lock the Memory Error Control register (MECR) by either setting MECR[ECRWRDIS] or clearing CTRL2[ECRWRE].

72.3.15.1 Sources of the memory access

The FlexCAN memory can be accessed by two major sources (or requestors):

- Host (CPU): the largest word accessed is 32-bit.
- FlexCAN internal processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): the largest word accessed is 64-bit.

The way that noncorrectable errors are indicated and reported depends on the source of access.

72.3.15.2 Error indication

Memory errors are indicated by flags HANCEIF, FANCEIF, and CEIF in the Error Status Register (ERRSR). Noncorrectable errors detected in memory reads requested by the host are indicated separately than the ones detected in requests by FlexCAN internal processes. FlexCAN makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both noncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

A noncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit ERRSR[HANCEIF] is not masked, the same noncorrectable error will raise a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status Register (ERRSR). The overrun flags do not request interrupts. Overrun flags for noncorrectable errors indicate that other errors of the same nature were detected after current error being treated; overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

This is the recommended handling sequence for error indication:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the HANCEIF, FANCEIF, and CEIF flags.
4. If the overrun flag is active:
    a. Alert application that at least one error could not be managed.
    b. Clear the overrun flag.

The FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words the interrupt and overrun flags are set simultaneously.

72.3.15.3 Error reporting

The report registers Error Report Address register (RERRAR), Error Report Data register (RERRDR), and Error Report Syndrome register (RERRSYNR) provide detailed information about the address read, raw data, and syndrome read with error, and are indicated by the flags described in Error indication. The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If either of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error; or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32-bit follows the rules described in Error indication and in the description of Error Report Address Register (RERRAR).

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address Register (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs, such as the Legacy Rx FIFO Structure, Enhanced RX FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by setting MECR[RERRDIS] before reading the report registers.

72.3.15.4 Response to errors

Correctable errors have no consequence on FlexCAN operation because affected data is corrected before its use by the host or FlexCAN internal processes.

For host-initiated reads, a noncorrectable error may affect the host, but does not affect FlexCAN operation.

Non-correctable errors detected on memory reads requested by the FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in processes), when a noncorrectable error occurs, an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters in Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. When MECR[NCEFAFRZ] is negated, FlexCAN continues working and a corrupted frame is received.
- During arbitration process, when a noncorrectable error occurs, either a non-highest priority Tx message buffer may be mistakenly selected for transmission or its data may be corrupted. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. When MECR[NCEFAFRZ] is negated, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out process, when a noncorrectable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] is negated, the corrupted frame is transferred from the Tx SMB to the Protocol Engine (PE) sub-block and is transmitted on the CAN bus.
- A noncorrectable error can also be detected beyond the move-out process, when Tx data is read from Tx SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus.

  To prevent the frame from being successfully received by the external nodes, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter), and transmits an error flag just after CRC delimiter as a result of self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] is negated, FlexCAN may attempt to re-transmit the same frame, as long as no other higher priority Tx MB is subsequently configured for transmission.

  In the event the noncorrectable error persists, FlexCAN eventually reaches the Bus Off state because of consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] is set and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. The assertion of MECR[NCEFAFRZ] is the only way to prevent corrupted frames from being transmitted on the CAN bus up to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

72.3.15.5 Error injection

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. The relation between the error injection addresses and the respective ones in the module memory map is shown in the description of Error Injection Address Register (ERRIAR).

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by the host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, MECR[HAERRIE] and MECR[FAERRIE] must be cleared when configuring the memory injection registers.

72.4 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 458. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN receive pin	Input
CAN Tx	CAN transmit pin	Output

72.4.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

72.4.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

72.5 Initialization/application information

This section provides instructions for initializing the FlexCAN module.

72.5.1 FlexCAN initialization sequence

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see Freeze mode). Note that the module needs to be initialized after every reset.

The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
    a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
    b. Enable the warning interrupts by setting WRNEN.
    c. If required, disable frame self reception by setting SRXDIS.
    d. Enable the Legacy Rx FIFO by setting RFEN or the Enhanced Rx FIFO by setting ERFEN.
    e. If Legacy Rx FIFO or Enhanced Rx FIFO is enabled and DMA is required, set DMA.
    f. Enable the abort mechanism by setting AEN.
    g. Enable the local priority feature by setting LPRIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
    a. Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, and RJW.
    b. Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, and ERJW.
    c. Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, and FRJW.
    d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
    e. Determine the CAN FD bit rate by programming the FPRESDIV field.
    f. Determine the internal arbitration mode (LBUF).
3. All FlexCAN memory must be initialized if Error Code Correction (ECC) is enabled. See Detection and correction of memory errors.
4. Initialize the message buffers.
    a. The control and status word of all message buffers must be initialized.

b. If Rx FIFO was enabled, the ID filter table must be initialized.

c. Other entries in each message buffer should be initialized as required.

5. Initialize the Rx Individual Mask registers (RXIMRn).
6. Set required interrupt mask bits in
   - IMASK registers (for all MB interrupts)
   - CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)
7. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

72.6 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

72.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and the corresponding mnemonic . The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 459.

NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

Table 459. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 Register (CTRL1)	S/U	Yes	No
Free Running Timer Register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask Register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask Register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask Register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 Register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 Register (IMASK1)	S/U	Yes	Yes

Table continues on the next page...

Table 459. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Interrupt Flags 2 Register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 Register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask Register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
CAN Bit Timing Register (CBT)	S/U	Yes	No
Interrupt Masks 3 Register (IMASK3)	S/U	Yes	Yes
Interrupt Flags 3 Register (IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control Register (MECR)	S/U	Yes	Yes
Error Injection Address Register (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern Register (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern Register (ERRIPPR)	S/U	Yes	Yes
Error Report Address Register (RERRAR)	S/U	Yes	Yes
Error Report Data Register (RERRDR)	S/U	Yes	Yes
Error Report Syndrome Register (RERRSYNR)	S/U	Yes	Yes
Error Status Register (ERRSR)	S/U	Yes	Yes
Enhanced CAN Bit Timing Prescalers (EPRS)	S/U	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	S/U	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	S/U	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	S/U	Yes	No
CAN FD Control Register (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing Register (FDCBT)	S/U	Yes	No

Table continues on the next page...

Table 459. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
CAN FD CRC Register (FDCRC)	S/U	Yes	Yes
Enhanced Rx FIFO Control Register (ERFCR)	S/U	Yes	Yes
Enhanced Rx FIFO Interrupt Enable Register (ERFIER)	S/U	Yes	Yes
Enhanced Rx FIFO Status Register (ERFSR)	S/U	Yes	Yes
High Resolution Time Stamp (HR_TIME_STAMP)	S/U	No	No
Enhanced Rx FIFO	S/U	No	No
Enhanced Rx FIFO Filter Element (ERFFEL)	S/U	No	No

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

72.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers (MBs).

The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced Rx FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements.

The memory map for the Enhanced Rx FIFO is in Enhanced Rx FIFO structure.

72.6.2.1 CAN memory map

CAN_0 base address: 4030_4000h

CAN_1 base address: 4030_8000h

CAN_2 base address: 4030_C000h

CAN_3 base address: 4031_0000h

CAN_4 base address: 4031_4000h

CAN_5 base address: 4031_8000h

CAN_6 base address: 4031_C000h

CAN_7 base address: 4032_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	D890_000Fh

72.6.2.2 Module Configuration Register (MCR)

Offset

Register	Offset
MCR	0h

Function

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Diagram

Fields

Field	Function
31 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset. 0b - Enable the FlexCAN module. 1b - Disable the FlexCAN module.
30 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. This bit is set by hardware when a non-correctable error is detected (MECR[NCEFAFRZ] is asserted). 0b - Not enabled to enter Freeze mode. 1b - Enabled to enter Freeze mode.
29 RFEN	Legacy Rx FIFO Enable This bit controls whether the Legacy Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (80h–DCh) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Legacy Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 454. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE** This bit cannot be set when CAN FD operation is enabled (see FDEN bit). **NOTE** RFEN bit must not be set if ERFCR[ERFEN] is set.

HALT</td><td>Halt FlexCAN
Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the message buffers and the Control registers CTRL1 and CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered when FlexCAN is in a low power mode. The HALT bit is set by hardware when a non-correctable error is detected and MECR[NCEFAFRZ] is asserted.
0b - No Freeze mode request.
1b - Enters Freeze mode if the FRZ bit is asserted.</td></tr>
<tr><td>27
NOTRDY</td><td>FlexCAN Not Ready
This read-only bit indicates that FlexCAN is either in Disable mode or Freeze mode. It is negated when FlexCAN has exited these modes. This bit is not affected by soft reset.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FlexCAN module is either in Normal mode, Listen-Only mode, or Loop-Back mode. 1b - FlexCAN module is either in Disable mode or Freeze mode.
26 —	Reserved When writing to this field, always write the reset value.
25 SOFTRST	Soft Reset When SOFTRST is asserted, FlexCAN resets its internal state machines and some of the memory-mapped registers. SOFTRST can be asserted directly by the CPU when it writes to the MCR register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted when reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0b - No reset request. 1b - Resets the registers affected by soft reset.
24 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Freeze mode. This bit is not affected by soft reset. **NOTE** FRZACK will be asserted within 178 CAN bits from the Freeze mode request by the CPU, and negated within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - FlexCAN not in Freeze mode, prescaler running. 1b - FlexCAN in Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the "Access type" column of Table 459. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1b - FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.

Table continues on the next page...

Table continued from the previous page...

Field	Function
22 —	Reserved When writing to this field, always write the reset value.
21 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0b - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1b - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
20 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset. **NOTE** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0b - FlexCAN is not in a low-power mode. 1b - FlexCAN is in a low-power mode.
19 —	Reserved When writing to this field, always write the reset value.
18 —	Reserved When writing to this field, always write the reset value.
17 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Self-reception enabled. 1b - Self-reception disabled.
16 IRMQ	Individual Rx Masking And Queue Enable

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.
0b - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.
1b - Individual Rx masking and queue feature are enabled.</td></tr>
<tr><td>15
DMA</td><td>DMA Enable
DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Legacy Rx FIFO or Enhanced Rx FIFO, so consequently MCR[RFEN] or ERFCR[ERFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes.
NOTE
The descriptions of the field settings vary by module instance.

Field	Function
—	
13 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Local Priority disabled. 1b - Local Priority enabled.
12 AEN	Abort Enable When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE** When MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating mailboxes configured for transmission. **CAUTION** Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted. 0b - Abort disabled. 1b - Abort enabled.
11 FDEN	CAN FD operation enable This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only. **NOTE** FlexCAN is able to transmit FD frame format according to ISO 11898-1:2015. **NOTE** The Legacy Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted. 0b - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format. 1b - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats.
10 —	Reserved
9-8	ID Acceptance Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
IDAM	This 2-bit field identifies the format of the Legacy Rx FIFO ID filter table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Legacy Rx FIFO structure. This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 — 	Reserved
6-0 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE** MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in FlexCAN memory partition for CAN FD. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Legacy Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 454.

72.6.2.3 Control 1 Register (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

This Register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

If CTRL2[BTE] is set, then the PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields in the CTRL1 register are not used by the hardware, are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

The contents of this register are not affected by soft reset.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1).
23-22 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 PSEG2	Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
15 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Bus Off interrupt disabled. 1b - Bus Off interrupt enabled.
14 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Error interrupt disabled. 1b - Error interrupt enabled.
13 —	Reserved **NOTE** This field is writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot be asserted because this will impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and ETDC[ETDCEN] must be disabled when LPB is asserted. 0b - Loop Back disabled. 1b - Loop Back enabled.
11	Tx Warning Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
TWRNMSK	This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted. 0b - Tx Warning interrupt disabled. 1b - Tx Warning interrupt enabled.
10 RWRNMSK	Rx Warning Interrupt Mask This bit provides a mask for the Rx Warning interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0b - Rx Warning interrupt disabled. 1b - Rx Warning interrupt enabled.
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE** For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1). 0b - Just one sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used.
6 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE See Bus off in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Automatic recovering from Bus Off state enabled. 1b - Automatic recovering from Bus Off state disabled.
5 TSYN	Timer Sync This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If MCR[RFEN] is set (Legacy Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Timer sync feature disabled 1b - Timer sync feature enabled
4 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for message buffer transmission. When asserted, MCR[LPRIOEN] does not affect the priority arbitration. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in the ECR register are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of ESR1[FLTCONF] indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment This 3-bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation segment time = (PROPSEG + 1) × time-quanta. Time-quantum = one Sclock period.

72.6.2.4 Free Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0h after Reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see Mailbox lock mechanism).

72.6.2.5 Rx Mailboxes Global Mask Register (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

This register is located in RAM.

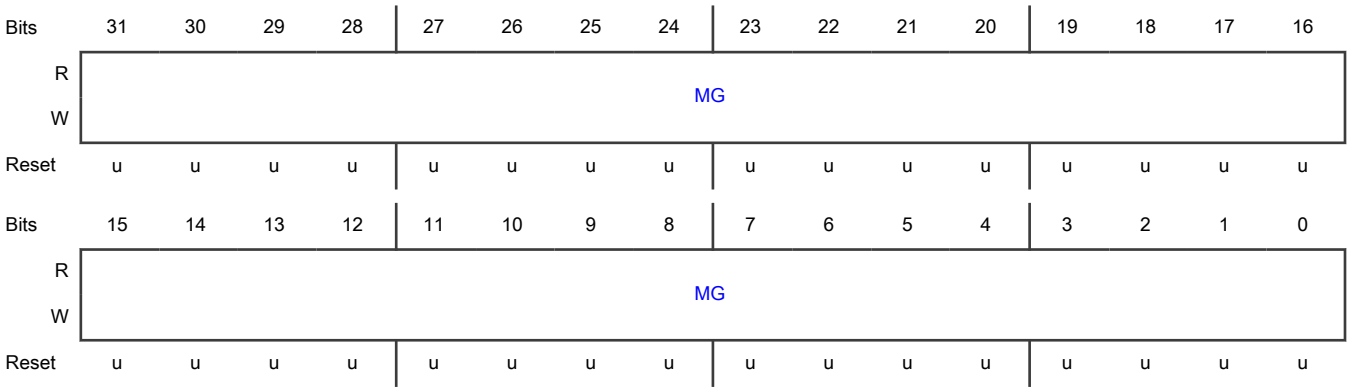
RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-0 MG	Rx Mailboxes Global Mask Bits These bits mask the mailbox filter bits. Note that the alignment with the ID word of the mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the mailbox. The following table shows in detail which MG bits mask each mailbox filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	—	0	note [2]	note [3]	MG[28:0]	MG[31:29]
0	—	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	—	—	—	—	MG[31:0]
1	1	0	—	—	MG[28:0]	MG[31:29]

<tr><th rowspan="2">SMB[RTR] [1]</th><th rowspan="2">CTRL2[RRS]</th><th rowspan="2">CTRL2[EACEN]</th><th colspan="4">Mailbox filter fields</th></tr>
<tr><th>MB[RTR]</th><th>MB[IDE]</th><th>MB[ID]</th><th>Reserved</th></tr>
<tr><td>1</td><td>1</td><td>1</td><td>MG[31]</td><td>MG[30]</td><td>MG[28:0]</td><td>MG[29]</td></tr>
</table>
1. RTR bit of the incoming frame. It is saved into an auxiliary MB called Rx serial message buffer (Rx SMB).
2. If CTRL2[EACEN] is negated, the RTR bit of mailbox is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is negated, the IDE bit of mailbox is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.
</td></tr>
</table>

72.6.2.6 Rx 14 Mask Register (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

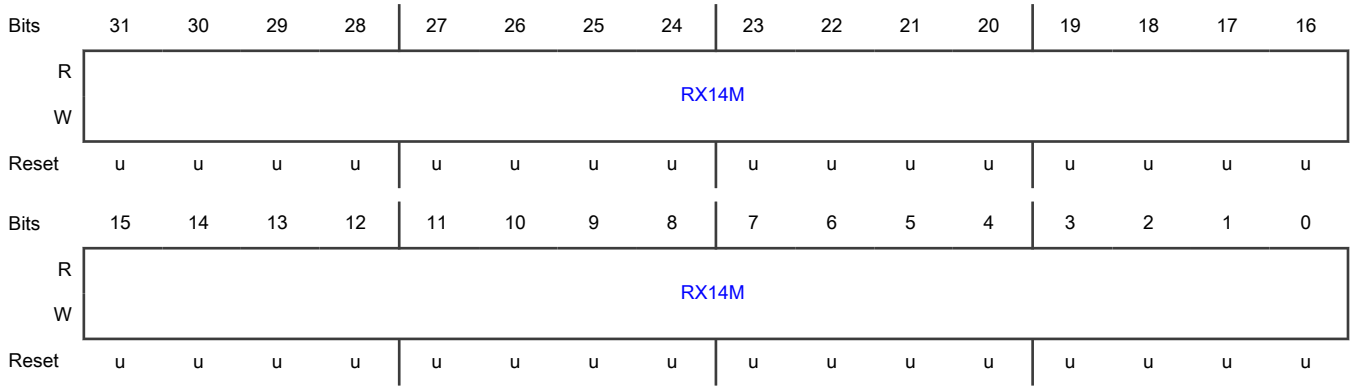
This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of message buffer 14.

This register can only be programmed when the module is in Freeze mode as it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	Rx Buffer 14 Mask Bits Each mask bit masks the corresponding mailbox 14 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

72.6.2.7 Rx 15 Mask Register (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

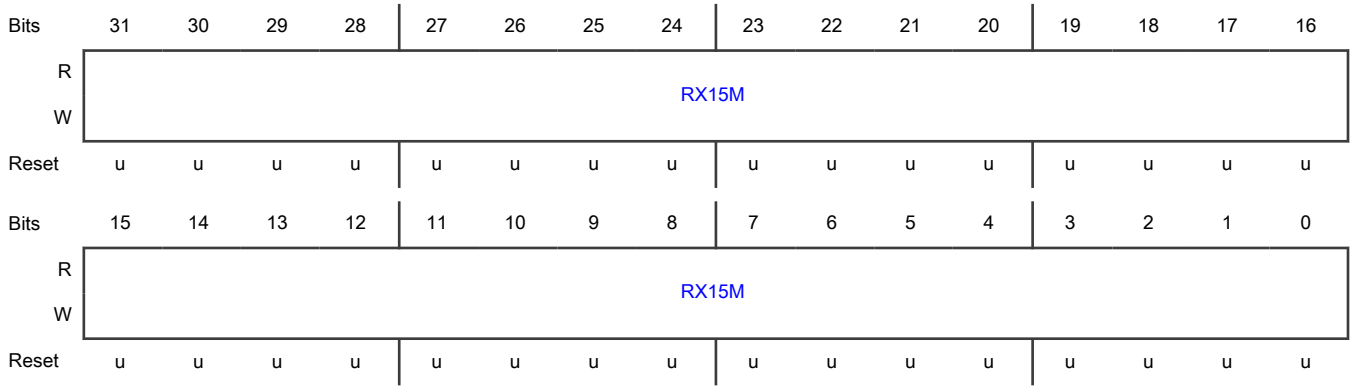
This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of message buffer 15.

This register can be programmed only when the module is in Freeze mode because it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-0 RX15M	Rx Buffer 15 Mask Bits Each mask bit masks the corresponding mailbox 15 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register.

	0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

72.6.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
- Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.

- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for fast bits Receive error counter for errors detected in the data phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for fast bits Transmit error counter for errors detected in the data phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Receive error counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
7-0 TXERRCNT	Transmit Error Counter Transmit error counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

72.6.2.9 Error and Status 1 Register (ESR1)

Offset

Register	Offset
ESR1	20h

Function

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading Host can clear these field.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt bits:

- BOFFINT
- BOFFDONEINT
- ERRINT

- ERRINT_FAST
- TWRNINT
- RWRNINT

It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames have accumulated.

Table 460. Can bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
BIT1ERR_FAST	After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
30 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set This bit indicates that a CRC error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a form error has been detected by the receiver node in the data phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a stuffing error has been detected in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-22 —	Reserved
21	Error Overrun

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERROVR	This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0b - Overrun has not occurred. 1b - Overrun has occurred.
20 ERRINT_FAST	Error interrupt for errors detected in Data Phase of CAN FD frames with BRS bit set This bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If the corresponding mask bit CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates setting of any error bit detected in the data phase of CAN FD frames with the BRS bit set.
19 BOFFDONEINT	Bus Off Done Interrupt This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall ESR1 register description. 0b - FlexCAN is not synchronized to the CAN bus. 1b - FlexCAN is synchronized to the CAN bus.
17 TWRNINT	Tx Warning Interrupt Flag If MCR[WRNEN] is asserted, TWRNINT is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[WRNEN] is negated, this flag is masked. CPU must clear this flag before disabling MCR[WRNEN]. Otherwise it will be set when MCR[WRNEN] is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0b - No such occurrence. 1b - The Tx error counter transitioned from less than 96 to greater than or equal to 96.
16 RWRNINT	Rx Warning Interrupt Flag If MCR[WRNEN] is asserted, RWRNINT is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register

Table continues on the next page...

Table continued from the previous page...

Field	Function
	(CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0b - No such occurrence. 1b - The Rx error counter transitioned from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - An ACK error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error This bit indicates that a Cyclic Redundancy Check (CRC) error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
11	Form Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRMERR	This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A Form Error occurred since last read of this register.
10 STFERR	Stuffing Error This bit indicates that a stuffing error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
9 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is greater than or equal to 96.
8 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	IDLE This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description. 0b - No such occurrence. 1b - CAN bus is now IDLE.
6 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description. 0b - FlexCAN is not transmitting a message. 1b - FlexCAN is transmitting a message.
5-4	Fault Confinement State

Table continues on the next page...

Table continued from the previous page...

Field	Function
FLTCONF	This 2-bit field indicates the confinement state of the FlexCAN module. If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off
3 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall ESR1 register description. 0b - FlexCAN is not receiving a message. 1b - FlexCAN is receiving a message.
2 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters Bus Off state. If the corresponding mask bit in the Control Register 1 (CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt This bit indicates that at least one of the error bits (BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, or STFERR) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates setting of any error bit in the Error and Status register.
0 —	Reserved

72.6.2.10 Interrupt Masks 2 Register (IMASK2)

Offset

Register	Offset
IMASK2	24h

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BUF63TO32M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BUF63TO32M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF63TO32M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB63 to MB32. **NOTE** Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

72.6.2.11 Interrupt Masks 1 Register (IMASK1)

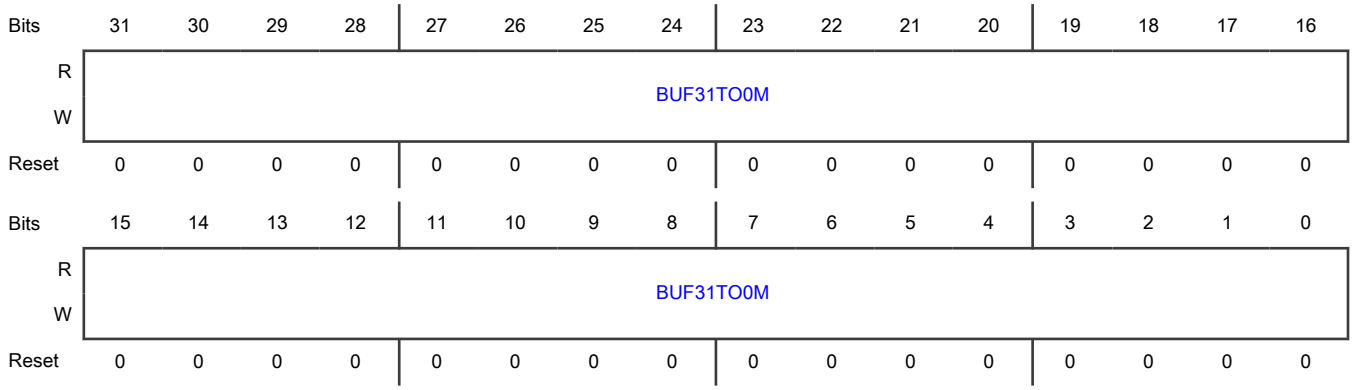
Offset

Register	Offset
IMASK1	28h

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

Diagram



Fields

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB31 to MB0. **NOTE** Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

72.6.2.12 Interrupt Flags 2 Register (IFLAG2)

Offset

Register	Offset
IFLAG2	2Ch

Function

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	BUF63TO32I															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF63TO32I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB63 to MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

72.6.2.13 Interrupt Flags 1 Register (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Legacy Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent Legacy FIFO interrupts when the Legacy Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO , BUF0I is used to empty Legacy FIFO, and BUF4I to BUF1I bits are reserved.

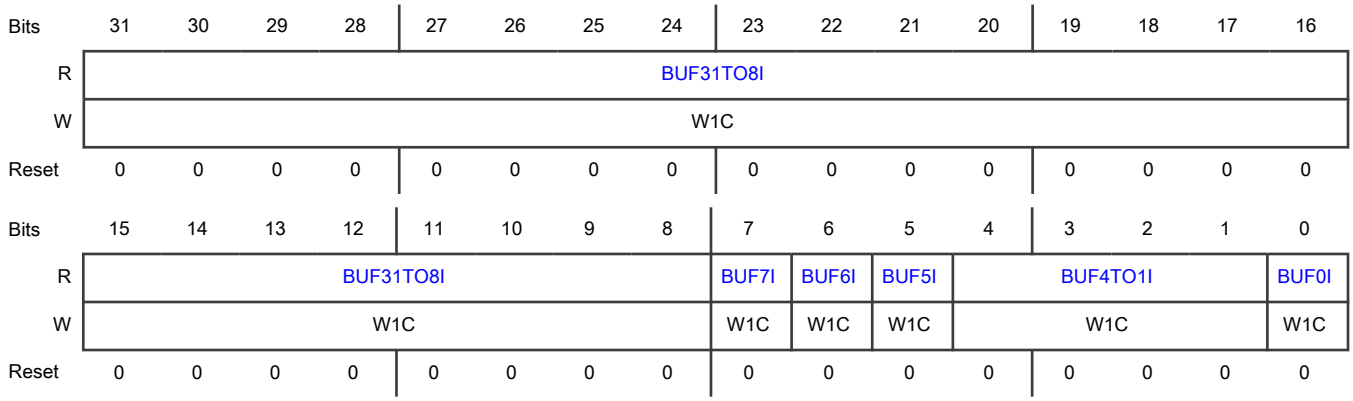
Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Legacy Rx FIFO region; see Legacy Rx FIFO. Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is negated, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy Rx FIFO filters beyond MB7. For example, when RFFN is 8h, the MB0–23 range is occupied by Legacy Rx FIFO filters and related IFLAG bits must be cleared.

When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Legacy Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not

used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of Legacy FIFO, and BUF0I is used to empty Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Legacy Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. When MCR[DMA] is negated, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] is enabled.

Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Diagram



Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB31 to MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt Or Legacy Rx FIFO Overflow When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF7I flag represents Legacy Rx FIFO overflow when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a mailbox. **NOTE** The descriptions of the field settings vary by module instance.

5

BUF5I

Buffer MB5 Interrupt Or Frames available in Legacy Rx FIFO

When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this field flags the interrupt for MB5.

NOTE

This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.

When MCR[RFEN] is set (Legacy Rx FIFO enabled), the BUF5I flag represents "Frames available in Legacy Rx FIFO" and indicates that at least one frame is available to be read from the Legacy Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I.

NOTE

The descriptions of the field settings vary by module instance.

Instance	Field value and description
CAN_0	0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the Legacy FIFO, when MCR[RFEN]=1 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Legacy Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.
CAN_1	0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the Legacy FIFO, when MCR[RFEN]=1 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Legacy Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.

Table continued from the previous page...

Field	Function
4-1 BUF4TO1I	Buffer MBi Interrupt Or Reserved When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE** These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when MCR[RFEN] is set. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
0 BUF0I	Buffer MB0 Interrupt Or Clear Legacy FIFO bit When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this field flags the interrupt for MB0. If the Legacy Rx FIFO is enabled, this bit is used to trigger the clear Legacy FIFO operation. This operation empties Legacy FIFO contents. Before performing this operation the CPU must service all Legacy FIFO related IFLAGs. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

72.6.2.14 Control 2 Register (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

This register complements Control1 register, providing control bits for memory write access in Freeze mode, for extending Legacy FIFO filter quantity, and to adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

This table shows how the Legacy Rx FIFO filter structure is determined by the value of CTRL2[RFFN]. See the CTRL2[RFFN] field description for more information.

Table 461. **Legacy** Rx FIFO filter: possible structures

Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for errors detected in the data phase of fast CAN FD frames This bit provides a mask for the ERRINT_FAST interrupt in ESR1 register. 0b - ERRINT_FAST error interrupt disabled. 1b - ERRINT_FAST error interrupt enabled.
30 BOFFDONEMSK	Bus Off Done Interrupt Mask This bit provides a mask for the bus off done interrupt in ESR1 register. 0b - Bus off done interrupt disabled. 1b - Bus off done interrupt enabled.
29 ECRWRE	Error-correction Configuration Register Write Enable This bit enables the MECR register to be updated. This bit is automatically set to 0 if the protocol described in Detection and correction of memory errors is not followed. 0b - Disable update. 1b - Enable update.
28 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. MCR[RFEN] must not be set during FlexCAN memory initialization. 0b - Maintain the write access restrictions. 1b - Enable unrestricted write access to FlexCAN memory.
27-24 RFFN	Number Of Legacy Rx FIFO Filters This 4-bit field defines the number of Rx Legacy FIFO filters, as shown in Table 461. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that cause the number of message buffers occupied by Legacy Rx FIFO and Legacy Rx FIFO ID Filter to exceed the number of mailboxes present, as defined by MCR[MAXMB].

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
NOTE
Each group of eight filters occupies a memory space equivalent to two message buffers, which means that the more filters are implemented the fewer mailboxes will be available.
Considering that the Legacy Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words, which can be calculated as follows:
(SETUP_MB - 6) × 4
where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB].
The number of remaining mailboxes available will be:
(SETUP_MB - 8) - (RFFN × 2)
If the number of Legacy Rx FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), then the exceeding ones will not be functional.
NOTE
• The number of the last remaining available mailboxes is defined by the smaller of NUMBER_OF_MB minus 1 and MCR[MAXMB].
• If Rx Individual Mask registers are not enabled then all Legacy Rx FIFO filters are affected by the Legacy Rx FIFO Global Mask.
</td></tr>
<tr><td>23-19
TASD</td><td>Tx Arbitration Start Delay
This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See Tx arbitration start delay for more details. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</td></tr>
<tr><td>18
MRP</td><td>Mailboxes Reception Priority
If this bit is set the matching process starts from the mailboxes and if no match occurs the matching continues on the Legacy Rx FIFO or Enhanced RX FIFO . This bit can be written only in Freeze mode because it is blocked by hardware in other modes.
NOTE
The descriptions of the field settings vary by module instance.
<table>

EACEN</td><td>Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes
This bit controls the comparison of IDE and RTR bits within Rx mailbox filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Legacy Rx FIFO or Enhanced Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Rx mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1b - Enables the comparison of both Rx mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free running timer counter. This bit can be written in Freeze mode only. 0b - The free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. 1b - The free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device-specific section for details about the external time tick.
14 PREXCEN	Protocol Exception Enable This bit enables the protocol exception feature. This field is writable only in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Protocol exception is disabled. 1b - Protocol exception is enabled.
13 BTE	Bit Timing Expansion enable This field enables the use of the EPRS, EDCBT and ENCBT registers to configure the CAN bit timing segments, instead of using the bit timing fields of CBT, FDCBT, and CTRL1 registers. If CTRL2[BTE] is set: • PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields in CTRL1 register are read as zero, and a write operation in them has no effect. • EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 fields in the CBT register, and the FDCBT register, are read as zero and a write operation to them has no effect. • The ETDCOFF, ETDCEN, ETDCFAIL, and ETDCVAL fields of the ETDC register are used by FlexCAN instead of TDCOFF, TDCEN, TDCFAIL, and TDCVAL fields in FDCTRL register, which are read as zero, and a write operation in them has no effect. • ETDC[TDMDIS] can be used for disabling transceiver delay measurement. 0b - CAN Bit timing expansion is disabled. 1b - CAN bit timing expansion is enabled.
12 ISOCANFDEN	ISO CAN FD Enable This field enables the CAN FD protocol according to ISO specification (ISO 11898-1:2015) (see CAN FD ISO compliance). This field is writable only in Freeze mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1:2015). 0b - FlexCAN operates using the non-ISO CAN FD protocol. 1b - FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1:2015).
11 EDFLTDIS	Edge Filter Disable This bit disables the edge filter used during the bus integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. This field is writable only in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Edge filter is enabled 1b - Edge filter is disabled
10 —	Reserved
9-8 MBTSBASE	Message Buffer Time Stamp Base This field selects which time base is used for capturing the 16-bit TIME_STAMP field of the message buffer register. There are three time base options: 1. TIMER 2. Lower 16 bits of high resolution time base 3. Upper 16 bits of high resolution time base This field can be written in Freeze Mode only. 00b - Message buffer time stamp base is TIMER 01b - Message buffer time stamp base is lower 16 bits of high resolution timer 10b - Message buffer time stamp base is upper 16 bits of high resolution timer 11b - Reserved
7-6 TSTAMPCAP	Time Stamp Capture Point This field configures the point in time when a 32-bit time base is captured during a CAN frame and stored in the high resolution time stamp register (HR_TIME_STAMP).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For classical CAN frames, capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the 7th bit of end of frame for transmission and the 6th bit of the end of frame for reception. For CAN FD frames, the high resolution time stamp can be captured at the start of frame, the point in time a CAN FD frame is considered valid, or the res bit. This field can be written in Freeze mode only. 00b - The high resolution time stamp capture is disabled 01b - The high resolution time stamp is captured in the end of the CAN frame 10b - The high resolution time stamp is captured in the start of the CAN frame 11b - The high resolution time stamp is captured in the start of frame for classical CAN frames and in res bit for CAN FD frames
5-0 —	Reserved

72.6.2.15 Error and Status 2 Register (ESR2)

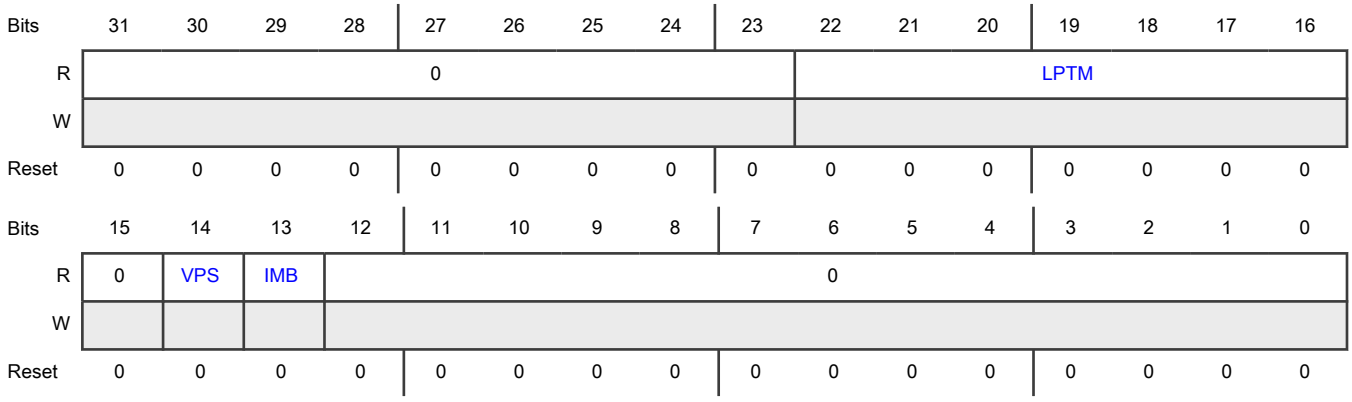
Offset

Register	Offset
ESR2	38h

Function

This register reports some general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive mailbox (see the ESR2[IMB] bit description). If there is no inactive mailbox then the mailbox indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] is negated, then the mailbox indicated is the one that has the greatest arbitration value (see Highest-priority mailbox first). If CTRL1[LBUF] is asserted then the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its mailbox number.
15 —	Reserved
14 VPS	Valid Priority Status This bit indicates whether ESR2[IMB] and ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive mailbox and only one Tx mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any mailbox. **NOTE** ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of an MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0b - Contents of IMB and LPTM are invalid. 1b - Contents of IMB and LPTM are valid.
13 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive mailbox (CODE field is either 1000b or 0b). This bit is asserted in the following cases: • During arbitration, if an ESR2[LPTM] is found and it is inactive. • If ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is always cleared in start of arbitration (see Arbitration process). **NOTE** ESR2[LPTM] mechanism has the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0b - If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive mailbox.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - If ESR2[VPS] is asserted, there is at least one inactive mailbox. LPTM content is the number of the first one.
12-0 —	Reserved

72.6.2.16 CRC Register (CRCR)

Offset

Register	Offset
CRCR	44h

Function

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-23 —	Reserved
22-16	CRC Mailbox

Table continues on the next page...

Table continued from the previous page...

Field	Function
MBCRC	This field indicates the number of the mailbox corresponding to the value in CRCR[TXCRC] field.
15 —	Reserved
14-0 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in FDCRC register.

72.6.2.17 Legacy Rx FIFO Global Mask Register (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

This register is located in RAM.

If Legacy Rx FIFO is enabled, RXFGMASK is used to mask the Legacy Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

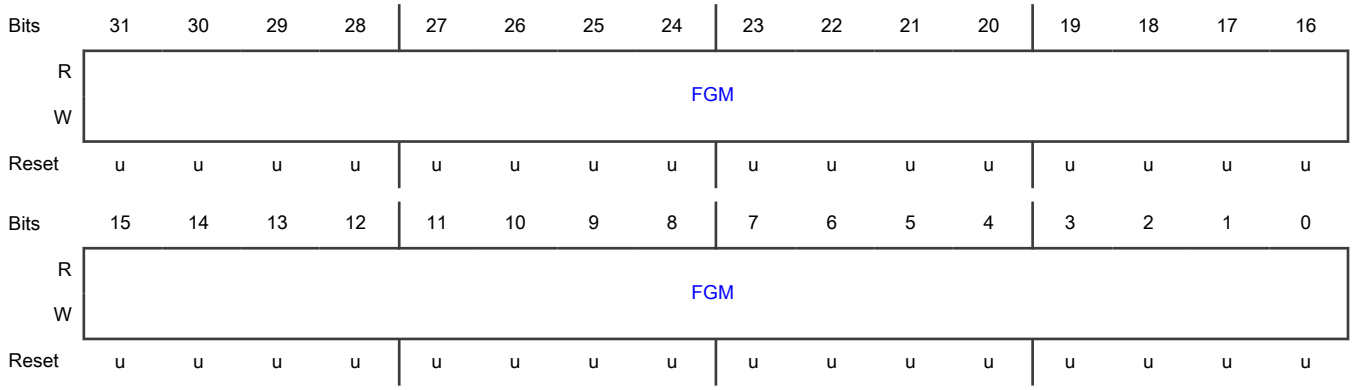
The following table shows how the FGM bits correspond to each IDAF field.

Table 462. Correspondence of Legacy Rx FIFO global mask bits to IDF fields

Legacy Rx FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Legacy Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy Rx FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy Rx FIFO Global Mask Bits These bits mask the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don’t care." 1b - The corresponding bit in the filter is checked.

72.6.2.18 Legacy Rx FIFO Information Register (RXFIR)

Offset

Register	Offset
RXFIR	4Ch

Function

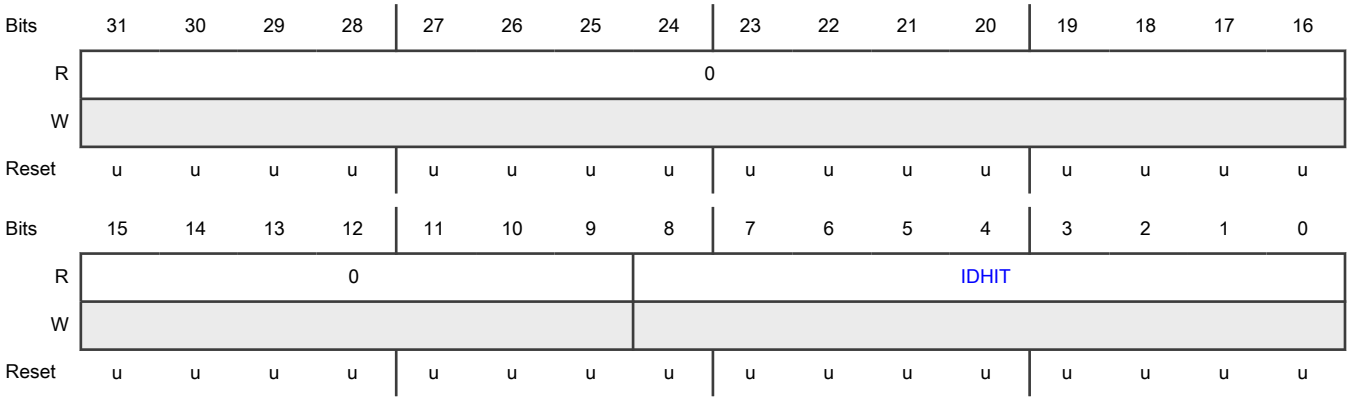
RXFIR provides information on Legacy Rx FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. The Legacy RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Legacy Rx FIFO. Also, its output is updated whenever the output of the Legacy Rx FIFO is updated with the next message. See Legacy Rx FIFO for instructions on reading this register.

NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case the register is read-only.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance filter was hit by the received message that is in the output of the Legacy Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is asserted.

72.6.2.19 CAN Bit Timing Register (CBT)

Offset

Register	Offset
CBT	50h

Function

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

NOTE

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

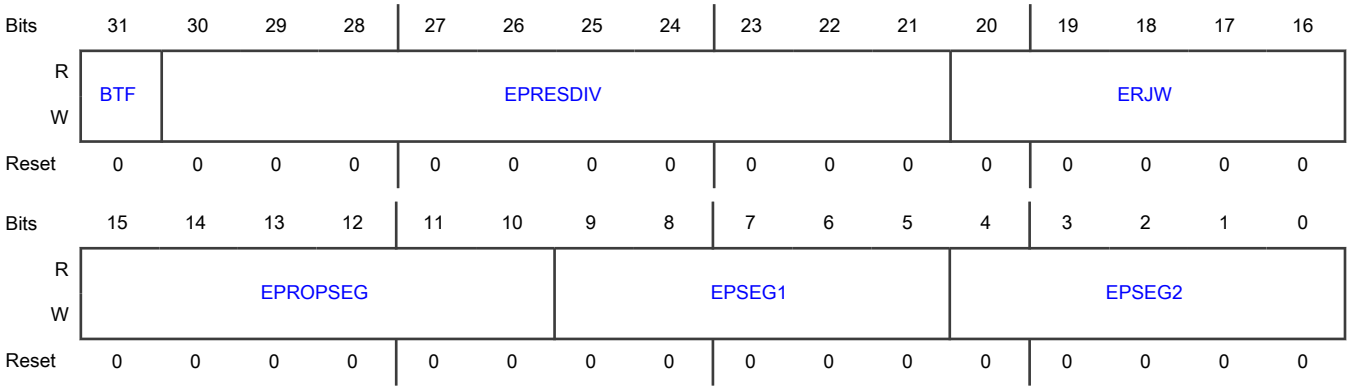
NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] is set, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 fields are read as zero, and a write operation into them has no effect.

Diagram



Fields

Field	Function
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2. and ERJW replacing the CAN bit timing variables defined in CTRL1 register. This field can be written in Freeze mode only. 0b - Extended bit time definitions disabled. 1b - Extended bit time definitions enabled.
30-21 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] is asserted, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[RJW] value range. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Resync Jump Width = ERJW + 1.
15-10 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the propagation segment in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 This 5-bit field defines the length of phase segment 1 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of phase segment 2 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

72.6.2.20 Interrupt Masks 3 Register (IMASK3)

Offset

Register	Offset
IMASK3	6Ch

Function

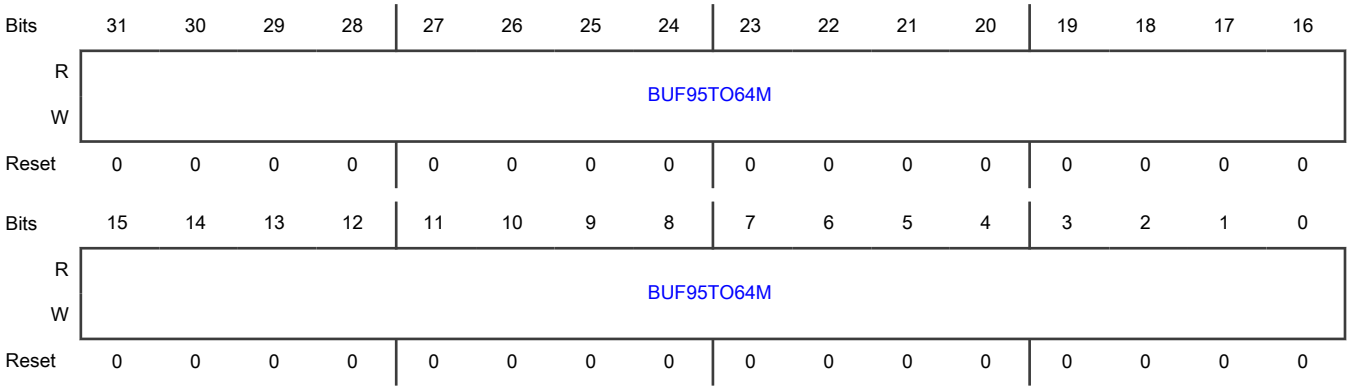
This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB95 to MB64. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG3 bit is set.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	IMASK3	—
CAN_1	IMASK3	—
CAN_2	IMASK3	—
CAN_3	—	IMASK3
CAN_4	—	IMASK3
CAN_5	—	IMASK3
CAN_6	—	IMASK3
CAN_7	—	IMASK3

Diagram



Fields

Field	Function
31-0 BUF95TO64M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB95 to MB64. When CAN FD is enabled, the MB range is defined in accordance with the MBDSRs bit fields of FDCTRL register. **NOTE** Setting or clearing a bit in the IMASK3 Register can assert or negate an interrupt request, if the corresponding IFLAG3 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

72.6.2.21 Interrupt Flags 3 Register (IFLAG3)

Offset

Register	Offset
IFLAG3	74h

Function

This register defines the flags for the 32 message buffer interrupts for MB95 to MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 bit. If the corresponding IMASK3 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG3 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

Fields

Field	Function
31-0 BUF95TO64	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB95 to MB64.When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of FDCTRL register. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

72.6.2.22 Rx Individual Mask Registers (RXIMR0 - RXIMR95)

Offset

For n = 0 to 95:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

The RX Individual Mask registers are used to store the acceptance masks for ID filtering in Rx MBs and the Legacy Rx FIFO.

When the Legacy Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Legacy Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Legacy Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see Legacy Rx FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	RXIMR0–RXIMR95	—

RXIMR64–RXIMR95	CAN_0–CAN_2: undefined CAN_3–CAN_7: Register not supported

Fields

Field	Function
31-0 MI	Individual Mask Bits Each individual mask bit masks the corresponding bit in both the mailbox filter and Legacy Rx FIFO ID filter table element in distinct ways. For mailbox filters, see the RXMGMASK register description. For Legacy Rx FIFO ID filter table elements, see the RXFGMASK register description. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

72.6.2.23 Memory Error Control Register (MECR)

Offset

Register	Offset
MECR	AE0h

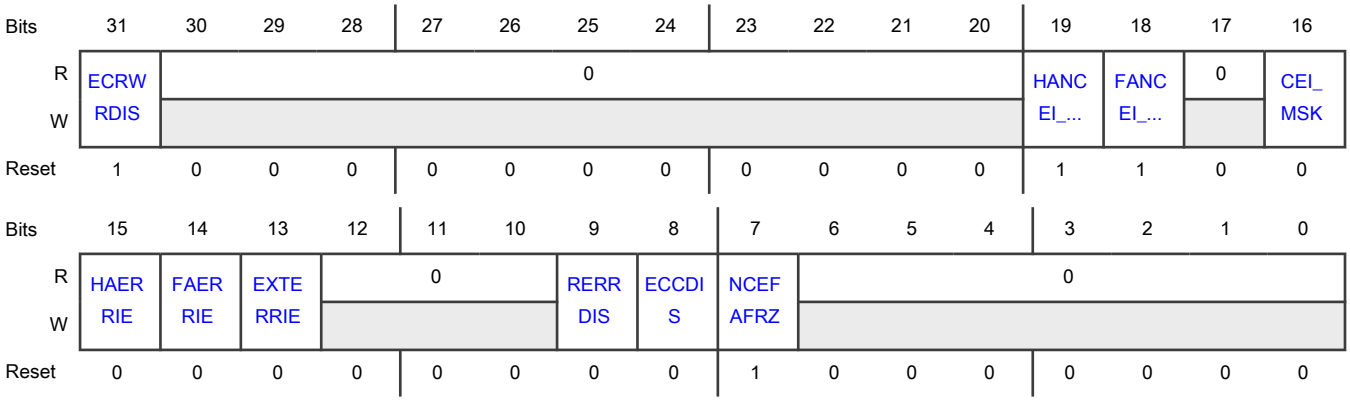
Function

This register contains control bits for memory error detection and correction (ECC).

NOTE

When bit CTRL2[ECRWRE] is 0, writes in this register are blocked, except in the ECRWRDIS bit.

Diagram



Fields

Field	Function
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This bit is automatically set to 1 (disabled) when CTRL2[ECRWRE] is enabled. The protocol described in section Detection and correction of memory errors must be followed. 0b - Write is enabled. 1b - Write is disabled.
30-20 —	Reserved
19 HANCEI_MSK	Host Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the host (CPU). 0b - Interrupt is disabled. 1b - Interrupt is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 FANCEI_MSK	FlexCAN Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the FlexCAN internal processes. 0b - Interrupt is disabled. 1b - Interrupt is enabled.
17 —	Reserved
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt in case of correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0b - Interrupt is disabled. 1b - Interrupt is enabled.
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0b - Injection is disabled. 1b - Injection is enabled.
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0b - Injection is disabled. 1b - Injection is enabled.
13 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern Register (ERRIDPR) and Error Injection Parity Pattern Register (ERRIPPR). 0b - Error injection is applied only to the 32-bit word. 1b - Error injection is applied to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When reading the report registers, this bit must be set to assure coherence on the consecutive register reads. 0b - Enable updates of the error report registers. 1b - Disable updates of the error report registers.
8 ECCDIS	Error Correction Disable Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0b - Enable memory error correction. 1b - Disable memory error correction.
7 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0b - Keep normal operation. 1b - Put FlexCAN in Freeze mode (see section "Freeze mode").
6-0 —	Reserved

72.6.2.24 Error Injection Address Register (ERRIAR)

Offset

Register	Offset
ERRIAR	AE4h

Function

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM (where pairs of values are provided, the first is the address for MCR[FDEN] negated, the second is for MCR[FDEN] asserted):

Table 463. Error injection address for Classical CAN format

RAM contents	Injection address	Memory map
FlexCAN registers	Not mapped	—

Table continues on the next page...

Table 463. Error injection address for Classical CAN format (continued)

RAM contents	Injection address	Memory map
MBs	0000h	0080h
RXIMRs	600h	0880h

4-0 PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

72.6.2.27 Error Report Address Register (RERRAR)

Offset

Register	Offset
RERRAR	AF0h

Function

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Table 464. Source of memory access

SAID[2:0]	Error during...

Field	Function
31-0 RDATA	Raw data word read from memory with error

72.6.2.29 Error Report Syndrome Register (RERRSYNR)

Offset

Register	Offset
RERRSYNR	AF8h

Function

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 465. Syndrome definition

SYNDn (hex)	Type	Bit affected
00	—	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeros non-correctable error
1F	—	All-ones non-correctable error
All others	—	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

16 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. If MECR[CEI_MSK] is set, the interrupt is asserted. 0b - No correctable errors were detected so far. 1b - A correctable error was detected.
15-4 —	Reserved
3 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by host when HANCEIF was set. No interrupt is associated with this flag. See Error indication. 0b - No overrun on non-correctable errors in host access 1b - Overrun on non-correctable errors in host access
2 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. See Error indication. 0b - No overrun on non-correctable errors in FlexCAN access 1b - Overrun on non-correctable errors in FlexCAN access
1 —	Reserved
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when CEIF was set. No interrupt is associated to this flag. See Error indication. 0b - No overrun on correctable errors 1b - Overrun on correctable errors

72.6.2.31 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

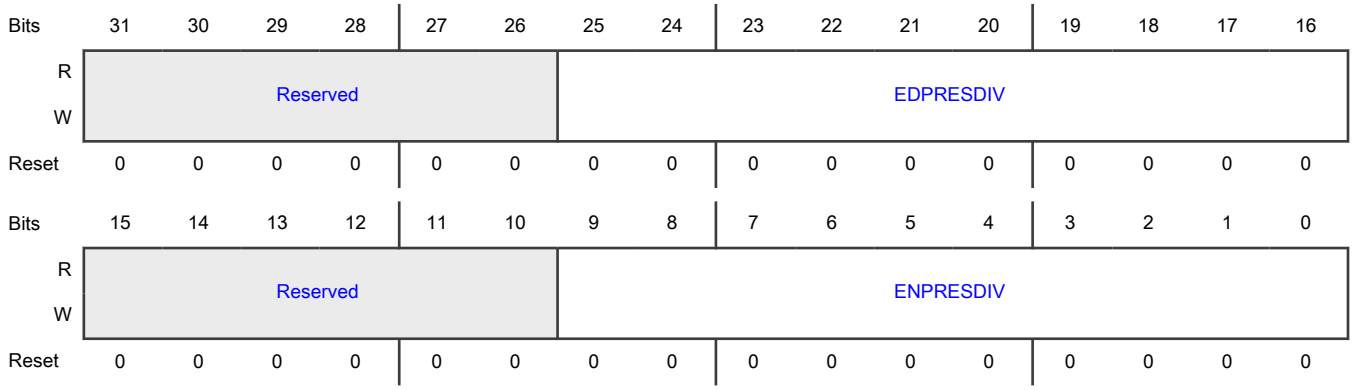
This register defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] is set.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

The contents of this register are not affected by soft reset.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor This field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data phase of a CAN FD message when CTRL2[BTE] is set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency / (EDPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for ENPRESDIV and EDPRESDIV. For more details see the first NOTE in section CAN FD frames.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor This field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CTRL2[BTE] is set; otherwise it reads as zero and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency / (ENPRESDIV + 1)

72.6.2.32 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

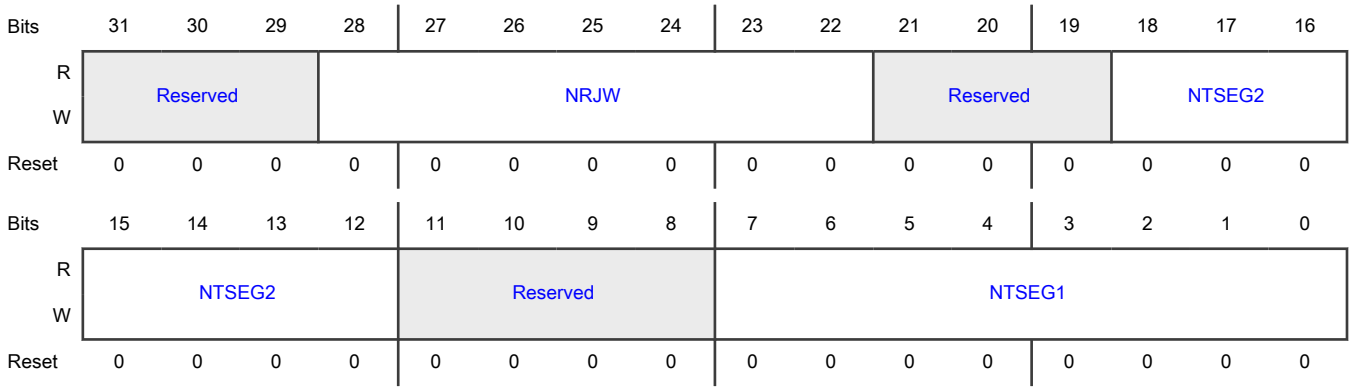
This register provides an alternative way to store the CAN bit timing variables described in the CTRL1 and CBT registers, to get higher CAN bit timing resolution.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

The contents of this register are not affected by soft reset.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width This field defines the maximum number of time quanta that a nominal bit time can be changed by one resynchronization when CTRL2[BTE] bit is asserted; otherwise it has no effect. One time quantum is equal to the Sclock period. Nominal Resync Jump Width = NRJW + 1.
21-19 —	Reserved
18-12	Nominal Time Segment 2

Table continues on the next page...

Table continued from the previous page...

Field	Function
NTSEG2	This field defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] is set; otherwise it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 This field defines the length of Time Segment 1 in the bit time when CTRL2[BTE] is set; otherwise it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

72.6.2.33 Enhanced Data Phase CAN bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

This register provides an alternative way to store the data phase CAN bit timing variables described in the FDCBT register to achieve higher CAN bit timing resolution.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

The contents of this register are not affected by soft reset.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

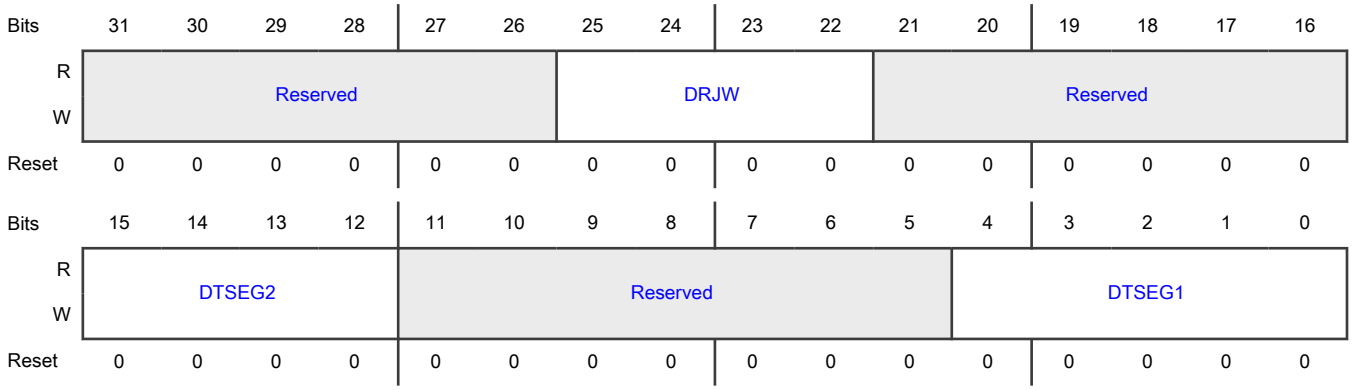
NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

DTSEG1 must be at least two time quanta.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width This field defines the maximum number of time quanta that a data phase bit time can be changed by one resynchronization when CTRL2[BTE] is set; otherwise it has no effect. Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 This field defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] is set; otherwise it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) x Time-Quanta. Time-Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 This field defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] is set; otherwise it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) x Time-Quanta. Time-Quantum = one Sclock period.

72.6.2.34 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

Function

This register contains extended versions of the fields FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the hardware only if CTRL2[BTE] is set; otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram

Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable This bit can be used for enabling and disabling the TDC feature. It can be written in Freeze mode only. **NOTE** Refer to Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled (see CTRL1[LPB] register). 0b - TDC is disabled 1b - TDC is enabled
30 TDMDIS	Transceiver Delay Measurement Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit can be used for disabling the transceiver delay measurement. When the TDC measurement is disabled, the secondary sample point position is determined only by the enhanced TDC offset (ETDCOFF) field. Otherwise, if the TCD measurement is enabled, then the secondary sample point position is determined by the sum of the transceiver delay measurement plus the enhanced TDC offset. This field is not affected by soft reset. **NOTE** This bit can be enabled only if CTRL2[BTE] is set. 0b - TDC measurement is enabled 1b - TDC measurement is disabled
29-23 —	Reserved
22-16 ETDCOFF	Enhanced Transceiver Delay Compensation Offset This field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. ETDCOFF can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** ETDCOFF must not be configured as zero. **NOTE** If CTRL2[BTE] is set after a chip level hard reset, ETCDOFF is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). ETDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write 1 to clear it. 0b - Measured loop delay is in range. 1b - Measured loop delay is out of range.
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value This register contains the ETDCOFF field added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS equal to recessive. This field is only updated by the hardware if ETDC[ETDCEN] is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is affected by soft reset. **NOTE** If TDMDIS is set, ETDCVAL stores ETDCOFF only.

72.6.2.35 CAN FD Control Register (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.
- Block R2 allocates MB64 to MB95.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

Table 466. Number of message buffers

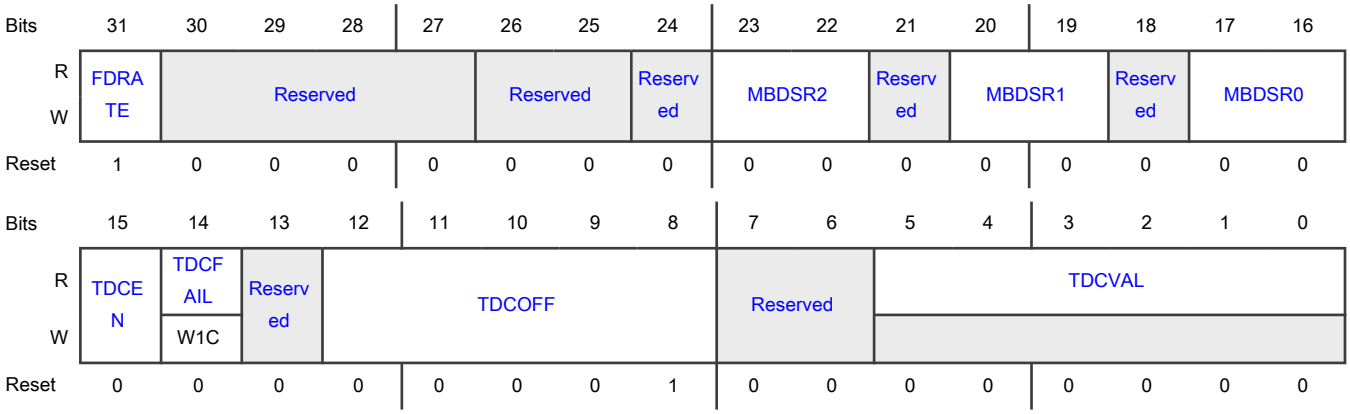
Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

NOTE

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages. The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle, or Bus Off state, or when the current frame under reception or transmission reaches the interframe space. By negating FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, no matter what the value is in the BRS bit of the Tx MBs. 0b - Transmit a frame in nominal rate. The BRS bit in the Tx MB has no effect. 1b - Transmit a frame with bit rate switching if the BRS bit in the Tx MB is recessive.
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 MBDSR2	Message Buffer Data Size for Region 2 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R2 of message buffers allocated in RAM. It can be written in Freeze mode only. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Table continued from the previous page...

This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R0 of message buffers allocated in RAM.
It can be written in Freeze mode only.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Selects 8 bytes per message buffer. 01b - Selects 16 bytes per message buffer. 10b - Selects 32 bytes per message buffer. 11b - Selects 64 bytes per message buffer.
15 TDCEN	Transceiver Delay Compensation Enable This bit can be used to enable and disable the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when Loop Back mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] is set, TDCEN is read as zero and a write operation has no effect. 0b - TDC is disabled 1b - TDC is enabled
14 TDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write one to clear it. **NOTE** If CTRL2[BTE] is set, TDCFAIL is read as zero and a write operation has no effect. 0b - Measured loop delay is in range. 1b - Measured loop delay is out of range.
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If CTRL2[BTE] is set, TDCOFF is read as zero and a write operation has no effect. **NOTE** It is not recommended to have TDCOFF equal to zero.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK). **NOTE** If CTRL2[BTE] is set, TDCVAL is read as zero. See Protocol timing for more details on how the loop delay measurement is performed.

72.6.2.36 CAN FD Bit Timing Register (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

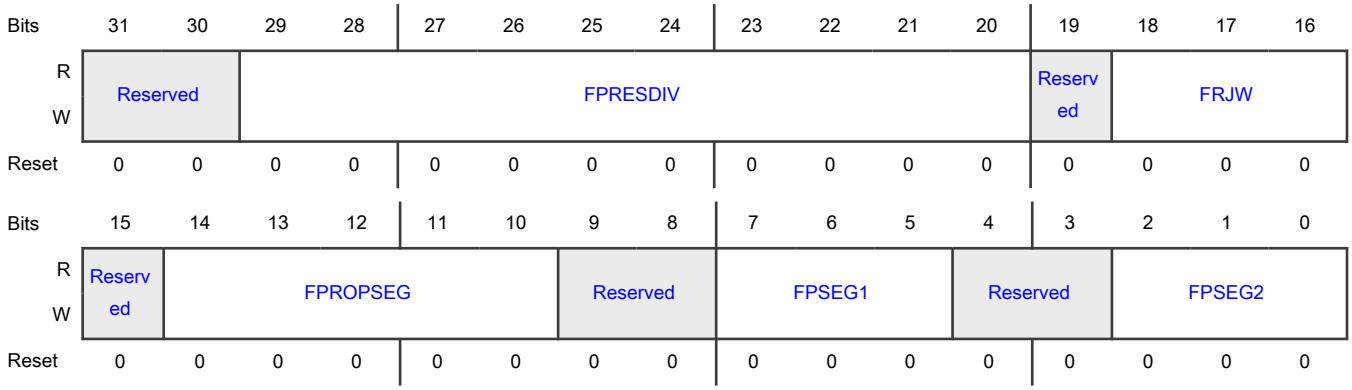
NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] is set, the FDCBT register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for FPRESDIV and PRESDIV (in CBT or CTRL1). For more details see the first NOTE in section CAN FD frames.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width This 3-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization in the data bit rate portion of a CAN FD message with the BRS bit set. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = FSJW + 1.
15 —	Reserved
14-10	Fast Propagation Segment

Table continues on the next page...

Table continued from the previous page...

Field	Function
FPROPSEG	This 5-bit field defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = FPROPSEG × Time-Quanta. Time-Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

72.6.2.37 CAN FD CRC Register (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time the Tx Interrupt flag is asserted.

$$CRC_15 = C599h: \ (x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$$

$$CRC_17 = 3685Bh: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$$

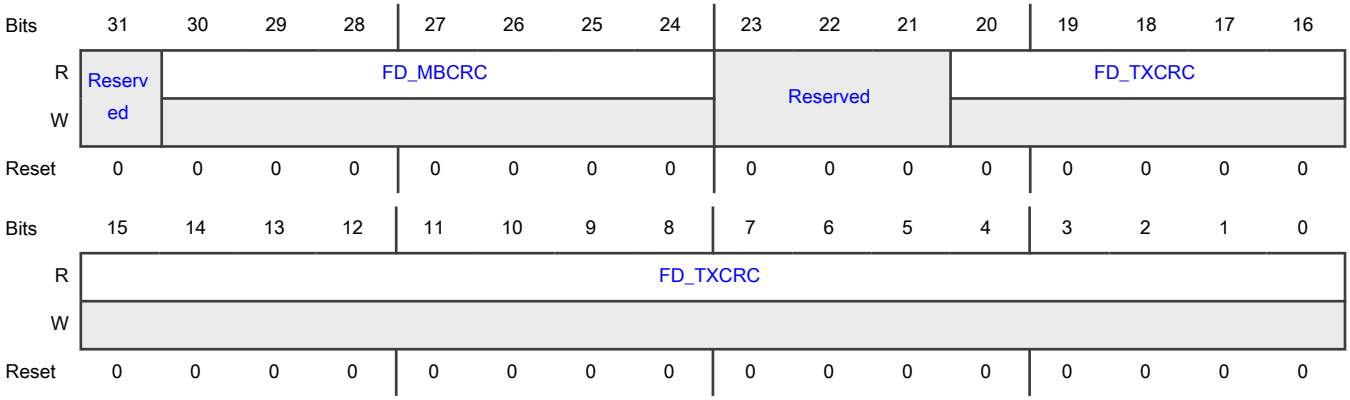
$$CRC_21 = 302899h: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$$

Equation 30. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Mailbox Number for FD_TXCRC This field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC register.

72.6.2.38 Enhanced Rx FIFO Control Register (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

Function

This register defines the Enhanced Rx FIFO configuration.

This register can be written only in Freeze mode.

All the contents of this register are affected by soft reset.

NOTE

Each module instance supports a different number of registers.

72.6.2.41 High Resolution Time Stamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

Offset

For n = 0 to 95:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Function

The High Resolution Time Stamp registers are used for storing a copy of a 32-bit timer at the start or end of a CAN frame.

HRST0 stores the 32-bit time stamp associated with MB0, HRSTS1 stores the the 32-bit time stamp associated with MB1, and so on.

These registers are not affected by reset.

NOTE

These registers must not be written out of Freeze mode.

Table 467. High Resolution Time Stamp register operation

TSTAMPCAP	Captured time base	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame.
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format.

NOTE

Each module instance supports a different number of registers.

72.6.2.42 Enhanced Rx FIFO Filter Element (ERFFEL0 - ERFFEL127)

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)

Function

These registers are used for storing the filter elements of the Enhanced Rx FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	ERFFEL0–ERFFEL127	—
CAN_1	ERFFEL0–ERFFEL127	—

Fields

Field	Function
31-0 FEL	Filter Element Bits Each filter element is used during the match process and, if the matching criteria are met, a message is stored in the Enhanced Rx FIFO.

72.6.3 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN memory partition for CAN FD for more detailed information.

Table 468. Message buffer structure — example with 64-byte payload

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0

		= Unimplemented or reserved		

EDL — Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 1010b (see table below).

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 469 and Table 470. See Functional description for additional information.

Table 469. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0100b: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the Move-in process), the CODE field is automatically updated to FULL.
0010b: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL.

Table continues on the next page...

Table 469. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
					See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4] — A frame was configured to recognize a Remote Request frame and transmit	RANSWER	—	TANSWER(1110b)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit

Table continues on the next page...

Table 469. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
a Response frame in return.[5]					a response frame. The code is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[6]	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 register (CTRL2)" for details.
4. Code 1010b is not considered Tx and an MB with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 470. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1000b: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.

Table continues on the next page...

Table 470. Message buffer code for Tx buffers (continued)

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1001b: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
1100b: DATA — MB is a Tx data frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1100b: REMOTE — MB is a Tx Remote Request frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
1110b: TANSWER — MB is a Tx Response frame from an incoming Remote Request frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010b). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 469, Table 470, and the description of the RRS field in Control 2 register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

NOTE

When configuring CAN FD frames, the RTR bit must be negated.

DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 8h–Fh of the MB space (see Table 468). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 472).

TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

Table 471. Time stamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured time base	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth

Table continues on the next page...

Table 471. Time stamp operation (continued)

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured time base	Capture point
				bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

PRIO — Local priority

This 3-bit field is used only when MCR[LPRIO_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 472. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4

Table continues on the next page...

Table 472. DATA BYTEs validity (continued)

DLC	Valid DATA BYTEs
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

72.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL[MBDSRn] bit fields as shown in table below.

Table 473. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload
2	64 to 95	MBDSR2	MBDSR2=00, 32 MBs with 8 bytes payload MBDSR2=01, 21 MBs with 16 bytes payload

Table continues on the next page...

Table 473. RAM partition (continued)

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
			MBDSR2=10, 12 MBs with 32 bytes payload MBDSR2=11, 7 MBs with 64 bytes payload

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Block2 to 32 bytes, Then the following table indicates how the message buffers will be arranged in RAM.

Table 474. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31
1	FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52
2	FDCTRL[MBDSR2]=10, 32 bytes payload	12	53 to 64

72.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

Table 475. 8-byte message buffers

72.6.6 Legacy Rx FIFO structure

When MCR[RFEN] is set, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy Rx FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy Rx FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy Rx FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy Rx FIFO data structure.

Table 479. Legacy Rx FIFO structure

	31 28	24 23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT		SRR	IDE	RTR	DLC	TIME STAMP	
84h		ID standard				ID extended		
88h	Data byte 0		Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved							
E0h	ID filter table element 0							
E4h	ID filter table element 1							
E8h–2D4h	ID filter table elements 2 to 125							
2D8h	ID filter table element 126							
2DCh	ID filter table element 127							
		= Unimplemented or reserved						

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Legacy Rx FIFO for more information.

Table 480. ID table structure

Format	31	30	29 24	23 16	15 14 13 8	7 1	0
A	RTR	IDE	RXIDA				

Table continues on the next page...

Table 480. ID table structure (continued)

			(standard = 29–19, extended = 29–1)			
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)	RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)
C	RXIDC_0 (std/ext = 31–24)		RXIDC_1 (std/ext = 23–16)	RXIDC_2 (std/ext = 15–8)		RXIDC_3 (std/ext = 7–0)
		= Unimplemented or Reserved				

RTR — Remote frame

This bit specifies if remote frames are accepted into the Legacy FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

IDE — Extended frame

Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx frame identifier (Format C)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

IDHIT — Identifier acceptance filter hit indicator

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Legacy Rx FIFO. See Legacy Rx FIFO for more information.

72.6.7 Enhanced Rx FIFO structure

When ERFCR[ERFEN] is set, the Enhanced Rx FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced Rx FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The following table shows the Enhanced Rx FIFO data structure.

Table 481. Enhanced RX FIFO Structure

	31	30	29	28	24	23	22	21	20	19	18	17	16	15	8	7	6	0
2000h	EDL	BRS	ESI	RESERVED			SRR	IDE	RTR	DLC				TIME STAMP LEGACY				

Table continues on the next page...

Table 481. Enhanced RX FIFO Structure (continued)

2004h	RESERVED	ID (STANDARD/EXTENDED)	ID (EXTENDED)	
2008h	Data byte 0	Data byte 1	Data byte 2	Data byte 3
200Ch	Data byte 4	Data byte 5	Data byte 6	Data byte 7

IH_OFF	RESERVED			ID HIT
TS_OFF	HR TIME STAMP			
2050h	19 Enhanced FIFO Elements (RESERVED)			
...				
263Ch				

NOTE

ID HIT offset and high resolution time stamp offset are changed dynamically according to data length code (DLC) as shown in Table 482.

Table 482. ID HIT offset and high resolution time stamp offset

Data Length Code (DLC)	ID HIT offset (IH_OFF)	High resolution time stamp offset (TS_OFF)
0	2008h	200Ch
1–4	200Ch	2010h
5–8	2010h	2014h
9	2014h	2018h
10	2018h	201Ch
11	201Ch	2020h

Table continues on the next page...

Table 482. ID HIT offset and high resolution time stamp offset (continued)

Data Length Code (DLC)	ID HIT offset (IH_OFF)	High resolution time stamp offset (TS_OFF)
12	2020h	2024h
13	2028h	202Ch
14	2038h	203Ch
15	2048h	204Ch

EDL — Extended Data Length

This bit distinguishes between classical CAN format and CAN FD format frames.

0 – Classical CAN frame format

1 – CAN FD frame format

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

0 – Bit rate is not switched in a CAN FD frame

1 – Bit rate is switched in a CAN FD frame

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive. This bit is meaningful only if EDL = 1.

0 – Transmitting node is error active

1 – Transmitting node is error passive

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

0 – Frame format is standard

1 – Frame format is extended

RTR — Remote Frame

0 = Indicates the current frame is a data frame

1 = Indicates the current frame is remote request

DLC — Data Length Code

This 4-bit field defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. Refer to Table 472 for more details.

LEGACY TIME STAMP — 16-bit Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured during the CAN frame. See Table 471 to find more details about legacy time stamp operation.

ID — Frame Identifier

In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be stored in the data field.

IDHIT — Identifier Acceptance Filter Hit Indicator

This field indicates which Enhanced Rx FIFO Filter Element (ERFFELn) was hit by the received message that is in the output of the Enhanced Rx FIFO. For each filter region, standard-ID filter space and extended-ID filter space, there is an independent index starting from zero. Table 483 shows how IDHIT is written by FlexCAN according to each filter element.

Table 483. IDHIT for Enhanced Rx FIFO

Enhanced Rx FIFO filter element — ERFFEL	ID HIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m–1)	m–1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n–m+1)	2x(n–m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist, and if NEXIF > NFE, then only extended-ID filter elements exist.

HR TIME STAMP — High-resolution Time Stamp

32-bit time base captured during the CAN frame. When CTRL2[TSTAMPCAP] is different from zero, a 32-bit time base is captured from a dedicated on-chip timer which operates in free running mode. See TSTAMPCAP field description in Control 2 Register (CTRL2) to find more details about capture point configuration of the high-resolution time stamp.

72.7 Glossary

Active message buffer	A message buffer is *active* if it can participate in the current matching or arbitration process.
Bus interface unit	FlexCAN submodule responsible for the interface to the CPU.
Bus off	See CAN Specification.[230]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[230] and ISO International Standard.[231]

[12] Controller Area Network – CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[13] ISO International Standard – ISO 11898 First Edition 1993 Road Vehicles – Interchange of Digital Information – Controller Area Network (CAN) for high-speed Communication.

CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[230]
Error frame	See CAN Specification.[230]
Error passive	See CAN Specification.[230]
Form error	See CAN Specification.[230]
Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[230]
Information processing time	See CAN Specification.[230]
Intermission	See CAN Specification.[230]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[230]
Phase buffer segment	See CAN Specification.[230]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[230]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

Chapter 73
Synchronous Audio Interface (SAI)

73.1 Chip-specific SAI information

73.1.1 SAI instances and configuration

Table 484. SAI instances

Instance	S32K322/S32K342/S32K314/S32K324/S32K344/S32K358	S32K311/S32K312
SAI_0	Yes	No
SAI_1	Yes	No

Table 485. SAI configuration

Chip	Instances	Synchronous operation between instances	DMA support	Data Rate/ channel	No. of Channels	Frame Synchronization	Master Clock Frequency	FIFO size(TX/RX)/ Channel	No. of words/ frame
S32K322, S32K342, S32K314, S32K324, S32K344, S32K358	SAI_0 SAI_1	No	Yes	12.288 Mbps	4 1	I2S, AC97, and CODEC/DSP interfaces	24.576 external audio	8X32 bit	8-16 words

NOTE

The SAI_BCLK (SAI_TX_BCLK, SAI_RX_BCLK), SAI_SYNC (SAI_TX_SYNC, SAI_RX_SYNC), and SAI_DATA (SAI_TX_DATA, SAI_RX_DATA) pins are shared between each module instance's (SAI_0, SAI_1) receiver and transmitter. See the IOMUX file attached to this document for details. At any specific time, either the SAI receiver or the SAI transmitter should be active or they should operate synchronously (only one active at a time). The SAI transmitter and SAI receiver should not be configured to operate simultaneously with inconsistent configurations.

NOTE

Timing specification of SAI master and SAI slave may limit maximum frequency.

73.2 Overview

The Synchronous Audio Interface (SAI) provides an interface that supports full-duplex serial interfaces with frame synchronization formats such as I^2S, AC97, TDM, and codec/DSP interfaces.

73.2.1 Block diagram

The following block diagram also shows the module clocks.

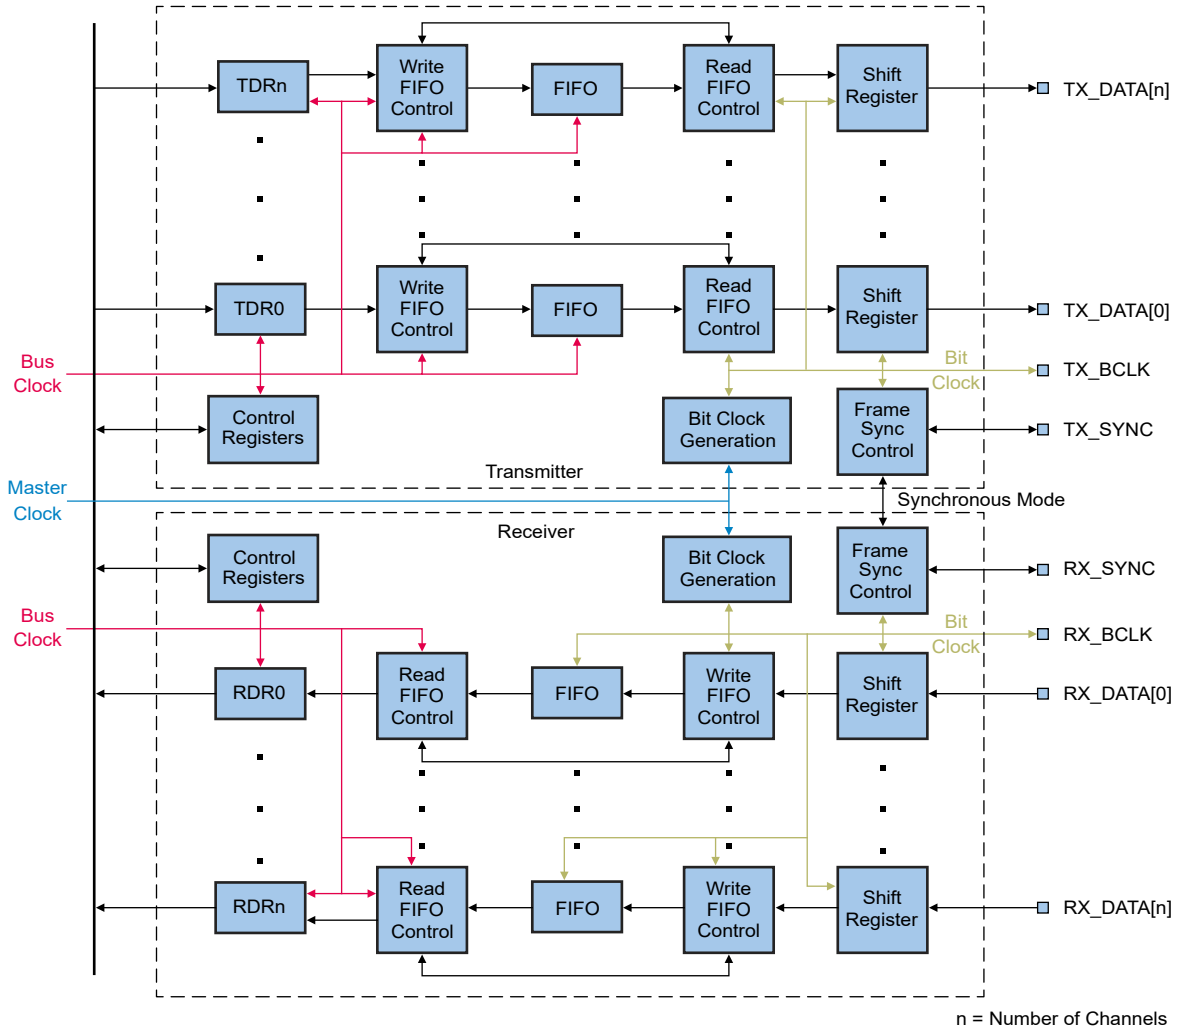

Figure 391. SAI block diagram

73.2.2 Features

Some of the features are not supported across all SAI instances; see the chip-specific SAI information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 4 data lines
- Receiver with independent bit clock and frame sync supporting 4 data lines
- Each data line can support a maximum frame size of 16 words
- 8- to 32-bit word size
- Word size configured separately for the first word and remaining words in a frame
- Asynchronous 8 x 32-bit FIFO for each transmit and receive data line supporting:
  - Graceful restart after FIFO error
  - Automatic restart after FIFO error without software intervention
  - 8-bit and 16-bit data packing into each 32-bit FIFO word
  - Multiple data line FIFOs combining into single data line FIFO

73.3 Functional description

This section provides a complete functional description of the block.

73.3.1 Modes of operation

Module power modes include Run mode, and Debug mode.

Run mode

In Run mode, the SAI transmitter and receiver operate normally.

Debug mode

In Debug mode, the SAI transmitter and/or receiver continues operating if the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

73.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in synchronous mode only after both the transmitter and receiver are enabled.
- Enable the transmitter last and disable the transmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in synchronous mode only after both the receiver and transmitter are enabled.
- Enable the receiver last and disable the receiver first.

When operating in synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter/receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration registers must be configured consistently across both the transmitter and receiver.

73.3.3 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal indicates the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Generate externally or internally
- Require active high or active low
- Assert with the first bit in frame or assert one bit early
- Assert for a duration of between 1 bit clock and the first word length

- Set frame length from 1 to 16 words per frame
- Support word length of 8 to 32 bits per word
  - — First word length and remaining word lengths can be configured separately
- Transmit/Receive words MSB first or LSB first

These configuration options cannot be changed after enabling the SAI transmitter or receiver.

73.3.4 Data FIFO

Each transmit and receive channel includes a 8 x 32-bit size FIFO. To access the FIFO data use the SAI Transmit/Receive Data Registers.

73.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 392 for LSB First configurations and Figure 393 for MSB First configurations.

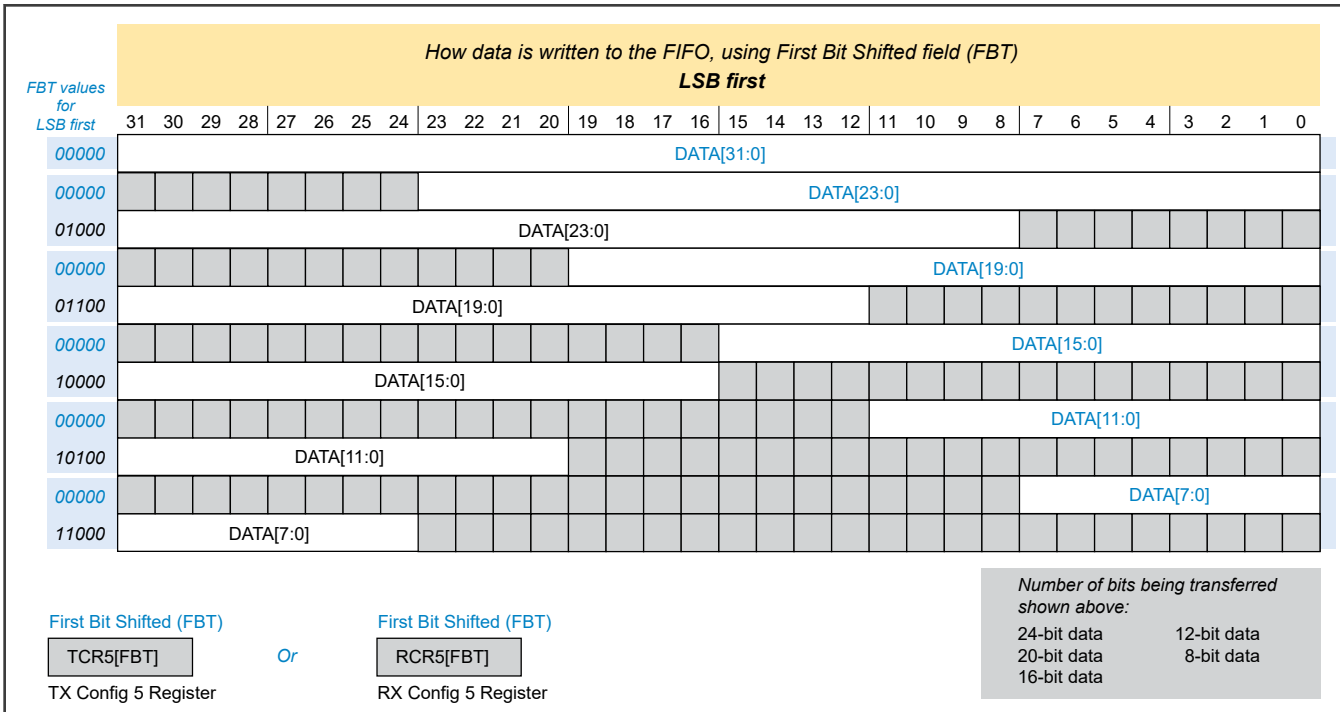

Figure 392. SAI first bit shifted, LSB first

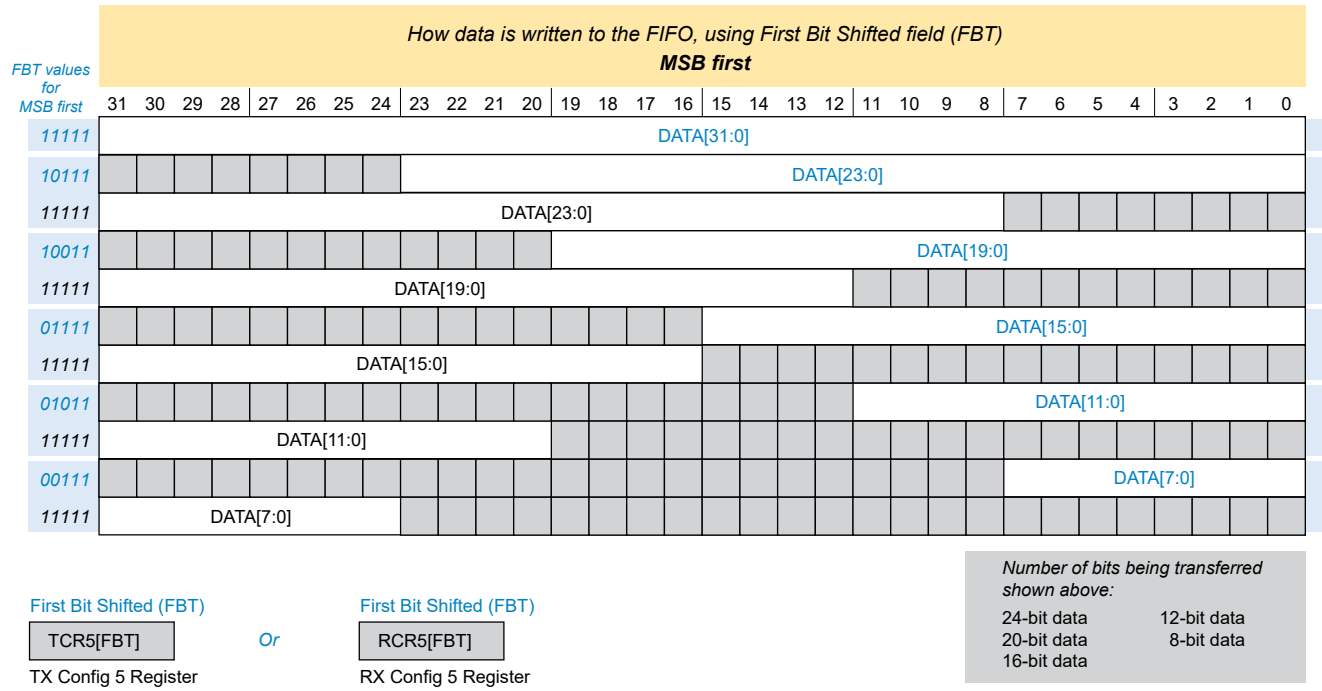

Figure 393. SAI first bit shifted, MSB first

73.3.4.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit, and 32-bit writes to the Transmit Data Register and the FIFO pointer increments after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, to avoid a FIFO underrun, write to the Transmit Data Register at least 3 bit clocks before the start of the next unmasked word.
- Before enabling the transmitter, initialize the Transmit FIFO with data (because after enabling the transmitter, the transmitter starts a new frame, and if no data is in the FIFO, then the transmitter immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding >Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit, and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, to avoid a FIFO overrun, read the Receive Data Register at least 3 bit clocks before the end of an unmasked word.

73.3.4.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been

written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

Using 16-bit FIFO packing for transmit, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset 0x0 (the first bit is selected by TCR5[FBT] and must be configured within this 16-bit word). The second word transmitted is taken from the 16-bit word at byte offset 0x2 (the first bit is selected by TCR5[FBT][3:0]). The transmitter transmits logic zero until the start of the next word once the 16-bit word has been transmitted.

Using 16-bit FIFO packing for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked-received words in each frame. The first word received is stored in the 16-bit word at byte offset 0x0 (the first bit is selected by RCR5[FBT] and must be configured within this 16-bit word). The second word received is stored in the 16-bit word at byte offset 0x2 (the first bit is selected by RCR5[FBT][3:0]). The receiver ignores received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset 0x0, second word in byte offset 0x1, third word in byte offset 0x2, and fourth word in byte offset 0x3. The TCR5[FBT] and/or RCR5[FBT] must be configured within byte offset 0x0.

73.3.4.4 FIFO Combine

FIFO Combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when using FIFO Combine mode.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register accesses the first enabled channel FIFO, while the second access to a FIFO register accesses the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels load at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted loads from the first enabled channel FIFO, while the second word transmitted loads from the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always loads from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received stores to the first enabled channel FIFO, while the second word received stores to the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always stores to the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels loads or stores each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags assert if any of the enabled data channel meets the warning flag or request flag conditions.

73.3.5 Word mask register

The SAI transmitter and receiver each contain a word mask register (Transmit Mask (TMR) and Receive Mask (RMR)) that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

73.3.6 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous interrupts are only generated when the system clock is gated provided the corresponding BCLK continues.

73.3.6.1 FIFO request flag

The FIFO request flag sets based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag sets when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and clears when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag sets when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and clears when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

73.3.6.2 FIFO warning flag

The FIFO warning flag sets based on the number of entries in the FIFO.

The transmit warning flag sets when the number of entries in any of the enabled transmit FIFOs is empty and clears when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag sets when the number of entries in any of the enabled receive FIFOs is full and clears when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

73.3.6.3 FIFO error flag

The Transmit FIFO Error Flag (TCSR[FEF] = 1]) sets when any of the enabled transmit FIFOs underrun. After the error flag sets, all enabled transmit channels transmit zero data before TCSR[FEF] clears.

When FIFO Continue on Error is enabled (TCR4[FCONT] = 1), the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun, but only after new data writes to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

The Receive FIFO Error Flag sets (RCSR[FEF] = 1) when any of the enabled receive FIFOs overflow. After the flag is set, all enabled receive channels discard received data until RCSR[FEF] clears and the next receive frame starts. Empty all enabled receive FIFOs before RCSR[FEF] clears.

When Receive FIFO Continue on Error is enabled (RCR4[FCONT] = 1), the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO Error Flag can generate only an interrupt.

73.3.6.4 Sync error flag

The Sync Error Flag (TCSR[SEF] or RCSR[SEF]) sets, when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag sets. When the Sync Error Flag sets, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The Sync Error Flag can only generate an interrupt.

73.3.6.5 Word start flag

The Word Start Flag sets (TCSR[WSF] = 1) at the start of the second bit clock for the selected word, as configured by the Word Flag Configuration field (TCR3[WDFL]).

The Word Start Flag can generate an interrupt only.

73.3.7 Clocking

The SAI clocks include:

- Audio master clock
- Bit clock
- Bus clock

Audio master clock

The audio master clock generates the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled, before the SAI transmitter or receiver is enabled
- Disabled, after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver uses an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in Stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

73.3.8 Reset

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags, and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This FIFO reset empties the FIFO contents and is used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. Use only when the corresponding TCR3[TCE] is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This FIFO reset empties the FIFO contents. Use after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[RCE] bit. Use this reset only when the corresponding RCR3[RCE] bit is clear.

73.4 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[3:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O

Fields

Field	Function
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmitter is disabled. 1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 —	Reserved Software should only write zero to this reserved bit.
29 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0b - Transmitter is disabled in Debug mode, after completing the current frame. 1b - Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmit bit clock is disabled. 1b - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. **NOTE** The FIFO reset is asserted for one cycle only. Reading this field always returns zero. Reset FIFO pointers when the transmitter is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers.

29 —	Reserved
28 BCI	Bit Clock Input

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock . **NOTE** When BCI=1 both the input buffer and output buffer must be enabled for the BCLK pad. 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock. 0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide by one of the audio master clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

73.5.1.7 Transmit Configuration 3 (TCR3)

Offset

Register	Offset
TCR3	14h

Function

Contains the transmit channel settings.

Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer.

NOTE
When there is only a single channel, there is no need for individual channel FIFO reset (TCR3[CFR]). In the case of a single channel, use the global FIFO reset (TCSR[FR]).

0b - No effect.

1b - Transmit data channel N FIFO is reset.

NOTE
This field is not supported in every instance. The following table includes only supported registers.

<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI_0</td><td>TCR3</td><td>—</td></tr><tr><td>SAI_1</td><td>—</td><td>TCR3</td></tr></table></td></tr>
<tr><td>23-20

—</td><td>Reserved</td></tr>
<tr><td>19-16

TCE</td><td>Transmit Channel Enable

Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation.

The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N.

0b - Transmit data channel N is disabled.

1b - Transmit data channel N is enabled.

NOTE
This field is not supported in every instance. The following table includes only supported registers.

Fields

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>31-29
—</td><td>Reserved</td></tr>
<tr><td>28
FCONT</td><td>FIFO Continue on Error
Configures when the SAI will continue transmitting after a FIFO error has been detected.
0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.
1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.</td></tr>
<tr><td>27-26
FCOMB</td><td>FIFO Combine Mode
When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel.
When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.
NOTE
This field is not supported in every instance. The following table includes only supported registers.
<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI_0</td><td>TCR4</td><td>—</td></tr><tr><td>SAI_1</td><td>—</td><td>TCR4</td></tr></table>
00b - FIFO combine mode disabled.
01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers).
10b - FIFO combine mode enabled on FIFO writes (by software).
11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).</td></tr>
</table>

Table continued from the previous page...

Field	Function
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00b - FIFO packing is disabled. 01b - Reserved 10b - 8-bit FIFO packing is enabled. 11b - 16-bit FIFO packing is enabled.
23-20 —	Reserved
19-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 16 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3	Frame Sync Early

Table continues on the next page...

Table continued from the previous page...

Field	Function
FSE	0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

73.5.1.9 Transmit Configuration 5 (TCR5)

Offset

Register	Offset
TCR5	1Ch

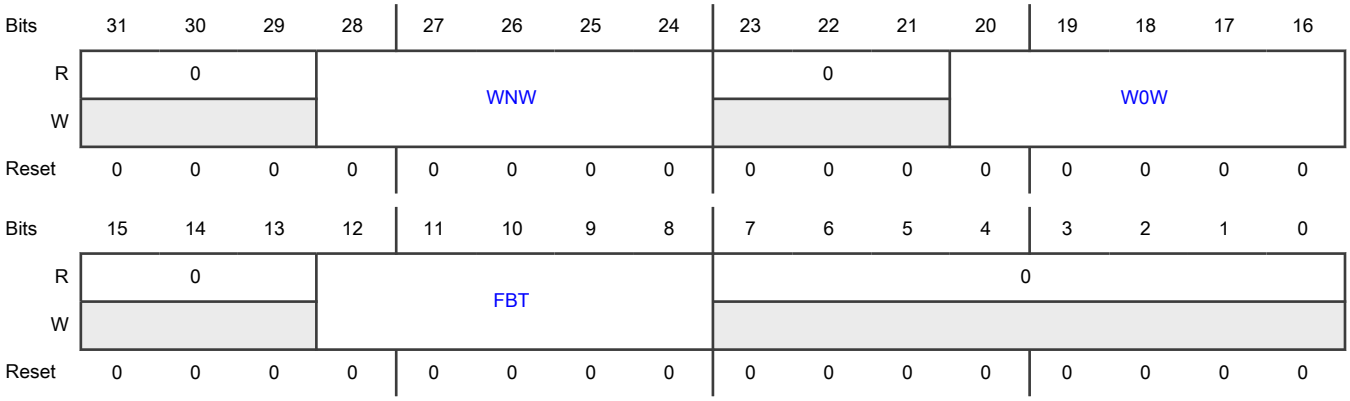
Function

Contains transmit word width and bit index settings.

NOTE

This register must not be altered when TCSR[TE] is set.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported. Bit settings 0 – 6 (0b - 0_0110b) not supported. 0_0111b - 8 bits per word 0_1000b - 9 bits per word 0_1001b-1_1110b - (WNW value + 1) bits per word 1_1111b - 32 bits per word
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame. Bit settings 0 – 6 (0b - 0_0110b) not supported. 0_0111b - 8 bits per word 0_1000b - 9 bits per word 0_1001b-1_1110b - (W0W value + 1) bits per word 1_1111b - 32 bits per word
15-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First. See Data alignment. 0_0000b - Bit index is 0. 0_0001b-1_1110b - Bit index is FBT value. 1_1111b - Bit index is 31.
7-0 —	Reserved

73.5.1.10 Transmit Data (TDR0 - TDR3)

Offset

Register	Offset
TDR0	20h
TDR1	24h
TDR2	28h
TDR3	2Ch

Function

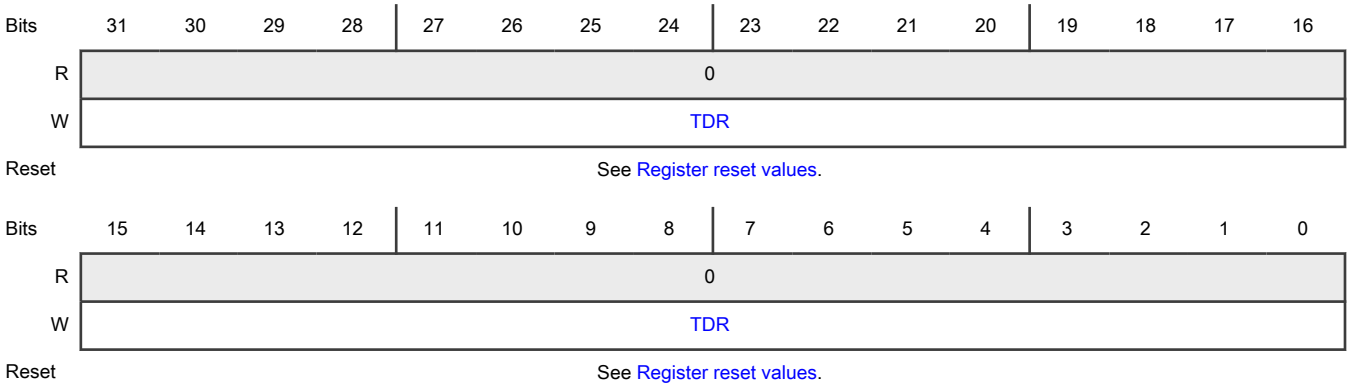
Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
SAI_0	TDR0–TDR3	—
SAI_1	TDR0	TDR1–TDR3

Diagram



Register reset values

Register	Reset value
TDR0	SAI_0,SAI_1: 0000_0000h

Fields

Field	Function
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receiver is disabled. 1b - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 —	Reserved Software should only write zero to this reserved bit.
29 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0b - Receiver is disabled in Debug mode, after completing the current frame. 1b - Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0b - Receive bit clock is disabled. 1b - Receive bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. **NOTE** The FIFO reset is asserted for one cycle only. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. **NOTE** The software reset remains asserted until cleared by software. Software clears the bit by writing 0. 0b - No effect. 1b - Software reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0b - Receive overflow not detected. 1b - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full. 1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.

73.5.1.15 Receive Configuration 2 (RCR2)

Offset

Register	Offset
RCR2	90h

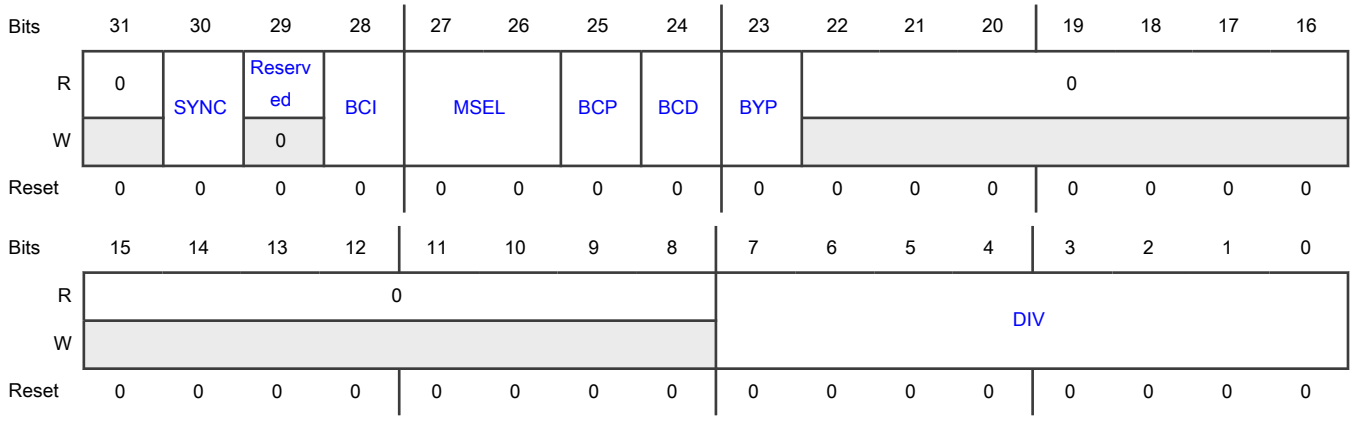
Function

Contains the SYNC mode and clock setting fields.

NOTE

This register must not be altered when RCSR[RE] is set.

Diagram



Fields

Field	Function
31 —	Reserved
30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation. 0b - Asynchronous mode. 1b - Synchronous with transmitter.
29 —	Reserved
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock .

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When BCI=1 both the input buffer and output buffer must be enabled for the BCLK pad. 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock. 0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide by one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected.

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.

1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.</td></tr>
<tr><td>27-26

FCOMB</td><td>FIFO Combine Mode

When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.

When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled, then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.

NOTE
This field is not supported in every instance. The following table includes only supported registers.

<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI_0</td><td>RCR4</td><td>—</td></tr><tr><td>SAI_1</td><td>—</td><td>RCR4</td></tr></table>
00b - FIFO combine mode disabled.

01b - FIFO combine mode enabled on FIFO writes (from receive shift registers).

10b - FIFO combine mode enabled on FIFO reads (by software).

11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).</td></tr>
<tr><td>25-24

FPACK</td><td>FIFO Packing Mode

Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.

00b - FIFO packing is disabled

01b - Reserved.</td></tr>
</table>

Field	Function
	10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-20 —	Reserved
19-16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 16 words. 0000b - 1 word per frame 0001b - 2 words per frame 0010b-1110b - (FRSZ value + 1) words per frame 1111b - 16 words per frame
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame. 0_0000b - 1 bit clock 0_0001b - 2 bit clocks 0_0010b-1_1110b - (SYWD value + 1) bit clocks 1_1111b - 32 bit clocks
7-6 —	Reserved
5 —	Reserved Software should only write zero to this bit.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0b - LSB is received first. 1b - MSB is received first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame Sync is generated externally in Slave mode. 1b - Frame Sync is generated internally in Master mode.

73.5.1.18 Receive Configuration 5 (RCR5)

Offset

Register	Offset
RCR5	9Ch

Function

Contains receive word and bit index settings.

NOTE

This register must not be altered when RCSR[RE] is set.

Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported. Bit settings 0 – 6 (0b - 0_0110b) not supported. 0_0111b - 8 bits per word 0_1000b - 9 bits per word 0_1001b-1_1110b - (WNW value + 1) bits per word 1_1111b - 32 bits per word
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame. 0_0000b - 1 bit per word 0_0001b - 2 bits per word 0_0010b-1_1110b - (W0W value + 1) bits per word 1_1111b - 32 bits per word
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First. See Data alignment. 0_0000b - Bit index is 0. 0_0001b-1_1110b - Bit index is FBT value. 1_1111b - Bit index is 31.
7-0 —	Reserved

73.5.1.19 Receive Data (RDR0 - RDR3)

Offset

Register	Offset
RDR0	A0h
RDR1	A4h
RDR2	A8h
RDR3	ACh

Function

Reads from this register when the receive FIFO is not empty return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
SAI_0	RDR0–RDR3	—

15 RCP	Receive Channel Pointer When FIFO Combine mode is enabled for reads, indicates that this data channel is the next FIFO to be read. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
SAI_0	RFR0–RFR3	—
SAI_1	—	RFR0

0b - No effect.

1b - FIFO combine is enabled for FIFO reads and this FIFO will be read on the next FIFO read.

14-4 —	Reserved
3-0 RFP	Read FIFO Pointer FIFO read pointer for receive data channel.

73.5.1.21 Receive Mask (RMR)

Offset

Register	Offset
RMR	E0h

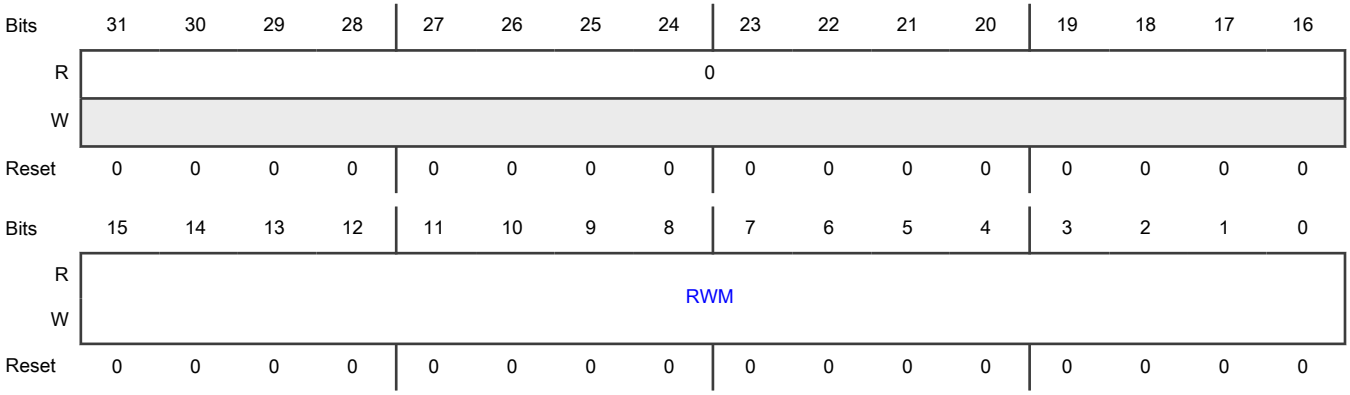
Function

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0000_0000_0000_0000b - Word N is enabled. 0000_0000_0000_0001b - Word N is masked.

Chapter 74
Ethernet Media Access Controller (EMAC)

74.1 Chip-specific EMAC information

74.1.1 EMAC instance and configuration

This chip supports up to 1 instance of EMAC IP.

Table 486. EMAC instance

Instance	S32K322/S32K342/S32K314/S32K324/S32K344	S32K311/S32K312/S32K358
EMAC	Yes	No

NOTE

DWC_EQOS refer to the Synopsys Ethernet MAC IP.

NOTE

The description for some EMAC registers include references to configurations of the Synopsis Ethernet MAC IP. Refer to MAC_HW_Feature registers for the specific features available in this chip.

NOTE

EMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

Following key features are supported:

- This chip supports only MII/RMII interfaces
- 4 bit MII interface operating at 2.5/25/50Mhz, MII can run at 10/100/200 Mbps.
- 2 bit RMII interface operating at 50Mhz, RMII can run at 10/100Mbps
- 4 bit MII-Lite interface operating at 2.5/25Mhz
- 4 PPS are supported using DMA trigger
- 200Mbps data rate is supported on Ethernet MII interface
- MTL Receive FIFO size 8192bytes
- MTL Transmit FIFO size 8192bytes

NOTE

The DMA referred within EMAC chapter refers to the internal EMAC DMA engine and not the device AXBS master DMA.

NOTE

Register access beyond 8k address space is not supported and will generate a transfer error.

NOTE

Always use store and forward mode if possible. In cut through mode, if multiple masters are active then there is chance (even in round robin arbitration mode) that EMAC DMA may starve for data resulting in insufficient data in TX FIFO leading to Tx underflow. To avoid this, increase MTL_TxQ0_Operation_Mode[TTC] value as needed.

The table below provides the information on the specific configuration utilized for the S32K3x4 and K342 devices.

Table 487. Specific configuration information

Application Interface		
	Application interface configuration	EQOS-AHB
	Data width	32
	Endian mode	Little Endian
	Address width	32
	CSR interfcae	APB3 interface
General feature		
	Mode of operation	10/100
	Enable double VLAN processing	Yes
	Enable Que/channel based VLAN tag inertion on Tx	Yes
	Enable SA and VLAN insertion on Tx	Enabled by default
Buffer managemnet		
	MTL Receive FIFO size in bytes	8192
	MTL Receive FIFO size in bytes	8192
	Enable debug memory access	Yes
	Use single port memory	Yes

	Enable receive TCP/IP Checksum Check	Enabled by default
	Enable transmit TCP/IP Checksum offload	Enabled by default
	Enable support for Tx COE in Tx queue 0	Yes
	Enable support for Tx COE in Tx queue 1	No
	Enable TCP Segmentation offloading for TCP/IP	No
	Enable Split Header Feature	No
	Enable IPv4 ARP offload	No
RMON counters		
	Enable MAC Management Counters(MMC)	Yes
	Enable the MAC Management Counters for Reciever TCP/IP Checksum offload	No
Automotive safety feature		
	Enable all automotive safety feature	Yes

74.1.2 Impact of MAC flush commands on MAC_PPSx_Target_Time_Seconds register

If the software discards the media clock generation request by configuring the PPSCTRL_PPSCMD (or PPSCMD#i) field of MAC_PPS_Control register to 0, the MAC does not flush the captured presentation time, i.e., the MAC_PPSx_Target_Time_Seconds register contents don't get changed.

74.4 Introduction

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

EMAC:

- Supports the 10/100 Mbps application in compliance with IEEE802.3-2015 specifications
- Can support advanced applications such as time-sensitive networking and AVB
- Supports a MAC core that has prominent features such as a flexible receive parser, media clock recovery and generation, and safety

74.4.1 Features

EMAC supports these features in addition to the default feature defined in the IEEE802.3 specification:

- MII (10/100 Mbps), RMII (10/100 Mbps)
- Time-aware shaper (IEEE802.1bv), time synchronization (IEEE802.1AS-rev), and frame preemption (IEEE802.1Qbu) for time-sensitive networking
- Media clock recovery and generation for AVB
- AMBA 2.0 for AHB master and APB3 interface
- RMII specification version 1.2 from RMII consortium
- Separate interface for transmit, receive, and control paths
- Two-buffer ring

- Broadcast and multicast packet duplication
- Full-duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the pulse per second (PPS) output signal
- MDIO clause 22 and clause 45 interface for configuration and management of the PHY device
- Preamble and SFD insertion and deletion
- Automatic CRC and pad generation/stripping option
- Option to disable CRC checking
- Programmable insert packet gap
- Source address insertion or replacement
- VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control, insertion, replacement, and deletion of up to two VLAN tags, insertion, replacement, and deletion of queue or channel-based VLAN tags
- IEEE802.1Q VLAN tag detection and an option to delete the tags in the receive packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes that allow:
  - Up to two additional 48-bit perfect DA filters with masks for each byte
  - Up to two 48-bit SA comparison checks with masks for each byte
  - 64-bit hash filter for multicast and unicast DA addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Passing of all incoming packets (according to filter) with a status report
- Additional packet filtering that is based on:
  - Virtual local area network (VLAN) tag—perfect match and hash-based filtering, which is based on either outer or inner VLAN tag, is possible
  - Layer 3 and layer 4—TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag—filtering based on four filter selections

NOTE

The DCB feature discussed in the following section(s) is not supported.

74.4.2 Functional block diagram

This figure shows the EMAC block diagram. EMAC has four main blocks to perform all the functions.

- The AHB interface is connected to all DMA channels.
- The DMA arbiter helps in the arbitration of all paths (transmit and receive) in DMA channels.
- Each channel has a separate set of control and status registers (CSRs) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

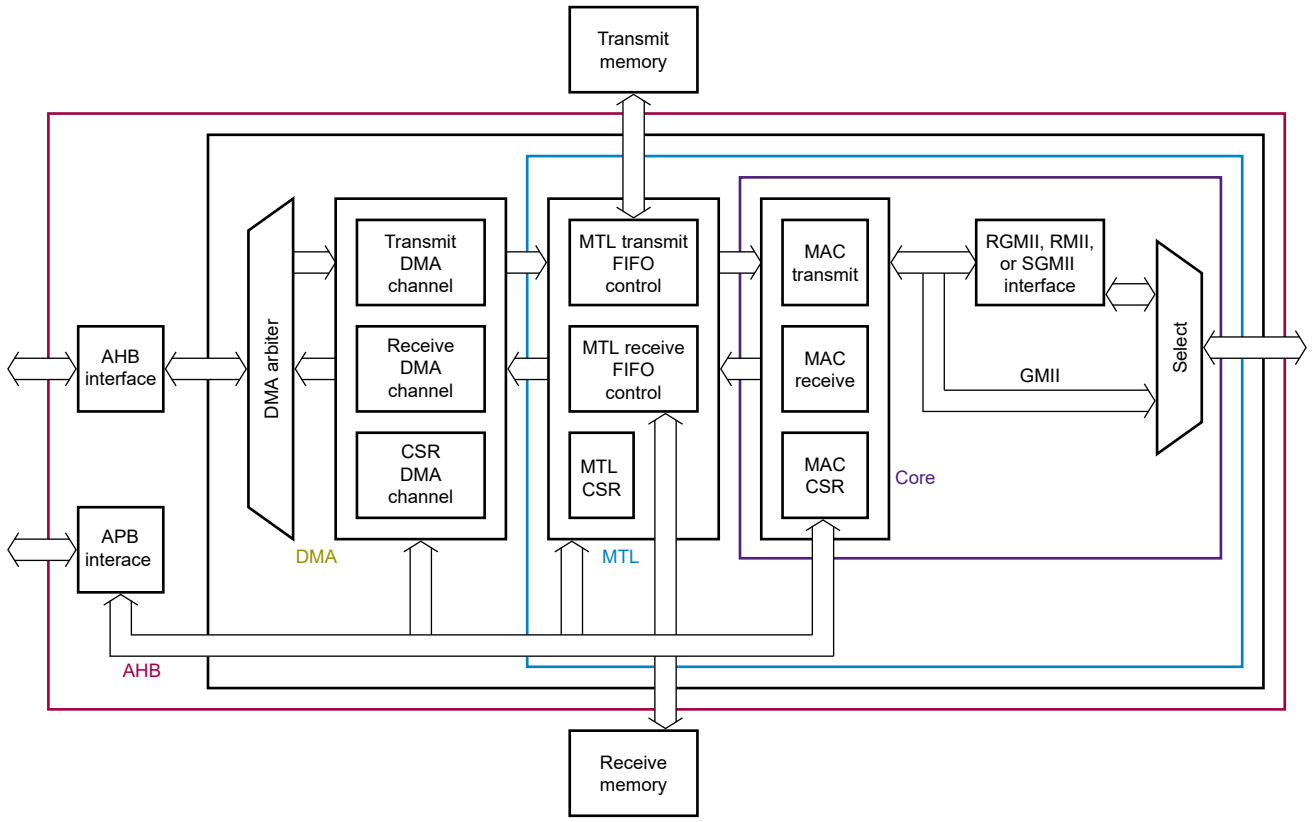

Figure 394. System-level block diagram

74.5 Architecture

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The section describes EMAC interfaces, protocols, and functionality. These are its main blocks:

- AHB master and APB3 slave interface
- DMA controller
- MTL
- MAC
- Interrupts

74.5.1 AHB master and CSR slave (APB3) interface

The 32-bit APB3 slave interface:

- Provides access to DMA, MTL, and MAC control and status registers (CSRs)
- Supports the 32-bit write and read transfers to these CSRs
- Supports single- and all-burst transfers, and an OKAY response

The DMA block uses the AHB master interface to interact with the external world. The AHB master interface:

- Controls data transfer
- Is AMBA 2.0-compliant with no restrictions
- Supports 32-bit data transfer

- Supports single and INCR transfers
- Supports burst-length modes such as Fixed, Unspecified, and Mixed

74.5.2 DMA inclusions

DMA controller:

- Includes independent transmit (Tx) and receive (Rx) engines, and a CSR space. The transmit engine transfers data from the system memory to the MTL interface, whereas the receive engine transfers data from the MTL interface to the system memory.
- Is designed for packet-oriented data transfers such as packets in Ethernet.
- Communicates with the host through CSR, descriptor lists, and data buffers.

DMA descriptors

DMA supports up to two transmit and two receive descriptor lists (or DMA channels). The base address of each list is written to the respective transmit and receive descriptor list address registers. A descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one, and DMA_CH0_Control[DSL] contols the offset. The number of descriptors in the list is programmed using the respective DMA Channel 0 Tx Descriptor Ring Length (DMA_CH0_TxDesc_Ring_Length) and DMA Channel 0 Rx Descriptor Ring Length (DMA_CH0_RxDesc_Ring_Length) registers. After the DMA processes the last descriptor in the list, it automatically jumps to the descriptor in the list address register to create a descriptor ring.

EMAC supports the ring structure for DMA descriptors. For more information, see Descriptors .

The DMA engine uses descriptors to efficiently move data from source to destination with minimal host intervention, and the DMA controller can be programmed to interrupt the host in certain situations. These situations may include packet transmit and receive transfer completion and other normal or error conditions.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory, enabling two buffers to be used and physically addressed rather than contiguous buffers in the memory.

Data buffers

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of the next packet when an EOP is detected.

The next few sections discuss DMA controller.

74.5.2.1 DMA controller bus burst access

DMA engines attempt to transfer data in a burst of the maximum size programmed using DMA_CH0_Tx_Control[TxPBL] and DMA_CH0_Rx_Control[RxPBL] of the respective DMAs, which always access the receive and transmit descriptors in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers that the DMA initates can be split into multiple burst transfers according to the AHB requirements and settings specified in DMA System Bus Mode (DMA_SysBus_Mode).

The transmit DMA initiates a data transfer only when sufficient space is available in the MTL transmit queue to accommodate either of these:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in the transmit buffer without EOP
- Number of bytes till EOP

The receive DMA initiates a data transfer in these conditions:

- Sufficient data is available in the MTL receive queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the receive queue

DMA indicates the start address and the number of transfers required to the AHB master interface. When the interface is configured for fixed-length burst, it transfers data by using the best combination of the INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed burst ends on the AHB interface, DMA performs dummy transfers to complete the fixed burst. Otherwise, DMA_SysBus_Mode[FB] becomes 0. The DMA transfers the data using undefined length (INCR) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first-burst transfer that AHB initates is less than or equal to the size of the configured PBL value, and the subsequent beats start at an address aligned to this value. The DMA can only align the address for beats up to size 16 (for PBL > 16) for the AHB interface because it does not support more than INCR16.

74.5.2.2 DMA application data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with an address aligned to the bus width and dummy data (old data) in the invalid byte lanes. The process of write transfer typically happens during the beginning or end of an Ethernet packet transfer. The software driver must discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 488. Data buffer alignment examples

Examples	
Buffer read	If the transmit buffer address is FF2h (for a 32-bit data bus) and 15 bytes need to be transferred, the DMA reads five full words from address FF0h. However, when DMA transfers data to the MTL transmit queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL transmit queue, unless it is the end of the packet.
Buffer write	If the receive buffer address is FF2h (for a 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address FF0h. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first receive buffer of the packet. It ignores the offset address and performs full-word writes for the middle and last receive buffers of the packet.

74.5.2.3 DMA buffer size calculations

DMA does not update the size fields in the transmit and receive descriptors. It updates only the status fields (RDES and TDES) of the descriptors. The driver performs the size calculations.

The transmit DMA transfers the exact number of bytes (as the buffer size field of TDES2 indicates) to MAC. If a descriptor is marked as first (TDES3[FD] = 1), the DMA marks the first transfer from the buffer as SOP, and if the descriptor is marked as last (TDES3[LD]), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or MTL sends the end of packet. When TDES3[FD] = 1, the amount of valid data in a buffer is accurately indicated by the buffer size fields in DMA Channel Rx Control (DMA_CH0_Rx_Control) minus the data buffer pointer offset. The offset is 0 when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by DMA_CH0_Rx_Control[RBSZ_13_y] and DMA_CH0_Rx_Control[RBSZ_x_0]). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL fields of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The receive DMA always transfers the start of the next packet with a new descriptor.

74.5.2.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB master interface. These two types of arbitrations are supported:

- Round-robin: If DMA_Mode[DA] = 0 and both transmit and receive DMAs simultaneously request access, the arbiter allocates the data bus in ratio sets defined in DMA_Mode[PR].
- Fixed-priority: If DMA_Mode[DA] = 1, receive DMA is always prioritized over transmit DMA for data access by default. If DMA_Mode[TXPR] = 1, transmit DMA is prioritized over receive DMA as explained in Table 506.

74.5.3 MTL

MTL provides the FIFO memory interface to buffer and regulate the packets between system memory and MAC. It also enables data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: transmit path and receive path. MTL communicates with the host through ATI on the transmit path and through ARI on the receive path.

74.5.3.1 Transmit path

The internal DMA:

- Handles all transactions for the transmit path through ATI.
- Pushes the Ethernet packet reads from system memory to the corresponding queue.

The Ethernet packet, then, pops out and is transfered to MAC when the queue reaches its threshold (Threshold mode) or if the complete packet is in the queue (Store-and-Forward mode). When EOP is transferred, the status of the transmission is taken from MAC and transferred back to the internal DMA.

74.5.3.1.1 Transmit control word

This control information related to packet transmission is provided as part of the control word through the ATI interface:

- Packet length (if DCB is enabled with WFQ scheduling algorithm)
- CRC pad control
- Source address insertion control
- VLAN insertion and replacement control and VLAN tag for outer and inner VLAN tags
- TCP/IP checksum insertion control
- One-step timestamping control correction
- Transmit timestamp enable

74.5.3.1.2 Transmit operation

These two modes of operation trigger data read towards MAC:

- Threshold (or cut-through) mode: This is the default mode. In this mode, as soon as the number of bytes in the queue crosses the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to MAC. The threshold level is configured by using MTL_TxQ0_Operation_Mode[TTC].
- Store-and-Forward mode: In this mode, MTL pops the packet out to MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the queue.
  - The transmit FIFO becomes almost full.
  - The ATI watermark becomes low.

  The watermark becomes low when the requested queue is not spacious enough to accommodate the requested burst length on ATI. Therefore, MTL, when operating in Store-and-Forward mode, allows packet transmission even if the packet length is bigger than the transmit queue size.

You can flush the complete content of the transmit queue by writing 1 to MTL_TxQ0_Operation_Mode[FTQ] or MTL_TxQ1_Operation_Mode[FTQ], depending on the queue. Doing so initializes the queue pointers to the default state. The FTQ

field returns to 0 by itself. If you write 1 to the FTQ field during a packet transfer from MTL to MAC, MTL stops further transfers because MTL considers the queue to be empty. Therefore, an underflow event occurs at the MAC transmitter.

74.5.3.1.3 Initialization flow

After reset, MTL is ready to manage the data flow between DMA and MAC.

- With single-transmit queue configurations, there are no initialization requirements for enabling MTL.
- With multiple-transmit queue configurations, initialize the queue size for each of the queues by programming MTL_TxQ0_Operation_Mode[TQS] corresponding to a transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

74.5.3.2 Receive path

MAC sends packets to the MTL receive module and pushes them into the receive queue. MTL indicates the status (fill level) of the queue to the application or DMA when it crosses the configured receive threshold (MTL_RxQ0_Operation_Mode[RTC]), or when the MTL receive module receives the complete packet in Store-and-Forward mode. MTL also indicates the fill level of the queue so that DMA can initiate preconfigured burst transfers to the AHB interface.

74.5.3.2.1 Receive operation

During a receive operation, MTL is MAC's slave. This is the general sequence of events:

1. When MAC receives a packet, it indicates the availability of receive data.
2. MAC indicates the SOP and EOP delimiters.
3. MTL accepts the data and pushes it into the corresponding receive queue.
4. When MAC transfers EOP to the MTL receive module, MAC also drives the status word that MTL pushes into the corresponding receive queue.
5. MTL takes the data out of the queue and sends it to DMA depending on these modes:
   - Threshold mode
   - Store-and-Forward mode

   The sections that follow discuss these modes.

74.5.3.2.1.1 Threshold mode

In Threshold (default) mode, MTL reads the data and indicates its availability to the application or DMA when one of these occurs:

- Data bytes equal to the threshold amount are written to the receive queue (to MTL_RxQ0_Operation_Mode[RTC] and MTL_RxQ1_Operation_Mode[RTC]).
- A full packet of data is received into the queue.

74.5.3.2.1.2 Store-and-Forward mode

In this mode (when MTL_RxQ0_Operation_Mode[RSF] = 1), the initial receive queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the receive queue. In this mode, all error packets are dropped (if configured through MTL_RxQ0_Operation_Mode[FEP]) in such a way that only valid packets are read and forwarded to the application.

74.5.3.2.2 Multi-packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In Store-and-Forward mode, the packet data is available after the packet status. MTL is capable of storing any number of packets in the queue as long as it is not full.

If MAC receives a packet when the corresponding receive queue is full, MTL ignores that packet and overflow pulse generates on the corresponding receive queue. In addition, MTL increments the overflow counter in MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt) for the corresponding queue.

74.5.3.2.3 Error handling in receive operation

MTL performs these actions if the MTL receive queue is full before it receives the EOP data from MAC:

1. Declares an overflow
2. Drops the whole packet (including the status word)
3. Increments the overflow counter in DMA (MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt))

This is true even if MTL_RxQ0_Operation_Mode[FEP] is 1.

If the start address of such a packet is already transferred to the read controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL receive queue is configured to operate in the Store-and-Forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL receive control logic can filter errors and undersized packets, if enabled by using MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]. If the start address of one such packet is already transferred to the receive queue read controller, the packet is not filtered. The start address of the packet is transferred to the read controller after the packet crosses the receive threshold defined using MTL_RxQ0_Operation_Mode[RTC].

If the MTL receive queue is configured to operate in Store-and-Forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. MTL then starts transferring the next packet, if it's available.

74.5.4 MAC

MAC can support the MII and RMII PHY interface and it consists of:

- MTI
- MRI
- MCI

74.5.4.1 MAC transmission

The MAC transmission process is as follows:

1. The transmission initiates when MTL pushes in data with the SOP signal asserted.
2. After the SOP signal is detected, MAC accepts the data and begins transmitting to RMII or MII.
3. After the EOP signal is transferred to MAC, it performs one of these steps:
   - Completes normal packet transmission and sends the transmission status to MTL
   - Sends retry requests if a normal collision (in Half-Duplex mode) occurs during transmission, and until one of the following is true:
     - Packet is successfully transmitted.
     - Maximum retry requests have expired. When this happens, MAC aborts the packet transmission with "excessive collision transmit" status. MAC accepts and drops all further data until it receives the next SOP. The MTL block must retransmit the same packet from SOP on observing a retry request (in the status) from MAC.
   - If any one of the following happens, MAC aborts the packet transmission:

- No carrier (Half-Duplex mode)
- Loss of carrier (Half-Duplex mode)
- Excessive deferral (Half-Duplex mode)
- Late collisions (Half-Duplex mode)
- Jabber
- MAC accepts and drops all further data until it receives the next SOP

4. MAC issues an underflow status if MTL is not able to provide data continuously during transmission. Until the next SOP is received, MAC accepts and drops all further data.
5. During the normal transfer of a packet from MTL, if MAC receives an SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as a continuation of the previous packet.

74.5.4.2 MAC reception

The receive operation initiates as follows:

1. MAC detects a state-of-frame data on RMII or MII.
2. MAC strips the preamble and SFD before processing an Ethernet packet.
3. The MAC AFM:
   - Checks the header fields (SA and DA) of an incoming packet for filtering
   - Verifies the CRC contained in the packet's FCS field
4. MAC's AFM checks the header fields (SA and DA) of an incoming packet for filtering.
5. FCS verifies the CRC of the received packet.
6. MAC stores the received packet in a shallow buffer until address filtering is performed.
7. AFM drops the packet if it fails the address filter.

74.5.5 Interrupts

EMAC supports interrupt coalescing, which reduces the number of interrupts generated by the module and reduces the CPU load. MAC Interrupt Status (MAC_Interrupt_Status) captures various interrupt events. If the interrupt enable field of an interrupt is 1, the corresponding interrupt generates based on the event status in the Status registers. The Interrupt mode (INTM) field decides whether the interrupt signal is a level signal or pulse signal. See the following table and interrupt map file attached to this document for details.

Table 489. Interrupt request

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Common interrupt	MAC Interrupt Enable (MAC_Interrupt_Enable)	MAC Interrupt Status (MAC_Interrupt_Status)
	MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask)	MMC Receive Interrupt (MMC_Rx_Interrupt)
	MMC Transmit Interrupt Mask (MMC_Tx_Interrupt_Mask)	MMC Transmit Interrupt (MMC_Tx_Interrupt)
	MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask)	MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt)

Table continues on the next page...

Table 489. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
	MMC FPE Receive Interrupt Mask (MMC_FPE_Rx_Interrupt_Mask)	MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt)
	MTL Debug Control (MTL_DBG_CTL)	MTL Debug Status (MTL_DBG_STS)
	MTL EST Interrupt Enable (MTL_EST_Intr_Enable)	MTL EST Status (MTL_EST_Status)
	MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)	MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)
	MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)	MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)
	MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)	MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH0_Interrupt_Status
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH1_Interrupt_Status
		DMA Interrupt Status (DMA_Interrupt_Status) (First level status. Indicates major block event source: DMA channel, MTL or MAC)
		MTL Interrupt Status (MTL_Interrupt_Status) (Status summary for MTL block interrupts: Rx Parser, EST, FIFO Debug, Queue 1/Queue 0)
Tx interrupt 0/1	DMA Channel Tx Control (DMA_CH0_Tx_Control)	DMA Channel 0 Status (DMA_CH0_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)	
	DMA Channel 1 Tx Control (DMA_CH1_Tx_Control)	DMA Channel 1 Status (DMA_CH1_Status)
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)	
Rx interrupt 0/1	DMA Channel Rx Control (DMA_CH0_Rx_Control)	DMA Channel 0 Status (DMA_CH0_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)	
	DMA Channel 1 Rx Control (DMA_CH1_Rx_Control)	DMA Channel 1 Status (DMA_CH1_Status)
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)	

Table continues on the next page...

Table 489. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Safety interrupt	MTL ECC Interrupt Enable (MTL_ECC_Interrupt_Enable)	MTL ECC Interrupt Status (MTL_ECC_Interrupt_Status)
		MTL Safety Interript Status (MTL_Safety_Interrupt_Status)
	MTL DPP Control (MTL_DPP_Control)	MAC DPP FSM Interrupt Status (MAC_DPP_FSM_Interrupt_Status)
	MAC FSM Control (MAC_FSM_Control)	

These are the interrupt output signals that are synchronous to the CSR clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – interrupt per transmit channel
- Sbd_perch_rx_intr_o [max_dma_ch] – interrupt per receive channel

NOTE

max_dma_ch = number of transmit/receive queues, which is 2

The sbd_intr_o common interrupt is a level signal. When it is asserted, a corresponding interrupt event source can be found in DMA Interrupt Status (DMA_Interrupt_Status), which is a read-only register that contains the event source fields corresponding to each DMA channel (transmit and receive queue pair), MAC transaction layer, and MAC blocks. You must then read the following registers and look for the fields that are 1:

- MAC Interrupt Status (MAC_Interrupt_Status)
- MTL Interrupt Status (MTL_Interrupt_Status)
- DMA Channel 0 Status (DMA_CH0_Status)

The sbd_intr_o interrupt deasserts only when all the enabled interrupt events are clear in their respective status registers, and correspondingly, all the fields in DMA Interrupt Status (DMA_Interrupt_Status) are 0. DMA Channel 0 Status (DMA_CH0_Status) captures all the interrupt events of that transmit DMA and receive DMA channel pair.

DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable) contains the corresponding enable fields for each of the interrupt events. These are the two groups of interrupts in the DMA channel:

- Normal—DMA_CH0_Status[NIS] indicates this interrupt, which is used for events that occur during the normal transfer of packets (TI, RI, TBU).
- Abnormal—DMA_CH0_Status[AIS] indicates this interrupt, which is used for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts generate.

The common sbd_intr_o output signal asserts for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable).

EMAC also supports these per-channel transfer-complete interrupt signals:

- sbd_perch_tx_intr_o[max_dma_ch] (transmit per channel interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (receive per channel interrupts)

The behavior of the RI/TI/sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depends on the configuration specified in DMA_Mode[INTM]. This table explains the transfer complete interrupt behavior.

Table 490. Transfer complete interrupt behavior

Interrupt mode	Behavior of sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of the TI/RI interrupts and sbd_intr_o
INTM = 1	In this mode, these signals indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are 1, respectively. Therefore, they are level signals that you clear by writing 1 to these fields. The signals do not assert when DMA_CH0_Status[RI] or DMA_CH0_Status[TI] is 0.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are configured as explained. For any RI/TI events: • The sbd_intr_o signal does not assert. • DMA_CH0_Status[NIS] remains 0.
INTM = 2	In this mode, RI/TI are queued and indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when any of these fields is 1. RI and TI are level signals that you clear by writing 1 to these fields. However, the fields become 1 again if another TI/RI event is detected before DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 for the previous event.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 whenever the transfer complete event is detected and are reset whenever the software driver changes them to 0 by writing 1. However, if another transfer complete event is detected before the software changes it to 0 (services it), EMAC automatically writes 1 to these fields again. The generation of the sbd_intr_o signal; however, is not based on DMA_CH0_Status[RI] or DMA_CH0_Status[TI].

74.6 Signal descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

74.6.1 Module signals

This table provides port/signal names and their descriptions. See the IOMUX file attached to this document for details.

Table 491. Module signals

Port name (clock/signal)	I/O	Description
MII_RMII_TXCLK (Clock)	I	MII: The external PHY provides this transmission clock, which operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All transmission signals that MAC generates are synchronous to this clock, which is required for all PHY interfaces.

Table continues on the next page...

Table 491. Module signals (continued)

Port name (clock/signal)	I/O	Description
		RMII: The RMII interface uses this 50 MHz clock. If you select RMII mode, MII_RX_CLK (25 MHz or 2.5 MHz) must be derived from the RMII reference clock.
MII_RX_CLK (Clock)	I	The external PHY provides this receive clock for the MII and RMII interfaces. The clock operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All MII receive signals that MAC receives are synchronous to MII_RX_CLK. The clock's input is required for all PHY interfaces.
EMAC_PPS[3:0] (Signals)	I/O	This group of signals is used as pulse per second in Output mode and as media clock generation trigger in Input mode. The signals trigger input to DUT to capture presentation time. Based on the presentation control value of MAC PPS Control (MAC_PPS_Control), the signals can be defined as pulse or level signals.
MII_RMII_TX_EN (Signal)	O	MAC drives this signal, which performs multiple functions depending on the selected PHY interface as described in this list: • MII: When high, indicates that valid data is being transmitted to the phy_txd_o bus. MII_RMII_TX_EN is synchronous to MII_RMII_TX_CLK. • RMII: When high, indicates that valid data is being transmitted to the phy_txd_o bus. MII_RMII_TX_EN is synchronous to MII_RMII_RX_CLK.
MII_RMII_TXD[3:0] (Signals)	O	This is a group of transmit data signals driven by MAC. These signals perform multiple functions depending on the selected PHY interface as described in this list: • MII: Bits[3:0] provide the MII transmit data nibble. The data is valid only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_MII_TX_CLK. • RMII: Bits[1:0] provide the RMII transmit data. The data is valid

Table continues on the next page...

Table 491. Module signals (continued)

Port name (clock/signal)	I/O	Description
		only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_RMII_TX_CLK.
MII_CRS (Signal)	I	This signal is valid only in MII mode. The PHY drives this signal high when the transmit or receive medium is not idle, and drives the signal low when both these mediums are idle. The signal is not synchronous to any clock.
MII_COL (Signal)	I	This signal is valid only in MII mode. The PHY drives this signal high when a collision is detected on the medium. The signal is not synchronous to any clock.
MII_RMII_RX_DV (Signal)	I	The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list: • MII: Indicates that the data on the MII_RXD bus is valid. It remains high continuously from the first recovered byte or nibble of the packet through the final recovered byte or nibble of the packet. MII_RMII_RX_DV is synchronous to MII_RX_CLK. • RMII: Contains the CRS and data valid information of the receive interface. MII_RMII_RX_DV is synchronous to MII_RMII_TX_CLK.
MII_RMII_RX_ER (Signal)	I	The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list: • MII: Indicates an error or carrier extension in the received packet of the MII_RXD[3:0] bus. MII_RMII_RX_ER is synchronous to MII_RX_CLK. • RMII: Is not used.
MII_RMII_RXD[3:0] (Signals)	I	This is a group of data signals received from the PHY. These signals perform multiple functions depending on the selected PHY interface as described in this list:

Table continues on the next page...

Table 491. Module signals (continued)

Port name (clock/signal)	I/O	Description
		• MII: Bits [3:0] provide the MII receive data nibble. The data is valid only when the MII_RMII_RX_DV signals are high. MII_RMII_RXD[3:0] is synchronous to MII_RX_CLK. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the MII_RMII_RX_DV signal is high. MII_RMII_RXD[3:0] is synchronous to MII_RMII_TX_CLK.
MII_RMII_MDC	O	MAC provides timing reference for MII_RMII_MDIO or MII through this periodic clock. The application clock generates this clock through a clock divider that MAC_MDIO_Address[CR] controls.
MII_RMII_MDIO (Signal)	I/O	MDIO uses this signal to transfer control and data information to PHY.

74.7 EMAC register descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

NOTE

This chip has 16 KB allocated per Ethernet controller for configuration space. EMAC uses only 8 KB of this memory and the remaining 8 KB is reserved for future use. Writing to the reserved memory may lead to unintended behavior.

74.7.1 EMAC memory map

EMAC base address: 4048_0000h

Fields

Field	Function
31 —	Reserved
30-28 SARC	Source Address Insertion Or Replacement Control Controls the source address insertion or replacement for all the transmitted packets. Bit 30 of this field specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of bits [29:28]: • 2'b0x: The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. • 2'b10: If bit 30 = 0, MAC inserts the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the Enable MAC Address Register 1 option is selected while configuring the core, MAC inserts the content of the MAC Address 1 registers in the SA field of all the transmitted packets. • 2'b11: If bit 30 = 0, MAC replaces the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the MAC Address Register 1 is enabled, MAC replaces the content of the MAC Address 1 registers in the SA field of all the transmitted packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packet can use the updated value. This means that the current packet does not use the updated value. 000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010b - Contents of are inserted in the SA field 011b - Contents of replace the SA field 110b - Contents of are inserted in the SA field 111b - Contents of replace the SA field
27 IPC	Checksum Offload Indicates the status of IP header or payload checksum checking. If this field is 1, the field enables IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When the field becomes 0, the COE function in the receiver is disabled. The Layer 3 and Layer 4 packet filter and enable split header features automatically select the IPC full checksum offload engine on the receive side. When any of these features are enabled, you must write 1 to this field. 0b - Disabled 1b - Enabled
26-24 IPG	Inter-Packet Gap Controls the minimum IPG between packets during transmission. The range of minimum IPG is valid in Full-Duplex mode, and in this mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, MAC does not consider the minimum IPG. This function (IPG less than 96-bit times) is valid only when MAC_Ext_Configuration[EIPGEN] is 0. If this field is 1, the minimum IPG (greater than 96-bit times) is controlled according to the field's description. 000b - 96-bit times IPG 001b - 88-bit times IPG 010b - 80-bit times IPG 011b - 72-bit times IPG 100b - 64-bit times IPG 101b - 56-bit times IPG 110b - 48-bit times IPG 111b - 40-bit times IPG
23	Giant Packet Size Limit Control Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
GPSLCE	Enables and disables giant packet size limit control. If this field = 1, MAC considers the value of MAC_Ext_Configuration[GPSL] to declare a received packet as a giant packet. This field must be programmed to have a size of more than 1,518 bytes. Otherwise, MAC considers 1,518 bytes as the giant packet limit. When this field becomes 0, MAC considers the received packet as a giant packet if its size is greater than 1,518 bytes (1522 bytes for a tagged packet). The WD, JE, and S2KP fields have a higher precedence over this field, which means MAC considers a received packet as a giant packet when its size is greater than 9,018 bytes (9,022 bytes for a tagged packet) with JE = 1 and the size of the jumbo packet greater than 2,000 bytes and S2KP = 1. If the WD field is 1, the field terminates the received packet if it reaches the watchdog limit. Therefore, the programmed giant packet limit must be less than the watchdog limit to get the giant packet status. 0b - Disabled 1b - Enabled
22 S2KP	IEEE 802.3 Support For 2K Packets Indicates the status of IEEE 802.3 support for 2K packets. If this field is 1, MAC considers all the packets with up to 2,000-byte length as normal. When the JE field is not 1, MAC considers all the received packets of size more than 2K bytes as giant packets. When this field becomes 0 and the JE field is not 1, MAC considers all the received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this field and the JE field impacts the giant packet status, see this status based on the S2KP and JE fields. If the JE field is 1, writing 1 to the S2KP field has no effect on the giant packet status. 0b - Disabled 1b - Enabled
21 CST	CRC Stripping For Type Packets Indicates the status of CRC stripping for Type packets. If this field is 1, the last four bytes (FCS) of all the Ether-type packets are stripped and dropped before forwarding the packet to the application. This field is valid only when the receive packet size is more than or equal to 1536 bytes. For information about how the settings of this field and the ACS field impact the packet length, see MAC Configuration (MAC_Configuration). 0b - Disabled 1b - Enabled
20 ACS	Automatic Pad Or CRC Stripping Indicates the status of automatic pad or CRC stripping. If this field is 1, MAC strips the pad or the FCS field on the incoming packets only if the size of the packets is less than 1,536 bytes. All the received packets with a size greater than or equal to 1,536 bytes are passed to the application without stripping the pad or the FCS field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, MAC passes all the incoming packets to the application, without any modification. For information about how the settings of this field and the CST field impact the packet length, see MAC Configuration (MAC_Configuration). 0b - Disabled 1b - Enabled
19 WD	Watchdog Disable Indicates the status of watchdog. If this field is 1, MAC disables the watchdog timer on the receiver. MAC can receive packets of up to 16,383 bytes. When this field becomes 0, MAC does not allow more than 2,048 bytes (10,240 if the JE field = 1) of the packet being received. MAC cuts off bytes received after 2,048. 0b - Enabled 1b - Disabled
18 —	Reserved
17 JD	Jabber Disable Indicates the status of jabber. If this field is 1, MAC disables the jabber timer on the transmitter. It can transfer packets of up to 16,383 bytes. If this field is 0 and the application sends more than 2,048 bytes of data (10,240 if the JE field = 1) during transmission, MAC does not send the rest of the bytes in that packet. 0b - Enabled 1b - Disabled
16 JE	Jumbo Packet Enable Indicates the status of jumbo packets. If this field is 1, MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN-tagged packets) without reporting a giant packet error in the receive packet status. 0b - Disabled 1b - Enabled
15 PS	Port Select Selects the Ethernet line speed. This field, along with the FES field, selects the exact line speed. In the 10/100 Mbit/s-only (always 1) or 1000 Mbit/s-only (always 0) configurations, this field is read-only (RO) with an appropriate value. By default, with

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10/100/1000 Mbit/s configurations, this field is read-write (R/W). The mac_speed_o[1] signal reflects the value of this field. 0b - For 1000 or 2500 Mbit/s operations 1b - For 10 or 100 Mbit/s operations
14 FES	Speed Indicates the speed. This field selects the speed mode. The mac_speed_o[0] signal indicates the value of this field. 0b - 10 Mbit/s if PS = 1 and 1 Gbps if PS = 0 1b - 100 Mbit/s if PS = 1 and 2.5 Gbps if PS = 0
13 DM	Duplex Mode Indicates the mode in which MAC operates. If this field is 1, MAC operates in Full-Duplex mode in which it can transmit and receive simultaneously. The field can only be read, with 1 as its default value, in full-duplex-only configurations. 0b - Half-duplex mode 1b - Full-duplex mode
12 LM	Loopback Mode Indicates the status of Loopback mode If this field is 1, MAC operates in Loopback mode at GMII or MII. This mode requires the (G)MII Rx clock input (clk_rx_i) signal to function properly because the transmit clock is not internally looped back. 0b - Disabled 1b - Enabled
11 ECRSFD	Enable Carrier Sense In Full-Duplex Mode Indicates whether ECRSFD is enabled or disabled. If this field is 1, the MAC transmitter checks the CRS signal before packet transmission in Full-Duplex mode. MAC starts transmitting only when the CRS signal is low. If this field becomes 0, the MAC transmitter ignores the status of the CRS signal. 0b - Disabled 1b - Enabled
10 DO	Disable Receive Own Enables or disables receive own. If this field is 1, MAC disables the reception of packets when the gmii_txen_o signal asserts in Half-Duplex mode. When the field is 0, MAC receives all the packets that PHY sent. This field is not applicable in Full-Duplex mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enabled 1b - Disabled
9 DCRS	Disable Carrier Sense During Transmission Enables or disables carrier sense during transmission. If this field is 1, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in Half-Duplex mode. As a result, no errors generate because of loss of carrier or no carrier during transmission. When this field becomes 0, the MAC transmitter generates errors because of carrier sense. MAC can even abort the transmission. 0b - Enabled 1b - Disabled
8 DR	Disable Retry Enables or disables retry attempts. If this field is 1, MAC attempts only one transmission. When a collision occurs on GMII or MII, MAC ignores the current packet transmission and reports a packet abort with excessive collision errors in the transmit packet status. If this field becomes 0, MAC retries based on the settings of the BL field of this register. The settings of this field apply only in Half-Duplex mode. 0b - Enabled 1b - Disabled
7 —	Reserved
6-5 BL	Back-Off Limit Determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbit/s; 512 bit times for 10/100 Mbit/s) for which MAC waits before rescheduling a transmission attempt during retry attempts after a collision. • *n* = retransmission attempt • *r* = random integer that takes the value in the range 0 <= r < 2^k This field is applicable only in Half-Duplex mode. 00b - k = min(n,10) 01b - k = min(n,8) 10b - k = min(n,4) 11b - k = min(n,1)
4 DC	Deferral Check Indicates the status of the deferral check function.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, the deferral check function is enabled in MAC, which issues a packet abort status, with Tx_Excessive_Deferral_Error[TXEXSDEF] = 1 in the transmit packet status, when the transmit state machine is deferred for more than 24,288 bit times in 10 Mbit/s or 100 Mbit/s mode. If MAC is configured for a 1000/2500 Mbit/s operation, the threshold for deferral is 155,680 bit times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active, and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of this collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer resets to 0 and restarts. When this field becomes 0, the deferral check function disables and MAC defers until the CRS signal becomes inactive. This field is applicable only in Half-Duplex mode. 0b - Disabled 1b - Enabled
3-2 PRELEN	Preamble Length for Transmit Packets Controls the number of preamble bytes that are added to the beginning of every transmit packet. Preamble reduction occurs only when MAC operates in Full-Duplex mode. 00b - 7 bytes 01b - 5 bytes 10b - 3 bytes 11b - Reserved
1 TE	Transmitter Enable Indicates the status of the transmitter. • If this field is 1, the MAC transmit state machine is enabled for transmission on GMII or MII. • When the field becomes 0, the MAC transmit state machine is disabled after it completes the transmission of the current packet. The transmit state machine does not transmit any more packets. 0b - Disabled 1b - Enabled
0 RE	Receiver Enable Indicates the status of the receiver. If this field is 1, MAC's receive state machine is enabled for receiving packets from GMII or MII. When this field becomes 0, the MAC receive state machine is disabled after it completes the reception of the current packet. The receive state machine does not receive any more packets from GMII or MII. 0b - Disabled 1b - Enabled

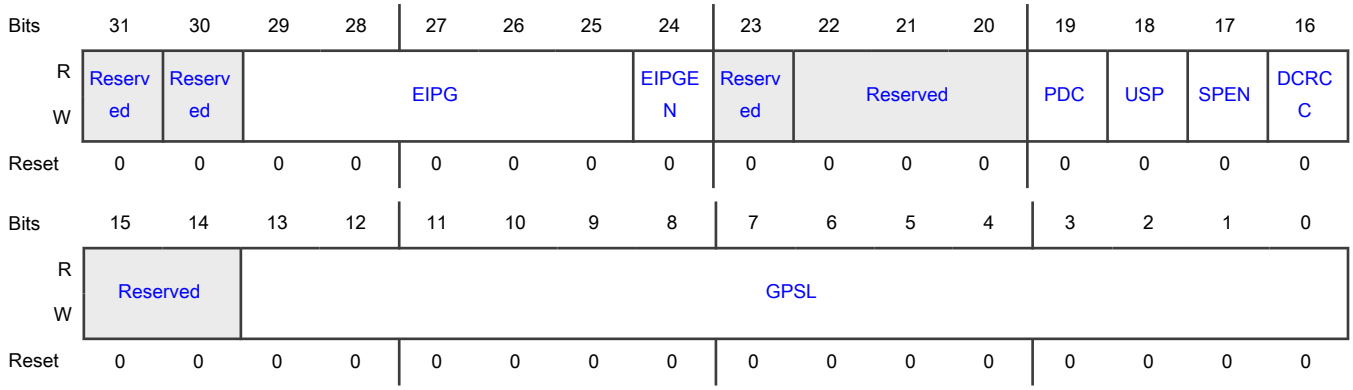
74.7.3 MAC Extended Configuration (MAC_Ext_Configuration)

Offset

Register	Offset
MAC_Ext_Configuration	4h

Function
Establishes MAC's operating mode.

Diagram



Fields

Field	Function
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap Indicates the value of the extended inter-packet gap. The value of this field is applicable when EIPGEN = 1. The most-significant bits of this field, along with those of MAC_Configuration[IPG], render the minimum IPG greater than 96-bit times in steps of 8-bit times. 8'h00: 104-bit times 8'h01: 112-bit times 8'h02: 120-bit times ---------- 8'hFF: 2144-bit times
24	Extended Inter-Packet Gap Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
EIPGEN	Indicates the status of the extended inter-packet gap. • If this field is 1, MAC interprets the EIPG field of this register and the IPG field of MAC Configuration (MAC_Configuration) together as minimum IPG greater than 96-bit times in steps of 8-bit times. • If this field is 0, MAC ignores the EIPG field of this regsiter and interprets the IPG field of MAC Configuration (MAC_Configuration) as minimum IPG less than or equal to 96-bit times in steps of 8-bit times. **NOTE** You must enable the extended inter-packet gap feature when operating in Full-Duplex mode only. There could be undesirable effects on the back-pressure function and frame transmission if the feature is enabled in Half-Duplex mode. 0b - Disabled 1b - Enabled
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control Indicates the packet duplication control status. • If this field is 1, the received packet with multicast or broadcast destination address is routed to multiple receive DMA channels. MAC_Address0_High[DCS] identifies the receive DMA channels (corresponding to the MAC Address register) that match the multicast or broadcast destination addresses in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the receive DMA channel. • If this field is 0, the received packet routes to a single receive DMA channel. MAC_Address0_High[DCS] identifies the receive DMA channel corresponding to the MAC Address register that matches the destination address in the received packet. The DCS field is interpreted as a binary value. 0b - Disabled 1b - Enabled
18 USP	Unicast Slow Protocol Packet Detect Indicates the status of unicast slow-protocol packet detection. • If this field is 1, MAC detects the slow-protocol packets with unicast address of the station specified in MAC Address 0 High (MAC_Address0_High) and MAC Address 0 Low (MAC_Address0_Low). MAC also detects the slow-protocol packets with the slow-protocol multicast address (01-80-C2-00-00-02). • If this field is 0, MAC detects only slow-protocol packets with the slow protocol multicast address specified in IEEE 802.3-2015, section 5.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
17 SPEN	Slow Protocol Detection Enable Enables or disables slow protocol detection. • If this field is 0, EMAC forwards all error-free, slow-protocol packets to the application. EMAC considers such packets as normal-type packets. • If this field is 1, EMAC processes the slow-protocol packets (Ether type 8809h) and provides the slow protocol sub-type and code fields in receive status. 0b - Disabled 1b - Enabled
16 DCRCC	Disable CRC Checking For Received Packets Indicates the status of CRC checking. If this field is 1, MAC receiver does not check the CRC field in the received packets. When this field becomes 0, the MAC receiver always checks the CRC field in the received packets. 0b - Enabled 1b - Disabled
15-14 —	Reserved
13-0 GPSL	Giant Packet Size Limit Declares the status of a packet based on its size. If the received packet size (in bytes) is greater than the value programmed in this field, MAC declares the received packet as a giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Also, any other programmed value is considered as 1,518 bytes. For VLAN-tagged packets, MAC adds 4 bytes to the programmed value. If MAC_VLAN_Tag_Ctrl[EDVLP] = 1, MAC adds 8 bytes to the programmed value for double VLAN-tagged packets. The value of GPSL is valid if MAC_Configuration[GPSLCE] = 1.

74.7.4 MAC Packet Filter (MAC_Packet_Filter)

Offset

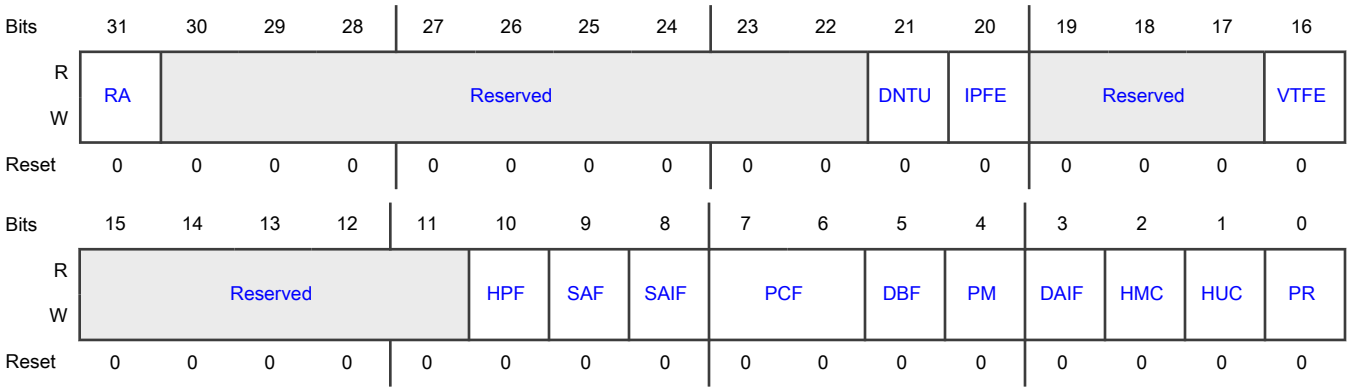
Register	Offset
MAC_Packet_Filter	8h

Function

Contains the filter controls for receiving packets.

Some of the controls from this register go to MAC's address check block that performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as pass bad packets and pass control packets.

Diagram



Fields

Field	Function
31 RA	Receive All Indicates whether the received packets are enabled or disabled. • If this field is 1, the MAC Receiver module passes all the received packets to the application, irrespective of their passing the address filter. The result (pass or fail) of the SA or DA filtering is updated in the corresponding field of the receive status word. • If this field is 0, the module passes only those packets to the application that pass the SA or DA address filter. 0b - Receive All is disabled 1b - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP Over IP Packets Indicates whether MAC drops or forwards non-TCP/UDP protocols over IP packets. • If this field is 1, MAC drops these protocols over IP packets. MAC forwards only those packets that the layer 4 filter processes. • If this field is 0, MAC forwards all these protocols over IP packets. 0b - Forwards 1b - Drops
20 IPFE	Layer 3 and Layer 4 Filter Enable Indicates the status of layer 3 and layer 4 filters.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, MAC drops packets that do not match the enabled layer 3 and layer 4 filters. If these two filters are not enabled for matching, this field does not have any effect. • If this field is 0, MAC forwards all the packets irrespective of the match status of the layer 3 and layer 4 fields. 0b - Disabled 1b - Enabled
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable Indicates the status of VLAN tag filter. • If this field is 1, MAC drops the VLAN-tagged packets that do not match the VLAN tag. • If this field is 0, MAC forwards all the packets irrespective of the match status of the VLAN tag. 0b - Disabled 1b - Enabled
15-11 —	Reserved
10 HPF	Hash Or Perfect Filter Indicates the status of hash or perfect filter. • If this field is 1, the address filter passes a packet if it matches either perfect filtering or hash filtering as defined by the HMC or HUC fields of this register. • If this field is 0 and HUC = 1 or HMC = 1, the packet passes only if it matches the hash filter. 0b - Disabled 1b - Enabled
9 SAF	Source Address Filter Enable Indicates the status of SA filtering. • If this field is 1, MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, MAC drops the packet. • When this field becomes 0, MAC forwards the received packet to the application with an updated field value, depending on the SA address comparison. **NOTE** According to the IEEE specification, bit 47 of the SA field is reserved. However, MAC compares all the 48 bits. You must consider this when programming the MAC address registers for SA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
8 SAIF	SA Inverse Filtering Indicates the status of SA inverse filtering. • If this field is 1, the address check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA address filter. • If this field becomes 0 and the SA of a packet does not match the values programmed in the SA registers, the SA is marked as failing the SA address filter. 0b - Disabled 1b - Enabled
7-6 PCF	Pass Control Packets Controls the forwarding of all the control packets (including unicast and multicast pause packets). 00b - MAC filters all the control packets from reaching the application 01b - MAC forwards all the control packets, except pause packets, to the application even if they fail the address filter 10b - MAC forwards all the control packets to the application even if they fail the address filter 11b - MAC forwards all the control packets that pass the address filter
5 DBF	Disable Broadcast Packets Enables or disables broadcast packets. • If this field is 1, AFM blocks all the incoming broadcast packets. In addition, it overrides all the other filter settings. • If this field is 0, AFM passes all the received broadcast packets. 0b - Enabled 1b - Disabled
4 PM	Pass All Multicast Enables or disables the passing of received packets. • If this field is 1, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is 1) are passed. • If this field is 0, filtering of multicast packets depends on the settings of the HMC field. 0b - Disabled 1b - Enabled
3 DAIF	DA Inverse Filtering Indicates the status of DA inverse filtering.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the Address Check block operates in Inverse Filtering mode for the DA address comparison of both unicast and multicast packets. • If this field is 0, normal filtering of packets is performed. 0b - Disabled 1b - Enabled
2 HMC	Hash Multicast Indicates the status of hast multicast. • If this field is 1, MAC performs the destination address filtering of received multicast packets according to the hash table. • If this field is 0, MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Disabled 1b - Enabled
1 HUC	Hash Unicast Indicates the status of hash unicast. • If this field is 1, MAC performs the destination address filtering of unicast packets according to the hash table. • When this field becomes 0, MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values you program in the MAC Address registers. 0b - Disabled 1b - Enabled
0 PR	Promiscuous Mode Indicates the status of Promiscuous mode. If this field is 1, the address filtering module passes all the incoming packets irrespective of the destination or source address. MAC clears the SA or DA filter fail status fields of the receive status word when PR = 1. 0b - Disabled 1b - Enabled

74.7.5 MAC Watchdog Timeout (MAC_Watchdog_Timeout)

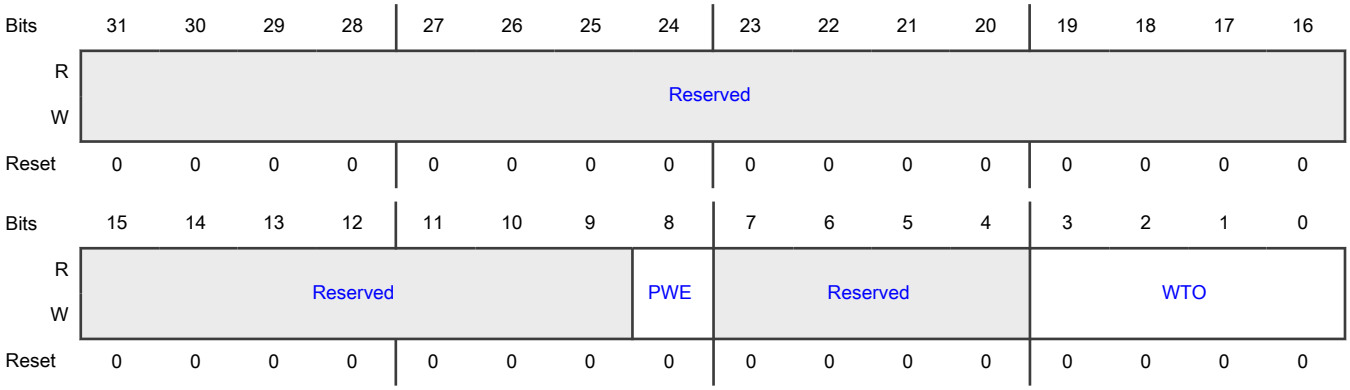
Offset

Register	Offset
MAC_Watchdog_Timeout	Ch

Function

Controls the watchdog timeout for received packets.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 PWE	Programmable Watchdog Enable Indicates the status of programmable watchdog. • If this field is 1 and MAC_Configuration[WD] is 0, the WTO field of this register is used as watchdog timeout for a received packet. • If this field is 0, MAC_Configuration[WD] and MAC_Configuration[JE] control the watchdog timeout for a received packet. 0b - Disabled 1b - Enabled
7-4 —	Reserved
3-0 WTO	Watchdog Timeout Indicates the size of watchdog timer. If PWE = 1 and MAC_Configuration[WD] = 0, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, the packet terminates as an error packet. **NOTE** If PWE = 1, the value in this field must exceed 1,522 (05F2h). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and dropped. 0000b - 2 KB 0001b - 3 KB

74.7.6 MAC Hash Table First 32 Bits (MAC_Hash_Table_Reg0)

Offset

Register	Offset
MAC_Hash_Table_Reg0	10h

Function

Contains the first 32 bits of the hash table, when the total width of the hash table is 128 bits or 256 bits.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Use the upper 6, 7, or 8 bits from the value obtained in step 2.

If this field is 1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Function
31-0 HT31T0	MAC Hash Table First 32 Bits Contains the first 32 bits [31:0] of the hash table.

74.7.7 MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1)

Offset

Register	Offset
MAC_Hash_Table_Reg1	14h

Function

Contains the second 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 6, 7, or 8 bits from the value obtained in step 2.

If the corresponding bit value of this register is 1'b1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

74.7.8 MAC VLAN Tag (MAC_VLAN_Tag)

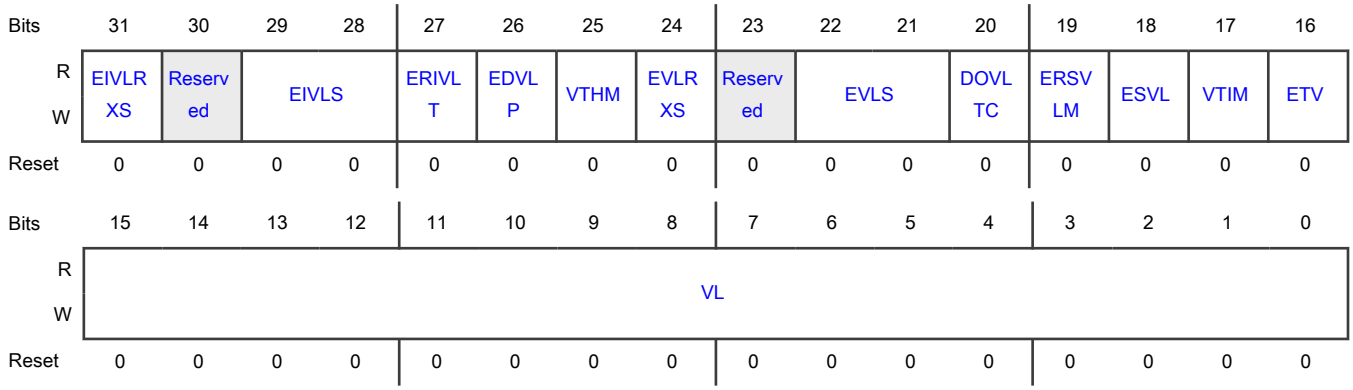
Offset

Register	Offset
MAC_VLAN_Tag	50h

Function

Identifies the IEEE 802.1Q VLAN type packets.

Diagram



Fields

Field	Function
31 EIVLRXS	Enable Inner VLAN Tag In Receive Status Indicates whether the inner VLAN tag in receive status is enabled or disabled. • If this field is 1, MAC provides the inner VLAN tag in the receive status. • If this field is 0, MAC does not provide the inner VLAN tag in the receive status. 0b - Disabled 1b - Enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping Indicates the stripping operation on the inner VLAN tag in a received packet. The field enables or disables inner VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	Enable Inner VLAN Tag Comparison Enables or disables the inner VLAN tag. • If ERIVLT = VTHM = EDVLP = 1, the EMAC receiver enables the VLAN hash filtering operation on the inner VLAN tag (if present). • If ERIVLT = 0 and VTHM = 1, the EMAC receiver enables the VLAN hash filtering operation on the outer VLAN tag (if present). ERSVLM and DOVLTC determine which VLAN type is enabled for filtering. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
26 EDVLP	Enable Double VLAN Processing Enables or disables double VLAN processing. • If this field is 1, MAC enables processing of up to two VLAN tags on transmit and receive (if present). • If this field is 0, MAC enables processing of up to one VLAN tag on transmit and receive (if present). 0b - Disabled 1b - Enabled
25 VTHM	VLAN Tag Hash Table Match Indicates the status of VLAN tag hash table match. • If this field is 1, the most-significant four bits of CRC-32 of VLAN tag are used to index the content of MAC VLAN Hash Table (MAC_VLAN_Hash_Table). See VLAN filtering for details. • If MAC_VLAN_Hash_Table[VLHT] = 1, corresponding to the index, it indicates that the Ethernet packet matches the VLAN hash table. See VLAN filtering for details. • If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison. • If VTHM = 1, the VLAN hash match operation is not performed. 0b - Disabled 1b - Enabled
24 EVLRXS	Enable VLAN Tag In Receive Status Indicates whether the VLAN tag in receive status is enabled. • If this field is 1, MAC provides the outer VLAN tag in the receive status. • If this field is 0, MAC does not provide the outer VLAN tag in receive status. 0b - Disabled 1b - Enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20	Disable VLAN Type Check

Table continues on the next page...

Table continued from the previous page...

Field	Function
DOVLTC	Enables or disables VLAN type check for VLAN hash filtering. • If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. • If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN. • The VLAN filter is bypassed when VLAN type of received packet do not match the programmed VLAN type in the VLAN filter. 0b - Enabled 1b - Disabled
19 ERSVLM	Enable Receive S-VLAN Match Enables or disables receive S-VLAN match for VLAN hash filtering. • If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets. • If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets. The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching. 0b - Disabled 1b - Enabled
18 ESVL	Enable S-VLAN Enables or disables S-VLAN. If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets. 0b - Disabled 1b - Enabled
17 VTIM	VLAN Tag Inverse Match Enable Enables or disables VLAN tag inverse matching. • If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. • If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched. 0b - Disabled 1b - Enabled
16 ETV	Enable Tag For VLAN Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. • When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - Disabled 1b - Enabled
15-0 VL	VLAN Tag Identifier for Receive Packets Contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field: • 15:13 — User priority • 12 — Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • 11:0 — VID field of VLAN tag When ETV = 1, only the VID is used for comparison. When VL = 0, and ETV = 1, MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 8100h or 88a8h as VLAN packets.

74.7.9 MAC VLAN Tag Control (MAC_VLAN_Tag_Ctrl)

Offset

Register	Offset
MAC_VLAN_Tag_Ctrl	50h

Function

Is the redefined version of the MAC_VLAN_Tag register.

This register provides the control and addressing fields required for indirect access to the MAC_VLAN_Tag_Filter registers. It also contains the address offset, command type, and busy bit for CSR access of the MAC VLAN Hash Filter registers.

Table continued from the previous page...

Field	Function
26 EDVLP	Enable Double VLAN Processing Enables or disables double VLAN processing. • If this field is 1, MAC enables processing of up to two VLAN tags on transmit and receive (if present). • If this field is 0, MAC enables processing of up to one VLAN tag on transmit and receive (if present). 0b - Disabled 1b - Enabled
25 VTHM	VLAN Tag Hash Table Match Indicates the status of VLAN tag hash table match. • If this field is 1, the most-significant four bits of CRC-32 of VLAN tag are used to index the content of MAC VLAN Hash Table (MAC_VLAN_Hash_Table). See VLAN filtering for details. • If MAC_VLAN_Hash_Table[VLHT] = 1, corresponding to the index, it indicates that the Ethernet packet matches the VLAN hash table. See VLAN filtering for details. • If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison. • If VTHM = 1, the VLAN hash match operation is not performed. 0b - Disabled 1b - Enabled
24 EVLRXS	Enable VLAN Tag In Receive Status Indicates whether the VLAN tag in receive status is enabled. • If this field is 1, MAC provides the outer VLAN tag in the receive status. • If this field is 0, MAC does not provide the outer VLAN tag in receive status. 0b - Disabled 1b - Enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20	Disable VLAN Type Check

Table continues on the next page...

Table continued from the previous page...

Field	Function
DOVLTC	Enables or disables VLAN type check for VLAN hash filtering. • If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. • If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN. 0b - Enabled 1b - Disabled
19 ERSVLM	Enable Receive S-VLAN Match Enables or disables receive S-VLAN match for VLAN hash filtering. • If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets. • If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets. The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching. 0b - Disabled 1b - Enabled
18 ESVL	Enable S-VLAN Enables or disables S-VLAN. If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets. 0b - Disabled 1b - Enabled
17 VTIM	VLAN Tag Inverse Match Enable Enables or disables VLAN tag inverse matching. • If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. • If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched. 0b - Disabled 1b - Enabled
16 ETV	Enable Tag For VLAN Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering. • If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - Disabled 1b - Enabled
15-4 —	Reserved
3-2 OFS	Offset Holds the address offset of the MAC VLAN Tag Filter register that the application tries to access. The width of this field depends on the number of enabled MAC VLAN Tag registers.
1 CT	Command Type Specifies whether the current register access indicates a read or a write operation. It indicates a read operation if this field is 1 and a write operation when the field is 0. 0b - Write operation 1b - Read operation
0 OB	Operation Busy Indicates the operation busy status. • This field becomes 1 to initiate a read or write command for an indirect access to the Per VLAN Tag Filter register. • The field becomes 0 when the read or write command to Per VLAN Tag Filter indirect access register completes. The next indirect register access can be initiated only after the field resets. During a write operation, the field becomes 0 only after the data is written into a MAC_VLAN_Tag_Filter register. During a read operation, the data must be read from MAC VLAN Tag Data (MAC_VLAN_Tag_Data) only after this field becomes 0. 0b - Disabled 1b - Enabled

74.7.10 MAC VLAN Tag Data (MAC_VLAN_Tag_Data)

Offset

Register	Offset
MAC_VLAN_Tag_Data	54h

Function

Holds the read and write data for indirect access to the Per VLAN Tag registers.

- During read access, this register contains valid read data only after MAC_VLAN_Tag_Ctrl[OB] becomes 0.
- During write access, this register must become valid before you write 1 to MAC_VLAN_Tag_Ctrl[OB].

20 ERIVLT	Enable Inner VLAN Tag Enables or disables inner VLAN tag comparison. • This field is valid only when the double VLAN tag enable of the filter is set. • If this field and the EDVLP field is 1, the MAC receiver enables operation on the inner VLAN tag (if present). • If this field is 0, the MAC receiver enables operation on the outer VLAN tag (if present). 0b - Disabled 1b - Enabled
19 ERSVLM	Enable S-VLAN Match Enables or disables S-VLAN match for received frames. This field is valid only when the VLAN tag enable of the filter is set. • If this field is 1, the MAC receiver enables filtering or matching for S-VLAN (type = 88A8h) packets. • If this field is 0, the MAC receiver enables filtering or matching for C-VLAN (type = 8100h) packets. 0b - Disabled 1b - Enabled
18 DOVLTC	Disable VLAN Type Comparison Enables or disables VLAN type comparison. This field is valid only when the VEN field is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, MAC does not check whether the VLAN tag that ERIVLT specifies is of type S-VLAN or C-VLAN. • If this field is 0, MAC filters or matches the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. 0b - Enabled 1b - Disabled
17 ETV	VLAN Comparison Indicates 12-bit or 16-bit VLAN comparison. • This field is valid only when the VEN field is 1. • When the value of this field is 1, a 12-bit VLAN identifier is used for filter and comparison instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16-bit VLAN comparison 1b - 12-bit VLAN comparison
16 VEN	VLAN Tag Enable Enables or disables the VLAN tag. • If this field is 1, MAC compares the VLAN tag of the received packet with the VLAN tag ID. • If this field is 0, no comparison is performed irrespective of the programming of the other fields. 0b - Disabled 1b - Enabled
15-0 VID	VLAN Tag ID Holds the VLAN tag value that MAC uses for perfect comparison. The field is valid when VEN = 1.

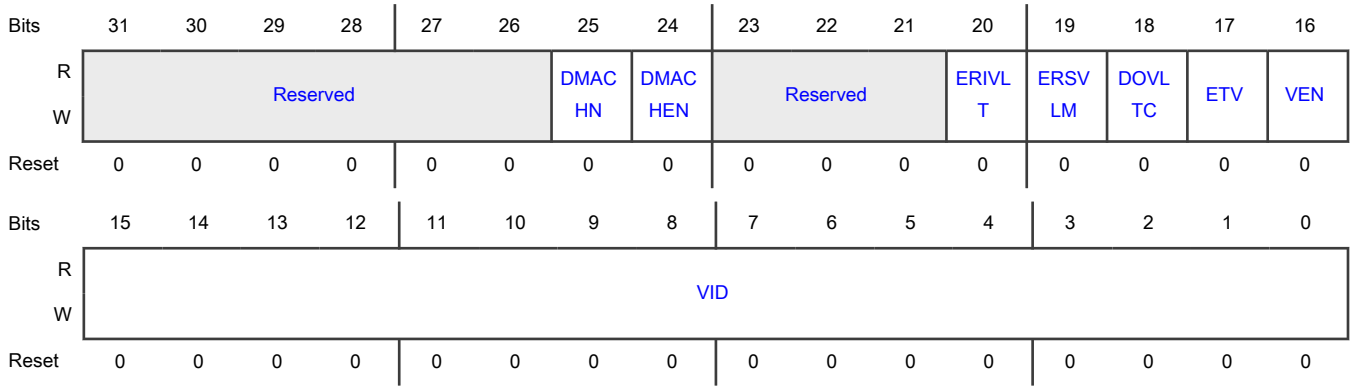
74.7.13 MAC VLAN Tag Filter 2 (MAC_VLAN_Tag_Filter2)

Offset

Register	Offset
MAC_VLAN_Tag_Filter2	54h

Function
Contains VLAN tag filter 2 control information.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 DMACHN	DMA Channel Number Indicates the DMA channel number to which the VLAN-tagged frame is to be routed if it passes the VLAN tag filter programmed using this field. If the routing based on VLAN tag filter is not necessary, this field does not need to be programmed.
24 DMACHEN	DMA Channel Number Enable Enables or disables the DMA channel number value programmed using the DMACHN field. If this field is 0, the routing does not occur based on the VLAN filter result. The frame is routed on the basis of DA-based DMA channel routing. 0b - Disabled 1b - Enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Enables or disables inner VLAN tag comparison. • This field is valid only when the double VLAN tag enable of the filter is set. • If this field and the EDVLP field is 1, the MAC receiver enables operation on the inner VLAN tag (if present). • If this field is 0, the MAC receiver enables operation on the outer VLAN tag (if present). 0b - Disabled 1b - Enabled
19	Enable S-VLAN Match

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERSVLM	Enables or disables S-VLAN match for received frames. This field is valid only when the VLAN tag enable of the filter is set. • If this field is 1, the MAC receiver enables filtering or matching for S-VLAN (type = 88A8h) packets. • If this field is 0, the MAC receiver enables filtering or matching for C-VLAN (type = 8100h) packets. 0b - Disabled 1b - Enabled
18 DOVLTC	Disable VLAN Type Comparison Enables or disables VLAN type comparison. This field is valid only when the VEN field is 1. • If this field is 1, MAC does not check whether the VLAN tag that ERIVLT specifies is of type S-VLAN or C-VLAN. • If this field is 0, MAC filters or matches the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. 0b - Enabled 1b - Disabled
17 ETV	VLAN Comparison Indicates 12-bit or 16-bit VLAN comparison. • This field is valid only when the VEN field is 1. • When the value of this field is 1, a 12-bit VLAN identifier is used for filter and comparison instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16-bit VLAN comparison 1b - 12-bit VLAN comparison
16 VEN	VLAN Tag Enable Enables or disables the VLAN tag. • If this field is 1, MAC compares the VLAN tag of the received packet with the VLAN tag ID. • If this field is 0, no comparison is performed irrespective of the programming of the other fields. 0b - Disabled 1b - Enabled
15-0 VID	VLAN Tag ID Holds the VLAN tag value that MAC uses for perfect comparison. The field is valid when VEN = 1.

74.7.14 MAC VLAN Tag Filter 3 (MAC_VLAN_Tag_Filter3)

Offset

Register	Offset
MAC_VLAN_Tag_Filter3	54h

Function

Contains VLAN tag filter 3 control information.

15-0 VID	VLAN Tag ID Holds the VLAN tag value that MAC uses for perfect comparison. The field is valid when VEN = 1.

74.7.15 MAC VLAN Hash Table (MAC_VLAN_Hash_Table)

Offset

Register	Offset
MAC_VLAN_Hash_Table	58h

Function

If MAC_VLAN_Tag_Ctrl[VTHM] = 1, the 16-bit VLAN hash table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on MAC_VLAN_Tag_Ctrl[ETV]) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC value are used to index the contents of the VLAN hash table. For example, hash value of 1000b selects bit 8 of the VLAN hash table.

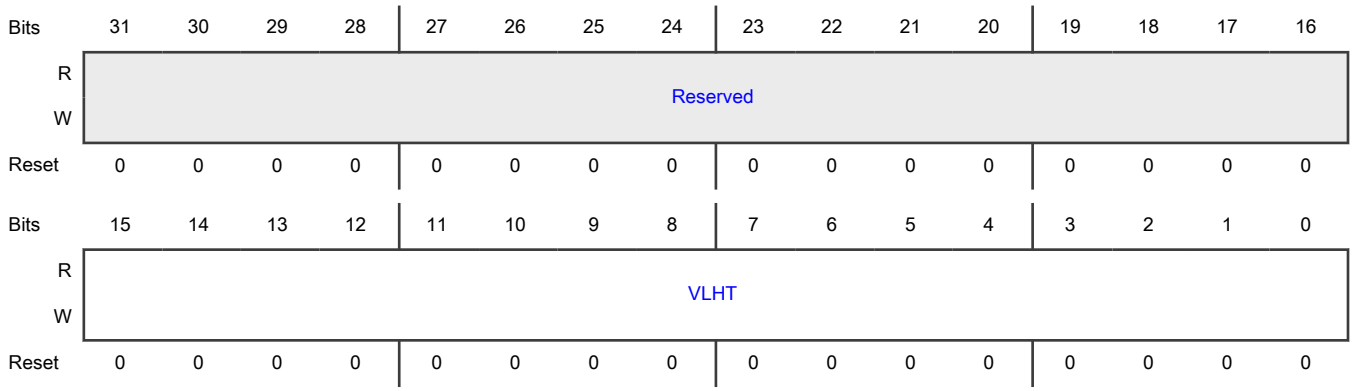
Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 of IEEE 802.3 for steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 4 bits from the value obtained in step 2.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [15:8] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the register are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 VLHT	VLAN Hash Table Contains the 16-bit VLAN hash table.

74.7.16 MAC VLAN Inclusion Or Replacement (MAC_VLAN_Incl)

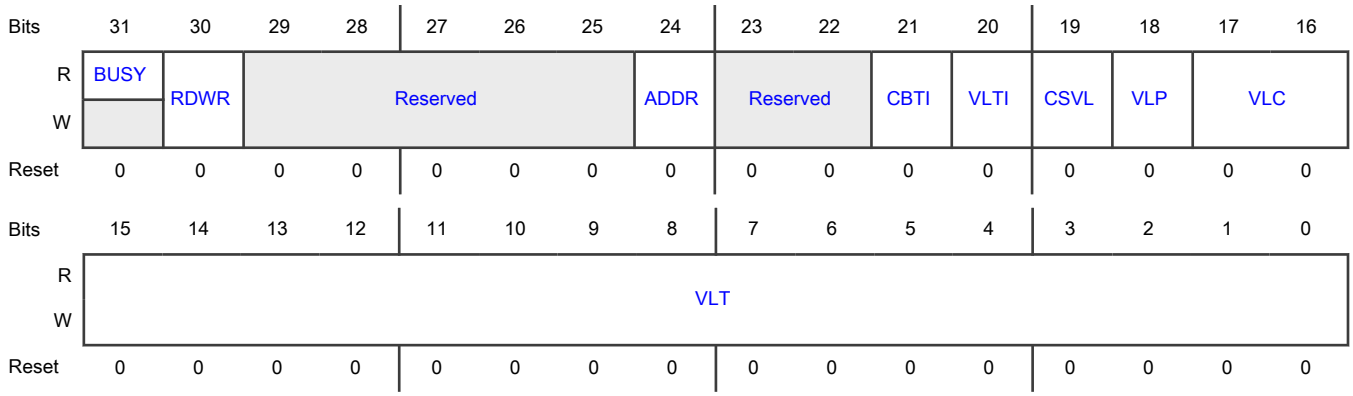
Offset

Register	Offset
MAC_VLAN_Incl	60h

Function

Contains the VLAN tag for insertion or replacement in the transmit packets and the VLAN tag insertion controls.

Diagram



Fields

Field	Function
31 BUSY	Busy Indicates the status of the read or write operation of indirect access to the queue- or channel-specific VLAN inclusion register. The write operation to a register completes when this field becomes 0. For a read operation, the read data is valid when the field becomes 0. The application must make sure that this field becomes 0 before attempting subsequent accesses to this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Busy status not detected 1b - Busy status detected
30 RDWR	Read Write Control Controls the read or write operation for indirectly accessing the queue- or channel-specific VLAN inclusion register. • If this field is 1, it indicates the write operation. • If this field is 0, it indicates the read operation. The value of this field is not impacted when the CBTI field becomes 0. 0b - Read operation of indirect access 1b - Write operation of indirect access
29-25 —	Reserved
24 ADDR	Address Selects one of the queue- or channel-specific VLAN inclusion registers for read or write access. The value of this field is not impacted when the CBTI field is 0.
23-22 —	Reserved
21 CBTI	Channel-Based Tag Insertion Indicates the status of channel-based tag insertion. If this field is 1: • The outer VLAN tag is inserted for all the packets that MAC transmits. • The tag value is taken from the queue- or channel-specific VLAN tag register. Also, the VLTI, VLP, VLC, and VLT fields of the register are ignored. • A write operation to byte 3 of this register initiates the read or write access to the indirect register. If this field is 0, the outer VLAN operation is based on the settings of the VLTI, VLP, VLC, and VLT fields of this register. 0b - Disabled 1b - Enabled
20 VLTI	VLAN Tag Input Indicates the status of the VLAN tag input. The value of this field being 1 indicates that the VLAN tag to be inserted or replaced in the transmit packet must be taken from the transmit descriptor.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
19 CSVL	C-VLAN Or S-VLAN Indicates whether C-VLAN or S-VLAN is inserted or replaced in the transmitted packets. • If this field is 1, S-VLAN type (88A8h) is inserted or replaced in the 13th and 14th bytes of the transmitted packets. • If this field is 0, C-VLAN type (8100h) is inserted or replaced in the 13th and 14th bytes of the transmitted packets. 0b - C-VLAN 1b - S-VLAN
18 VLP	VLAN Priority Control Indicates the status of VLAN priority control. • If this field is 1, the control bits [17:16] are used for VLAN deletion, insertion, or replacement. • If this field is 0, the mti_vlan_ctrl_i control input is used and bits [17:16] are ignored. 0b - Disabled 1b - Enabled
17-16 VLC	VLAN Tag Control Contains values for VLAN tag control in transmit packets. MAC: • Removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all the transmitted packets with VLAN tags. • Replaces VLT in bytes 15 and 16 of all the VLAN-type transmitted packets (bytes 13 and 14 are 8100h or 88a8h). MAC inserts the following into the packet in the order shown: 1. Type value (8100h or 88A8h) into bytes 13 and 14 2. MAC_VLAN_Tag_Data[VLT] into bytes 15 and 16 This operation is performed on all the transmitted packets, irrespective of whether they already have a VLAN tag. **NOTE** Changes to this field take effect only on the start of a packet. If you write to this field when a packet is being transmitted, only the subsequent packets can use the updated value. That is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag For Transmit Packets Contains the value of the VLAN tag to be inserted or replaced. This value must only be changed during the initialization phase or when the transmit lines are inactive. The following list describes the bits of this field: • Bits [15:13]: User priority • Bit 12: Canonical format indicator (CFI) or drop eligible indicator (DEI) • Bits [11:0]: MAC_VLAN_Tag_Data[VID]

74.7.17 MAC VLAN Inclusion 0 (MAC_VLAN_Incl0)

Offset

Register	Offset
MAC_VLAN_Incl0	60h

Function

Contains the VLAN tag for insertion in the transmit packets from transmit queue 0. The register also contains the VLAN tag insertion controls.

19 CSVL	C-VLAN Or S-VLAN Controls the insertion or replacement type in the 17th and 18th bytes of the transmitted packets. 0b - C-VLAN type (8100h) 1b - S-VLAN type (88A8h)

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 VLP	VLAN Priority Control Indicates the status of VLAN priority control. • If this field is 1, it's used for VLAN deletion, insertion, or replacement. • If this field is 0, the mti_vlan_ctrl_i control input is used and MAC_VLAN_Incl[VLC] is ignored. 0b - Disabled 1b - Enabled
17-16 VLC	VLAN Tag Control in Transmit Packets Indicates the value of VLAN tag control in transmit packets. The following list specifies these values: • 2'b00: No VLAN tag deletion, insertion, or replacement • 2'b01: VLAN tag deletion • 2'b10: VLAN tag insertion • 2'b11: VLAN tag replacement MAC: • Removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all the transmitted packets with VLAN tags • Inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (8100h or 88a8h) in bytes 17 and 18. This operation is performed on all the transmitted packets, irrespective of whether they already have a VLAN tag. • Replaces VLT in bytes 19 and 20 for all the VLAN-type transmitted packets (bytes 17 and 18 are 8100h or 88a8h). **NOTE** Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packets can use the updated value. That is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag For Transmit Packets Contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. The following list describes the bits of this field: • Bits [15:13]: User priority

74.7.26 MAC Q0 Tx Flow Control (MAC_Q0_Tx_Flow_Ctrl)

Offset

Register	Offset
MAC_Q0_Tx_Flow_Ctrl	70h

Function

Controls the generation and reception of the control (pause command) packets by MAC's flow control module. A write to the register with the Busy field = 1 triggers the flow control block to generate a pause packet. The 802.3x specification indicates the way the fields of the control packet are selected, and the pause time value from this register is used in the PT field of the control packet. The Busy field remains 1 until the control packet is transferred onto the cable. You must make sure that the Busy field is 0 before writing to this register.

If the value of the PFCE field in the MAC_Rx_Flow_Ctrl register is 1, this register controls the generation of priority flow control (PFC) frames with priorities mapped according to MAC_RxQ_Ctrl2[PSRQ0].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								DZPQ	PLT			Reserved		TFE	FCB_ BPA
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 PT	Pause Time Holds the value to be used in this field in the transmit control packet. If the bits of this field are configured to be double-synchronized with the (G)MII clock domain, consecutive writes to this register must be performed only after at least four clock cycles in the destination clock domain.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause Enables or disables zero-quanta pause packet generation. • If this field is 1, it disables the automatic generation of the zero-quanta pause packets that the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i) deasserts. • If this field is 0, normal operations with automatic zero-quanta pause packet generation are enabled. 0b - Enabled 1b - Disabled
6-4 PLT	Pause Low Threshold Configures the threshold of the pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the pause packet. The threshold values must always be less than the pause time configured in bits [31:16]. For example, if the PT field = 100H (256 slot times), and the PLT field = 001, a second pause packet automatically transmits if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first pause packet transmits. This list provides the threshold values for different values: • The slot time is defined as the time taken to transmit 512 bits (64 bytes) on GMII or MII. • This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + two pause packet sizes + IPG in slot times. 000b - Pause time minus 4 slot times (PT is 4 slot times) 001b - Pause time minus 28 slot times (PT is 28 slot times) 010b - Pause time minus 36 slot times (PT is 36 slot times) 011b - Pause time minus 144 slot times (PT is 144 slot times) 100b - Pause time minus 256 slot times (PT is 256 slot times) 101b - Pause time minus 512 slot times (PT is 512 slot times) 110b - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Indicates whether transmit flow control is enabled or disabled. • Full-Duplex mode: If this field is 1, MAC enables the flow control operation to the transmit pause packets. When the field becomes 0, MAC's flow control operation disables and MAC does not transmit any pause packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Half-Duplex mode: If this field is 1, MAC enables the backpressure operation. When the field becomes 0, the backpressure operation disables. 0b - Disabled 1b - Enabled
0 FCB_BPA	Flow Control Busy Or Backpressure Activate Initiates if a pause packet is in Full-Duplex mode and activates the backpressure function in Half-Duplex mode if the TFE field is 1. • Full-Duplex mode: In this mode, FCB_BPA must be read as 1'b0 before writing to this register. To initiate a pause packet, the application must set this field to 1'b1. During control packet transfer, the field's value continues to be 1 to indicate that a packet transmission is in progress. When pause packet transmission is complete, MAC resets this field to 1'b0. You must not write to this register until this field becomes 0. • Half-Duplex mode: If FCB_BPA = 1 and TFE = 1 too, MAC asserts backpressure in this mode. During the backpressure function, when MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register field is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When you configure MAC using Full-Duplex mode, this field automatically becomes 0. Access restrictions apply to this field: writing 1 sets it, writing 0 has no effect, and the field is self-clearing. 0b - Flow control busy or backpressure activate is disabled 1b - Flow control busy or backpressure activate is enabled

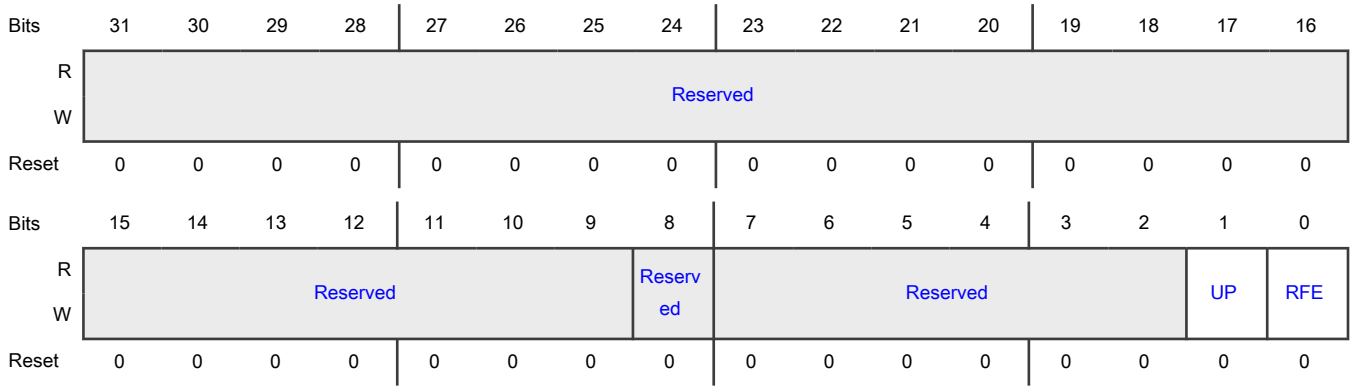
74.7.27 MAC Receive Flow Control (MAC_Rx_Flow_Ctrl)

Offset

Register	Offset
MAC_Rx_Flow_Ctrl	90h

Function
Controls the pausing of MAC transmit based on the received pause packet.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 —	Reserved
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect Indicates whether the unicast pause packet is enabled or disabled. A pause packet is processed when it has the unique multicast address specified in IEEE 802.3. • If this field is 1, MAC can detect pause packets with a unicast address of the station. This address must comply with the specifications in MAC Address 0 High (MAC_Address0_High) and MAC Address 0 Low (MAC_Address0_Low). • If this field is 0, MAC only detects pause packets with a unique multicast address. **NOTE** MAC does not process a pause packet if the multicast address is different from the unique multicast address. This applies to the received PFC packet if PFC is enabled. The unique multicast address (01_80_C2_00_00_01h) complies with the IEEE 802.1 Qbb-2011 specifications. 0b - Disabled 1b - Enabled
0 RFE	Receive Flow Control Enable Indicates whether the receive flow control is enabled or disabled. • If this field is 1 and MAC is operating in Full-Duplex mode, MAC decodes the received pause packet and disables its transmitter for a specified (pause) time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 0 or if MAC is operating in Half-Duplex mode, the decode function of the pause packet disables. When PFC is enabled, the flow control for PFC packets is enabled too. MAC decodes the received PFC packet and disables the transmit queue, with matching priorities, for a duration of the received pause time. 0b - Disabled 1b - Enabled

74.7.28 MAC RxQ Control 4 (MAC_RxQ_Ctrl4)

Offset

Register	Offset
MAC_RxQ_Ctrl4	94h

Function

Controls the routing of unicast and multicast packets that fail the destination or source address filter to the receive queues.

Diagram

Fields

Field	Function
31-27 —	Reserved
26-24 FPRQ	Frame Preemption Residue Queue Holds the receive queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA, DA, or VLAN filtering are routed based on the settings of the PSRQ fields in MAC RxQ Control 2 (MAC_RxQ_Ctrl2). All other frames are treated as residual frames and are routed to the queue number mentioned in this field. Queue 0 is used as the default queue for express frames, so you cannot write 0 to this field.
23-22 TPQC	Tagged PTP Over Ethernet Packets Queuing Control Controls the routing of the VLAN-tagged PTPoE packets. These are the allowed programmable options: • 2'b00: VLAN-tagged PTPoE packets are routed as generic VLAN-tagged packets (based on the PSRQ fields in MAC RxQ Control 2 (MAC_RxQ_Ctrl2) for only non-AV enabled receive queues). • 2'b01: VLAN-tagged PTPoE packets are routed to the receive queue that the PTPQ field of this register specifies (this Rx queue can be enabled for AV or non-AV traffic). • 2'b10: VLAN-tagged PTPoE packets are routed to only AV-enabled receive queues based on the settings of the PSRQ fields.
21 TACPQE	Tagged AV Control Packets Queuing Enable Indicates the status of tagged AV control packet queuing. • If this field is 1, MAC routes the received tagged AV control packets to the receive queue that the AVCPQ field specifies. • If this field is 0, MAC routes the received tagged AV control packets based on the tag priority matching the PSRQ fields in MAC RxQ Control 2 (MAC_RxQ_Ctrl2). 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 MCBCQEN	Multicast And Broadcast Queue Enable Specifies whether multicast or broadcast packet routing to the receive queue is enabled or disabled. The multicast or broadcast packets must be routed to the receive queue specified in the MCBCQ field. 0b - Disabled 1b - Enabled
19 —	Reserved
18-16 MCBCQ	Multicast And Broadcast Queue Specifies the receive queue onto which multicast or broadcast packets are routed. Any receive queue enabled for Generic, DCB, or AV traffic can be used to route the multicast or broadcast packets. 000b - Receive queue 0 001b - Receive queue 1 010b - Receive queue 2 011b - Receive queue 3 100b - Receive queue 4 101b - Receive queue 5 110b - Receive queue 6 111b - Receive queue 7
15 —	Reserved
14-12 UPQ	Untagged Packet Queue Indicates the receive queue to which the untagged packets need to be routed. Any receive queue enabled for generic, DCB, or AV traffic can be used to route the untagged packets. 000b - Receive queue 0 001b - Receive queue 1 010b - Receive queue 2 011b - Receive queue 3 100b - Receive queue 4 101b - Receive queue 5 110b - Receive queue 6 111b - Receive queue 7
11 —	Reserved

Fields

Field	Function
31-24 —	Reserved
23-16 —	Reserved
15-8 PSRQ1	Priorities Selected In Receive Queue 1 Determines the priorities assigned to receive queue 1. All the packets with priorities that match the values defined in this field are routed to receive queue 1. For example, if PSRQ1[4] = 1, packets with MAC_Ext_Configuration[USP] equal to 4 are routed to receive queue 1. You must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues. This means that the same priority is not mapped to multiple receive queues.
7-0 PSRQ0	Priorities Selected In Receive Queue 0 Determines the priorities assigned to receive queue 0. All the packets with priorities that match the values defined in this field are routed to receive queue 0. For example, if PSRQ0[5] = 1, packets with MAC_Ext_Configuration[USP] equal to 5 are routed to receive queue 0. You must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues. This means that the same priority is not mapped to multiple receive queues.

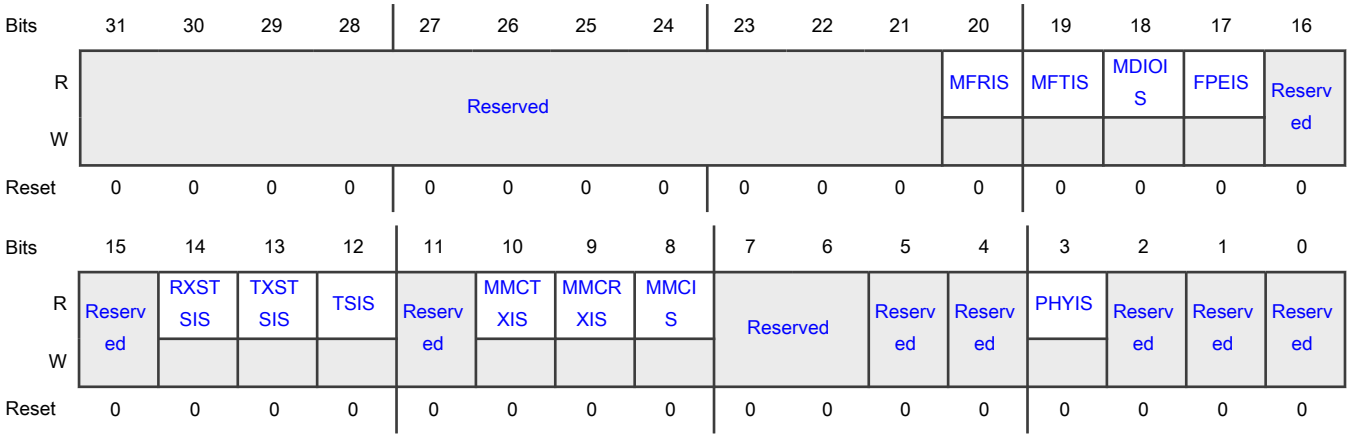
74.7.32 MAC Interrupt Status (MAC_Interrupt_Status)

Offset

Register	Offset
MAC_Interrupt_Status	B0h

Function
Contains the status of interrupts.

Diagram



Fields

Field	Function
31-21 —	Reserved
20 MFRIS	MMC FPE Receive Interrupt Status Indicates the status of MMC FPE receive interrupt. This field becomes 1 when any of the fields in MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt) is 1. The field becomes 0 when all the other fields in MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt) become 0 too. 0b - Inactive 1b - Active
19 MFTIS	MMC FPE Transmit Interrupt Status Indicates the status of MMC FPE transmit interrupt. This field becomes 1 when an interrupt generates in MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt). The field becomes 0 when all the other fields in this register become 0 too. This field is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Inactive 1b - Active
18 MDIOIS	MDIO Interrupt Status Indicates the status of an interrupt event after the completion of an MDIO operation. To reset this field, you must read this field or write 1 to it when MAC_CSR_SW_Ctrl[RCWE] = 1. Access restrictions apply to this field. It clears on a read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. The field automatically becomes 1 on an internal event. 0b - Inactive 1b - Active
17 FPEIS	Frame Preemption Interrupt Status Indicates the status of an interrupt event during the frame preemption operation (the value of RVER, RRSP, TVER, and TRSP fields of MAC FPE Control STS (MAC_FPE_CTRL_STS) = 1). To reset this field, you must clear the event in MAC FPE Control STS (MAC_FPE_CTRL_STS) that caused the interrupt. 0b - Inactive 1b - Ative
16 —	Reserved
15 —	Reserved
14 RXSTSIS	Receive Status Interrupt Indicates the status of received packets. This field becomes 1 when MAC_Rx_Tx_Status[RWT] = 1. The field becomes 0 when you read the corresponding interrupt source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status), or if you write to this interrupt source field when MAC_CSR_SW_Ctrl[RCWE] = 1. The field becomes 0 in either of these circumstances: • You read the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status). • You write 1 to the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Inactive 1b - Active
13 TXSTSIS	Transmit Status Interrupt Indicates the status of transmitted packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any of the following fields is 1 in MAC Rx Transmit Status (MAC_Rx_Tx_Status): • Excessive collision (EXCOL) • Late collision (LCOL) • Excessive deferral (EXDEF) • Loss of carrier (LCARR) • No carrier (NCARR) • Jabber timeout (TJT) This field becomes 0 in either of these circumstances: • You read the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status). • You write 1 to the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Inactive 1b - Active
12 TSIS	Timestamp Interrupt Status Indicates the status of timestamp interrupt. If the timestamp feature is enabled, this field becomes 1 when any of the following conditions is true: • The system time value is equal to or exceeds the value specified in MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds). • There is an overflow in MAC System Time In Seconds (MAC_System_Time_Seconds). • The target time error occurred, which means, the programmed target time already elapsed. In configurations other than EQOS_CORE, when the drop transmit status is enabled in MTL, this field becomes 1 when the captured transmit timestamp is updated in MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds) and MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds). The field becomes 0 in either of these circumstances: • You read the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status). • You write 1 to the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Inactive 1b - Active
11 —	Reserved
10 MMCTXIS	MMC Transmit Interrupt Status Indicates the status of MMC transmit interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field: • Becomes 1 when any field in MMC Transmit Interrupt (MMC_Tx_Interrupt) becomes 1. • Becomes 0 when all the fields in MMC Transmit Interrupt (MMC_Tx_Interrupt)return to 0. This field is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - Inactive 1b - Active
9 MMCRXIS	MMC Receive Interrupt Status Indicates the status of MMC receive interrupt. This field: • Becomes 1 when any field in MMC Receive Interrupt (MMC_Rx_Interrupt) becomes 1. • Becomes 0 when all the fields in MMC Receive Interrupt (MMC_Rx_Interrupt)return to 0. This field is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - Inactive 1b - Active
8 MMCIS	MMC Interrupt Status Indicates the status of MMC interrupt. This field becomes 1 when MMCRXIS = MMCTXIS = 1, and the field becomes 0 only when MMCRXIS = MMCTXIS = 0. MMCIS is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - Inactive 1b - Active
7-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 PHYIS	PHY Interrupt Indicates whether the PHY interrupt is detected. This field becomes 1 when rising edge is detected on the phy_intr_i input signal. The field becomes 0 when you read this register (or if you write 1 to this field when MAC_CSR_SW_Ctrl[RCWE] = 1). 0b - Not detected

3 PHYIE	PHY Interrupt Enable Indicates whether the assertion of the interrupt signal is enabled or disabled. If this field is 1, it enables the assertion of the interrupt signal because of the setting of MAC_Interrupt_Status[PHYIS]. 0b - Disabled 1b - Enabled
2 —	Reserved
1 —	Reserved
0 —	Reserved

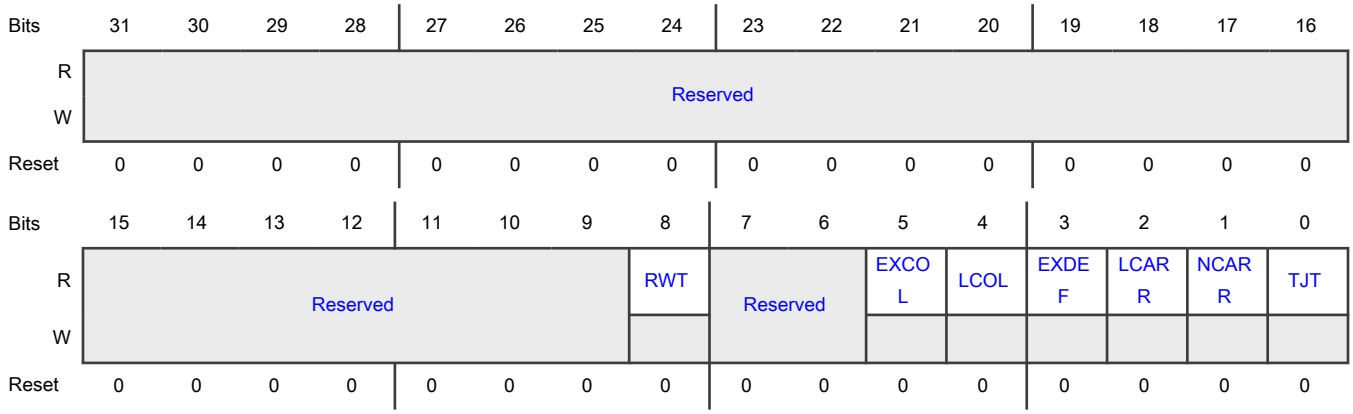
74.7.34 MAC Rx Transmit Status (MAC_Rx_Tx_Status)

Offset

Register	Offset
MAC_Rx_Tx_Status	B8h

Function
Contains the receive and transmit error status.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 RWT	Receive Watchdog Timeout Indicates the status of receive watchdog. This field becomes 1 when a packet with a length greater than 2,048 bytes is received (10,240 bytes when Jumbo Packet mode is enabled) and MAC_Configuration[WD] = 0. RWT becomes 1 when a packet with length greater than 16,383 bytes is received and MAC_Configuration[WD] = 1. Access restrictions apply to RWT. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. RWT automatically becomes 1 on an internal event occurrence. 0b - No receive watchdog timed out 1b - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions Indicates the status of excessive collision. If MTL_Operation_Mode[DTXSTS] = 1, this field, EXCOL, indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If MAC_Configuration[DR] = 1, EXCOL becomes 1 after the first collision and the packet transmission is aborted. Access restrictions apply to EXCOL. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. EXCOL automatically becomes 1 on an internal event occurrence. 0b - No collision 1b - Excessive collision is sensed
4	Late Collision

Table continues on the next page...

Table continued from the previous page...

Field	Function
LCOL	Indicates the status of late collision. If MTL_Operation_Mode[DTXSTS] = 1, this field, LCOL, indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including preamble in MII mode; 512 bytes including preamble and carrier extension in GMII mode). This field is invalid if an underflow error occurs. Access restrictions apply to LCOL. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. LCOL automatically becomes 1 on an internal event occurrence. 0b - No collision 1b - Late collision is sensed
3 EXDEF	Excessive Deferral Indicates whether the transmission ended because of excessive deferral. If MTL_Operation_Mode[DTXSTS] = 1 and MAC_Configuration[DC] = 1 too, this field, EXDEF, indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbit/s mode or when the jumbo packet is enabled). Access restrictions apply to EXDEF. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. EXDEF automatically becomes 1 on an internal event occurrence. 0b - No excessive deferral 1b - Excessive deferral
2 LCARR	Loss of Carrier Indicates the status of carrier signal. If MTL_Operation_Mode[DTXSTS] = 1, this field, LCARR, indicates that the loss of carrier occurred during packet transmission, which means, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. The field is valid only for packets transmitted without collision. Access restrictions apply to LCARR. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. LCARR automatically becomes 1 on an internal event occurrence. 0b - Carrier is present 1b - Loss of carrier
1 NCARR	No Carrier Indicates whether the carrier signal is present from the PHY at the end of preamble transmission. If MTL_Operation_Mode[DTXSTS] = 1, NCARR indicates that the carrier signal from the PHY is absent at the end of preamble transmission. Access restrictions apply to NCARR. It becomes 0 after either of these actions: • You read NCARR. • You write 1 to NCARR when MAC_CSR_SW_Ctrl[RCWE] = 1. NCARR automatically becomes 1 after an internal event occurs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Present 1b - Absent
0 TJT	Transmit Jabber Timeout Indicates whether a transmit-jabber timer timeout occurred. The timeout occurs after any of these events: • MAC_Configuration[JD] = 0 and the normal packet size exceeds 2,048 bytes. • MAC_Configuration[JD] = 0 and the jumbo packet size exceeds 10240 bytes. • MAC_Configuration[JD] = 1 and the normal packet size exceeds 16383 bytes. Access restrictions apply to TJT. It becomes 0 after either of these actions: • You read TJT. • You write 1 to TJT when MAC_CSR_SW_Ctrl[RCWE] = 1. TJT automatically becomes 1 after an internal event occurs. 0b - No transmit jabber timeout occurred 1b - Transmit jabber timeout occurred

74.7.35 MAC Version (MAC_Version)

Offset

Register	Offset
MAC_Version	110h

Function

Identifies the version of the module.

Fields

Field	Function
31-19 —	Reserved
18-17	MAC Transmit Packet Controller Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
TFCSTS	Indicates the state of the MAC transmit packet controller module. 00b - Idle state 01b - Waiting for one of these: status of the previous packet or IPG, or for the back-off period to be over 10b - Generating and transmitting a pause control packet (in Full-Duplex mode) 11b - Transferring input packet for transmission
16 TPESTS	MAC GMII Or MII Transmit Protocol Engine Status Indicates whether MAC GMII or MII transmit protocol engine is detected. If this field is 1, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data and is not in an idle state. 0b - Not detected 1b - Detected
15-3 —	Reserved
2-1 RFCFCSTS	MAC Receive Packet Controller FIFO Status Indicates the status of the small FIFO read and write controllers of the MAC receive packet controller module. If this field is 1, it indicates that the small FIFO read and write controllers of the MAC receive packet controller module are in an active state. 00b - Inactive 01b - Active
0 RPESTS	Receive Protocol Engine Status Indicates whether MAC GMII or MII receive protocol engine is detected. If this field is 1, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data and is not in an idle state. 0b - Not detected 1b - Detected

74.7.37 MAC Hardware Feature 0 (MAC_HW_Feature0)

Offset

Register	Offset
MAC_HW_Feature0	11Ch

Function

Indicates the presence of the first set of EMAC optional features or functions. You can use this register to dynamically enable or disable the programs related to these features.

Fields

Field	Function
31 —	Reserved
30-28 ACTPHYSEL	Active PHY Feature Indicates the selected active PHY interface. If you have multiple PHY interfaces (GMII, MII, RevMII, RGMII, RMII, RTBI, SGMII, SGMII, or TBI) in your configuration, this field indicates the sampled value of the phy_intf_sel_i signal during reset deassertion. 000b - GMII or MII 001b - RGMII 010b - SGMII 011b - TBI 100b - RMII 101b - RTBI 110b - SMII 111b - RevMII
27 SAVLANINS	SA or VLAN Insertion Feature Indicates whether the feature that enables SA or VLAN insertion on transmit is selected. This field becomes 1 if you select the "enable SA and VLAN insertion on Tx" option. 0b - Not selected 1b - Selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
26-25 TSTSSEL	Timestamp System Time Source Feature Indicates the source of the timestamp system time. This field becomes 1 if you select the "enable IEEE 1588 timestamp support" option. 00b - Internal 01b - External 10b - Both internal and external 11b - Reserved
24 MACADR64SEL	MAC Addresses 64-127 Indicates whether the feature that enables additional 64 MAC address regsiters (64-127) is selected. This field becomes 1 if you enable the "MAC addresses (64-127) select" option. 0b - Not selected 1b - Selected
23 MACADR32SEL	MAC Addresses 32-63 Indicates whether the feature that enables additional 32 MAC address registers (32-63) is selected. This field becomes 1 if you select the "MAC addresses 32-63 select" option. 0b - Not selected 1b - Selected
22-18 ADDMACADRSEL	MAC Addresses 1-31 Indicates whether the feature that enables additional 1-31 MAC address registers is selected. This field becomes 1 if you select a non-zero value for enabling the "MAC addresses 1-31 select" option. 0_0000b - Not selected 0_0001b - Selected
17 —	Reserved
16 RXCOESEL	Receive Checksum Offload Feature Indicates whether the feature that enables receive TCP/IP checksum offload is selected. This field becomes 1 if you select the "enable receive TCP/IP checksum check" option. 0b - Not selected 1b - Selected
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
14 TXCOESEL	Transmit Checksum Offload Feature Indicates whether the feature that enables transmit TCP/IP checksum insertion is selected. This field becomes 1 if you select the "enable transmit TCP/IP checksum insertion" option. 0b - Not selected 1b - Selected
13 EEESEL	Energy Efficient Ethernet (EEE) Feature Indicates whether the feature that enables EEE is selected. This field becomes 1 if you select the "enable EEE" option. 0b - Not selected 1b - Selected
12 TSSEL	IEEE 1588-2008 Timestamp Feature Indicates whether the option that enables IEEE 1588-2008 timestamp is selected. This field becomes 1 if you select the "enable IEEE 1588 timestamp support" option. 0b - Not selected 1b - Selected
11-10 —	Reserved
9 ARPOFFSEL	ARP Offload Feature Indicates whether the feature that enables ARP offload is selected. This field becomes 1 if you select the "enable IPv4 ARP offload" option. 0b - Not selected 1b - Selected
8 MMCSEL	MAC Management Counters (MMC) Feature Indicates whether the feature that enables MMC is selected. This field becomes 1 if you select the "enable MMC" option. 0b - Not selected 1b - Selected
7 MGKSEL	PMT Magic Packet Feature Indicates whether the feature that enables PMT magic detection is selected. This field becomes 1 if you select the "enable magic packet detection" option. 0b - Not selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Selected
6 RWKSEL	PMT Remote Wake-Up Packet Feature Indicates whether the feature that enables PMT remote wake-up packet detection is selected. This field becomes 1 if you select the "enable remote wake-up packet detection" option. 0b - Not selected 1b - Selected
5 SMASEL	SMA (MDIO) Interface Feature Indicates whether the feature that enables station management (MDIO interface) is selected. This field becomes 1 if you select the "enable station management (MDIO interface)" option. 0b - Not selected 1b - Selected
4 VLHASH	VLAN Hash Filter Feature Indicates whether the filtering option based on VLAN hash table is selected. This field becomes 1 if you select the "enable VLAN hash table based filtering" option. 0b - Not selected 1b - Selected
3 PCSSEL	PCS Select Indicates if either of the TBI, SGMII, or RTBI PHY interface options is selected. This field becomes 1 if you select any one of the TBI, SGMII, or RTBI PHY interface options. 0b - No 1b - Yes
2 HDSEL	Half-Duplex Support Feature Indicates whether half-duplex support is available as the mode of operation. This field becomes 1 if you select Half-Duplex as the mode of operation. 0b - Unavailable 1b - Available
1 GMIISEL	1000 Mbit/s Support Feature Indicates whether 1000 Mbit/s support is available as the mode of operation. This field becomes 1 if you select 1000 Mbit/s as the mode of operation. 0b - Unavailable 1b - Available

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 MIISEL	10 or 100 Mbit/s Support Feature Indicates whether 10 or 100 Mbit/s support is available as the mode of operation. This field becomes 1 if you select 10/100 Mbit/s as the mode of operation. 0b - Unavailable 1b - Available

74.7.38 MAC Hardware Feature 1 (MAC_HW_Feature1)

Offset

Register	Offset
MAC_HW_Feature1	120h

Function

Indicates the presence of the second set of optional features or functions of the module. You can use this register to dynamically enable or disable the programs related to these features.

Field	Function
	After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
23-18 —	Reserved
17 —	Reserved
16 MSTTES	Master Read Or Write Timeout Error Status Indicates whether an application or CSR timeout error is detected on the master (AXI, AHB, ARI, or ATI) interface. After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
15 —	Reserved
14 —	Reserved
13 —	Reserved
12 PTES	PTP FSM Timeout Error Status Indicates whether one of the PTP FSM timeout errors is detected. After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
11 ATES	APP FSM Timeout Error Status Indicates whether one of the APP FSM timeout errors is detected. After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 RTES	Receive FSM Timeout Error Status Indicates whether one of the receive FSM timeout errors is detected. After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
8 TTES	Transmit FSM Timeout Error Status Indicates whether one of the transmit FSM timeout errors is detected. After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
7 —	Reserved
6 —	Reserved
5 ARPES	Application Receive Interface Data Path Parity Error Status Indicates whether the parity checker detected a parity error on the application receive interface (or on PC6 as shown in the transmit data path parity protection diagram). After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
4 MTSPES	MTL Transmit Status Data Path Parity Checker Error Status Indicates whether the parity checker detected a parity error for the MTL transmit status data on ATI (or on PC5 as shown in the transmit data path parity protection diagram). After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
3 MPES	MTL Data Path Parity Checker Error Status Indicates whether the parity checker detected a parity error on the MTL transmit write controller interface (or on PC4 as shown in the transmit data path parity protection diagram). After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 RDPES	Read Descriptor Parity Checker Error Status Indicates whether the parity checker detected a parity error on the DMA read descriptor interface (or on PC3 as shown in the transmit data path parity protection diagram). After a read operation, the field's value clears to 0. 0b - Not detected 1b - Detected
1 —	Reserved
0 —	Reserved

74.7.42 MAC FSM Control (MAC_FSM_Control)

Offset

Register	Offset
MAC_FSM_Control	148h

Function

Is used to control the FSM state parity and timeout error injection in Debug mode.

R W	MAC_SCS1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 MAC_SCS1	MAC SCS 1 Is reserved for NXP internal use. The value of this field must always be 0 unless NXP instructs you otherwise. Writing 1 to any of the bits of this field might cause expected chip behavior.

74.7.45 MAC MDIO Address (MAC_MDIO_Address)

Offset

Register	Offset
MAC_MDIO_Address	200h

Function
Controls the management cycles to external PHY through a management interface.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved				PSE	BTB	PA						RDA			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved	NTC			CR				Reserved			SKAP	GOC_1	GOC_0	C45E	GB
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27 PSE	Preamble Suppression Enable Indicates the status of preamble suppression. • If this field is 1, SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. • If this field is 0, the MDIO frame always includes 32 bits of preamble as defined in the IEEE specification.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
26 BTB	Back-To-Back Transactions Indicates the status of back-to-back transactions. When BTB = 1 and NTC > 0, MAC indicates the completion of a read or write command at the end of a frame transfer (before the trailing clocks are transmitted). Therefore, you can initiate the next command, and that command executes immediately irrespective of the number of trailing clocks generated for the previous frame. When BTB = 0, the read or write command completes (GB = 0) only after the trailing clocks generate. In this mode, you must ensure that: • NTC is always generated after each frame. • BTB must not be equal to 1 when NTC = 0. 0b - Disabled 1b - Enabled
25-21 PA	Physical Layer Address Indicates whether MAC accesses clause 22 PHY devices (out of 32) or clause 45 capable PHYs (out of 32).
20-16 RDA	Register Or Device Address Indicates whether MAC accesses clause 22 PHY devices (out of 32) or clause 45 capable PHYs (out of 32).
15 —	Reserved
14-12 NTC	Number Of Trailing Clocks Controls the number of trailing clock cycles generated on the gmii_mdc_o (MDC) signal after the end of MDIO frame transmission. The valid values can range from 0 to 7. Writing 3h to this field indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8 CR	CSR Clock Range Determines the frequency of the MDC clock according to the CSR clock frequencies used in your design: • 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 • 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 • 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 • 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 • 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 • 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 • 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 When bit 3 of this field is 0, the suggested CSR clock-frequency range applicable to each value ensures that the MDC clock frequency is approximately between 1.0 MHz and 2.5 MHz. When bit 3 of this field is 1, you can achieve a higher MDC clock frequency than the IEEE 802.3 frequency limit of 2.5 MHz, and program a clock divider of a lower value. For example, if the CSR clock frequency is 100 MHz and you write 1010 to this field, the resultant MDC clock frequency equals 12.5 MHz, which is above the range specified in IEEE 802.3. Program these values only if the interfacing chips support faster MDC clocks: • 1000: CSR clock/4 • 1001: CSR clock/6 • 1010: CSR clock/8 • 1011: CSR clock/10 • 1100: CSR clock/12 • 1101: CSR clock/14 • 1110: CSR clock/16 • 1111: CSR clock/18 These bits are not used for accessing RevMII. They are read-only if the RevMII interface is selected as a single PHY interface.
7-5 —	Reserved
4 SKAP	Skip Address Packet Indicates the status of the skip address packet. If this field is 1, SMA does not send the address packets before read, write, or post-read increment address packets. This field is valid only when C45E = 1. 0b - Disabled 1b - Enabled
3 GOC_1	GMII Operation Command 1 Indicates the status of GMII operation command 1. GMII operation command 1 represents the higher bit of the operation command to PHY or RevMII. The fields GOC_1 and GOC_O indicate these values: • 00: Reserved • 01: Write • 10: Post-read increment address for clause 45 PHY • 11: Read

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When clause 22 PHY or RevMII is enabled, only write and read commands are valid. 0b - Disabled 1b - Enabled
2 GOC_0	GMII Operation Command 0 Indicates the status of GMII operation command 0. GMII operation command 0 represents the lower bit of the operation command to PHY or RevMII. When in SMA mode (MDIO master), this field, along with the GOC_1 field, determines the operation to be performed to PHY. This field is read-only and tied to 1 when only RevMII is selected in configuration. 0b - Disabled 1b - Enabled
1 C45E	Clause 45 PHY Enable Indicates the status of clause 45 PHY. • If this field is 1, clause 45 capable PHY is connected to MDIO. • If this field is 0, clause 22 capable PHY is connected to MDIO. 0b - Disabled 1b - Enabled
0 GB	GMII Busy Indicates the status of GMII busy. Writing 1 to this field instructs SMA to initiate a read or write access to the MDIO slave. MAC writes 0 to the field after the MDIO frame transfer is complete. Therefore, you must not write or change any of the fields in the MAC_MDIO_Address and MAC_MDIO_Data registers as long as the value of this field is 1. For write transfers, before writing 1 to this field, you must write a 16-bit data to MAC_MDIO_Data[GD] and MAC_MDIO_Data[RA] if C45E = 1. If C45E = 1, you must also write to MAC_MDIO_Data[RA] before initiating a read transfer. After a read transfer completes (GB = 0), a data read from the PHY register is valid in MAC_MDIO_Data[GD]. **NOTE** Even if the addressed PHY is not present, there is no change in the functionality of this field. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Disabled 1b - Enabled

74.7.46 MAC MDIO Data (MAC_MDIO_Data)

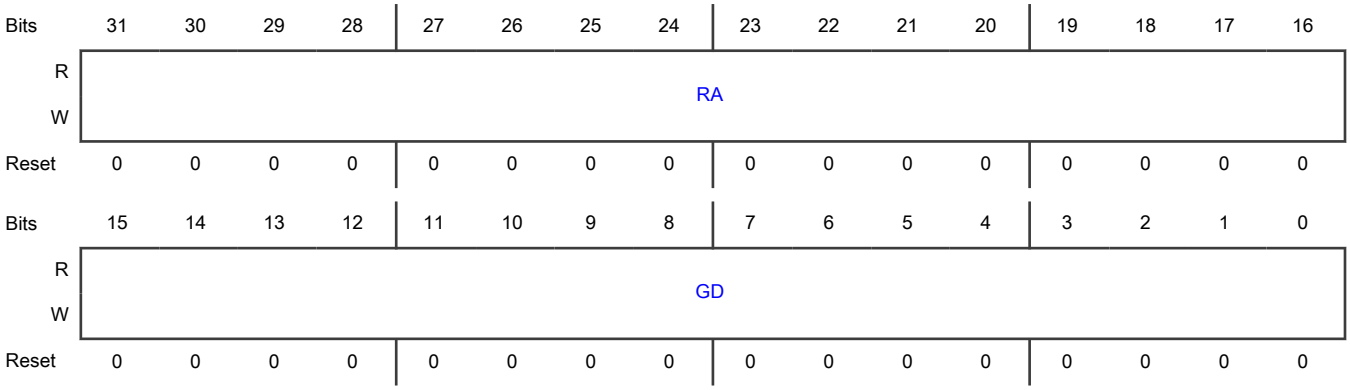
Offset

Register	Offset
MAC_MDIO_Data	204h

Function

Is used to store the write data to be written to the PHY register located at the address specified in MAC MDIO Address (MAC_MDIO_Address). This register also stores the read data from the PHY register located at the address that MAC MDIO Address (MAC_MDIO_Address) specifies.

Diagram



Fields

Field	Function
31-16 RA	Register Address Contains the PHY register address intended for the MDIO frame. This field is valid only when MAC_MDIO_Address[C45E] = 1.
15-0 GD	GMII Data Contains the 16-bit data value read from PHY or RevMII after a management read operation or the 16-bit data value to be written to PHY or RevMII before a management write operation.

74.7.47 MAC CSR Software Control (MAC_CSR_SW_Ctrl)

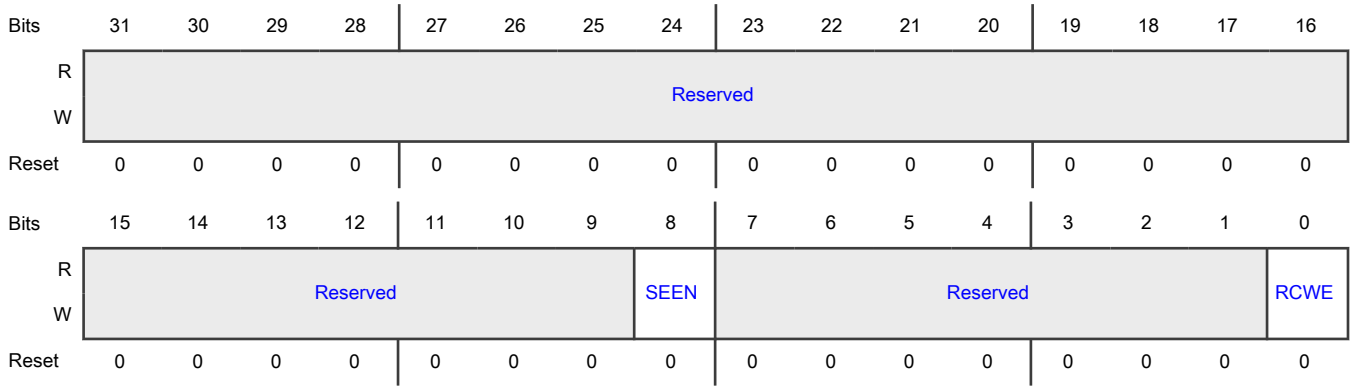
Offset

Register	Offset
MAC_CSR_SW_Ctrl	230h

Function

Contains software programmable controls for changing the CSR access response and clearing the status bits on read.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 SEEN	Slave Error Response Enable Indicates the status of the slave error response. • If this field is 1, MAC responds with a slave error for accesses to reserved registers in the CSR space. • If this field is 0, MAC sends an "okay" response to registers accessed from the CSR space. 0b - Disabled 1b - Enabled
7-1 —	Reserved
0 RCWE	Enable Register Write 1 To Clear (W1C) Enables and disables the W1C feature for some registers. When this field is 1, the access mode of some of the other fields changes from R2C to W1C. When this field is 0, the access mode of those fields remains R2C. 0b - Disabled 1b - Enabled

74.7.48 MAC FPE Control STS (MAC_FPE_CTRL_STS)

Offset

Register	Offset
MAC_FPE_CTRL_STS	234h

Function

Controls the operation of frame preemption.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved												TRSP	TVER	RRSP	RVER

R W	Reserved												S1_SET_0	SRSP	SVER	EFPE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19 TRSP	Transmitted Respond Frame Indicates whether the respond frame is transmitted. This field becomes 1 when a respond frame is transmitted (triggered by writing 1 to the SRSP field). An interrupt can be generated for this event if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. TRSP becomes a W1C field when MAC_CSR_SW_Ctrl[RCWE] = 1, and becomes an R2C field when MAC_CSR_SW_Ctrl[RCWE] = 0. Thus, TRSP becomes 0 sometimes when you read it and sometimes when you write 1 to it. It automatically becomes 1 on an internal event. 0b - Not transmitted 1b - Transmitted
18 TVER	Transmitted Verify Frame Indicates whether the verify frame is transmitted. This field becomes 1 when a verify frame is transmitted (triggered by writing 1 to the SVER field). An interrupt can be generated for this event if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. The field clears on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. It automatically becomes 1 on an internal event. 0b - Not transmitted 1b - Transmitted
17 RRSP	Received Respond Frame Indicates whether the respond frame is received.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when a respond frame is received. An interrupt can be generated for this event if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. The field clears on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. It automatically becomes 1 on an internal event. 0b - Not received 1b - Received
16 RVER	Received Verify Frame Indicates whether the verify frame is received. This field becomes 1 when a verify frame is received. An interrupt can be generated on the transmission of a packet if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. The field clears on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. It automatically becomes 1 on an internal event. 0b - Not received 1b - Received
15-4 —	Reserved
3 S1_SET_0	S1 SET 0 Is reserved for NXP internal use and must always be 0 unless instructed by NXP. Writing 1 to this field may cause unexpected behavior.
2 SRSP	Send Respond mPacket Indicates the status of the send respond mPacket. If this field is 1, it indicates the hardware to send a respond mPacket. The hardware resets the field after sending the respond mPacket. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Disabled 1b - Enabled
1 SVER	Send Verify mPacket Enables and disables the sending of a verify mPacket. Write 1 to this field to command EMAC to send a verify mPacket. EMAC writes 0 to this field after sending the verify mPacket. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Disabled 1b - Enabled
0	Enable Transmit Frame Preemption

Table continues on the next page...

Table continued from the previous page...

Field	Function
EFPE	Enables or disables the frame preemption transmit functionality. 0b - Disabled 1b - Enabled

74.7.49 MAC Presentation Time (MAC_Presn_Time_ns)

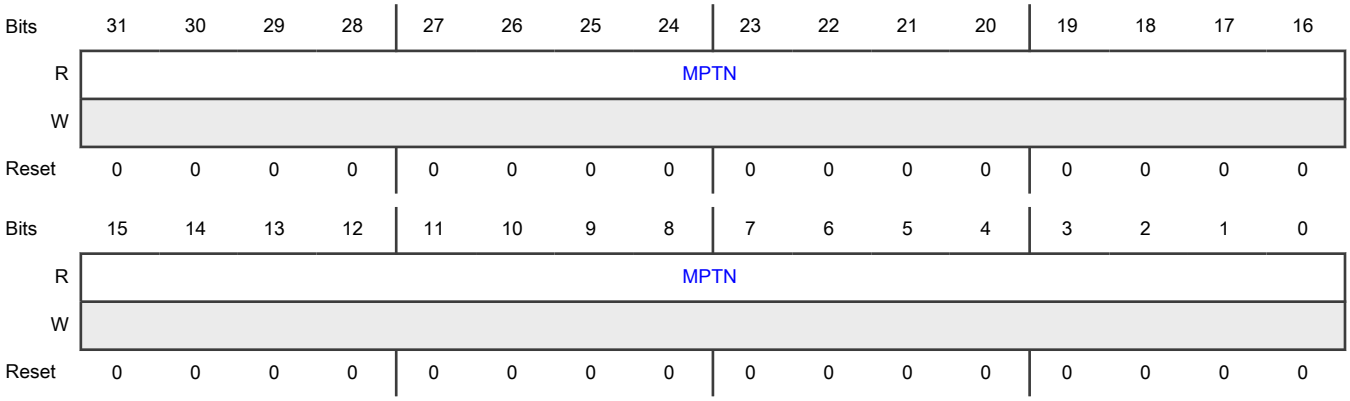
Offset

Register	Offset
MAC_Presn_Time_ns	240h

Function

Contains the 32-bit binary rollover equivalent time of the PTP system time (in nanoseconds) and exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

Diagram



Fields

Field	Function
31-0 MPTN	MAC 1722 Presentation Time (In Nanoseconds) Indicates the value of the 32-bit binary rollover equivalent time of the PTP System Time (in ns).

74.7.50 MAC Presentation Time Update (MAC_Presn_Time_Updt)

Offset

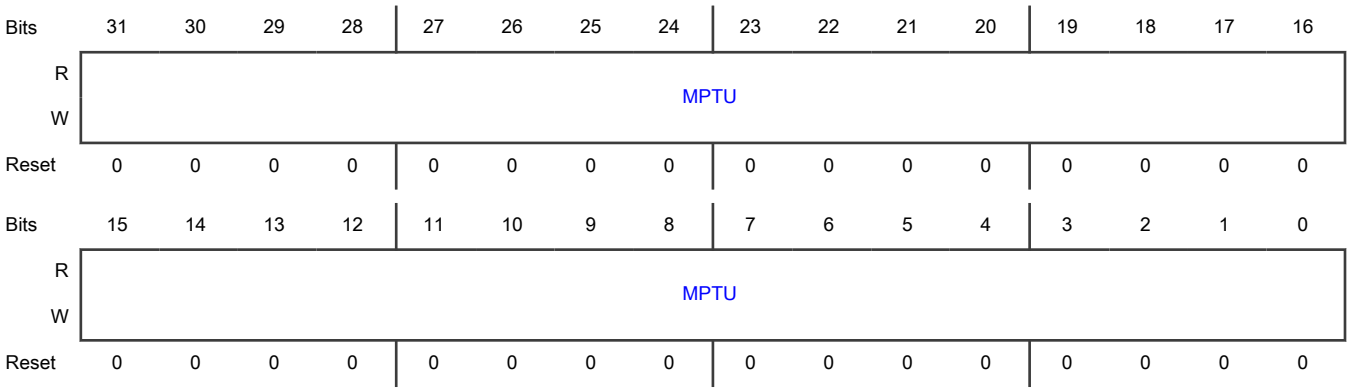
Register	Offset
MAC_Presn_Time_Updt	244h

Function

Holds the 32-bit value of MAC 1722 presentation time (in ns), which must be added to the current presentation time counter value. Initialization happens when MAC_Timestamp_Control[TSINIT] = 1, and an update happens when MAC_Timestamp_Control[TSUPDT] = 1.

Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

Diagram



Fields

Field	Function
31-0 MPTU	MAC 1722 Presentation Time Update Holds the initial value or the update value for the presentation time. When used for an update, this field holds the 32-bit value (in ns), which must be added to the current presentation time counter value. Initialization happens when MAC_Timestamp_Control[TSINIT] = 1, and an update happens when MAC_Timestamp_Control[TSUPDT] = 1. When MAC_System_Time_Nanoseconds_Update[ADDSUB] = 1, this value is directly used for subtraction.

74.7.51 MAC Address 0 High (MAC_Address0_High)

Offset

Register	Offset
MAC_Address0_High	300h

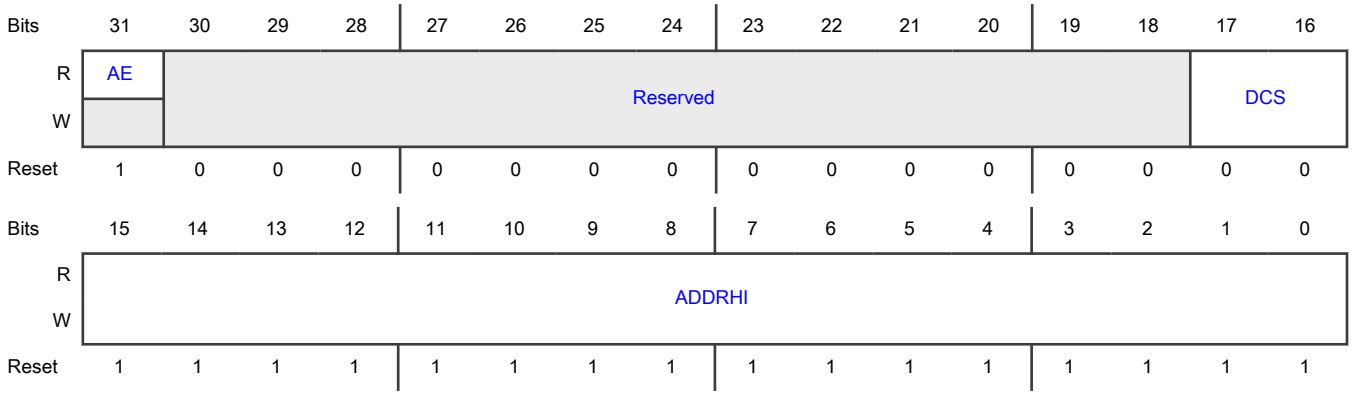
Function

Holds the upper 16 bits of the first 6-byte MAC address of the station.

The first DA byte that is received on the (G)MII interface corresponds to the LS byte (bits [7:0]) of MAC Address 0 Low (MAC_Address0_Low). For example, if 112233445566h is received (11h in lane 0 of the first column) on (G)MII as the destination address, MAC Address 0 Low (MAC_Address0_Low)[47:0] is compared to 665544332211h.

If MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 0 Low (MAC_Address0_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 0 Low (MAC_Address0_Low) must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable Enables MAC address 0b - Disabled and invalid (the field's value must always be 1) 1b - Enabled
30-18 —	Reserved
17-16 DCS	DMA Channel Select If MAC_Ext_Configuration[PDC] = 0, this field contains the binary representation of the DMA channel number to which a receive packet whose DA matches MAC Address 0 Low (MAC_Address0_Low) content is routed. If MAC_Ext_Configuration[PDC] = 1, this field contains the one-hot representation of one or more DMA channel numbers to which a receive packet whose DA matches MAC Address 0 Low (MAC_Address0_Low) content is routed.
15-0 ADDRHI	MAC Address 0 [47:32] Contains the upper 16 bits [47:32] of the first 6-byte MAC address. MAC uses this field for filtering the received packets and inserting the MAC address in the transmit flow control (pause) packets.

74.7.52 MAC Address 0 Low (MAC_Address0_Low)

Offset

Register	Offset
MAC_Address0_Low	304h

Function

Holds the lower 32 bits of the 6-byte first MAC address of the station.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRLO															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRLO															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-0 ADDRLO	MAC Address 0 [31:0] Contains the lower 32 bits of the first 6-byte MAC address. MAC uses this field to filter the received packets and insert the MAC address in the transmit flow control (pause) packets.

74.7.53 MAC Address 1 High (MAC_Address1_High)

Offset

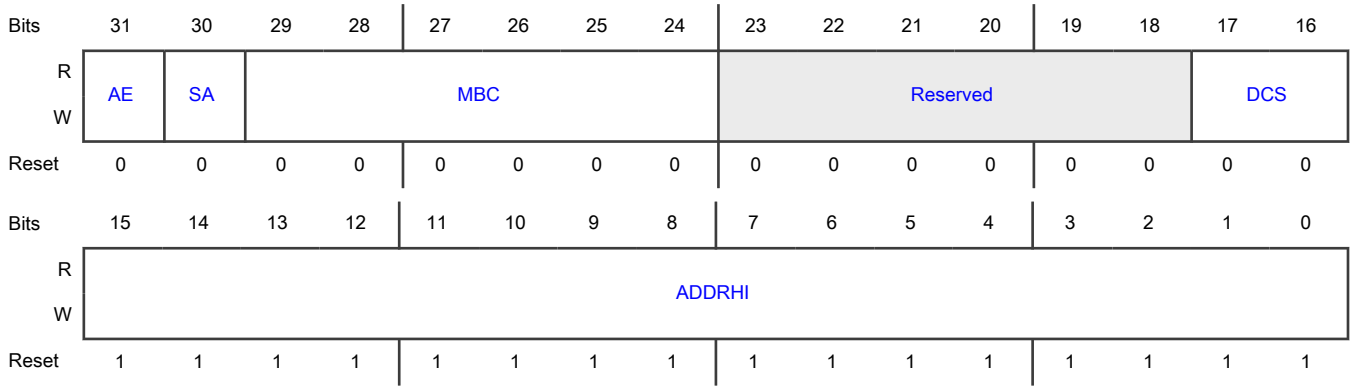
Register	Offset
MAC_Address1_High	308h

Function

Holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 1 Low (MAC_Address1_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 1 Low (MAC_Address1_Low) must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable Indicates whether the MAC address is enabled or ignored. If this field is 1, the address filter module uses the second MAC address for perfect filtering. If this field is 0, the address filter module ignores the address used for filtering. 0b - Ignored 1b - Enabled
30 SA	Source Address Indicates whether the MAC address is compared to the source or destination address. If this field is 1, MAC Address 1[47:0] is compared to the SA fields of the received packet. If this field is 0, MAC Address 1[47:0] is compared to the DA fields of the received packet. 0b - Destination address 1b - Source address
29-24 MBC	Mask Byte Control Contains mask control bits for comparing each of the MAC address bytes. If this field is 1, MAC does not compare the corresponding byte of the received DA or SA with the contents of the MAC address 1 registers. Each bit controls the masking of the bytes as follows: • Bit 29: MAC Address 1 High[15:8] • Bit 28: MAC Address 1 High[7:0] • Bit 27: MAC Address 1 Low[31:24] • - .. • Bit 24: MAC Address 1 Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-18	Reserved

Field	Function
—	
17-16 DCS	DMA Channel Select If MAC_Ext_Configuration[PDC] = 0, this field contains the binary representation of the DMA channel number to which a receive packet whose DA matches MAC Address 1 Low (MAC_Address1_Low) content is routed. If MAC_Ext_Configuration[PDC] = 1, this field contains the one-hot representation of one or more DMA Channel numbers to which a receive packet whose DA matches MAC Address 1 Low (MAC_Address1_Low) content is routed.
15-0 ADDRHI	MAC Address 1 [47:32] Contains the upper 16 bits [47:32] of the second 6-byte MAC address.

74.7.54 MAC Address 1 Low (MAC_Address1_Low)

Offset

Register	Offset
MAC_Address1_Low	30Ch

Function

Holds the lower 32 bits of the second 6-byte MAC address of the station.

Diagram

Fields

Field	Function
31-0	MAC Address 1 [31:0] Contains the lower 32 bits of the second 6-byte MAC address.

Table continues on the next page...

Field	Function
ADDRLO	The contents of this field are undefined until you load them after the initialization process.

74.7.55 MAC Address 2 High (MAC_Address2_High)

Offset

Register	Offset
MAC_Address2_High	310h

Function

Holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 1 Low (MAC_Address1_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 1 Low (MAC_Address1_Low) must be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Function
31 AE	Address Enable Indicates whether the MAC address is enabled or ignored. If this field is 1, the address filter module uses the second MAC address for perfect filtering. If this field is 0, the address filter module ignores the address for filtering. 0b - Ignored 1b - Enabled
30 SA	Source Address Indicates whether the MAC address is compared to the source or destination address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, MAC Address 1[47:0] is compared to the SA fields of the received packet. If this field is 0, MAC Address 1[47:0] is compared to the DA fields of the received packet. 0b - Destination address 1b - Source address
29-24 MBC	Mask Byte Control Contains mask control bits for comparing each of the MAC address bytes. If this field is 1, MAC does not compare the corresponding byte of the received DA or SA with the contents of MAC address 1 registers. Each bit controls the masking of the bytes as follows: • Bit 29: MAC Address 1 High[15:8] • Bit 28: MAC Address 1 High[7:0] • Bit 27: MAC Address 1 Low[31:24] • - .. • Bit 24: MAC Address 1 Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-18 —	Reserved
17-16 DCS	DMA Channel Select If MAC_Ext_Configuration[PDC] = 0, this field contains the binary representation of the DMA channel number to which a receive packet whose DA matches MAC Address 2 Low (MAC_Address2_Low) content is routed. If MAC_Ext_Configuration[PDC] = 1, this field contains the one-hot representation of one or more DMA Channel numbers to which a receive packet whose DA matches MAC Address 2 Low (MAC_Address2_Low) content is routed.
15-0 ADDRHI	MAC Address 1 [47:32] Contains the upper 16 bits [47:32] of the second 6-byte MAC address.

74.7.56 MAC Address 2 Low (MAC_Address2_Low)

Offset

Register	Offset
MAC_Address2_Low	314h

Function
Holds the lower 32 bits of the second 6-byte MAC address of the station.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-9 —	Reserved
8 UCDBC	Update MMC Counters For Dropped Broadcast Packets Indicates the status of MMC counters for dropped broadcast packets. • If this field is 1, MAC updates all the related MMC counters for broadcast packets that are dropped because MAC_Packet_Filter[DBF] = 1. • If this field is 0, the MMC counters are not updated for dropped broadcast packets. **NOTE** The CNTRST field has a higher priority than the CNTPRST field. Therefore, if you write 1 to both these fields in the same write cycle, all the counters are cleared and the CNTPRST field becomes 0. 0b - Disabled 1b - Enabled
7-6 —	Reserved
5 CNTPRSTLVL	Full-Half Preset Indicates whether full-half preset is enabled or disabled. • If this field is 0 and the CNTPRST field is 1, all the MMC counters are preset to the almost-half value. All octet counters are preset to 7FFF_F800h (half 2 Kbytes) and all packet counters are preset to 7FFF_FFF0h (half 16). • If this field is 1 and the CNTPRST field is 1 too, all MMC counters are preset to the almost-full value. All octet counters are preset to FFFF_F800h (full 2 Kbytes) and all packet counters are preset to FFFF_FFF0h (full 16). For 16-bit counters, the almost-half preset values are 7800h and 7FF0h for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0b - Disabled 1b - Enabled
4 CNTPRST	Counters Preset Indicates whether MMC counter preset is enabled or disabled. If this field is 1, all the counters are initialized or preset to almost full or almost half according to the settings of the CNTPRSTLVL field. This field clears automatically after 1 clock cycle, and along with the CNTPRSTLVL field, is useful for debugging and testing the assertion of interrupts because of the MMC counter becoming half-full or full. Access restrictions apply to this field, which clears automatically. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
3 CNTFREEZ	MMC Counter Freeze Indicates the status of MMC counter freeze. If this field is 1, the field freezes all the MMC counters to their current values. Until this field becomes 0, no MMC counter is updated because of any transmitted or received packets. If an MMC counter is read when RSTONRD = 1, that counter is also cleared in this mode. 0b - Disabled 1b - Enabled
2 RSTONRD	Reset On Read Indicates whether the reset on read for MMC counters is enabled or disabled. If this field is 1, MMC counters are reset to 0 after read (they clear automatically after reset). The counters are cleared when the least significant byte lane (bits [7:0]) is read. 0b - Disabled 1b - Enabled
1 CNTSTOPRO	Counter Stop Rollover Indicates the status of counter stop rollover. If this field is 1, the counter does not roll over to 0 after reaching the maximum value. 0b - Disabled 1b - Enabled
0 CNTRST	Counters Reset Indicates whether MMC counters are reset. If this field is 1, all the counters are reset. This field clears automatically after 1 clock cycle. Access restrictions apply to this field that clears automatically. 0b - Counters are not reset 1b - All counters are reset

74.7.58 MMC Receive Interrupt (MMC_Rx_Interrupt)

Offset

Register	Offset
MMC_Rx_Interrupt	704h

Function

Maintains the interrupts generated from all receive statistics counters when the following conditions occur:

- Receive statistic counters reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter).
- Receive statistic counters cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter).

If MMC_Control[CNTSTOPRO] = 1, interrupts are set but the counter remains at all-ones. This is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

NOTE

R_SS_RC means that this register bit is set internally, and is cleared when the counter register is read.

74.7.59 MMC Transmit Interrupt (MMC_Tx_Interrupt)

Offset

Register	Offset
MMC_Tx_Interrupt	708h

Function

Maintains the interrupts generated from all the transmit statistics counters.

This register maintains those interrupts that are generated when transmit statistic counters:

- Reach half of their maximum values (8000_0000h for a 32-bit counter and 0x8000 for a 16-bit counter)
- Cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter)

If MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones.

This is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

This field becomes 1 when the txunderflowerror counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
12 TXBCGBPIS	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit broadcast good bad packet counter interrupt is detected. This field becomes 1 when the txbroadcastpackets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 TXMCGBPIS	MMC Transmit Multicast Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit multicast good bad packet counter interrupt is detected. This field becomes 1 when the txmulticastpackets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10 TXUCGBPIS	MMC Transmit Unicast Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit unicast good bad packet counter interrupt is detected. This field becomes 1 when the txunicastpackets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
9 TX1024TMAXOCTGBPIS	MMC Transmit 1024 To Maximum Octet Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit 1024 to maximum octet good bad packet counter interrupt is detected. This field becomes 1 when the tx1024tomaxoctets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
8 TX512T1023OCTGBPIS	MMC Transmit 512 To 1023 Octet Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit 512 to 1023 octet good bad packet counter interrupt is detected. This field becomes 1 when the tx512to1023octets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
7	MMC Transmit 256 To 511 Octet Good Bad Packet Counter Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
TX256T511OCTGBPIS	Indicates whether the status of the MMC transmit 256 to 511 octet good bad packet counter interrupt is detected. This field becomes 1 when the tx256to511octets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
6 TX128T255OCTGBPIS	MMC Transmit 128 To 255 Octet Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit 128 to 255 octet good bad packet counter interrupt is detected. This field becomes 1 when the tx128to255octets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
5 TX65T127OCTGBPIS	MMC Transmit 65 To 127 Octet Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit 65 to 127 octet good bad packet counter interrupt is detected. This field becomes 1 when the tx65to127octets_gb counter reaches half of its maximum value, and also when it reaches the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
4 TX64OCTGBPIS	MMC Transmit 64-Octet Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit 64-octet good bad packet counter interrupt is detected. This field becomes 1 when the tx64octets_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
3 TXMCGPIS	MMC Transmit Multicast Good Packet Counter Interrupt Status Indicates whether the status of the MMC transmit multicast good packet counter interrupt is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when the txmulticastpackets_g counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
2 TXBCGPIS	MMC Transmit Broadcast Good Packet Counter Interrupt Status Indicates whether the status of the MMC transmit broadcast good packet counter interrupt is detected. This field becomes 1 when the txbroadcastpackets_g counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
1 TXGBPKTIS	MMC Transmit Good Bad Packet Counter Interrupt Status Indicates whether the status of the MMC transmit good bad packet counter interrupt is detected. This field becomes 1 when the txpacketcount_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 TXGBOCTIS	MMC Transmit Good Bad Octet Counter Interrupt Status Indicates whether the status of the MMC transmit good bad octet counter interrupt is detected. This field becomes 1 when the txoctetcount_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

74.7.60 MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask)

Offset

Register	Offset
MMC_Rx_Interrupt_Mask	70Ch

Function

Maintains the masks for interrupts generated from all the receive statistic counters. These interrupts are generated when the receive statistic counters reach half of their maximum values or the maximum values.

Diagram

25 RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Indicates the status of the MMC receive control packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxctrlpackets_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
24 RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Indicates the status of the MMC receive error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxrcverror counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
23	MMC Receive Watchdog Error Packet Counter Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXWDOGPIM	Indicates the status of the MMC receive watchdog error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxwatchdog counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
22 RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive VLAN good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxvlanpackets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
21 RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Indicates the status of the MMC receive FIFO overflow packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxfifooverflow counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
20 RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Indicates the status of the MMC receive pause packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxpausepackets counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
19 RXORANGEPIM	MMC Receive Out-Of-Range Error Packet Counter Interrupt Mask Indicates the status of the MMC receive out-of-range error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxoutofrangetype counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
18 RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Indicates the status of the MMC receive length error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxlengtherror counter reaches half of its maximum value or the maximum value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
17 RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Indicates the status of the MMC receive unicast good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxunicastpackets_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
16 RX1024TMAXOCTGBPIM	MMC Receive 1024 To Maximum Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 1024 to maximum octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
15 RX512T1023OCTGBPIM	MMC Receive 512 To 1023 Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 512 to 1023 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx512to1023octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
14 RX256T511OCTGBPIM	MMC Receive 256 To 511 Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 256 to 511 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx256to511octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
13 RX128T255OCTGBPIM	MMC Receive 128 To 255 Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 128 to 255 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx128to255octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
12	MMC Receive 65 To 127 Octet Good Bad Packet Counter Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RX65T127OCTGBPIM	Indicates the status of the MMC receive 65 to 127 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx65to127octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
11 RX64OCTGBPIM	MMC Receive 64-Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 64-octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx64octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
10 RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask Indicates the status of the MMC receive oversize good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxoversize_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
9 RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask Indicates the status of the MMC receive undersize good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxundersize_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
8 RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask Indicates the status of the MMC receive jabber error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxjabbererror counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
7 RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask Indicates the status of the MMC receive runt packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxrunterror counter reaches half of its maximum value or the maximum value.

Table continues on the next page...

74.7.96 Receive Jabber Error Packets (Rx_Jabber_Error_Packets)

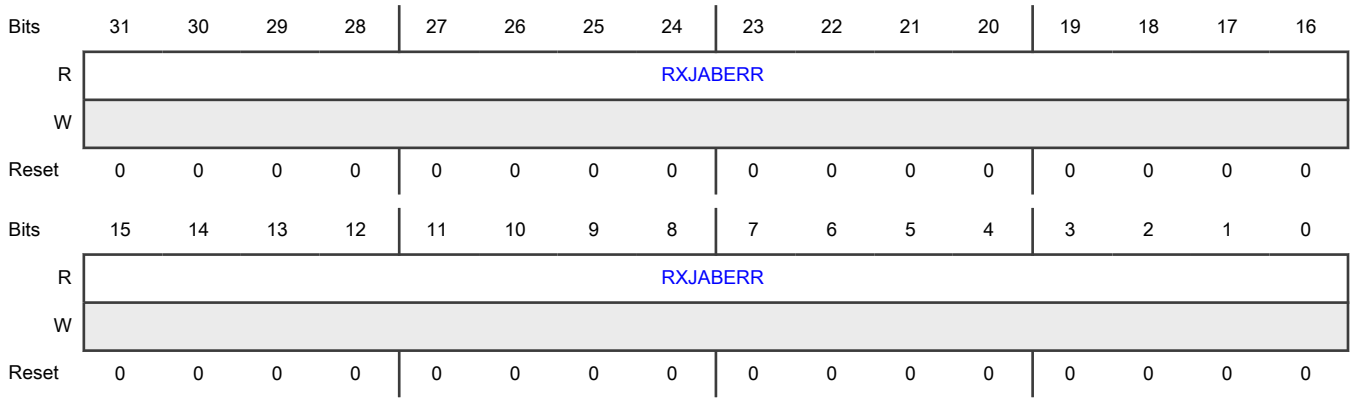
Offset

Register	Offset
Rx_Jabber_Error_Packets	7A0h

Function

Provides the number of giant packets that the module received, having a length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN-tagged packets), and with a CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN-tagged packets) are considered as giant packets.

Diagram



Fields

Field	Function
31-0 RXJABERR	Receive Jabber Error Packets Indicates the number of giant packets received, having a length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN-tagged packets), and with a CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN-tagged packets) are considered as giant packets.

74.7.97 Receive Undersize Packets Good (Rx_Undersize_Packets_Good)

Offset

Register	Offset
Rx_Undersize_Packets_Good	7A4h

Function

Provides the number of packets that the module received, having a length less than 64 bytes, but without any errors.

Diagram

Fields

Field	Function
31-0 RXUNDERSZG	Receive Undersize Packets Good Indicates the number of packets received, having a length less than 64 bytes, but without any errors.

74.7.98 Receive Oversize Packets Good (Rx_Oversize_Packets_Good)

Offset

Register	Offset
Rx_Oversize_Packets_Good	7A8h

Function

Provides the number of packets that the module received without any errors, having a length greater than the maximum size (1,518 bytes or 1,522 bytes for VLAN-tagged packets; 2000 bytes if MAC_Configuration[S2KP] = 1).

Diagram

Fields

Field	Function
31-0 RXOVERSZG	Receive Oversize Packets Good Indicates the number of packets received without errors, with a length greater than the maximum size (1,518 bytes or 1,522 bytes for VLAN-tagged packets; 2000 bytes if MAC_Configuration[S2KP] = 1).

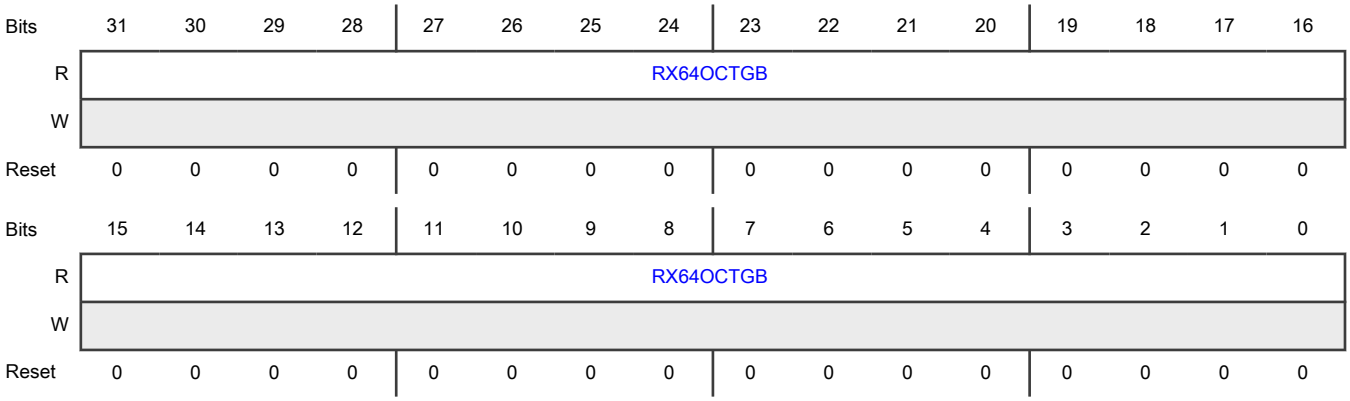
74.7.99 Receive 64 Octets Packets Good Bad (Rx_64Octets_Packets_Good_Bad)

Offset

Register	Offset
Rx_64Octets_Packets_Good_Bad	7ACh

Function
Provides the number of 64-byte good and bad packets that the module received, exclusive of the preamble.

Diagram



Fields

Field	Function
31-0 RX64OCTGB	Receive 64 Octets Packets Good Bad Provides the number of 64-byte good and bad packets that the module received, exclusive of the preamble.

74.7.100 Receive 65-127 Octets Packets Good Bad (Rx_65To127Octets_Packets_Good_Bad)

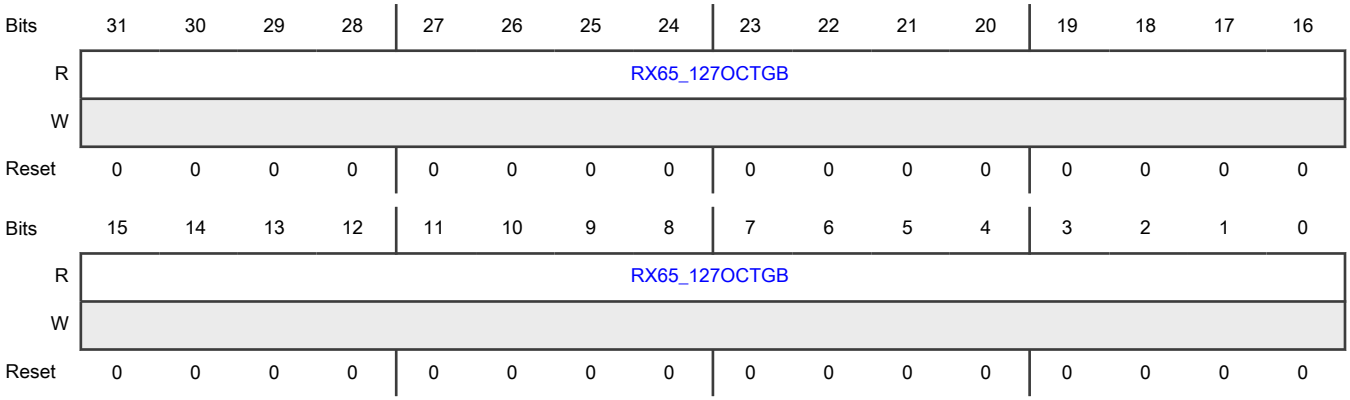
Offset

Register	Offset
Rx_65To127Octets_Packets_Good_Bad	7B0h

Function

Provides the number of good and bad packets that the module received, ranging between 65 and 127 (inclusive) bytes, exclusive of the preamble.

Diagram



Fields

Field	Function
31-0 RX65_127OCTGB	Receive 65-127 Octets Packets Good Bad Indicates the number of good and bad packets received, ranging between 65 and 127 (inclusive) bytes, exclusive of the preamble.

74.7.101 Receive 128-255 Octets Packets Good Bad (Rx_128To255Octets_Packets_Good_Bad)

Offset

Register	Offset
Rx_128To255Octets_Packets_Good_Bad	7B4h

Function

Provides the number of good and bad packets that the module received, with packet length between 128 and 255 (inclusive) bytes, exclusive of the preamble.

74.7.103 Receive 512-1023 Octets Packets Good Bad (Rx_512To1023Octets_Packets_Good_Bad)

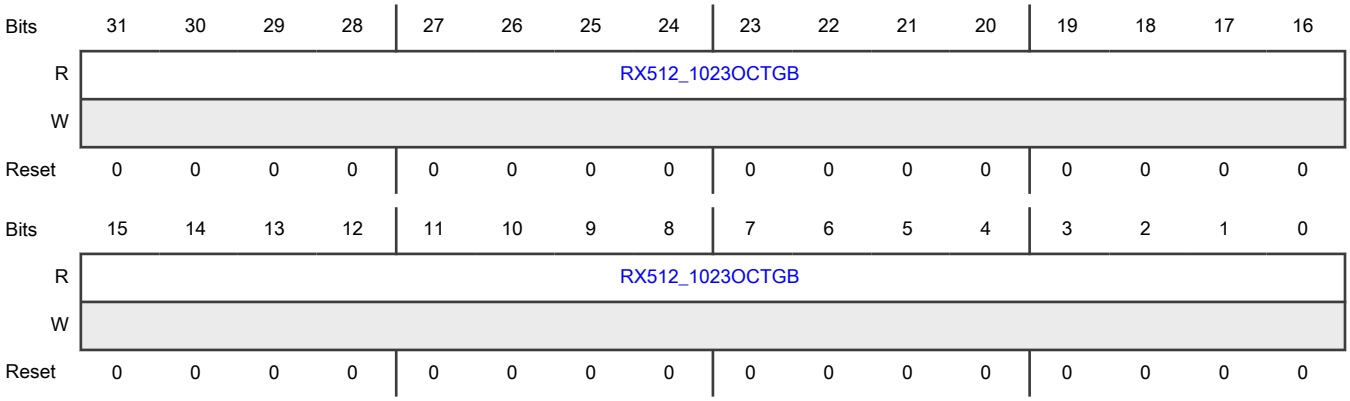
Offset

Register	Offset
Rx_512To1023Octets_Packets_Good_Bad	7BCh

Function

Provides the number of good and bad packets that the module received, having a packet length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.

Diagram



Fields

Field	Function
31-0 RX512_1023OCTGB	Receive 512-1023 Octets Packets Good Bad Indicates the number of good and bad packets received, having a packet length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.

74.7.104 Receive 1024 To Max Octets Good Bad (Rx_1024ToMaxOctets_Packets_Good_Bad)

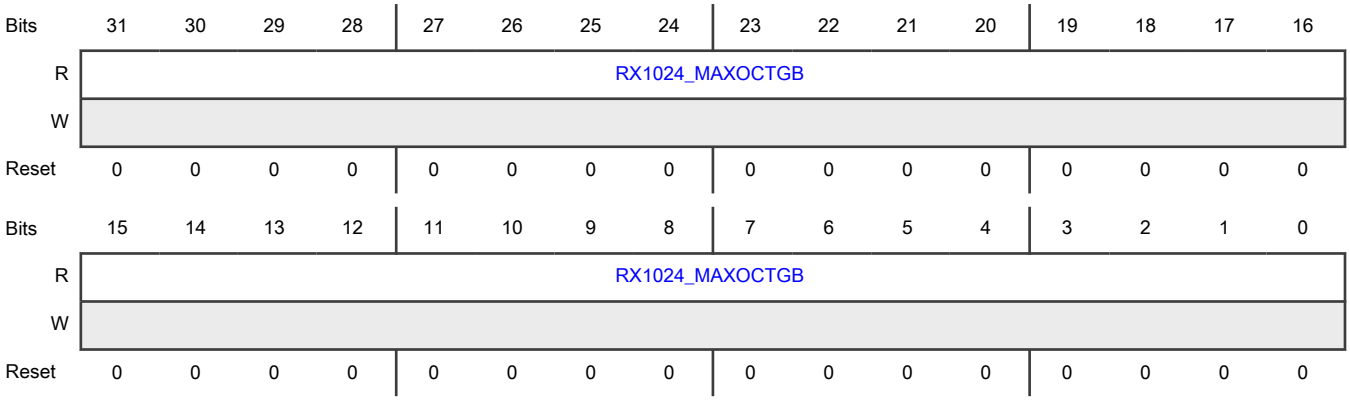
Offset

Register	Offset
Rx_1024ToMaxOctets_Packets_Good_Bad	7C0h

Function

Provides the number of good and bad packets that the module received, having an inclusive packet length between 1024 bytes and the maximum byte size, exclusive of the preamble.

Diagram



Fields

Field	Function
31-0 RX1024_MAXOCTGB	Receive 1024-Max Octets Good Bad Indicates the number of good and bad packets received with length between 1024 and the maximum size (inclusive) bytes, exclusive of the preamble.

74.7.105 Receive Unicast Packets Good (Rx_Unicast_Packets_Good)

Offset

Register	Offset
Rx_Unicast_Packets_Good	7C4h

Function

Provides the number of good unicast packets that the module received.

74.7.106 Receive Length Error Packets (Rx_Length_Error_Packets)

Offset

Register	Offset
Rx_Length_Error_Packets	7C8h

Function

Provides the number of packets that the module received with a length error (the Length/Type (LT) field of the RDES3 normal descriptor not equal to the packet size) for all the packets with a valid length field. For more information on the LT field, see the "RDES3 normal descriptor (write-back format)" section.

Field	Function
31-0 RXVLANPKTGB	Receive VLAN Packets Good Bad Indicates the number of good and bad VLAN packets received.

74.7.111 Receive Watchdog Error Packets (Rx_Watchdog_Error_Packets)

Offset

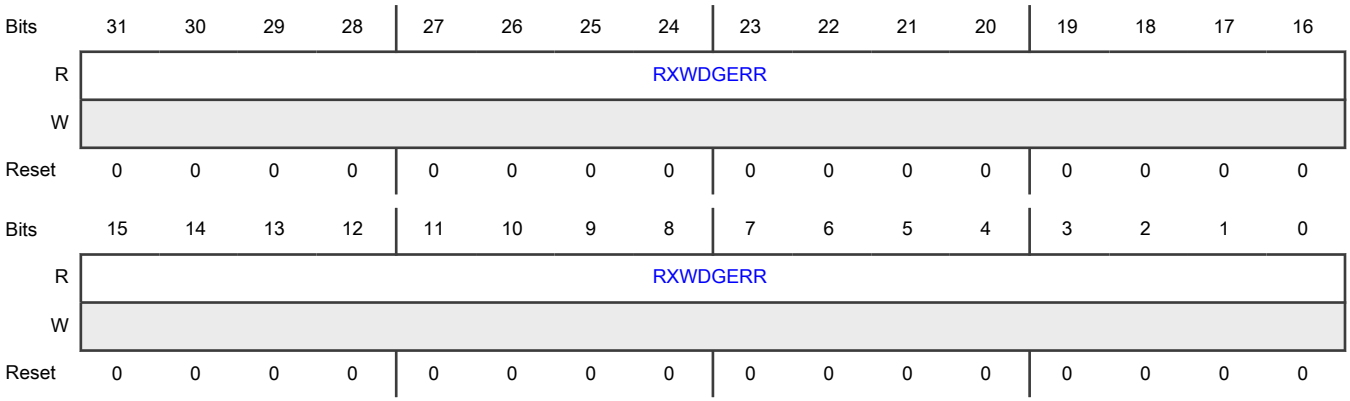
Register	Offset
Rx_Watchdog_Error_Packets	7DCh

Function

Provides the number of packets that the module received with a watchdog timeout error. Packets with a data load larger than the following are received:

- 2,048 bytes when MAC_Configuration[JE] = 0 and MAC_Configuration[WD] = 0
- 10,240 bytes when MAC_Configuration[JE] = 1 and MAC_Configuration[WD] = 0
- 16,384 bytes when MAC_Configuration[WD] = 1 or the value programmed in MAC Watchdog Timeout (MAC_Watchdog_Timeout)

Diagram



Fields

Field	Function
31-0 RXWDGERR	Receive Watchdog Error Packets Indicates the number of packets received with a watchdog timeout error. Packets with a data load larger than the following are received:

Table continues on the next page...

Field	Function
	• 2,048 bytes when MAC_Configuration[JE] = 0 and MAC_Configuration[WD] = 0 • 10,240 bytes when MAC_Configuration[JE] = 1 and MAC_Configuration[WD] = 0 • 16,384 bytes when MAC_Configuration[WD] = 1 or the value programmed in MAC Watchdog Timeout (MAC_Watchdog_Timeout)

74.7.112 Receive Receive Error Packets (Rx_Receive_Error_Packets)

Offset

Register	Offset
Rx_Receive_Error_Packets	7E0h

Function

Provides the number of packets that the module received with a receive or packet extension error on GMII or MII.

Diagram

74.7.114 MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt)

Offset

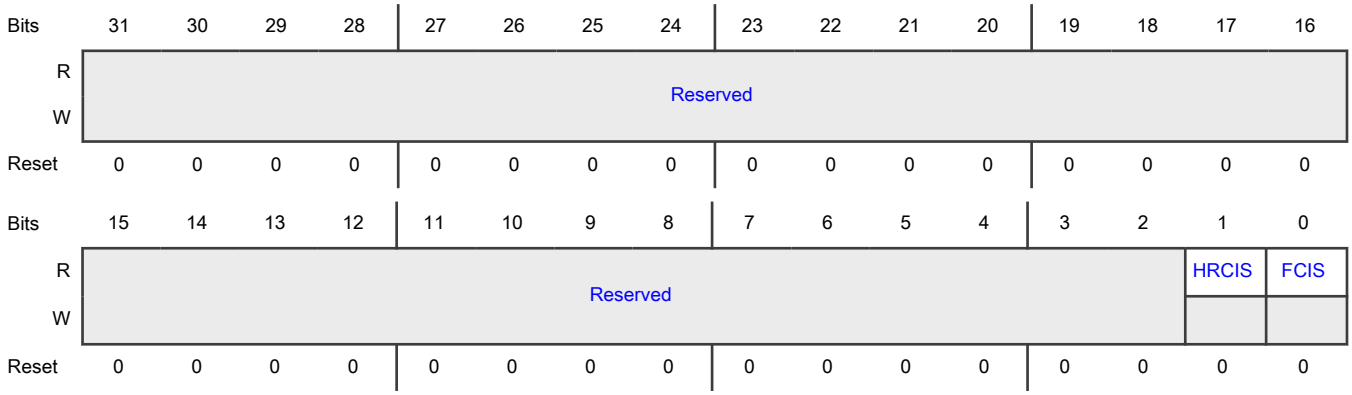
Register	Offset
MMC_FPE_Tx_Interrupt	8A0h

Function

Maintains the interrupts generated from all the FPE-related transmit statistic counters when they reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter), and when they cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter). When MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones.

An interrupt bit of this register becomes 0 when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 HRCIS	MMC Transmit Hold Request Counter Interrupt Status Indicates whether the MMC Transmit hold request counter interrupt status is detected. This field: • Becomes 1 when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value. • Exists when any one of the receive or transmit MMC counters is enabled during FPE with AV_EST-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 FCIS	MMC Transmit FPE Fragment Counter Interrupt Status Indicates whether the MMC Transmit FPE fragment counter interrupt status is detected. This field: • Becomes 1 when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. • Exists when any one of the receive or transmit MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

74.7.115 MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask)

Offset

Register	Offset
MMC_FPE_Tx_Interrupt_Mask	8A4h

Function

Maintains the masks for interrupts generated from all FPE-related transmit statistics counters. MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask) maintains the masks for the interrupts generated when FPE-related receive statistic counters reach half of their maximum value or the maximum value.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

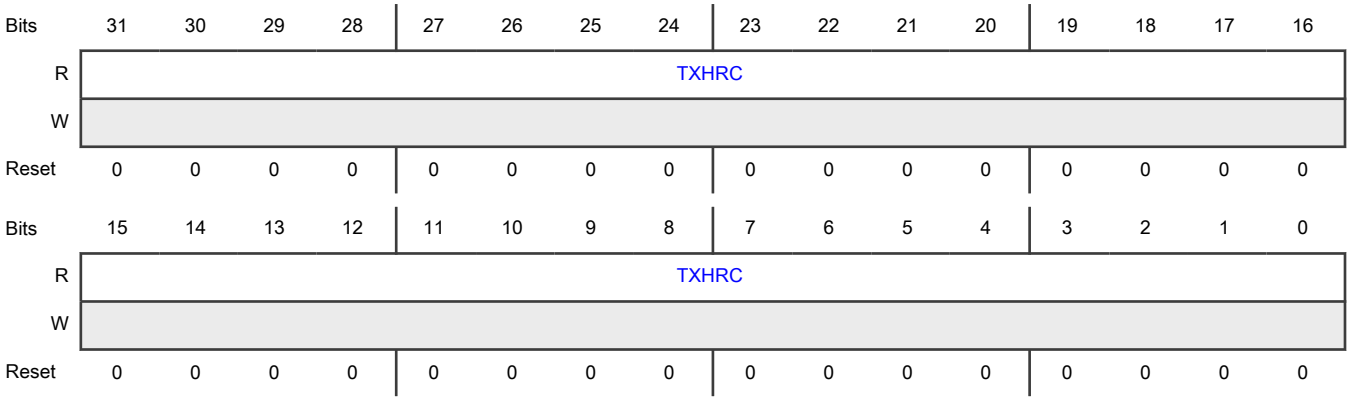
74.7.117 Transmit Hold Request Counter (MMC_Tx_Hold_Req_Cntr)

Offset

Register	Offset
MMC_Tx_Hold_Req_Cntr	8ACh

Function
Provides the count of times that a hold request is given to MAC.

Diagram



Fields

Field	Function
31-0 TXHRC	Transmit Hold Request Counter Indicates the count of times that a hold request is given to MAC. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE with AV_EST-enabled configuration.

74.7.118 MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt)

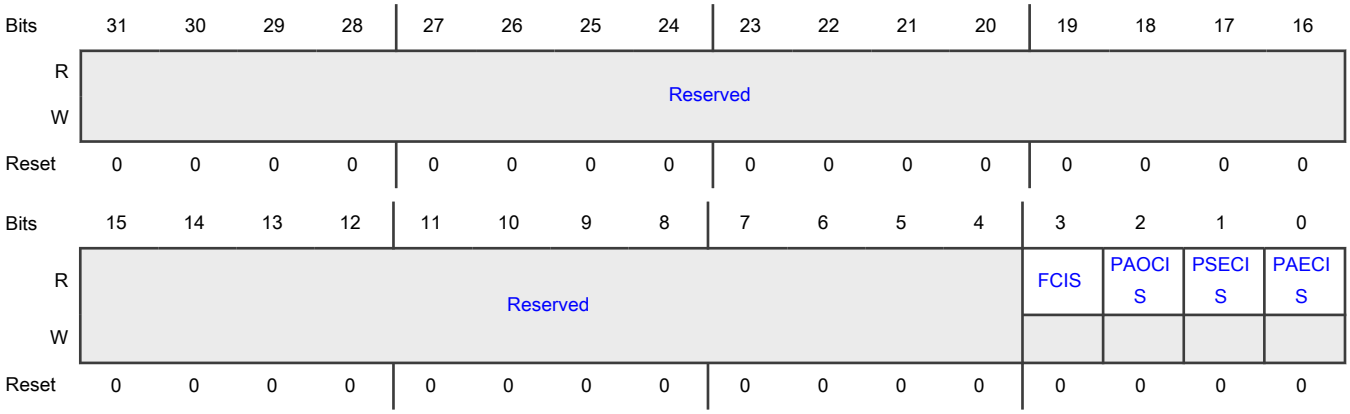
Offset

Register	Offset
MMC_FPE_Rx_Interrupt	8C0h

Function
Maintains the interrupts generated from all the FPE-related receive statistic counters, when these transmit statistic counters reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter), and when they cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for 16-bit counter). When MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones. An interrupt bit of this register becomes 0 when the respective

MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 FCIS	MMC Receive FPE Fragment Counter Interrupt Status Indicates whether the MMC receive FPE fragment counter interrupt status is detected. This field becomes 1 when the Rx_FPE_Fragment_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
2 PAOCIS	MMC Receive Packet Assembly OK Counter Interrupt Status Indicates whether the MMC receive packet assembly OK counter interrupt status is detected. This field becomes 1 when the Rx_Packet_Assemble_Ok_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 PSECIS	MMC Receive, Transmit, Packet SMD Error Counter Interrupt Status Indicates whether the status of the MMC receive packet SMD error counter interrupt is detected. This field becomes 1 when the Rx_Packet_SMD_Err_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 PAECIS	MMC Receive, transmit, Packet Assembly Error Counter Interrupt Status Indicates whether the status of the MMC receive packet assembly error counter interrupt is detected. This field becomes 1 when the Rx_Packet_Assemble_Err_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during the FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

74.7.119 MMC FPE Receive Interrupt Mask (MMC_FPE_Rx_Interrupt_Mask)

Offset

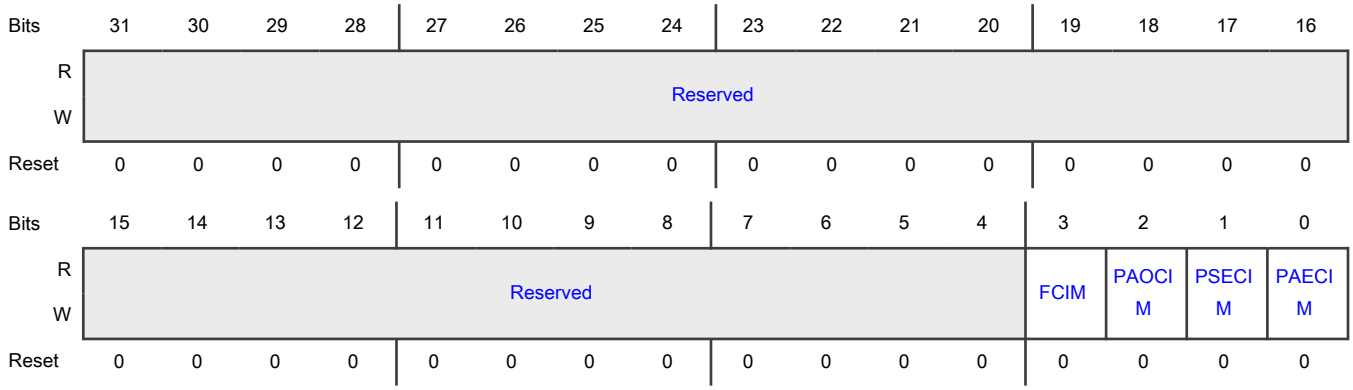
Register	Offset
MMC_FPE_Rx_Interrupt_Mask	8C4h

Function

Maintains the masks for interrupts generated from all FPE-related receive statistic counters.

This register maintains the masks for the interrupts generated when FPE-related receive statistic counters reach half of their maximum value or the maximum value.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 FCIM	MMC Receive FPE Fragment Counter Interrupt Mask Indicates the status of the MMC receive FPE fragment counter interrupt mask. Writing 1 to this field masks the interrupt when the Tx_FPE_Fragment_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. 0b - Disabled 1b - Enabled
2 PAOCIM	MMC Receive Packet Assembly OK Counter Interrupt Mask Indicates the status of the MMC receive packet assembly OK counter interrupt mask. Writing 1 to this field masks the interrupt when the Rx_Packet_Assemble_Ok_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. 0b - Disabled 1b - Enabled
1 PSECIM	MMC Receive Packet SMD Error Counter Interrupt Mask Indicates the status of the MMC receive packet SMD error counter interrupt mask. Writing 1 to this field masks the interrupt when the Rx_Packet_SMD_Err_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

Table continues on the next page...

Fields

Field	Function
31-0 PSEC	Packet SMD Error Counter Indicates the number of MAC frames rejected because of an unknown SMD value and MAC frame fragments rejected because of arriving with SMD-C when there was no preceding preempted frame. Exists when at least one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

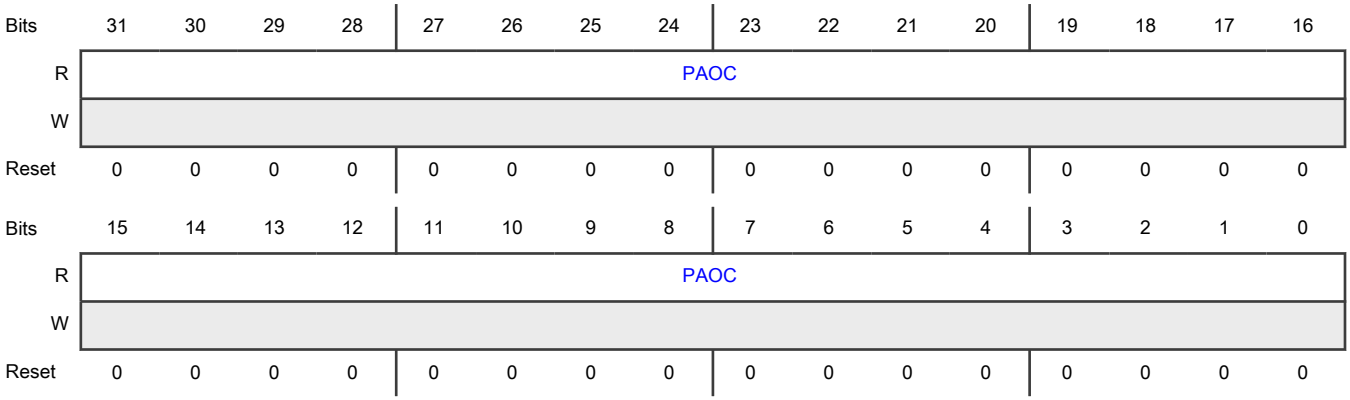
74.7.122 MMC Receive Packet Assembly OK Counter (MMC_Rx_Packet_Assembly_OK_Cntr)

Offset

Register	Offset
MMC_Rx_Packet_Assembly_OK_Cntr	8D0h

Function
Provides the number of MAC frames that were successfully reassembled and delivered to MAC.

Diagram



Fields

Field	Function
31-0 PAOC	Packet Assembly OK Counter Indicates the number of MAC frames that were successfully reassembled and delivered to MAC. Exists when at least one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

74.7.123 MMC Receive FPE Fragment Counter (MMC_Rx_FPE_Fragment_Cntr)

Offset

Register	Offset
MMC_Rx_FPE_Fragment_Cntr	8D4h

Function
Provides the number of additional mPackets received because of preemption.

Fields

Field	Function
31-29 —	Reserved
28 DMCHEN0	DMA Channel Select Enable Indicates the status of the DMA channel number. • If this field is 1, it enables the selection of the DMA channel number for the packet that the L3_L4 filter passes. The DMCHN fields indicate the DMA channel number. • If this field is 0, the filter does not decide the DMA channel number. 0b - Disabled 1b - Enabled
27-25 —	Reserved
24 DMCHN0	DMA Channel Number Indicates the DMA channel number. If the value of the DMCHEN fields is 1, this field selects the DMA channel number to which the packet that this filter passes is routed. The width of this field depends on the number of the DMA channels present in your configuration.
23-22 —	Reserved
21 L4DPIM0	Layer 4 Destination Port Inverse Match Enable Indicates the status of layer 4 destination port inverse matching. • If this field is 1, MAC_Layer4_Address0[L4DP0] is enabled for inverse matching. • If this field is 0, MAC_Layer4_Address0[L4DP0] is enabled for perfect matching. This field is valid and applicable only when the L4DPM0 field is 1. 0b - Disabled 1b - Enabled
20 L4DPM0	Layer 4 Destination Port Match Enable Indicates the status of layer 4 destination port matching. • If this field is 1, MAC_Layer4_Address0[L4DP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4DP0] for matching. 0b - Disabled 1b - Enabled
19	Layer 4 Source Port Inverse Match Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
L4SPIM0	Indicates the status of layer 4 source port inverse matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for inverse matching. • If this field is 0, MAC_Layer4_Address0[L4SP0] is enabled for perfect matching. This field is valid and applicable only when MAC_Layer4_Address0[L4SP0] = 1. 0b - Disabled 1b - Enabled
18 L4SPM0	Layer 4 Source Port Match Enable Indicates the status of layer 4 source port matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4SP0] for matching. 0b - Disabled 1b - Enabled
17 —	Reserved
16 L4PEN0	Layer 4 Protocol Enable Indicates the status of layer 4 protocol. • If this field is 1, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] are used for matching UDP packets. • If this field is 0, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] are used for matching TCP packets. Layer 4 matching is performed only when the L4SPM0 field or the L4DPM0 field is 1. 0b - Disabled 1b - Enabled
15-11 L3HDBM0	Layer 3 IP DA Higher Bits Match IPv4 packets: This field contains the number of higher bits of IP DA that are matched in the IPv4 packets. The following list describes the values of this field: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • - .. • 31: All bits except MSb are masked. IPv6 packets:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Bits [12:11] of this field correspond to bits [6:5] of the L3HSBM0 field, which indicates the number of lower bits of IP SA or DA that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 fields: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • .. • 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 field or the L3SAM0 field is 1.
10-6 L3HSBM0	Layer 3 IP SA Higher Bits Match IPv4 packets: This field contains the number of lower bits of IP SA that are masked for matching in the IPv4 packets. The following list describes the values of this field: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • .. • 31: All bits except MSb are masked. IPv6 packets: This field contains bits [4:0] of L3HSBM0. These bits indicate the number of higher bits of IP SA or DA matched in the IPv6 packets. The field is valid and applicable only when the L3DAM0 field or the L3SAM0 field is 1.
5 L3DAIM0	Layer 3 IP DA Inverse Match Enable Indicates the status of layer 3 IP DA inverse matching. • If this field is 1, layer 3 IP DA is enabled for inverse matching. • If this field is 0, layer 3 IP DA is enabled for perfect matching. This field is valid and applicable only if L3DAM0 = 1. 0b - Disabled 1b - Enabled
4 L3DAM0	Layer 3 IP DA Match Enable Indicates the status of layer 3 IP DA matching. • If this field is 1, layer 3 IP DA is enabled for matching. • If this field is 0, MAC ignores layer 3 IP DA for matching.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If L3PEN0 = 1, you must write 1 to either this field or the L3SAM0 field because either the IPv6 DA or SA can be checked for filtering. 0b - Disabled 1b - Enabled
3 L3SAIM0	Layer 3 IP SA Inverse Match Enable Indicates the status of layer 3 IP SA inverse matching. • If this field is 1, layer 3 IP SA is enabled for inverse matching. • If this field is 0, layer 3 IP SA is enabled for perfect matching. This field is valid and applicable only if the L3SAM0 field is 1. 0b - Disabled 1b - Enabled
2 L3SAM0	Layer 3 IP SA Match Enable Indicates the status of layer 3 IP SA matching. • If this field is 1, layer 3 IP SA matching is enabled. • If this field is 0, MAC ignores layer 3 IP SA matching. **NOTE** If L3PEN0 = 1, you must write 1 to either this field or the L3DAM0 field because either IPv6 SA or DA can be checked for filtering. 0b - Disabled 1b - Enabled
1 —	Reserved
0 L3PEN0	Layer 3 Protocol Enable Indicates the status of layer 3 protocol. • If this field is 1, the layer 3 IP SA or DA matching is enabled for IPv6 packets. • If this field is 0, the layer 3 IP SA or DA matching is enabled for IPv4 packets. The layer 3 matching is performed only when either the L3SAM0 field or the L3DAM0 field is 1. 0b - Disabled 1b - Enabled

74.7.125 MAC Layer 4 Address 0 (MAC_Layer4_Address0)

Offset

Register	Offset
MAC_Layer4_Address0	904h

Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if MAC_Packet_Filter[IPFE] is 0 when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

The layer 3 matching is performed only when either MAC_L3_L4_Control0[L3SAM0] or MAC_L3_L4_Control0[L3DAM0] is 1. 0b - Disabled 1b - Enabled

74.7.131 MAC Layer 4 Address 1 (MAC_Layer4_Address1)

Offset

Register	Offset
MAC_Layer4_Address1	934h

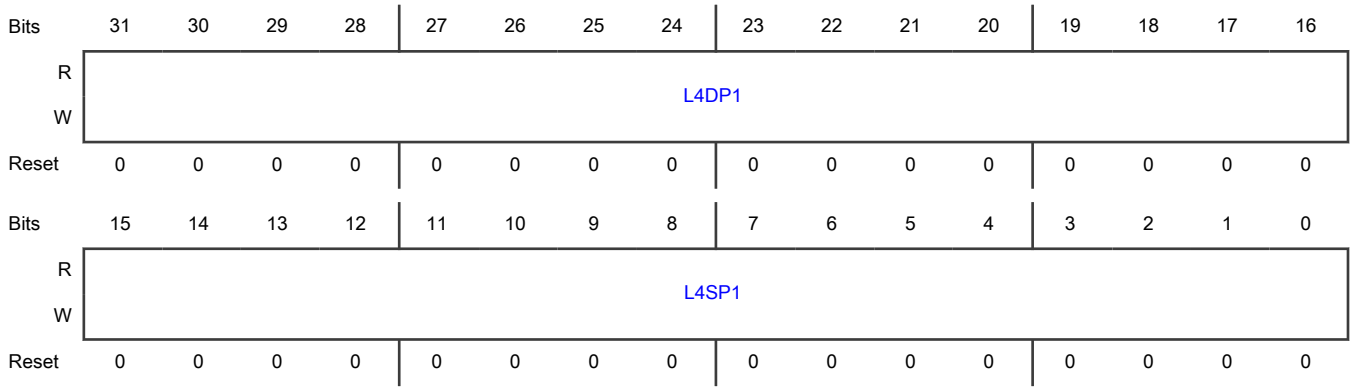
Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

Diagram



Fields

Field	Function
31-16 L4DP1	Layer 4 Destination Port Number 1 Indicates layer 4 destination port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4DPM0] = 1, this field contains the value to be matched with the TCP destination port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4DPM0] are 1, this field contains the value to be matched with the UDP destination port number field in the IPv4 or IPv6 packets.
15-0 L4SP1	Layer 4 Source Port Number 1 Indicates layer 4 source port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4SPM0] = 1, this field contains the value to be matched with the TCP source port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4SPM0] are 1, this field contains the value to be matched with the UDP source port number field in the IPv4 or IPv6 packets.

74.7.132 MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1)

Offset

Register	Offset
MAC_Layer3_Addr0_Reg1	940h

Function

Contains the 32-bit IP source address field for IPv4 packets. For IPv6 packets, the field contains bits [31:0] of the 128-bit IP source address or destination address field.

Diagram

The layer 3 matching is performed only when either MAC_L3_L4_Control0[L3SAM0] or MAC_L3_L4_Control0[L3DAM0] is 1. 0b - Disabled 1b - Enabled

74.7.137 MAC Layer 4 Address 2 (MAC_Layer4_Address2)

Offset

Register	Offset
MAC_Layer4_Address2	964h

Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

18 L4SPM3	Layer 4 Source Port Match Enable 3 Indicates the status of layer 4 source port matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4SP0] for matching. 0b - Disabled 1b - Enabled
17 —	Reserved
16 L4PEN3	Layer 4 Protocol Enable 3 Indicates the status of layer 4 protocol. • If this field is 1, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] of UDP packets are used for matching. • If this field is 0, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] of TCP packets are used for matching. Layer 4 matching is performed only when the L4SPM0 field or the L4DPM0 field is 1. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-11 L3HDBM3	Layer 3 IP DA Higher Bits Match 3 IPv4 Packets: This field contains the number of higher bits of IP DA that are matched in the IPv4 packets. The following list describes the values of this field: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • .. • 31: All bits except MSb are masked. IPv6 Packets: Bits [12:11] of this field correspond to bits [6:5] of MAC_L3_L4_Control0[L3HSBM0], which indicates the number of lower bits of IP SA or DA that are masked in the IPv6 packets. The following list describes the concatenated values of MAC_L3_L4_Control0[L3HDBM0][1:0] and MAC_L3_L4_Control0[L3HSBM0]: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked • .. • 127: All bits except MSb are masked. This field is valid and applicable only when MAC_L3_L4_Control0[L3DAM0] or MAC_L3_L4_Control0[L3SAM0] is 1. .
10-6 L3HSBM3	Layer 3 IP SA Higher Bits Match 3 IPv4 packets: This field contains the number of lower bits of IP SA that are masked for matching in the IPv4 packets. The following list describes the values of this field: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • .. • 31: All bits except MSb are masked. IPv6 packets: This field contains bits [4:0] of MAC_L3_L4_Control0[L3HSBM0]. These bits indicate the number of higher bits of IP SA or DA matched in the IPv6 packets. The field is valid and applicable only when MAC_L3_L4_Control0[L3DAM0] or MAC_L3_L4_Control0[L3SAM0] is 1.
5	Layer 3 IP DA Inverse Match Enable 3

Table continues on the next page...

Table continued from the previous page...

Field	Function
L3DAIM3	Indicates the status of layer 3 IP DA inverse matching. • If this field is 1, layer 3 IP DA is enabled for inverse matching. • If this field is 0, layer 3 IP DA is enabled for perfect matching. This field is valid and applicable only if MAC_L3_L4_Control0[L3DAM0] = 1. 0b - Disabled 1b - Enabled
4 L3DAM3	Layer 3 IP DA Match Enable 3 Indicates the status of layer 3 IP DA matching. • If this field is 1, layer 3 IP DA is enabled for matching. • If this field is 0, MAC ignores layer 3 IP DA for matching. **NOTE** If MAC_L3_L4_Control0[L3PEN0] = 1, you must write 1 to either this field or to MAC_L3_L4_Control0[L3SAM0] because either the IPv6 DA or SA can be checked for filtering. 0b - Disabled 1b - Enabled
3 L3SAIM3	Layer 3 IP SA Inverse Match Enable 3 Indicates the status of layer 3 IP SA inverse matching. • If this field is 1, layer 3 IP SA is enabled for inverse matching. • If this field is 0, layer 3 IP SA is enabled for perfect matching. This field is valid and applicable only if MAC_L3_L4_Control0[L3SAM0] is 1. 0b - Disabled 1b - Enabled
2 L3SAM3	Layer 3 IP SA Match Enable 3 Indicates the status of layer 3 IP SA matching. • If this field is 1, layer 3 IP SA matching is enabled. • If this field is 0, MAC ignores layer 3 IP SA matching. **NOTE** If MAC_L3_L4_Control0[L3PEN0] = 1, you must write 1 to either this field or to MAC_L3_L4_Control0[L3DAM0] because either IPv6 SA or DA can be checked for filtering. 0b - Disabled 1b - Enabled
1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
0 L3PEN3	Layer 3 Protocol Enable 3 Indicates the status of layer 3 protocol. • If this field is 1, the layer 3 IP SA or DA matching is enabled for IPv6 packets. • If this field is 0, the layer 3 IP SA or DA matching is enabled for IPv4 packets. The layer 3 matching is performed only when either MAC_L3_L4_Control0[L3SAM0] or MAC_L3_L4_Control0[L3DAM0] is 1. 0b - Disabled 1b - Enabled

74.7.143 MAC Layer 4 Address 3 (MAC_Layer4_Address3)

Offset

Register	Offset
MAC_Layer4_Address3	994h

Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

Diagram

Fields

Field	Function
31-16 L4DP3	Layer 4 Destination Port Number 3 Indicates layer 4 destination port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4DPM0] = 1, this field contains the value to be matched with the TCP destination port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4DPM0] are 1, this field contains the value to be matched with the UDP destination port number field in the IPv4 or IPv6 packets.
15-0 L4SP3	Layer 4 Source Port Number 3 Indicates layer 4 source port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4SPM0] = 1, this field contains the value to be matched with the TCP source port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4SPM0] are 1, this field contains the value to be matched with the UDP source port number field in the IPv4 or IPv6 packets.

74.7.144 MAC Layer 3 Address 0 Reg 3 (MAC_Layer3_Addr0_Reg3)

Offset

Register	Offset
MAC_Layer3_Addr0_Reg3	9A0h

Function

Contains the 32-bit IP source address field for IPv4 packets. For IPv6 packets, the field contains bits [31:0] of the 128-bit IP source address or destination address field.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 L3A33	Layer 3 Address 3 Indicates layer 3 address 3. • If MAC_L3_L4_Control0[L3PEN0] and MAC_L3_L4_Control0[L3SAM0] are 1, this field contains the value to be matched with bits [127:96] of the IP source address field in the IPv6 packets. • If MAC_L3_L4_Control0[L3PEN0] and MAC_L3_L4_Control0[L3DAM0] are 1, this field contains the value to be matched with bits [127:96] of the IP destination address field in the IPv6 packets. • If MAC_L3_L4_Control0[L3PEN0] = 0, this field is not used.

74.7.148 MAC Timestamp Control (MAC_Timestamp_Control)

Offset

Register	Offset
MAC_Timestamp_Control	B00h

Function

Controls the operation of the system time generator and processing of PTP packets for timestamping in the receiver.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-29 —	Reserved
28 AV8021ASMEN	AV 802.1AS Mode Enable Indicates the status of AV 802.1AS mode. If this field is 1, MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, which means using the IEEE 802.1AS mode of operation. If MAC_HW_Feature1[PTOEN] = 1, for the purpose of PTP offload, the transport-specific field in the PTP header is generated and checked based on the value of the AV8021ASMEN field. 0b - Disabled 1b - Enabled
27-25 —	Reserved
24 TXTSSTSM	Transmit Timestamp Status Mode Indicates the status of transmit timestamp status mode. • If this field is 1, MAC overwrites the previous transmit timestamp status even if the software does not read it. MAC indicates this by writing 1 to MAC_Tx_Timestamp_Status_Nanoseconds[TXTSSMIS]. • If this field is 0, MAC ignores the timestamp status of the current packet if the software does not read the timestamp status of the previous packet. MAC indicates this by writing 1 to MAC_Tx_Timestamp_Status_Nanoseconds[TXTSSMIS]. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-21 —	Reserved
20 ESTI	External System Time Input Indicates the status of external system time input. If this field is 1, MAC uses the external 64-bit reference system time input for these functions: • To consider the timestamp provided as status • To insert the timestamp in transmit PTP packets if the one-step timestamp or the timestamp offload feature is enabled If this field is 1, MAC uses the internal reference system time. 0b - Disabled 1b - Enabled
19 —	Reserved
18 TSENMACADDR	Enable MAC Address For PTP Packet Filtering Indicates whether the MAC address for PTP packet filtering is enabled. If this field is 1, the DA MAC address, which matches any MAC Address register, is used to filter the PTP packets when PTP is directly sent over Ethernet. If this field is 1, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in the MAC address registers are considered for processing when PTP is directly sent over Ethernet. • For a normal time stamping operation, MAC address registers 0 to 31 are considered for unicast destination address matching. • For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0b - Disabled 1b - Enabled
17-16 SNAPTYPSEL	Select PTP Packets For Taking Snapshots Determines the set of PTP packet types for which a snapshot needs to be taken. This field, along with the TSEVNTENA and TSMSTRENA fields, determines the set of PTP packet types for which a snapshot needs to be taken. See Receive path functions for encoding.
15 TSMSTRENA	Enable Snapshot For Messages Relevant To Master Indicates whether the snapshot for messages relevant to master is enabled. If this field is 1, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
14 TSEVNTENA	Enable Timestamp Snapshot For Event Messages Enables or disables timestamp snapshot for event messages. If this field is 1, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When the field becomes 0, the snapshot is taken for all the messages except Announce, Management, and Signaling. For more information on timestamp snapshot dependency on register bits, see Receive path functions. 0b - Disabled 1b - Enabled
13 TSIPV4ENA	Enable Processing Of PTP Packets Sent Over IPv4-UDP Indicates whether the processing of PTP packets sent over IPv4-UDP is enabled. If this field is 1, the MAC receiver processes the PTP packets encapsulated in the IPv4-UDP packets. When this field becomes 0, MAC ignores the PTP transported over the IPv4-UDP packets. The default value of this field is 1. 0b - Disabled 1b - Enabled
12 TSIPV6ENA	Enable Processing Of PTP Packets Sent Over IPv6-UDP Indicates whether the processing of PTP packets sent over IPv6-UDP is enabled. If this field is 1, the MAC receiver processes the PTP packets encapsulated in the IPv6-UDP packets. If the value is 0, MAC ignores the PTP transported over IPv6-UDP packets. 0b - Disabled 1b - Enabled
11 TSIPENA	Enable Processing Of PTP Over Ethernet Packets Indicates the status of PTP processing over Ethernet packets. If this field is 1, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When the field becomes 0, MAC ignores the PTP over Ethernet packets. 0b - Disabled 1b - Enabled
10 TSVER2ENA	Enable PTP Packet Processing For Version 2 Format Indicates the status of PTP packet processing for version 2 format. If this field is 1, the IEEE 1588 version 2 format is used to process the PTP packets. When this field becomes 0, the IEEE 1588 version 1 format is used to process the PTP packets. See PTP processing and control for more information on the IEEE 1588 formats.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
9 TSCTRLSSR	Timestamp Digital Or Binary Rollover Control Indicates the status of timestamp digital or binary rollover control. • If this field is 1, the Timestamp Low register rolls over after the 3B9A_C9FFh value (that is, 1 nanosecond accuracy) and increments the timestamp (high) seconds. • If this field is 0, the rollover value of the Subsecond register is 7FFF_FFFFh. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this field. 0b - Disabled 1b - Enabled
8 TSENALL	Enable Timestamp For All Packets Indicates the status of timestamp snapshot for all packets. If this field is 1, the timestamp snapshot is enabled for all packets that MAC receives. 0b - Disabled 1b - Enabled
7 —	Reserved
6 PTGE	Presentation Time Generation Enable Indicates the status of presentation time generation. If this field is 1, the presentation time generation is enabled. 0b - Disabled 1b - Enabled
5 TSADDREG	Update Addend Register Indicates whether MAC Timestamp Addend (MAC_Timestamp_Addend) is updated. If this field is 1, the contents of MAC Timestamp Addend (MAC_Timestamp_Addend) are updated in the PTP block for fine correction. The field becomes 0 after the update completes. The value of the field must also be 0 before you write 1 to it. Access restrictions apply to this field that clears automatically. Writing 0 has no effect. 0b - Not updated 1b - Updated
4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 TSUPDT	Update Timestamp Indicates whether the timestamp is updated. If this field is 1, the system time is updated (added or subtracted) with the value specified in MAC System Time Seconds Update (MAC_System_Time_Seconds_Update) and MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update). The value of this field must be 0 before you update it. It resets after the update is complete in hardware. MAC_System_Time_Higher_Word_Seconds[TSHWR], if enabled during core configuration, is not updated. When media clock generation and recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled, MAC Presentation Time Update (MAC_Presn_Time_Updt) must also be updated before you write 1 to this field. Access restrictions apply to this field that clears automatically. Writing 0 has no effect. 0b - Not updated 1b - Updated
2 TSINIT	Initialize Timestamp Indicates whether the timestamp is initialized. If this field is 1, the system time is initialized (overwritten) with the value specified in MAC System Time Seconds Update (MAC_System_Time_Seconds_Update) and MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update). The value of this field must be 0 before you update it, and the field is reset after the initialization is complete. MAC_System_Time_Higher_Word_Seconds[TSHWR], if enabled during core configuration, can only be initialized. When media clock generation and recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled, MAC Presentation Time Update (MAC_Presn_Time_Updt) must also be updated before you write 1 to this field. Access restrictions apply to this field that clears automatically. Writing 0 has no effect. 0b - Not initialized 1b - Initialized
1 TSCFUPDT	Fine Or Coarse Timestamp Update Indicates the method used to update system timestamp. • If this field is 1, the fine method is used to update system timestamp. • If this field is 0, the coarse method is used to update the system timestamp. 0b - Coarse method 1b - Fine method
0 TSENA	Timestamp Enable Enables or disables timestamp for transmit and receive packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the timestamp is added for transmit and receive packets. • If this field is 0, timestamp is not added for transmit and receive packets and the timestamp generator is also suspended. You need to initialize the timestamp (system time) after enabling this mode. On the receive side, MAC processes the 1588 packets only if this field is 1. 0b - Disabled 1b - Enabled

74.7.149 MAC Sub Second Increment (MAC_Sub_Second_Increment)

Offset

Register	Offset
MAC_Sub_Second_Increment	B04h

Function

Specifies the value to be added to the internal system time register at every cycle of the clk_ptp_ref_i clock.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-16 SSINC	Sub-Second Increment Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Contains the sub-second incement value, which accumulates every clock cycle (of clk_ptp_i) with the contents of the Subsecond register. For example, if the PTP clock is 50 MHz (period is 20 ns), you must program 20 (14h) when MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds) has an accuracy of 1 ns (MAC_Timestamp_Control[TSCTRLSSR] = 1). When TSCTRLSSR = 0, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you must program a value of 43 (2Bh), which is derived by 20 ns/0.465.
15-8 SNSINC	Sub-Nanosecond Increment Value Contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated in the sub-nanoseconds field of the Subsecond register. For example, if MAC_Timestamp_Control[TSCTRLSSR] = 1, and if the required increment is 5.3 ns, then this field must be 4Ch and the SSINC field must be 05h.
7-0 —	Reserved

74.7.150 MAC System Time In Seconds (MAC_System_Time_Seconds)

Offset

Register	Offset
MAC_System_Time_Seconds	B08h

Function

Indicates, along with MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds), the current value of the system time that MAC maintains. Although it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to the CSR clock).

Fields

Field	Function
31-0 TSS	Timestamp Second Indicates the current value, in seconds, of the system time that MAC maintains.

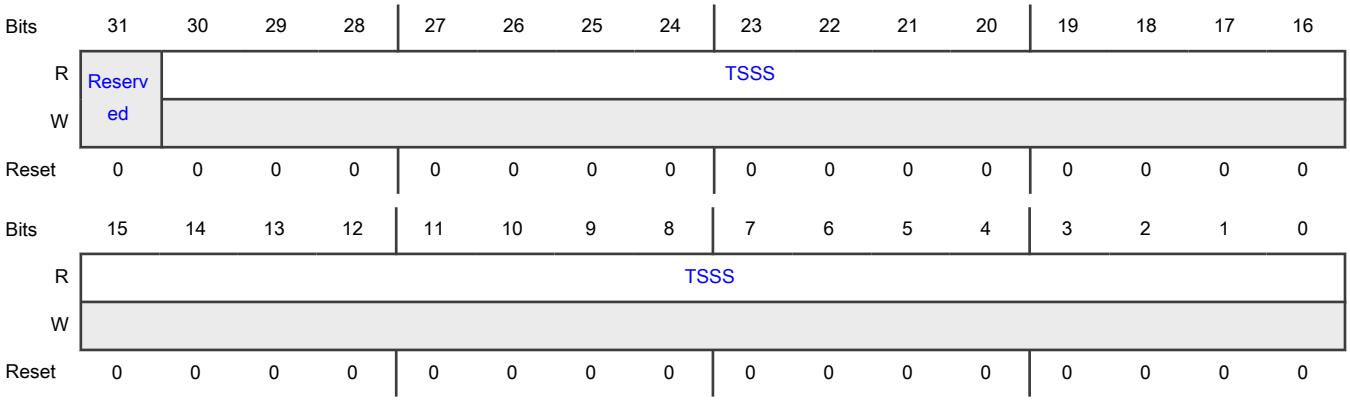
74.7.151 MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds)

Offset

Register	Offset
MAC_System_Time_Nanoseconds	B0Ch

Function
Indicates, along with MAC System Time In Seconds (MAC_System_Time_Seconds), the current value of the system time that MAC maintains.

Diagram



Fields

Field	Function
31 —	Reserved
30-0 TSSS	Timestamp Sub Seconds Indicates the sub-second representation of time, with an accuracy of 0.46 ns. When MAC_Timestamp_Control[TSCTRLSSR] = 1, each bit represents 1 ns. The maximum value is 3B9A_C9FFh after which it rolls over to 0.

74.7.152 MAC System Time Seconds Update (MAC_System_Time_Seconds_Update)

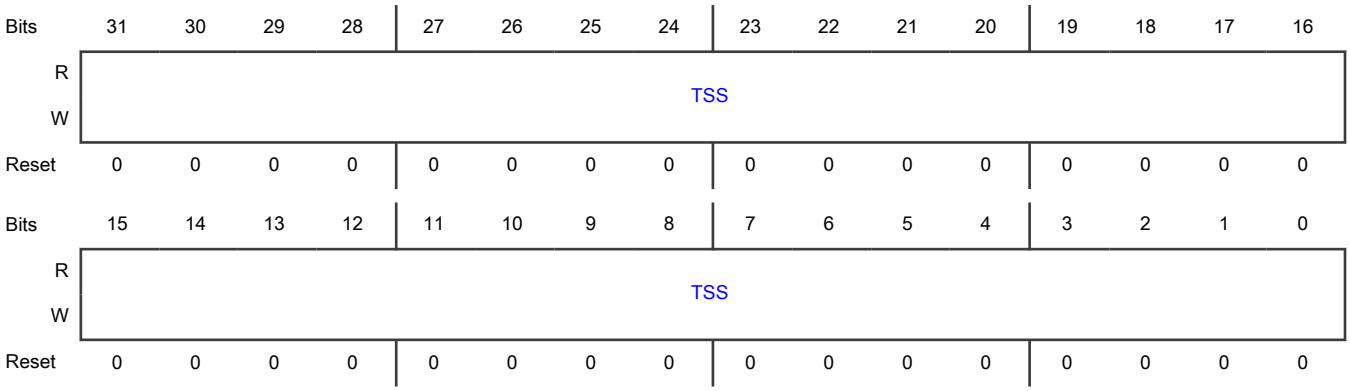
Offset

Register	Offset
MAC_System_Time_Seconds_Update	B10h

Function

Initializes or updates, along with MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update), the system time that MAC maintains. You must write both to this register and the MAC System Time Nanoseconds Update register before writing 1 to MAC_Timestamp_Control[TSINIT] and MAC_Timestamp_Control[TSUPDT].

Diagram



Fields

Field	Function
31-0 TSS	Timestamp Seconds Indicates the timestamp seconds value. The value in this field is the seconds part of the update. • If MAC_System_Time_Nanoseconds_Update[ADDSUB] = 0, this field must be programmed with the seconds part of the update value. • If MAC_System_Time_Nanoseconds_Update[ADDSUB] = 1, this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, MAC_System_Time_Seconds[TSS] must be FFFF_FFFEh (that is, 2^32 - 2).

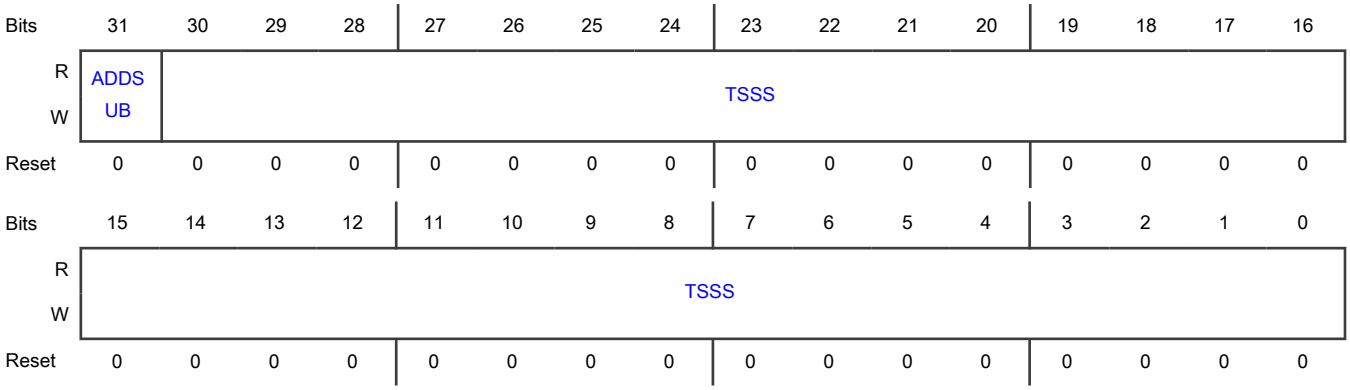
74.7.153 MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update)

Offset

Register	Offset
MAC_System_Time_Nanoseconds_Update	B14h

Function
Indicates system time nanoseconds update.

Diagram



Fields

Field	Function
31 ADDSUB	Add Or Subtract Time Indicates whether the time value is added or subtracted from the contents of the update register. • If this field is 1, the time value is subtracted from the contents of the update register. • If this field is 0, the time value is added to the contents of the update register. 0b - Add time 1b - Subtract time
30-0 TSSS	Timestamp Subseconds Indicates the sub-second part of the update. • If ADDSUB = 0, this field must be programmed with the sub-second part of the update value, with an accuracy based on MAC_Timestamp_Control[TSCTRLSSR]. • If ADDSUB = 0, this field must be programmed with the complement of the sub-second part of the update value as described below. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, the programmed value must be 10^9 - <sub-second value>, and if MAC_Timestamp_Control[TSCTRLSSR] = 0, the programmed value must be 2^31 - <sub-second_value>.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If MAC_Timestamp_Control[TSCTRLSSR] = 0, each bit of it represents an accuracy of 0.46 ns, and if MAC_Timestamp_Control[TSCTRLSSR] = 1, each bit represents 1 ns and the programmed value must not exceed 3B9A_C9FFh. For example, if 2.000000001 seconds need to be subtracted from the system time, this field must be 7FFF_FFFFh (that is, 2^31 - 1) if MAC_Timestamp_Control[TSCTRLSSR] = 0. This field must be 3B9A_C9FFh (that is, 10^9 - 1) if MAC_Timestamp_Control[TSCTRLSSR] = 1.

74.7.154 MAC Timestamp Addend (MAC_Timestamp_Addend)

Offset

Register	Offset
MAC_Timestamp_Addend	B18h

Function

Is used only when the system time is configured for Fine Update mode (MAC_Timestamp_Control[TSINIT] = 1). The contents of this register are added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i), and the system time is updated whenever the accumulator overflows.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TSAR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TSAR	Timestamp Addend Register Indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

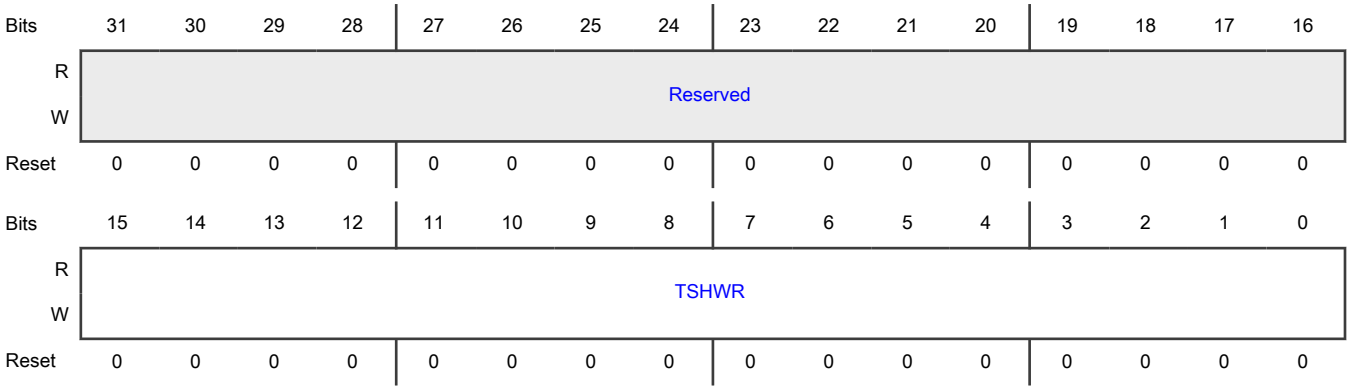
74.7.155 MAC System Time Higher Word In Seconds (MAC_System_Time_Higher_Word_Seconds)

Offset

Register	Offset
MAC_System_Time_Higher_Word_Seconds	B1Ch

Function
Indicates system time - higher word in seconds.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 TSHWR	Timestamp Higher Word Register Contains the most-significant 16 bits of the timestamp seconds value. This register is optional, and you can add it if you select the IEEE 1588 higher-word register option. You write to this register directly to initialize the value, which increments when there is an overflow from the 32 bits of MAC System Time In Seconds (MAC_System_Time_Seconds). Access restrictions apply to this field, which updates based on an event occurrence.

74.7.156 MAC Timestamp Status (MAC_Timestamp_Status)

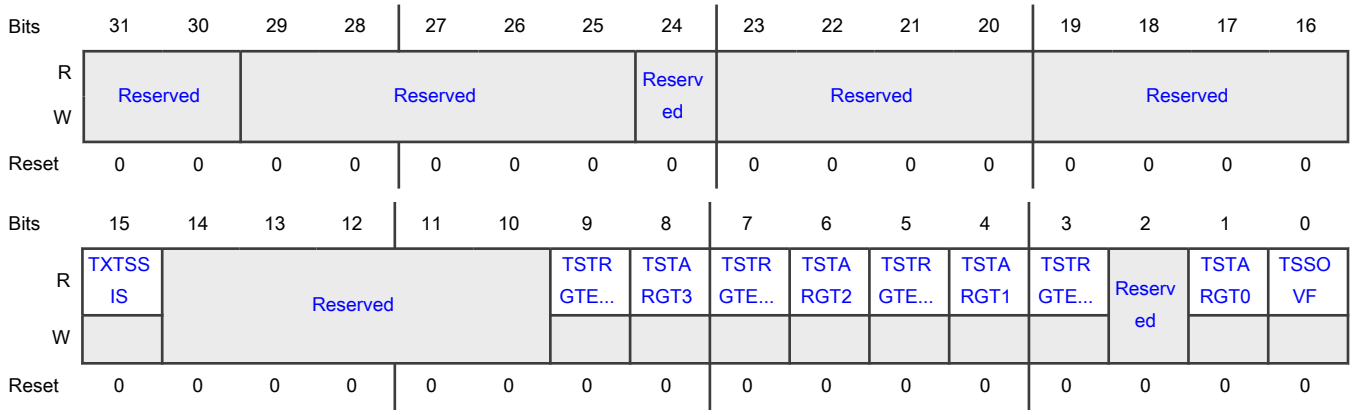
Offset

Register	Offset
MAC_Timestamp_Status	B20h

Function

Indicates timestamp status. All the bits except [27:25] are cleared when the application reads this register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-25 —	Reserved
24 —	Reserved
23-20 —	Reserved
19-16 —	Reserved
15 TXTSSIS	Transmit Timestamp Status Interrupt Status Indicates whether the transmit timestamp interrupt status is detected. In non-EQOS_CORE configurations, if the drop transmit status is enabled in MTL, this field becomes 1 when the captured transmit timestamp is updated in MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds) and MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds). If MAC_HW_Feature1[PTOEN] = 1, TXTSSIS becomes 1 when the captured transmit timestamp is updated in MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds) and MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds) for PTO-generated delay request and Pdelay request packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 0 if you read or write to MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Not detected 1b - Detected
14-10 —	Reserved
9 TSTRGTERR3	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 if the latest target time programmed in MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds) and MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
8 TSTARGT3	Timestamp Target Time Reached For Target Time PPS3 Indicates whether the timestamp target time reached for target time PPS3 status is detected. If this field is 1, it indicates that the value of the system time is greater than or equal to the value specified in MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds) and MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds). Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
7 TSTRGTERR2	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 when the latest target time programmed in MAC PPS2 Taget Time In Seconds (MAC_PPS2_Target_Time_Seconds) and MAC PPS2 Target Time In Nanoseconds (MAC_PPS2_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
6 TSTARGT2	Timestamp Target Time Reached For Target Time PPS2 Indicates whether the timestamp target time reached for the target time PPS2 status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, it indicates that the value of system time is greater than or equal to the value specified in MAC PPS2 Taget Time In Seconds (MAC_PPS2_Target_Time_Seconds) and MAC PPS2 Target Time In Nanoseconds (MAC_PPS2_Target_Time_Nanoseconds). Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
5 TSTRGTERR1	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 when the latest target time programmed in MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
4 TSTARGT1	Timestamp Target Time Reached For Target Time PPS1 Indicates whether the timestamp target time reached for target time PPS1 status is detected. If this field is 1, it indicates that the value of system time is greater than or equal to the value specified in MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds) Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
3 TSTRGTERR0	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 when the latest target time programmed in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 TSTARGT0	Timestamp Target Time Reached Indicates whether the timestamp target time reached status is detected. If this field is 1, it indicates that the value of the system time is greater than or equal to the value specified in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 TSSOVF	Timestamp Seconds Overflow Indicates whether the timestamp seconds overflow status is detected. If this field is 1, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

74.7.157 MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds)

Offset

Register	Offset
MAC_Tx_Timestamp_Status_Nanoseconds	B30h

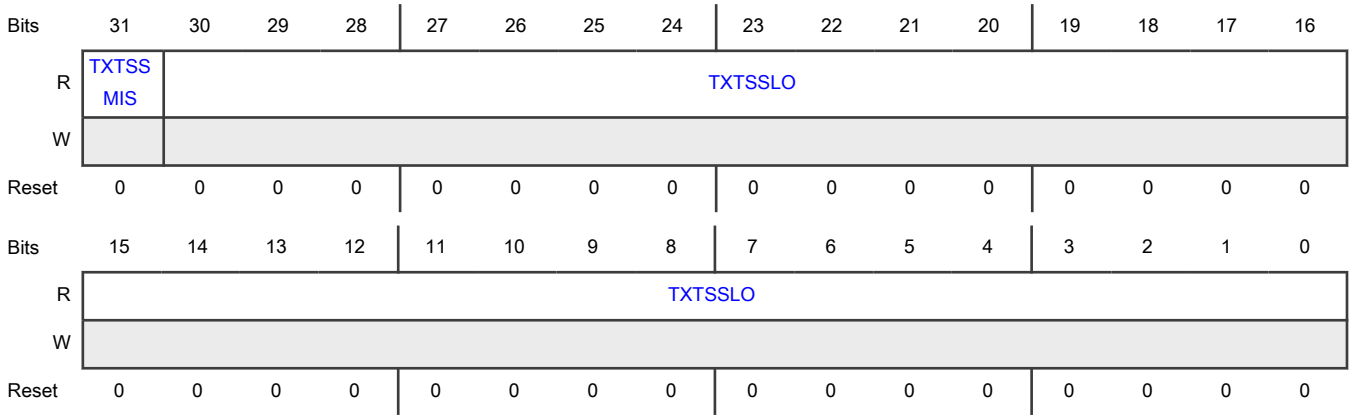
Function

Contains the nanosecond part of the timestamp captured for tansmit packets when the transmit status is disabled.

This register, along with MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds), gives the 64-bit timestamp captured for the PTP packet that MAC successfully transmits. The application considers reading this value after the last byte of this register is read. In Little-Endian mode, this means when bits [31:24] are read, and in Big-Endian mode, this means when bits [7:0] are read.

If the application does not read these registers and the timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the settings specified in MAC_Timestamp_Control[TXTSSTSM]. The status bit TXTSC bit [15] in the MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

Diagram



Fields

Field	Function
31 TXTSSMIS	Transmit Timestamp Status Missed Indicates whether the transmit timestamp missed status is detected. If this field is 1, it indicates one of these conditions: • The timestamp of the current packet is ignored if MAC_Timestamp_Control[TXTSSTSM] = 0. • The timestamp of the previous packet is overwritten with the timestamp of the current packet if MAC_Timestamp_Control[TXTSSTSM] = 1. Access restrictions apply to this field that cleas on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
30-0 TXTSSLO	Transmit Timestamp Status Low Contains 31 bits of the Nanoseconds field of the transmit packet's captured timestamp.

74.7.158 MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds)

Offset

Register	Offset
MAC_Tx_Timestamp_Status_Seconds	B34h

Function

Contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	TXTSSHI															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TXTSSHI	Transmit Timestamp Status High Contains the lower 32 bits of the Seconds field of the transmitted packet's captured timestamp.

74.7.159 MAC Timestamp Ingress Asymmetry Correction (MAC_Timestamp_Ingress_Asym_Corr)

Offset

Register	Offset
MAC_Timestamp_Ingress_Asym_Corr	B50h

Function

Contains the ingress asymmetry correction value to be used when updating the correction field in the PDelay_Resp PTP messages.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	OSTIAC															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction Contains the ingress path asymmetry value to be added to the correctionField of the Pdelay_Resp PTP packet. The programmed value must be expressed in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 00028000h. This value can also be negative, which is represented in the two's-complement form with bit 31 representing the sign bit.

74.7.160 MAC Timestamp Egress Asymmetry Correction (MAC_Timestamp_Egress_Asym_Corr)

Offset

Register	Offset
MAC_Timestamp_Egress_Asym_Corr	B54h

Function

Contains the egress asymmetry correction value to be used when updating the correction field in the PDelay_Req PTP messages.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	OSTEAC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OSTEAC	One-Step Timestamp Egress Asymmetry Correction Contains the egress path asymmetry value to be subtracted from the correctionField of the Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be FFFD_8000h, which is the two's-complement of 0002_8000h (2.5 * 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0003_4CCCh (3.3 * 216).

74.7.161 MAC Timestamp Ingress Correction In Nanoseconds (MAC_Timestamp_Ingress_Corr_Nanosecond)

Offset

Register	Offset
MAC_Timestamp_Ingress_Corr_Nanosecond	B58h

Function

Contains the correction value, in nanoseconds, to be used with the captured timestamp value in the ingress path.

Diagram

7-0 —	Reserved

74.7.167 MAC PPS Control (MAC_PPS_Control)

Offset

Register	Offset
MAC_PPS_Control	B70h

Function

Indicates PPS control.

In this register:

- Bits [30:24] are valid only when four flexible PPS outputs are selected.
- Bits [22:16] are valid only when three or more flexible PPS outputs are selected.
- Bits [14:8] are valid only when two or more flexible PPS outputs are selected.
- Bits [6:4] are valid only when the flexible PPS feature is selected.

Diagram

Fields

Field	Function
31 MCGREN3	MCGR Mode Enable For PPS3 Output Enables the third PPS instance to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode.
30-29 TRGTMODSEL3	Target Time Register Mode For PPS3 Output Indicates MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds) and MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds) mode for the PPS3 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
28 —	Reserved
27-24 PPSCMD3	Flexible PPS3 Output Control Controls the flexible PPS3 output (ptp_pps_o[3]) signal. The functioning of this field is similar to that of PPSCMD0[2:0] (presentation time control bits). If MCGREN3 = 1, PPSCMD3 that includes bits [27:24] are considered as presentation time control bits for media clock generation and recovery for comparator instance 3. If MCGREN3 is not 1, only three bits [26:24] are considered as PPSCMD3 and the fourth bit becomes 0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect.
23 MCGREN2	MCGR Mode Enable For PPS2 Output Enables or disables the second PPS instance to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode. 0b - Disabled 1b - Enabled
22-21 TRGTMODSEL2	Target Time Register Mode For PPS2 Output Indicates MAC PPS2 Taget Time In Seconds (MAC_PPS2_Target_Time_Seconds) and MAC PPS2 Target Time In Nanoseconds (MAC_PPS2_Target_Time_Nanoseconds) mode for the PPS2 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01b - Reserved

Table continues on the next page...

	10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
20 —	Reserved
19-16 PPSCMD2	Flexible PPS2 Output Control Controls the flexible PPS2 output (ptp_pps_o[2]) signal. The functioning of this field is similar to that of the PPSCMD0 (presentation time control bits). If MCGREN2 = 1, the bits included in PPSCMD2 [19:16] are considered as presentation time control bits for media clock generation and recovery for comparator instance 2. If MCGREN2 is not 1, only three bits [18:16] are used as PPSCMD2 and the fourth bit becomes 0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect.
15 MCGREN1	MCGR Mode Enable For PPS1 Output Enables or disables the first PPS instance to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode. 0b - Disabled 1b - Enabled
14-13 TRGTMODSEL1	Target Time Register Mode For PPS1 Output Indicates MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds) mode for the PPS1 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be 1 in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
12 —	Reserved
11-8 PPSCMD1	Flexible PPS1 Output Control Controls the flexible PPS1 output (ptp_pps_o[1]) signal. The functioning of this field is similar to that of the PPSCMD0 field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If MCGREN1 = 1, the bits included in PPSCMD1 [11:8] are considered as presentation time control bits for media clock generation and recovery for comparator instance 1. The functioning of PPSCMD1 is similar to that of the PPSCMD0 presentation time control bits. If MCGREN1 is not 1, only three bits [10:8] are used as PPSCMD1 and the fourth bit becomes 0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect.
7 MCGREN0	MCGR Mode Enable For PPS0 Output Indictaes whether the 0th PPS instance is enabled to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode. 0b - PPS mode 1b - MCGR mode
6-5 TRGTMODSEL0	Target Time Register Mode For PPS0 Output Indicates MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) mode for the PPS0 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be 1 in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
4 PPSEN0	Flexible PPS Output Mode Enable 0 Indicates the status of Flexible PPS Output mode. • If this field is 1, the PPSCTRL_PPSCMD field functions as PPSCMD. • If this field is 0, the PPSCTRL_PPSCMD field functions as PPSCTRL (fixed PPS mode). 0b - Disabled 1b - Enabled
3-0 PPSCTRL_PPSCMD	PPS Output Frequency Control Controls the frequency of the PPS0 output (ptp_pps_o[0] signal). The default value of this field is 0, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For the other values of PPSCTRL, the PPS output becomes a generated clock having these frequencies: • 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. • 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. • 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. • 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• .. • 1111: The binary rollover is 32.768 kHz and the digital rollover is 16.384 kHz. **NOTE** In Binary Rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In Digital Rollover mode, the PPS output frequency is an average number. The actual clock has a different frequency that is synchronized every second. For example, • If PPSCTRL = 0001, PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms. • If PPSCTRL = 0010, PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and a 537 ms period. The second clock has a period of 463 ms (268 ms low and 195 ms high). • If PPSCTRL = 0011, PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and a 268 ms period, and the fourth clock of 195 ms period (134 ms low and 61 ms high). This behavior is a result of the non-linear toggling of bits in Digital Rollover mode in MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds) or flexible PPS output (ptp_pps_o[0]) control. Programming these bits with a non-zero value instructs MAC to initiate an event. When the command is transferred or synchronized with the PTP clock domain, these bits automatically become 0. You must ensure that these bits are programmed only when they are "all-zero." The following list describes the values of PPSCMD0. • 0000: No command • 0001: Start a single pulse. This command generates a single pulse rising at the start point defined in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds), for a duration defined in MAC PPS0 Width (MAC_PPS0_Width). • 0010: Start pulse train. This command generates the train of pulses rising at the start point defined in the Target Time registers and for a duration defined in MAC PPS0 Width (MAC_PPS0_Width), repeated at an interval defined in the PPS Interval registers. By default, the PPS pulse train runs freely unless the "stop pulse train at time" or "stop pulse train immediately" command stops it. • 0011: Cancel start. This command cancels the start single pulse and start pulse train commands if the system time has not crossed the programmed start time. • 0100: Stop pulse train at time. This command stops the train of pulses that the start pulse train command (PPSCMD = 0010) initiates after the time programmed in the Target Time registers elapses. • 0101: Stop pulse train immediately. This command immediately stops the train of pulses that the start pulse train command (PPSCMD = 0010) initiates. • 110: Cancel stop pulse train. This command cancels the stop pulse train at the time command if the programmed stop time has not elapsed. The PPS pulse train runs freely if the command executes successfully. • 0111-1111: Reserved or presentation time control. If MAC_PPS_Control[MCGREN0] = 0, then these are treated as presentation time control bits. This list describes the values of PPSCMD0:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0000: The MCGR operation is not carried out. If set to this value in the mid of clock recovery or generation, all the processing inputs are flushed. • 0001: Captures the presentation time at the rising edge of mcg_pst_trig_i[0] in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) • 0010: Captures the presentation time at the falling edge of mcg_pst_trig_i[0] in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) • 0011: Captures the presentation time at both the edges of mcg_pst_trig_i[0] in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) • 0100-1000: Reserved • 1001: Toggle output on compare • 1010: Pulse output low on compare for one PTP-clock cycle • 1011: Pulse output high on compare for one PTP-clock cycle • 1100-1111: Reserved

74.7.168 MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds)

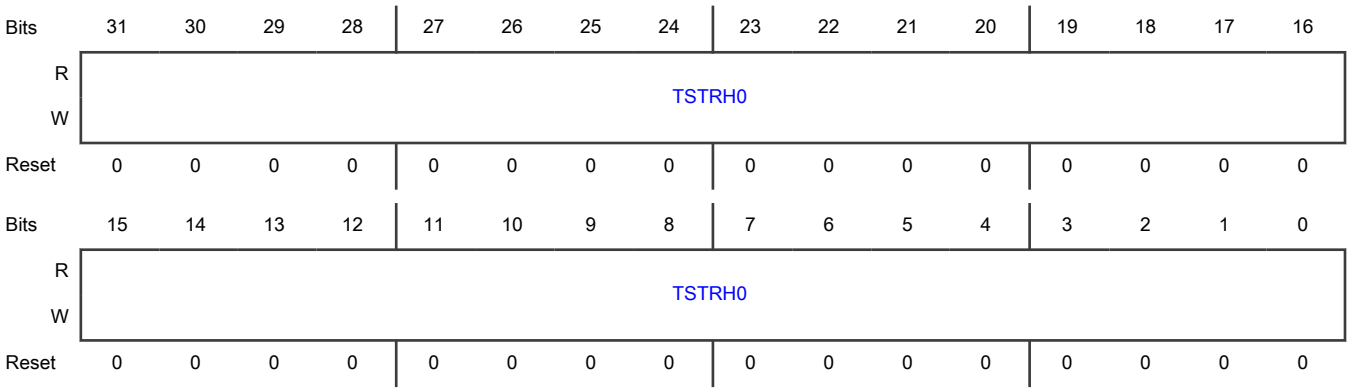
Offset

Register	Offset
MAC_PPS0_Target_Time_Seconds	B80h

Function

Is used, along with the PPS Target Time Nanoseconds register, to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]) when the system time exceeds the value programmed in these registers.

Diagram



Fields

Field	Function
31-0 TSTRH0	PPS Target Time In Seconds Register Stores the target time in seconds. When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt (if enabled), based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control). If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger.

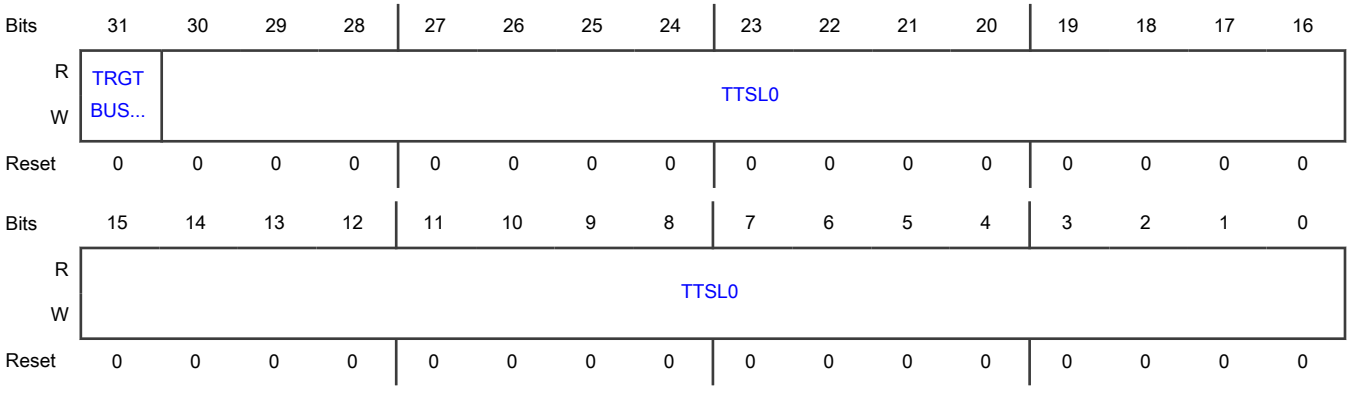
74.7.169 MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds)

Offset

Register	Offset
MAC_PPS0_Target_Time_Nanoseconds	B84h

Function
Indicates the target time in nanoseconds for PPS0.

Diagram



Fields

Field	Function
31 TRGTBUSY0	PPS Target Time Busy Status 0 Indicates whether the PPS target time busy status 0 is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. This instructs MAC to synchronize the Target Time registers with the PTP clock domain. • MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted. 0b - Not detected 1b - Detected
30-0 TTSL0	Target Time Low For PPS0 Stores the time in (signed) nanoseconds. If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0]. • If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be calculated as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. Access restriction apply to this field that clears automatically. Writing 0 to it has no effect.

74.7.170 MAC PPS0 Interval (MAC_PPS0_Interval)

Offset

Register	Offset
MAC_PPS0_Interval	B88h

Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PPSINT0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSINT0	PPS Output Signal Interval 0 Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register.

74.7.171 MAC PPS0 Width (MAC_PPS0_Width)

Offset

Register	Offset
MAC_PPS0_Width	B8Ch

Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

R W	PPSWIDTH0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSWIDTH0	PPS Output Signal Width 0 Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register. **NOTE** The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval).

74.7.172 MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds)

Offset

Register	Offset
MAC_PPS1_Target_Time_Seconds	B90h

Function
Is used to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]), along with the PPS Target Time Nanoseconds register, when the system time exceeds the value programmed in these registers.

Diagram

Field	Function
31-0 TSTRH3	PPS Target Time In Seconds 3 Stores the target time in seconds. When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control). If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger.

74.7.181 MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds)

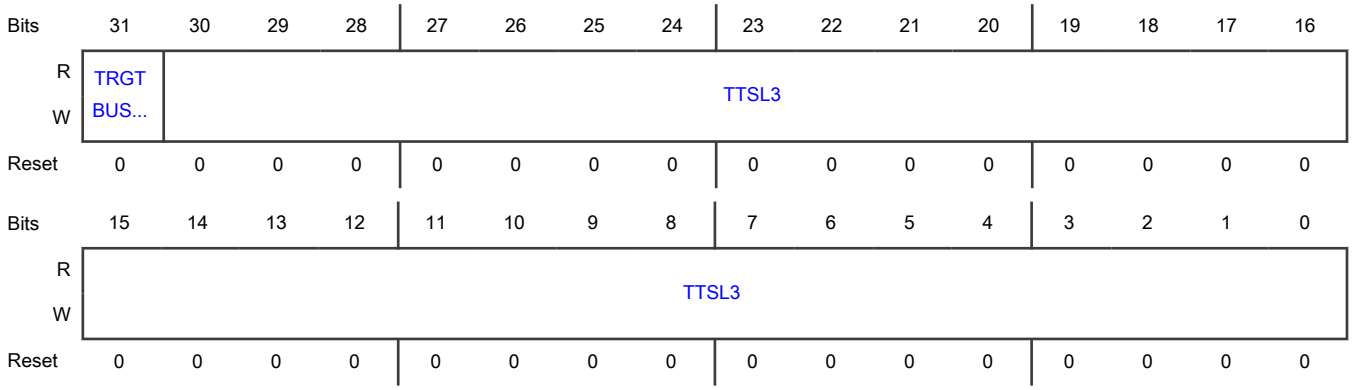
Offset

Register	Offset
MAC_PPS3_Target_Time_Nanoseconds	BB4h

Function

Indicates the target time in nanoseconds for PPS3.

Diagram



Fields

Field	Function
31 TRGTBUSY3	PPS Target Time Register Busy 3 Indicates whether the PPS target time register busy status is detected. MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. This instructs MAC to synchronize the Target Time registers with the PTP clock domain. MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted. 0b - Not detected 1b - Detected
30-0 TTSL3	Target Time Low For PPS3 Stores the time in (signed) nanoseconds. If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0]. • If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be defined as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. Access restriction apply to this field that clears automatically. Writing 0 to it has no effect.

74.7.182 MAC PPS3 Interval (MAC_PPS3_Interval)

Offset

Register	Offset
MAC_PPS3_Interval	BB8h

Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PPSINT3															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PPSINT3															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSINT3	PPS Output Signal Interval Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register.

74.7.183 MAC PPS3 Width (MAC_PPS3_Width)

Offset

Register	Offset
MAC_PPS3_Width	BBCh

Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PPSWIDTH3															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PPSWIDTH3															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSWIDTH3	PPS Output Signal Width 3 Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register. **NOTE** The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval).

74.7.184 MTL Operation Mode (MTL_Operation_Mode)

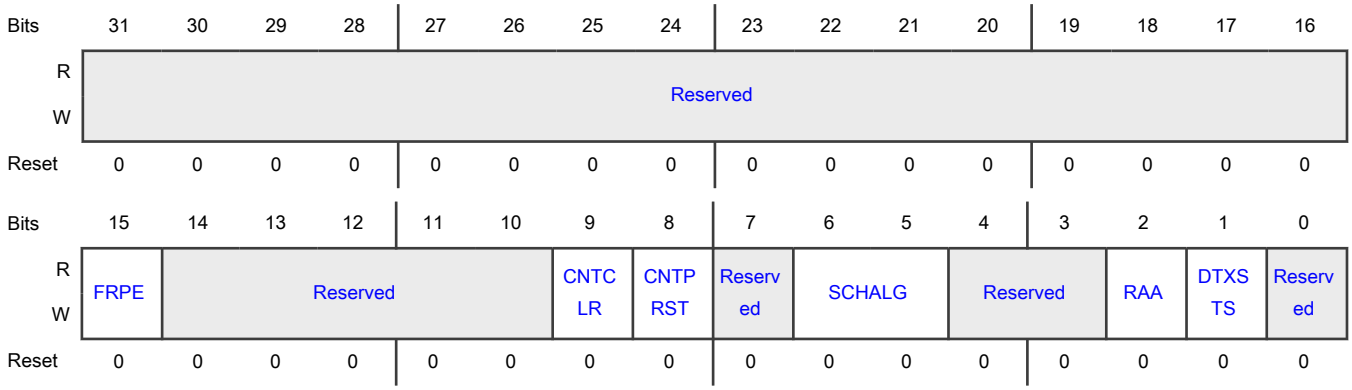
Offset

Register	Offset
MTL_Operation_Mode	C00h

Function

Establishes the transmit and receive operating modes and commands.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 FRPE	Flexible Receive Parser Enable Indicates the status of the flexible receive parser. • If this field is 1, the programmable receive parser functionality is enabled. • If the receive parser is disabled and is in the middle of parsing, the receive parser functionality is disabled only after completing the current packet parsing. When the receive parser is enabled from the disabled state, the receive parser is activated for the next immediate packet. 0b - Disabled 1b - Enabled
14-10 —	Reserved
9 CNTCLR	Counters Reset Indicates whether the counters are reset. • If this field is 1, all the counters are reset. The field cleares automatically after one clock cycle. • If you write 1 to this field along with the CNTPRST field, the CNT_PRESET field takes precedence. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect. 0b - Not reset 1b - Reset
8 CNTPRST	Counters Preset Indicates the status of preset counters. If this field is 1,

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• MTL Tx Queue 0 Underflow (MTL_TxQ0_Underflow)[bits 0-7] is initialized or preset to 12'h7F0. • Missed packet and overflow packet counters in MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt)[bits 0-7] are initialized or preset to 12'h7F0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect. 0b - Disabled 1b - Enabled
7 —	Reserved
6-5 SCHALG	Transmit Scheduling Algorithm Indicates the algorithm for transmit scheduling. 00b - WRR algorithm 01b - WFQ algorithm when DCB feature selected; otherwise, reserved 10b - DWRR algorithm when DCB feature selected; otherwise, reserved 11b - Strict priority algorithm
4-3 —	Reserved
2 RAA	Receive Arbitration Algorithm Is used to select the arbitration algorithm for the receive side. Queue 0 has the lowest priority and the last queue has the highest priority. 0b - Strict priority (SP) 1b - Weighted strict priority (WSP)
1 DTXSTS	Drop Transmit Status Indicates whether the drop transmit status is enabled. • If this field is 1, the transmit packet status received from MAC is dropped in MTL. • If this field is 0, the transmit packet status received from MAC is forwarded to the application. 0b - Disabled 1b - Enabled
0 —	Reserved

74.7.185 MTL Debug Control (MTL_DBG_CTL)

Offset

Register	Offset
MTL_DBG_CTL	C08h

Function

Controls, along with MTL Debug Status (MTL_DBG_STS), the operation mode of FIFO debug access.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-19 —	Reserved
18-17 EIEC	ECC Inject Error Control Indicates the status of the ECC inject error control feature for transmit, receive, and TSO memories. If EIEE = 1, following are the errors inserted based on the value encoded in this field. 00b - 1-bit error 01b - 2-bit errors 10b - 3-bit errors 11b - 1-bit error in the address field
16 EIEE	ECC Inject Error Enable Indicates the status of the ECC error injection feature for transmit, receive, and TSO memories. • If the value if this field is 1, it enables the ECC error injection feature. • If the value if this field is 0, it disables the ECC error injection feature. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
15 STSIE	Transmit Status Available Interrupt Status Enable Indicates whether the transmit packet available interrupt status is enabled. If this field is 1, an interrupt is generated when transmit status is available in Slave mode. 0b - Disabled 1b - Enabled
14 PKTIE	Receive Packet Available Interrupt Status Enable Indicates whether the receive packet available interrupt status is enabled. If this field is 1, an interrupt is generated when EOP of the received packet is written to the receive FIFO. 0b - Disabled 1b - Enabled
13-12 FIFOSEL	FIFO Selected for Access Indicates the FIFO selected for debug access. 00b - Transmit FIFO 01b - Transmit status FIFO (only read access when SLVMOD is set) 10b - TSO FIFO (cannot be accessed when SLVMOD is set) 11b - Receive FIFO
11 FIFOWREN	FIFO Write Enable Indicates the status of FIFO write. If this field is 1, it enables the write operation on the selected FIFO when FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled 1b - Enabled
10 FIFORDEN	FIFO Read Enable Indicates the status of FIFO read. If this field is 1, it enables the read operation on the selected FIFO when FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
9 RSTSEL	Reset Pointers Of Selected FIFO Indicates whether the resetting of pointers for the selected FIFO is enabled. If this field is 1, the pointers of the currently selected FIFO are reset when FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled 1b - Enabled
8 RSTALL	Reset All Pointers Indicates whether the resetting of all the pointers is enabled. If this field is 1, the pointers of all the FIFOs are reset when the FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled 1b - Enabled
7 —	Reserved
6-5 PKTSTATE	Encoded Packet State Is used to write the control information to the transmit FIFO or receive FIFO. These are the values related to the transmit FIFO: • 00: Packet data • 01: Control word • 10: SOP data • 11: EOP data These are the values related to the receive FIFO: • 00: Packet data • 01: Normal status • 10: Last status • 11: EOP 00b - Packet data

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Control word/normal status 10b - SOP data/last status 11b - EOP data/EOP
4 —	Reserved
3-2 BYTEEN	Byte Enables Indicates the number of data bytes valid in the data register during a write operation. This is valid only when MTL_DBG_STS[PKTSTATE] is 2'b10 (EOP), and the transmit FIFO or receive FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and byte 1 valid 10b - Byte 0, byte 1, and byte 2 valid 11b - All four bytes valid
1 DBGMOD	Debug Mode Access to FIFO Indicates the status of Debug mode access to FIFO. If this field is 1, it indicates that the current access to FIFO is read, write, and debug. In this mode, the following access types are allowed: • Read and write access to transmit FIFO, TSO FIFO, and receive FIFO • Read access to transmit status FIFO If this field is 0, it indicates that the current access to FIFO is slave access bypassing DMA. In this mode, the following access types are allowed: • Write access to transmit FIFO • Read access to receive FIFO and transmit status FIFO 0b - Disabled 1b - Enabled
0 FDBGEN	FIFO Debug Access Enable Indicates the status of FIFO debug access. • If this field is 1, it indicates that the FIFO debug mode access is enabled. • If the value of the field is 0, it indicates that FIFO can be accessed only through a master interface. 0b - Disabled 1b - Enabled

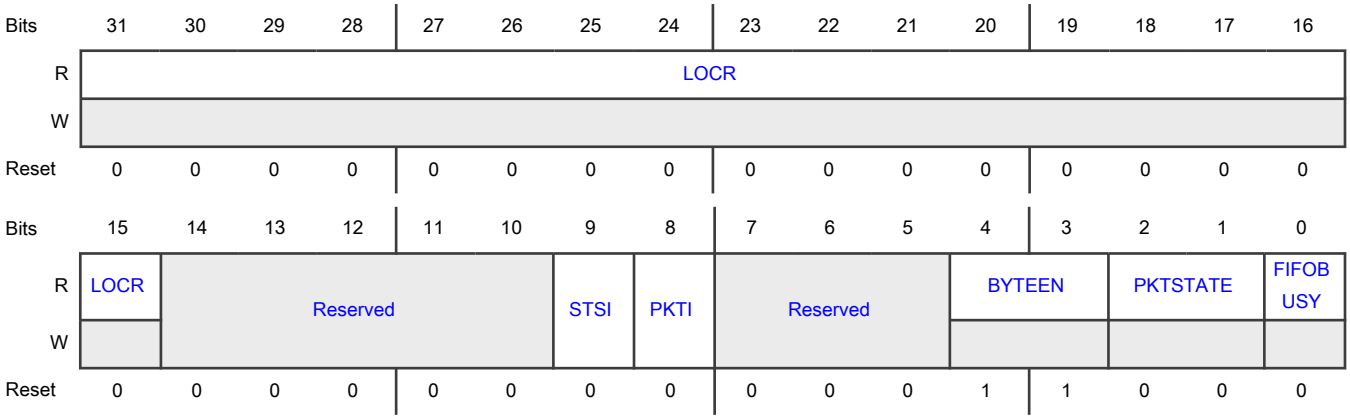
74.7.186 MTL Debug Status (MTL_DBG_STS)

Offset

Register	Offset
MTL_DBG_STS	C0Ch

Function
Contains the status of FIFO debug access.

Diagram



Fields

Field	Function
31-15 LOCR	Remaining Locations In FIFO Indicates the remaining locations in FIFO. For Slave Access mode, the field indicates the space available in the selected FIFO, and for Debug Access mode, this field contains the write or read pointer value of the selected FIFO during the write or read operation, respectively. Reset: In single transmit queue configurations, (DWC_EQOS_TXFIFO_SIZE/(DWC_EQOS_DATAWIDTH/8)), otherwise 0000h.
14-10 —	Reserved
9 STSI	Transmit Status Available Interrupt Status Indicates whether the transmit status available interrupt status is detected. If this field is 1, it indicates that Slave mode transmit packet is transmitted, and the status is available in transmit status FIFO. The field resets when you write 1 to it. 0b - Not detected 1b - Detected
8	Receive Packet Available Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
PKTI	Indicates whether the receive packet available interrupt status is detected. If this field is 1, it indicates that the MAC layer has written the EOP of the received packet to the receive FIFO. The field resets when you write 1 to it. 0b - Not detected 1b - Detected
7-5 —	Reserved
4-3 BYTEEN	Byte Enables Indicates the number of data bytes valid in the data register during a read operation. This is valid only when MTL_DBG_STS[PKTSTATE] is 2'b10 (EOP), and the transmit FIFO or receive FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and byte 1 valid 10b - Byte 0, byte 1, and byte 2 valid 11b - All four bytes valid
2-1 PKTSTATE	Encoded Packet State Is used to get the control or status information of the selected FIFO. These are the values related to the transmit FIFO. • 00: Packet data • 01: Control word • 10: SOP data • 11: EOP data These are the values related to the receive FIFO. • 00: Packet data • 01: Normal status • 10: Last status • 11: EOP This field is applicable only for transmit and receive FIFOs during a read operation. 00b - Packet data 01b - Control word/normal status 10b - SOP data/last status 11b - EOP data/EOP
0 FIFOBUSY	FIFO Busy Indicates whether the FIFO busy status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, it indicates that a FIFO operation is in progress in MAC and the content of the following is invalid: • All other fields of this register • All the fields of MTL FIFO Debug Data (MTL_FIFO_Debug_Data) 0b - Not detected 1b - Detected

74.7.187 MTL FIFO Debug Data (MTL_FIFO_Debug_Data)

Offset

Register	Offset
MTL_FIFO_Debug_Data	C10h

Function

Contains the data to be written to or read from the FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	FDBGDATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	FDBGDATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 FDBGDATA	FIFO Debug Data Contains the data to be written to the transmit FIFO, receive FIFO, or TSO FIFO during a debug or slave access write operations. The field contains the data read from the transmit FIFO, receive FIFO, TSO FIFO, or transmit status FIFO during debug or slave access read operations.

74.7.188 MTL Interrupt Status (MTL_Interrupt_Status)

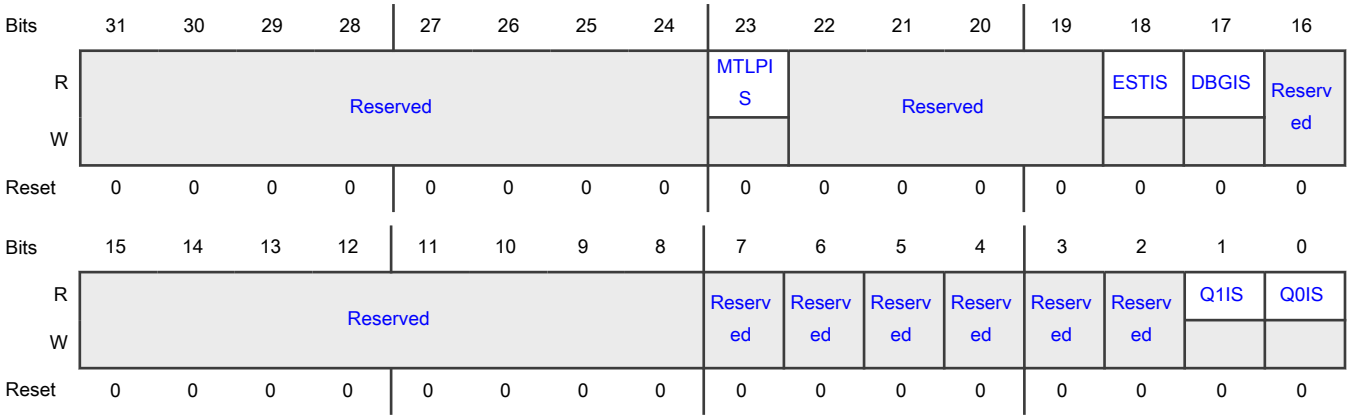
Offset

Register	Offset
MTL_Interrupt_Status	C20h

Function

Determines the interrupt status of MAC and MTL queues. The software driver (application) reads this register during an interrupt service routine or polling to perform this function.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 MTLPIS	MTL Receive Parser Interrupt Status Indicates whether the MTL receive parser interrupt status is detected. This field indicates an interrupt from the receive parser block. To reset this field, the application must read MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source. 0b - Not detected 1b - Detected
22-19 —	Reserved
18 ESTIS	EST (TAS- 802.1Qbv) Interrupt Status Indicates whether the EST (TAS- 802.1Qbv) interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates an interrupt event during the operation of 802.1Qbv. To reset the field, the application must clear the error or event that caused the interrupt. 0b - Not detected 1b - Detected
17 DBGIS	Debug Interrupt Status Indicates whether the debug interrupt status is detected. This field indicates an interrupt event during the slave access. To reset the field, the application must read MTL Debug Status (MTL_DBG_STS) to get the exact cause of the interrupt and clear its source. 0b - Not detected 1b - Detected
16 —	Reserved
15-8 —	Reserved
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 Q1IS	Queue 1 Interrupt Status Indicates whether the queue 1 interrupt status is detected. To reset this field, the application must read MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source. 0b - Not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Detected
0 Q0IS	Queue 0 Interrupt Status Indicates whether the queue 0 interrupt status is detected. To reset this field, the application must read MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source. 0b - Not detected 1b - Detected

74.7.189 MTL Receive Queue DMA Map 0 (MTL_RxQ_DMA_Map0)

Offset

Register	Offset
MTL_RxQ_DMA_Map0	C30h

Function
Reserves in EQOS-CORE and EQOS-MTL configurations.

Diagram

20 —	Reserved.
19-17 —	Reserved.
16 —	Reserved.
15-13 —	Reserved.
12 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection Enables or disables queue 1 for DA-based DMA channel selection. If this field is 1, it indicates that the packets received in queue 1 are routed to a particular DMA channel as decided in the MAC receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When this field becomes 0, it indicates that the packets received in queue 1 are routed to the DMA Channel programmed in the MTL_RxQ_DMA_Map0[Q1MDMACH] (bits [10:8]). 0b - Disabled 1b - Enabled
11-9 —	Reserved.
8 Q1MDMACH	Queue 1 Mapped to DMA Channel Controls the routing of the received packet in Queue 1 to the DMA channel: 000b - DMA Channel 0 001b - DMA Channel 1 010b - DMA Channel 2 011b - DMA Channel 3

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - DMA Channel 4 101b - DMA Channel 5 110b - DMA Channel 6 111b - DMA Channel 7 This field is valid when the MTL_RxQ_DMA_Map0[Q1DDMACH] resets. The field's width depends on the number of RX DMA channels and in some configurations all the values may not be valid . For example, if two RX DMA channels are selected, then only 000b and 001b are valid, the other bits are reserved.
7-5 —	Reserved.
4 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection Enables or disables queue 0 for DA-based DMA channel selection. If this field is 1, it indicates that the packets received in queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When this field becomes 0, it indicate that the packets received in queue 0 are routed to the DMA Channel programmed in the MTL_RxQ_DMA_Map0[Q0MDMACH]. 0b - Disable 1b - Enable
3-1 —	Reserved.
0 Q0MDMACH	Queue 0 Mapped to DMA Channel Controls the routing of the packet received in queue 0 to the DMA channel: 000b - DMA channel 0 001b - DMA channel 1 010b - DMA channel 2 011b - DMA channel 3 100b - DMA channel 4 101b - DMA channel 5 110b - DMA channel 6 111b - DMA channel 7 This field is valid when the MTL_RxQ_DMA_Map0[Q0DDMACH] resets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The field's width depends on the number of RX DMA channels in some configurations all the values may not be valid. For example, if the number of RX DMA channels selected is 2, only 000 and 001 bits are valid, the other bits are reserved.

74.7.190 MTL TBS Control (MTL_TBS_CTRL)

Offset

Register	Offset
MTL_TBS_CTRL	C40h

Function

Controls the operation of time based scheduling.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	LEOS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LEOS								Reserved	LEGOS			Reserved		LEOV	ESTM
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 LEOS	Launch Expiry Offset Computes the launch expiry time. To compute the launch expiry time the value in units of 256 nanoseconds is added to the launch time. The field value is valid only if MTL_TBS_CTRL[LEOV] is 1. Max value: 999,999,999 nanosecond should be smaller than CTR-1 value when ESTM mode = 1, because this value is a modulo CTR value.
7 —	Reserved.
6-4	Launch Expiry GSN Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
LEGOS	Computes the Launch expiry time. To compute the launch expiry time the number of GSN slots is to be added to the launch GSN. The field value is valid only if MTL_TBS_CTRL[LEOV] is 1.
3-2 —	Reserved.
1 LEOV	Launch Expiry Offset Valid Indicates if MTL_TBS_CTRL[LEOS] is valid or invalid. When this field is 1, it indicates that MTL_TBS_CTRL[LEOS] is valid. When not 1, it indicates that the launch expiry Offset is not valid and the MTL must not check for launch expiry time. 0b - Invalid 1b - Valid
0 ESTM	EST offset Mode Enables or disables EST Offset mode. If this field is 1, the launch time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the BTR of the current list. When this field becomes 0, the launch time value is used as an absolute value that must be compared with the system time [39:8]. 0b - Disabled 1b - Enabled

74.7.191 MTL EST Control (MTL_EST_Control)

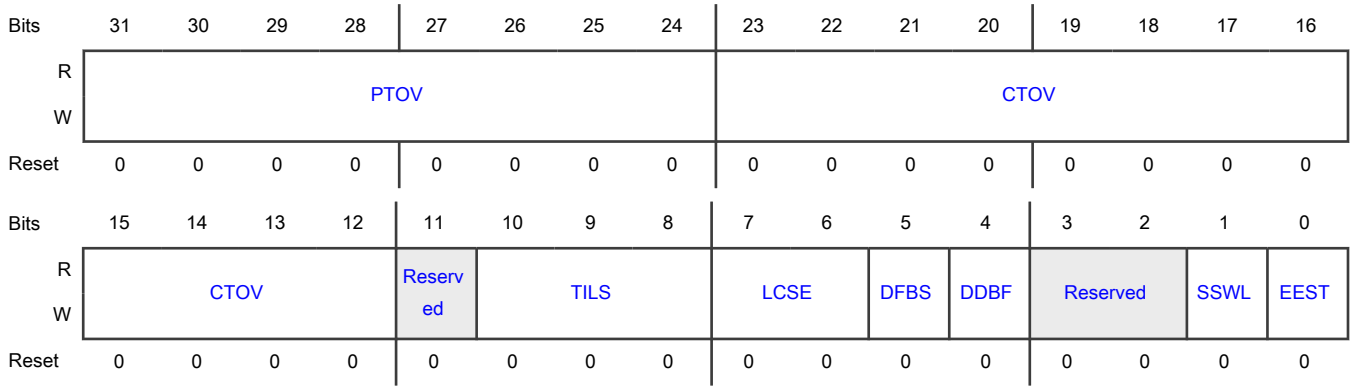
Offset

Register	Offset
MTL_EST_Control	C50h

Function

Controls the operation of enhancements to scheduled transmission (IEEE802.1Qbv).

Diagram



Fields

Field	Function
31-24 PTOV	PTP Time Offset Value Indicates the PTP time offset value. You must multiply 6 to the value of PTP clock period in nanoseconds. At the beginning of the installation of a new GCL this value avoid transmission overruns.
23-12 CTOV	Current Time Offset Value Provides a 12 bit time offset value in nano second which is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays and so on. This offset ensures that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).
11 —	Reserved.
10-8 TILS	Time Interval Left Shift Amount Provides the left shift amount for the programmed time interval values used in the gate control lists. 000b - No left shift needed (equal to x1ns) 001b - Left shift TI by 1 bit (equal to x2ns) 010b - Left shift TI by 2 bits (equal to x4ns) - - 100b - Left shift TI by 7 bits (equal to x128ns) On the basis of configuration you must consider one or more bits of this field as reserved or read-only.
7-6 LCSE	Loop Count to Report Scheduling Error Provides programmable number of GCL list iterations before reporting an HLBS error which is defined in MTL_EST_Status.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - 4 iterations 01b - 8 iterations 10b - 16 iterations 11b - 32 iterations
5 DFBS	Drop Frames Causing Scheduling Error Provides the status of the frames causing scheduling error. If this field is 1 then the frames report to cause an HOL blocking because the MTL_EST_Status[HLBS] is not scheduled after 4,8,16,and 32 (on the basis of MTL_EST_Control[LCSE]) GCL iterations are dropped. 0b - Do not drop frames 1b - Drop frames
4 DDBF	Do not Drop Frames during Frame Size Error Provides status of frames during Frame Size Error. If this field is 1, it indicates that the frames are not dropped during head-of-line blocking because of the frame size error (MTL_EST_Status[HLBF]). 0b - Drop frames during frame size error 1b - Do not Drop frames during frame size error
3-2 —	Reserved.
1 SSWL	Switch to Software Owned List If this field is 1, it indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. Enables or disables the switch to the software owned list. 0b - Disabled 1b - Enabled
0 EEST	Enable EST Enables or disables EST. If the field becomes 0, it indicate that the gate control list processing is halted and all gates are assumed to be in open state. The field must be 1 for the hardware to start processing the gate control lists. During the toggle from 0 to 1, when the MTL_EST_Control[SSWL] is 1, the gate control list processing starts. During the configuration when DWC_EQOS_ASP_ECC is selected, the hardware resets this field and disables the EST function if any uncorrectable error is detected in the EST memory .

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled

74.7.192 MTL EST Status (MTL_EST_Status)

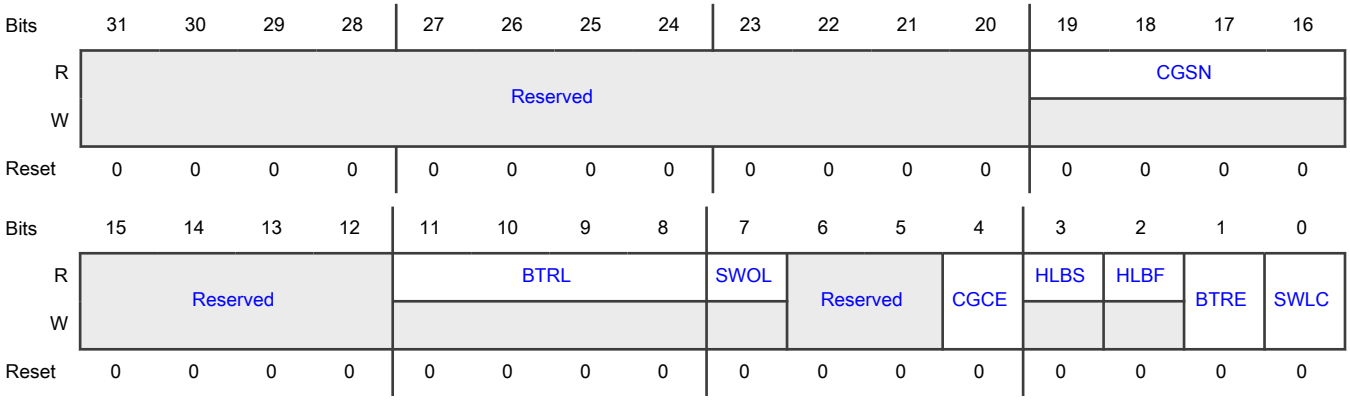
Offset

Register	Offset
MTL_EST_Status	C58h

Function

Provides status of enhancements to scheduled transmission (IEEE802.1Qbv).

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 CGSN	Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
15-12 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 BTRL	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "1111" indicates the iterations exceeded the value of 8 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
7 SWOL	S/W owned list When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0b - Gate control list number "0" is owned by software 1b - Gate control list number "1" is owned by software
6-5 —	Reserved.
4 CGCE	Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional Left Shifting. The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Constant Gate Control Error not detected 1b - Constant Gate Control Error detected
3 HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros. 0b - Head-Of-Line Blocking due to Scheduling not detected 1b - Head-Of-Line Blocking due to Scheduling detected
2 HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Head-Of-Line Blocking due to Frame Size not detected 1b - Head-Of-Line Blocking due to Frame Size detected
1 BTRE	BTR Error Indicates whether the BTR error is detected. When this field is 1, it indicates a programming error in the BTR of SWOL where the programmed value is less than the current time. If the BTRL = "1111", SWOL is not updated and software must reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "1111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restrictions apply to this field. It sets automatically to 1 on an internal event occurence. Writing 1 clears this field and writing 0 has no effect. 0b - BTR Error not detected 1b - BTR Error detected
0 SWLC	Switch to Software Owned List Complete Indicates whether the switch to software owned list complete is detected. When the field is 1, it indicates that the hardware has successfully switched to the SWOL, and updated the MTL_EST_Status[SWOL] to that effect. This field is 0 when MTL_EST_Control[SSWL] transitions from 0 to 1, or on a software write. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Not detected 1b - Detected

74.7.193 MTL EST Scheduling Error (MTL_EST_Sch_Error)

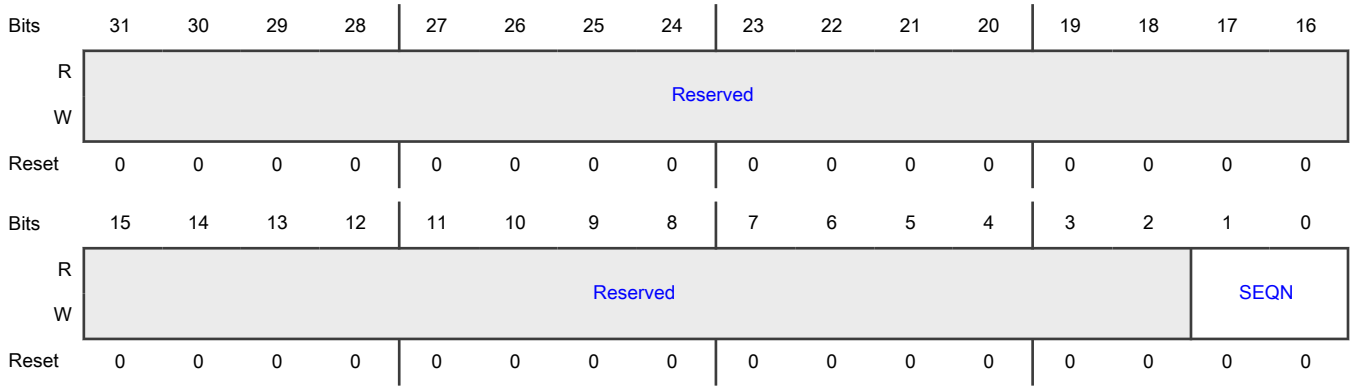
Offset

Register	Offset
MTL_EST_Sch_Error	C60h

Function

Provides the one hot encoded queue numbers that have the scheduling related error (timeout).

Diagram



Fields

Field	Function
31-2 —	Reserved.
1-0 SEQN	Schedule Error Queue Number Provides the one hot encoded queue numbers that have experienced error or timeout described in MTL_EST_Status[HLBS]. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.

74.7.194 MTL EST Frame Size Error (MTL_EST_Frm_Size_Error)

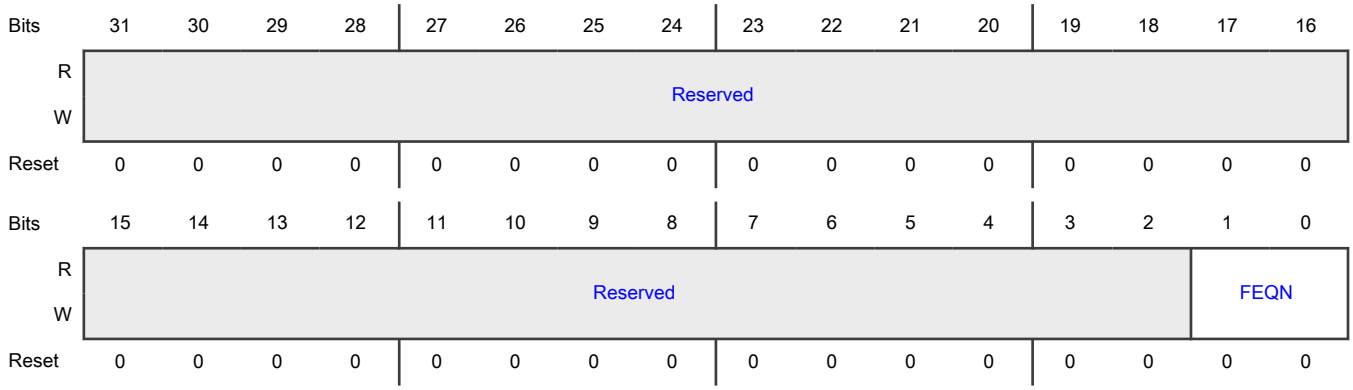
Offset

Register	Offset
MTL_EST_Frm_Size_Error	C64h

Function

Provides the one hot encoded queue numbers that have the frame Size related error.

Diagram



Fields

Field	Function
31-2 —	Reserved.
1-0 FEQN	Frame Size Error Queue Number Provides the one hot encoded queue Nnumbers that have experienced error described in MTL_EST_Status[HLBF]. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.

74.7.195 MTL EST Frame Size Capture (MTL_EST_Frm_Size_Capture)

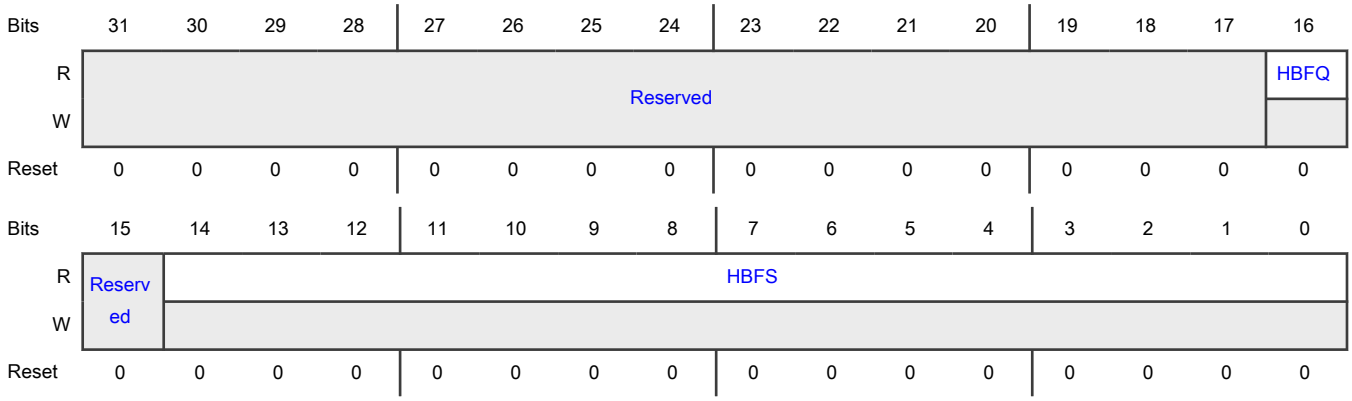
Offset

Register	Offset
MTL_EST_Frm_Size_Capture	C68h

Function

Captures the frame Size and queue number of the first occurrence of the frame Size related error. When you write 0, it captures the data of immediate next occurrence of a similar error.

Diagram



Fields

Field	Function
31-17 —	Reserved.
16 HBFQ	Queue Number of HLBF Captures the binary value of the first queue (number) which experiences the HLBF error (see MTL_EST_Status[HLBF]). Any subsequent queue errors similar to HLBF errors does not alter the value after it is written. After this field is 0, it captures the queue number of the next occurring HLBF error. Field's width is based on the number of transit queues configured; remaining fields are read-only. This field clears when MTL_EST_Frm_Size_Error is all zeros.
15 —	Reserved.
14-0 HBFS	Frame Size of HLBF Captures the frame Size of the dropped frame related to queue number indicated in MTL_EST_Frm_Size_Capture[HBFQ]. If this field is zero, then this register must be considered invalid. This field clears when MTL_EST_Frm_Size_Error is all zeros.

74.7.196 MTL EST Interrupt Enable (MTL_EST_Intr_Enable)

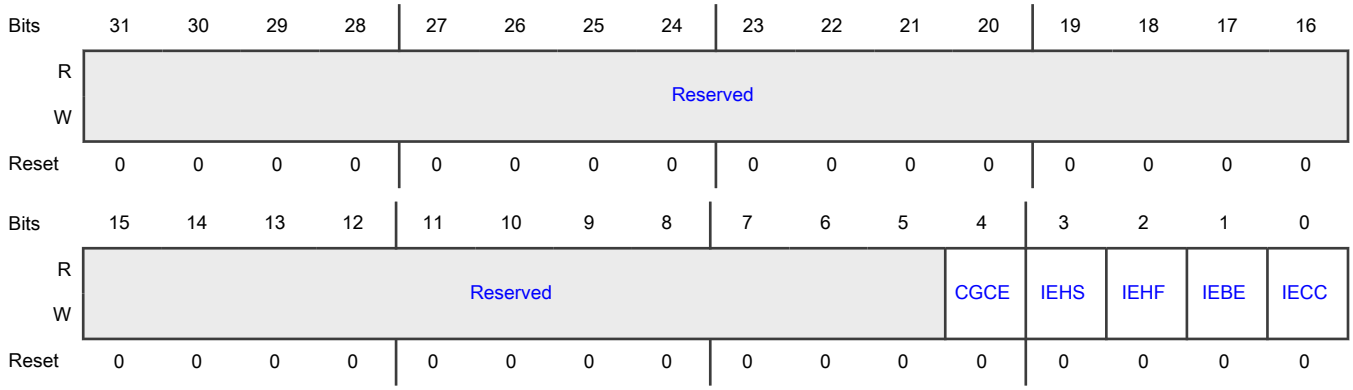
Offset

Register	Offset
MTL_EST_Intr_Enable	C70h

Function

Implements the interrupt enable fields for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status register.

Diagram



Fields

Field	Function
31-5 —	Reserved.
4 CGCE	Interrupt Enable for CGCE Indicates whether an interrupt for MTL_EST_Intr_Enable[CGCE] is enabled. When this field is 1, it generates an interrupt when the constant gate control error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt 0b - Disabled 1b - Enabled
3 IEHS	Interrupt Enable for HLBS Indicates whether an interrupt for MTL_EST_Status[HLBS] is enabled. When this field is 1, it generates an interrupt when the head-of-line blocking due to scheduling issue occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled
2 IEHF	Interrupt Enable for HLBF Indicates whether an interrupt for MTL_EST_Status[HLBF] is enabled. When this field is 1, it generates an interrupt when the head-of-line blocking due to frame size error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled
1 IEBE	Interrupt Enable for BTR Error Indicates whether an interrupt for BTR error is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it generates an interrupt when the BTR error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled
0 IECC	Interrupt Enable for Switch List Indicates whether the interrupt for switch list is enabled. When this field is 1, it generates an interrupt when the configuration change is successful and the hardware switches to the new list. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled

74.7.197 MTL EST GCL Control (MTL_EST_GCL_Control)

Offset

Register	Offset
MTL_EST_GCL_Control	C80h

Function

Provides the control information for reading and writing to the gate control lists.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								ESTEIEC		ESTEIEE	ERR0	Reserved

Fields

Field	Function
31-24	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23-22 ESTEIEC	ECC Inject Error Control for EST Memory Provides the status of inject error control for EST memory. When MTL_EST_GCL_Control[ESTEIEE] = 1, it indicates that on the basis of the value encoded in this field following errors are inserted. This field is valid only if you select DWC_EQOS_ASP_ECC feature during the configuration, otherwise it is reserved. 00b - Insert 1 bit error 01b - Insert 2 bit errors 10b - Insert 3 bit errors 11b - Insert 1 bit error in address field
21 ESTEIEE	EST ECC Inject Error Enable Indicates whether the EST ECC inject error is enabled. If this field along with MTL_EST_Control[EEST] = 1, it enables the ECC error injection feature. When this field becomes 0, it disables the ECC error injection feature. 0b - Disabled 1b - Enabled
20 ERR0	If this field is 1, it indicates that when the software writes to GCL the last write operation was aborted and when MTL_EST_Control[SSWL] is 1, GCL registers are prohibited. Access restriction apply to this field and automatically becomes 1 on an internal event occurrence. Writing 1 to this field clears it and writing 0 to this field has no effect. 0b - ERR0 is disabled 1b - ERR1 is enabled
19-16 —	Reserved.
15-8 ADDR	Gate Control List Address: (GCLA when GCRR is "0"). Provides the address (row number) of the gate control list at which the R/W operation has to be performed. By default the gate control list to which MTL_EST_Status[SWOL] points is selected for read and write. If MTL_EST_GCL_Control[DBGM] is 1, it indicates that MTL_EST_GCL_Control[DBGB] gives Debug mode access to read and write. The field's width depends on DWC_EQOS_EST_DEP and the unused bits must be treated as read only. Gate Control list Related Registers Address: (GCRA when GCRR is "1"). By default the GCL related register set pointed by MTL_EST_Status[SWOL] is selected for read or write. If MTL_EST_GCL_Control[DBGM], it indicates that MTL_EST_GCL_Control[DBGB] gives Debug mode access to read write. Lower 3 bits are only used in this mode, higher order bits are treated as dont cares.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - BTR Low (31:0) 001b - BTR High (63:31) 010b - CTR Low (31:0) 011b - CTR High (39:32) 100b - TER (31:0) 101b - LLR (n:0) (where n is (log{DWC_EQOS_EST_DEP} / log2)) Others - Reserved
7-6 —	Reserved.
5 DBGB	Debug Mode Bank Select Indicates whether the read and write in Debug mode is directed to bank 0 or bank 1. When this field is 0, it indicates that read or write in Debug mode must be directed to bank 0 (GCL0 and corresponding Time related registers). When this field is 1, it indicates that read or write in Debug mode should be directed to bank 1 (GCL1 and corresponding Time related registers). When MTL_EST_GCL_Control[DBGM] is 1 you can use this value and overrides with the MTL_EST_Status[SWOL] value. 0b - Directed to bank 0 1b - Directed to bank 1
4 DBGM	Debug Mode Enables or disables Debug mode. When this field is 1, it indicates that the read and write is in Debug mode where the MTL_EST_GCL_Control[DBGB] value explicitly provides the memory bank (for GCL and time related registers). When this field is 0, it indicates that MTL_EST_Status[SWOL] determines which bank to use. 0b - Disabled 1b - Enabled
3 —	Reserved.
2 GCRR	Gate Control Related Registers Enables or disables gate control related registers. When this field is 1, it indicates that the read or write access is for the GCL related registers (BTR, CTR, TER, LLR) for which GCRA provides the address. When this field is 0, it indicates that read and write must be directed to GCL from the address which GCLA provides. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 R1W0	Read '1', Write '0' Indicates whether this field performs read operation or write operation. When this field is 1 it indicates that it performs a read operation. When this field is 0 it indicates that it performs a write operation. 0b - Write operation 1b - Read operation
0 SRWO	Start Read/Write Operation Indicates whether the read/write operation is enabled. When this field is 1, it indicates that a read/write operation has started and is in progress. When hardware resets this field and MTL_EST_GCL_Control[ERR0] = 1 , it indicates that the read/write operation has completed or an error has occurred. Reads: When this field becomes 0, it indicates that MTL_EST_GCL_Data reads data. Writes: Before writing 1 to this field, you must program MTL_EST_GCL_Data with write data. Access restrictions apply to this field. It clears automatically. Writing 1 sets this field and writing 0 to it has no effect. 0b - Disabled 1b - Enabled

74.7.198 MTL EST GCL Data (MTL_EST_GCL_Data)

Offset

Register	Offset
MTL_EST_GCL_Data	C84h

Function

Holds the read data or write data in case of reads and writes respectively.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GCD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	GCD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 GCD	Gate Control Data Provides the data corresponding to the address selected in the MTL_EST_GCL_Control. This field is used for both read and write operations.

74.7.199 MTL FPE Control Status (MTL_FPE_CTRL_STS)

Offset

Register	Offset
MTL_FPE_CTRL_STS	C90h

Function

Controls the operation of, and provides status for frame preemption (IEEE802.1Qbu/802.3br).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved			HRS	Reserved											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved						PEC		Reserved						AFSZ	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-29 —	Reserved.
28 HRS	Hold/Release Status Indicates whether a set-and-release-MAC operation which was last executed and the pMAC is in release state or in hold state. 0b - Release state 1b - Hold state
27-16 —	Reserved.
15-10 —	Reserved.
9-8 PEC	Preemption Classification When this field is 1, it indicates that you must classify the corresponding queue as preemptable. When this field is 0, it indicates that you must classify the queue as express. When set indicates the corresponding Queue must be classified as preemptable, when '0' Queue is classified as express. When both EST (Qbv) and Preemption are enabled, Queue-0 is always assumed to be preemptable. When you enables EST (Qbv), the preemptable queues are always assumed to be in open state in gate control list.
7-2 —	Reserved.
1-0 AFSZ	Additional Fragment Size Indicates that, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ +1) * 64 bytes.

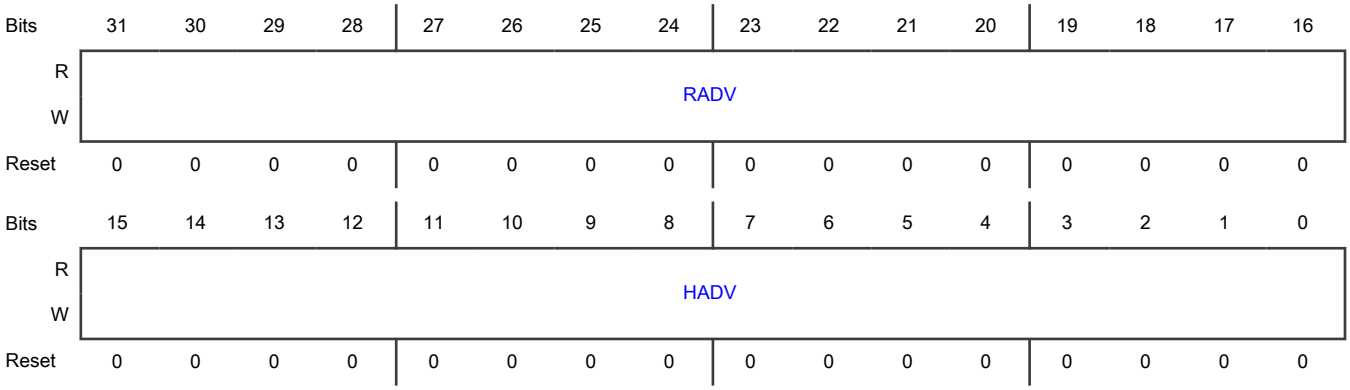
74.7.200 MTL FPE Advance (MTL_FPE_Advance)

Offset

Register	Offset
MTL_FPE_Advance	C94h

Function
Holds the hold and release advance time.

Diagram



Fields

Field	Function
31-16 RADV	Release Advance Provides the maximum time in nanoseconds that can elapse between issuing a release to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.
15-0 HADV	Hold Advance Provides the maximum time in nanoseconds that can elapse between issuing a hold to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.

74.7.201 MTL Rx Parser Control Status (MTL_RXP_Control_Status)

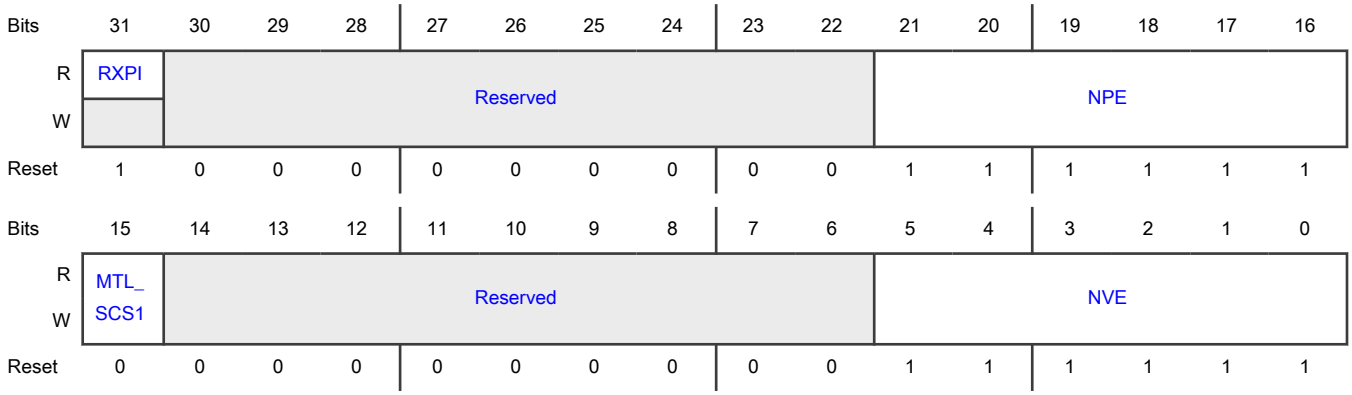
Offset

Register	Offset
MTL_RXP_Control_Status	CA0h

Function

Establishes the operating mode of receive parser and provides some status.

Diagram



Fields

Field	Function
31 RXPI	RX Parser in Idle State Indicates whether the receive parser is in idle state. When this field is 1, it indicates that the receive parser is in idle state and waiting for the processing of a new packet. When parser disables, you can use this field as a handshake with software and also the software can update the receive parser instruction table when you write 1 to this field. 0b - Not in Idle state 1b - Idle state
30-22 —	Reserved.
21-16 NPE	Number of parsable entries in the Instruction table Indicates the number of parsable entries in the instruction memory. This is used in receive parser logic to detect programming error. MTL_RXP_Interrupt_Control_Status[NPEOVIS] = 1, if the number of parsed entries for a packet is more than this entry.
15 MTL_SCS1	MTL_SCS1 Is reserved for NXP internal use. The value of this field must always be 0 unless NXP instructs you otherwise. Writing 1 to any of the bits of this field might cause unexpected behavior in th IP.
14-6 —	Reserved.
5-0 NVE	Number Of Valid Entry Address Or Index In The Instruction Table Indicates the number of valid entry address or index in the instruction memory.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The maximum valid entry address is = NVE + 1 and the addresses or indices range from 0 to 32. Therefore, if the value of this field is 32, the number of valid entry address is 33. This value is used in receive parser logic to detect if any programming errors exist. When parsing, the module writes 1 to NVEOVIS if the number of the memory address is found to be more than the defined maximum valid entry address number. **NOTE** The minimum value of this field must be two.

74.7.202 MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)

Offset

Register	Offset
MTL_RXP_Interrupt_Control_Status	CA4h

Function
Provides enable control for the interrupts and also provides interrupt status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved												PDRFIE	FOOVIE	NPEOVIE	NVEOVIE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved												PDRFIS	FOOVIS	NPEOVIS	NVEOVIS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved.
19 PDRFIE	Packet Drop due to RF Interrupt Enable Indicates whether the packet drop due to RF interrupt is enabled. If this field is 1, it enables the PDRFIS interrupt. When this field becomes 0, it disables the PDRFIS interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
18 FOOVIE	Frame Offset Overflow Interrupt Enable Indicates whether the frame offset overflow interrupt is enabled. If this field is 1, it enables the FOOVIS interrupt. When this field becomes 0, it disables the FOOVIS interrupt. 0b - Disabled 1b - Enabled
17 NPEOVIE	Number of Parsable Entries Overflow Interrupt Enable Enables or disables the number of parsable entries overflow interrupt. If this field is 1, it enables the NPEOVIS interrupt. When this field becomes 0, it disables the NPEOVIS interrupt. 0b - Disable 1b - Enable
16 NVEOVIE	Number of Valid Entries Overflow Interrupt Enable Enables or disables the number of valid entries overflow interrupt. If this field is 1, it enables the NVEOVIS interrupt. When this field becomes 0, it disables the NVEOVIS interrupt. 0b - Disable 1b - Enable
15-4 —	Reserved.
3 PDRFIS	Packet Dropped due to RF Interrupt Status Indicates whether the packet dropped due to RF interrupt status is detected. If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1. This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected
2	Frame Offset Overflow Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
FOOVIS	Indicates whether the frame offset overflow interrupt status is detected. If this field is 1, it indicates that when parsing, the instruction table entry's frame offset is more than the EOF offset. This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected
1 NPEOVIS	Number of Parsable Entries Overflow Interrupt Status Indicates whether the number of parsable entries overflow interrupt status is detected. If this field is 1, it indicates that when parsing a packet the number of parsed entries are more than NPE[] (MTL_RXP_Control_Status[NPE]). This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected
0 NVEOVIS	Number of Valid Entry Address/Index Overflow Interrupt Status Indicates whether the number of valid entry address or index overflow interrupt status is detected. If this field is 1, it indicates that when parsing, the instruction address is more than MTL_RXP_Control_Status[NVE]. For example, when MTL_RXP_Control_Status[NVE] = 31, the maximum valid entry address/index is NVE+1 that is 32 (addresses/indices = 0 to 32, or 33 entries). MTL_RXP_Interrupt_Control_Status[NVEOVIS] = 1 when currently processed entry indicates that the next address is 33 or more, that is 34th or later entries. This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected

74.7.203 MTL Rx Parser Drop Count (MTL_RXP_Drop_Cnt)

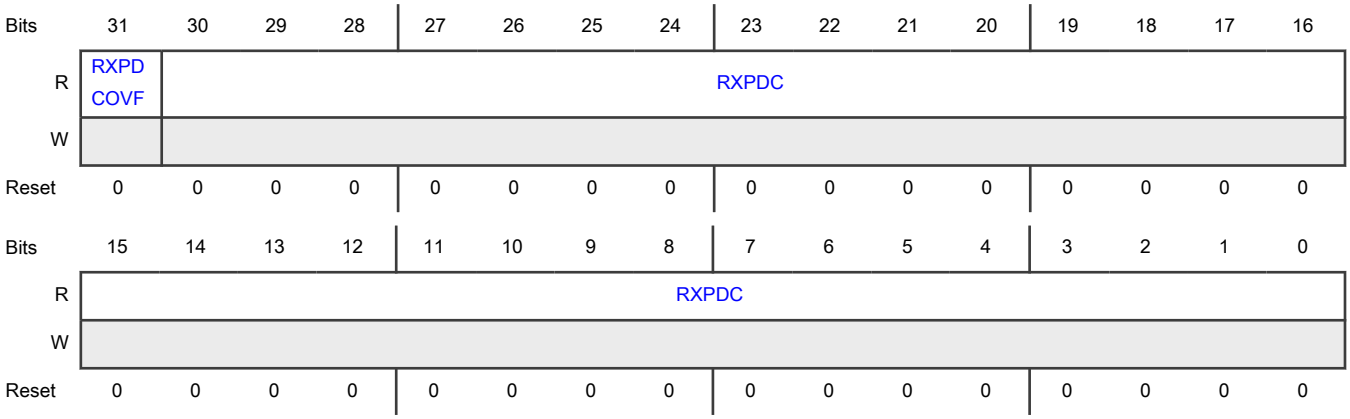
Offset

Register	Offset
MTL_RXP_Drop_Cnt	CA8h

Function

Provides the drop count of receive parser initiated drops.

Diagram



Fields

Field	Function
31 RXPDCOVF	Rx Parser Drop Counter Overflow Bit Indicates whether the receive parser drop count overflow has occurred. When this field is 1, it indicates that the MTL_RXP_Drop_Cnt[RXPDC] counter field has crossed the maximum limit. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPDC	Rx Parser Drop Count Provides the receive parser drop count. This 31-bit counter is implemented whenever a receive parser drops a packet due to RF = 1. The counter clears when you read the register.

74.7.204 MTL Rx Parser Error Count (MTL_RXP_Error_Cnt)

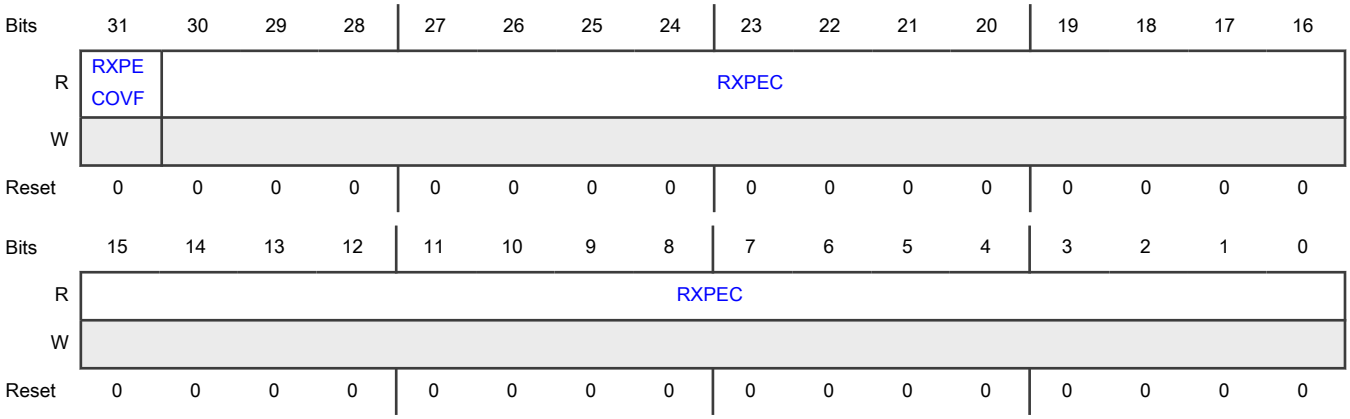
Offset

Register	Offset
MTL_RXP_Error_Cnt	CACh

Function

Provides the receive parser related error occurrence count.

Diagram



Fields

Field	Function
31 RXPECOVF	Rx Parser Error Counter Overflow Bit Indicates whether the receive parser error counter overflow has occurred. When this field is 1, it indicates that MTL_RXP_Error_Cnt[RXPEC] counter field has crossed the maximum limit. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPEC	Rx Parser Error Count Provides the receive parser error count. This 31-bit counter is implemented whenever a receive parser encounters following error scenarios: Entry address >= NVE[] Number parsed entries >= NPE[] Entry address > EOF data entry address The counter clears when you read the register.

74.7.205 MTL Rx Parser Indirect Access Control Status (MTL_RXP_Indirect_Acc_Control_Status)

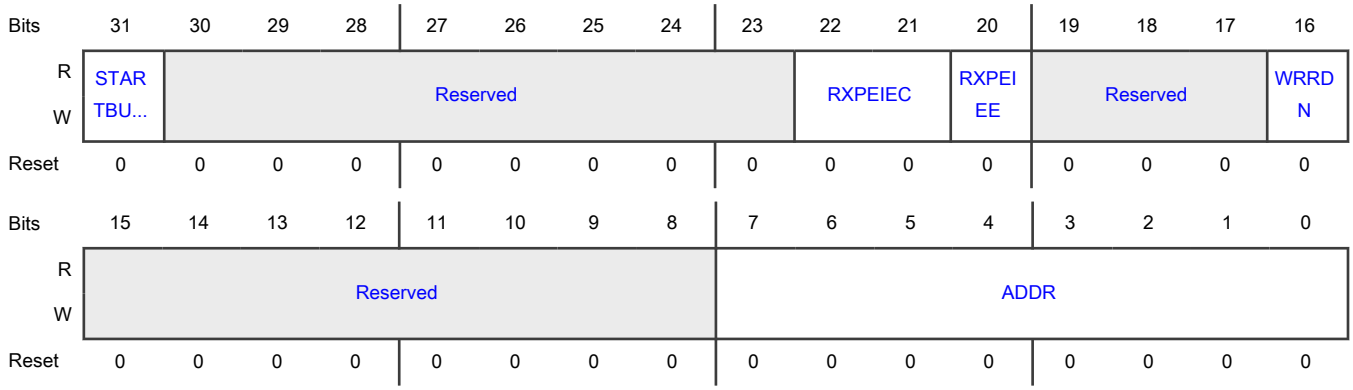
Offset

Register	Offset
MTL_RXP_Indirect_Acc_Control_Status	CB0h

Function

Provides the indirect access control and status for receive parser memory.

Diagram



Fields

Field	Function
31 STARTBUSY	FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions. This bit when set to 1 indicates that hardware is busy until its gets cleared by hardware and software should not issue any read or write operation. 0b - hardware not busy 1b - hardware is busy (Read/Write operation from/to the Rx Parser Memory)
30-23 —	Reserved.
22-21 RXPEIEC	ECC Inject Error Control for Rx Parser Memory Controls the ECC inject error for receive parser memory. When MTL_RXP_Indirect_Acc_Control_Status[RXPEIEE] = 1, it indicates that on the basis of the value encoded in this field following errors are inserted: 00b - Insert 1 bit error 01b - Insert 2 bit errors 10b - Insert 3 bit errors 11b - Insert 1 bit error in address field
20 RXPEIEE	ECC Inject Error Enable for Rx Parser Memory Indicates whether the ECC inject error for receive parser memory is enabled. If this field is 1, it enables the ECC error injection feature. When this field becomes 0, it disables the ECC error injection feature.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
19-17 —	Reserved.
16 WRRDN	Read Write Control Controls the read and write operation to the receive parser memory. If this field is 1, it indicates the write operation to the receive parser memory. When this field is 0, it indicates the read operation to the receive parser memory. 0b - Read operation to the receive parser memory 1b - Write operation to the receive parser memory
15-8 —	Reserved.
7-0 ADDR	FRP Instruction Table Offset Address Indicates the ADDR of the 32-bit entry in receive parser instruction table. Each entry has 128-bit (4x32-bit words). The X depends on the configurable DWC_EQOS_FRP_ENTRIES. If DWC_EQOS_FRP_ENTRIES = 256 , then X = 9 If DWC_EQOS_FRP_ENTRIES = 128 , then X = 8 If DWC_EQOS_FRP_ENTRIES = 64, then X = 7

74.7.206 MTL Rx Parser Indirect Access Data (MTL_RXP_Indirect_Acc_Data)

Offset

Register	Offset
MTL_RXP_Indirect_Acc_Data	CB4h

Function
Provides the data associated to indirect access to receive parser memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-9 —	Reserved.
8 MEEAO	MTL ECC Error Address Status Over-ride Enables or disables the MTL ECC error address status over-ride. When this field is 1, it indicates that MTL_ECC_Err_Addr_Status[EUEAS] and MTL_ECC_Err_Addr_Status[ECEAS] hold the last valid address where the error is detected. When this field becomes 0, it indicates that MTL_ECC_Err_Addr_Status[EUEAS] and MTL_ECC_Err_Addr_Status[ECEAS] hold the first address where the error is detected. 0b - Disable 1b - Enable
7-5 —	Reserved.
4 —	Reserved.
3 MRXPEE	MTL Rx Parser ECC Enable Indicates whether the MTL receive parser ECC is enabled. If this field is 1, it enables the ECC feature for receive parser memory. When this field is 0, it disables the ECC feature for receive parser memory. 0b - Disabled 1b - Enabled
2 MESTEE	MTL EST ECC Enable Indicates whether the MTL EST ECC is enabled. If this field is 1, it enables the ECC feature for EST memory. When this field is 0, it disables the ECC feature for EST memory. 0b - Disabled 1b - Enabled
1 MRXEE	MTL Rx FIFO ECC Enable Indicates whether the MTL Rx FIFO ECC is enabled. If this field is 1, it enables the ECC feature for MTL receive FIFO memory. When this field is 0, it disables the ECC feature for MTL receive FIFO memory. 0b - Disabled 1b - Enabled
0	MTL Tx FIFO ECC Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
MTXEE	Indicates whether the MTL Tx FIFO ECC is enabled. If this field is 1, it enables the ECC feature for MTL Tx FIFO memory. When field is 0, it disables the ECC feature for MTL Tx FIFO memory. 0b - Disabled 1b - Enabled

74.7.208 MTL Safety Interript Status (MTL_Safety_Interrupt_Status)

Offset

Register	Offset
MTL_Safety_Interrupt_Status	CC4h

Function

Provides safety interrupt status.

Field	Function
31 —	Reserved Indicates whether the MAC safety uncorrectable interrupt status is detected. 0b - Not detected 1b - Detected
30-2	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 MEUIS	MTL ECC Uncorrectable Error Interrupt Status Indicates whether the MTL ECC uncorrectable error interrupt status is detected. Indicates that an uncorrectable error interrupt event in the MTL ECC safety feature. The application must read MTL_ECC_Interrupt_Status to get the exact cause of the interrupt. 0b - Not detected 1b - Detected
0 MECIS	MTL ECC Correctable Error Interrupt Status Indicates whether the MTL ECC correctable error interrupt status is detected. Indicates that a correctable error interrupt event in the MTL ECC safety feature. The application must read MTL_ECC_Interrupt_Status to get the exact cause of the interrupt . 0b - MTL ECC Correctable error Interrupt Status not detected 1b - MTL ECC Correctable error Interrupt Status detected

74.7.209 MTL ECC Interrupt Enable (MTL_ECC_Interrupt_Enable)

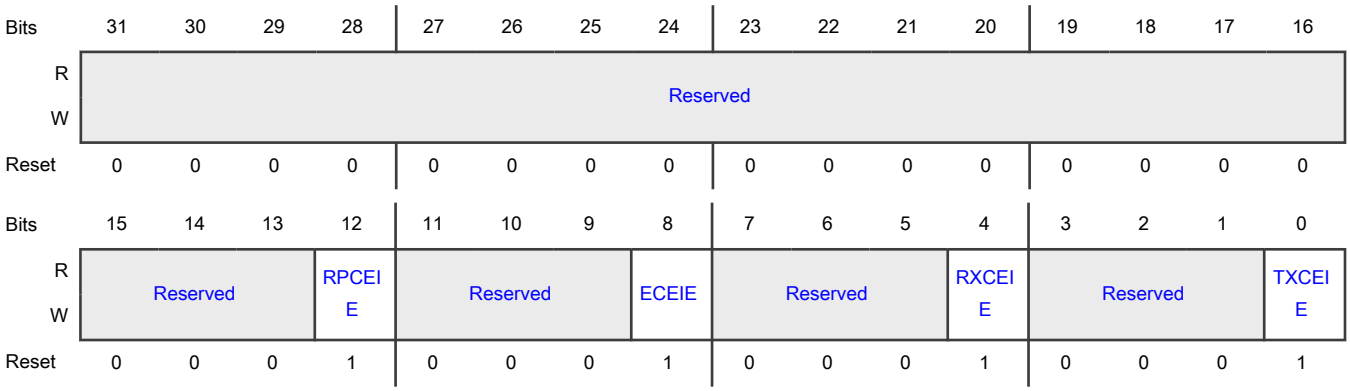
Offset

Register	Offset
MTL_ECC_Interrupt_Enable	CC8h

Function

Provides enable bits for the ECC interrupts.

Diagram



Fields

Field	Function
31-13 —	Reserved.
12 RPCEIE	Rx Parser Memory Correctable Error Interrupt Enable Indicates whether the Rx parser memory correctable error interrupt is enabled. When this field is 1, it generates an interrupt when an uncorrectable error is detected at the Rx parser memory interface. It is indicated in MTL_ECC_Interrupt_Status[RPCES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled
11-9 —	Reserved.
8 ECEIE	EST Memory Correctable Error Interrupt Enable Indicates whether the EST memory correctable error interrupt is enabled. When this field is 1, it generates an interrupt when a correctable error is detected at the MTL EST memory interface. It is indicated in MTL_ECC_Interrupt_Status[ECES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled
7-5 —	Reserved.
4 RXCEIE	Rx Memory Correctable Error Interrupt Enable Indicates whether the Rx memory correctable error interrupt is enabled. When this field is 1, it generates an interrupt when a correctable error is detected at the MTL Rx memory interface. It is indicated in MTL_ECC_Interrupt_Status[RXCES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled
3-1 —	Reserved.
0 TXCEIE	Tx Memory Correctable Error Interrupt Enable Indicates whether the Tx memory correctable error interrupt is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it generates an interrupt when a correctable error is detected at the MTL Tx memory interface. It is indicated in MTL_ECC_Interrupt_Status[TXCES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled

74.7.210 MTL ECC Interrupt Status (MTL_ECC_Interrupt_Status)

Offset

Register	Offset
MTL_ECC_Interrupt_Status	CCCh

Function
Provides MTL ECC Interrupt Status.

Diagram

74.7.211 MTL ECC Error Status (MTL_ECC_Err_Sts_Rctl)

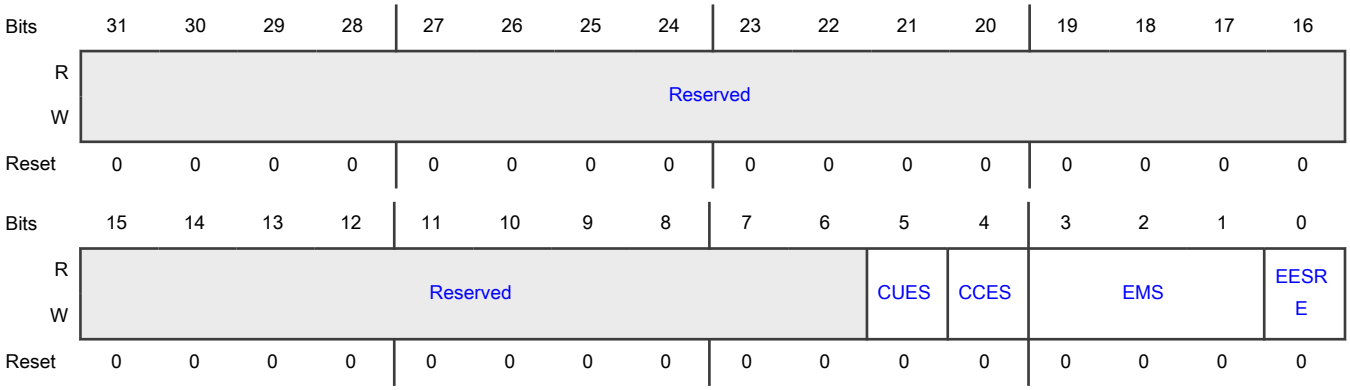
Offset

Register	Offset
MTL_ECC_Err_Sts_Rctl	CD0h

Function

Establishes the control for ECC error status capture.

Diagram



Fields

Field	Function
31-6 —	Reserved.
5 CUES	Clear Uncorrectable Error Status Indicates whether the clear uncorrectable error status is detected. When this field and MTL_ECC_Err_Sts_Rctl[EESRE] is 1, it indicates that based on the MTL_ECC_Err_Sts_Rctl[EMS], the respective memory's uncorrectable error address and uncorrectable error count values are cleared upon reading. When all the error status values are cleared hardware resets this field. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 CCES	Clear Correctable Error Status Indicates whether the clear correctable error status is detected. When this field and MTL_ECC_Err_Sts_Rctl[EESRE] is 1, it indicates that based on the MTL_ECC_Err_Sts_Rctl[EMS],, the respective memory's correctable error address and correctable error count values are cleared upon reading. When all the error status values are cleared, hardware resets this field. 0b - Not detected 1b - Detected
3-1 EMS	MTL ECC Memory Selection Provides the memory selection encoding. When MTL_ECC_Err_Sts_Rctl[EESRE] is 1, this field indicates which memory's error status value to be read. The memory selection encoding is as described below. 000b - MTL Tx memory 001b - MTL Rx memory 010b - MTL EST memory 011b - MTL Rx Parser memory 100b - DMA TSO memory
0 EESRE	MTL ECC Error Status Read Enable Indicates whether the MTL ECC error status read is enabled. When this field is 1, it indicates that based on MTL_ECC_Err_Sts_Rctl[EMS], the respective memory's error status values are captured as described below: • The correctable and uncorrectable error count values are captured into MTL_ECC_Err_Cnt_Status. • The address location of correctable and uncorrectable errors are captured into MTL_ECC_Err_Addr_Status. When all the status values are captured into MTL_ECC_Err_Cnt_Status and MTL_ECC_Err_Addr_Status, hardware resets this field. 0b - Disabled 1b - Enabled

74.7.212 MTL ECC Error Adress Status (MTL_ECC_Err_Addr_Status)

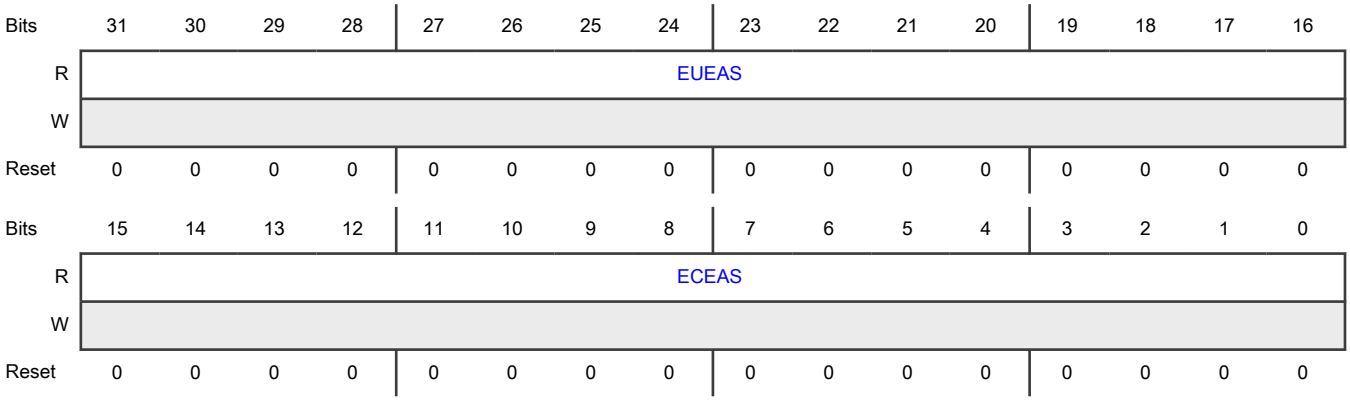
Offset

Register	Offset
MTL_ECC_Err_Addr_Status	CD4h

Function

Provides the memory addresses for the correctable and uncorrectable errors.

Diagram



Fields

Field	Function
31-16 EUEAS	MTL ECC Uncorrectable Error Address Status Based on the MTL_ECC_Err_Sts_Rctl[EMS], this field holds the respective memory's address locations for which an uncorrectable error or address mismatch is detected. When MTL_ECC_Control[MEEAO] = 1, this field holds the last valid address of memory for which either an uncorrectable error or an address mismatch is detected. When MTL_ECC_Control[MEEAO] = 0, this field holds the first address of the memory for which either an uncorrectable error or address mismatch is detected.
15-0 ECEAS	MTL ECC Correctable Error Address Status Based on the MTL_ECC_Err_Sts_Rctl[EMS], this field holds the respective memory's address locations for which a correctable error is detected. When MTL_ECC_Control[MEEAO] = 1, this field holds the last valid address of memory for which the correctable error or address mismatch is detected. When MTL_ECC_Control[MEEAO] = 0, this field holds the first address of the memory for which correctable error is detected.

74.7.213 MTL ECC Error Control Status (MTL_ECC_Err_Cntr_Status)

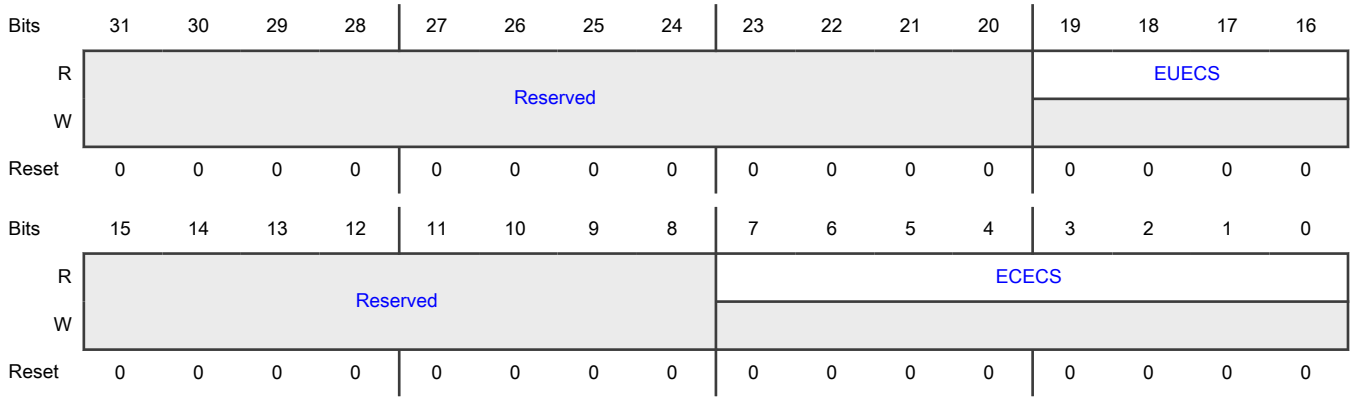
Offset

Register	Offset
MTL_ECC_Err_Cntr_Status	CD8h

Function

Provides ECC Error count for correctable and uncorrectable errors.

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 EUECS	MTL ECC Uncorrectable Error Counter Status Based on the EMS field of MTL_ECC_Err_Cntr_Rctl register, this field holds the respective memory's uncorrectable error count value.
15-8 —	Reserved.
7-0 ECECS	MTL ECC Correctable Error Counter Status Based on the EMS field of MTL_ECC_Err_Cntr_Rctl register, this field holds the respective memory's correctable error count value.

74.7.214 MTL DPP Control (MTL_DPP_Control)

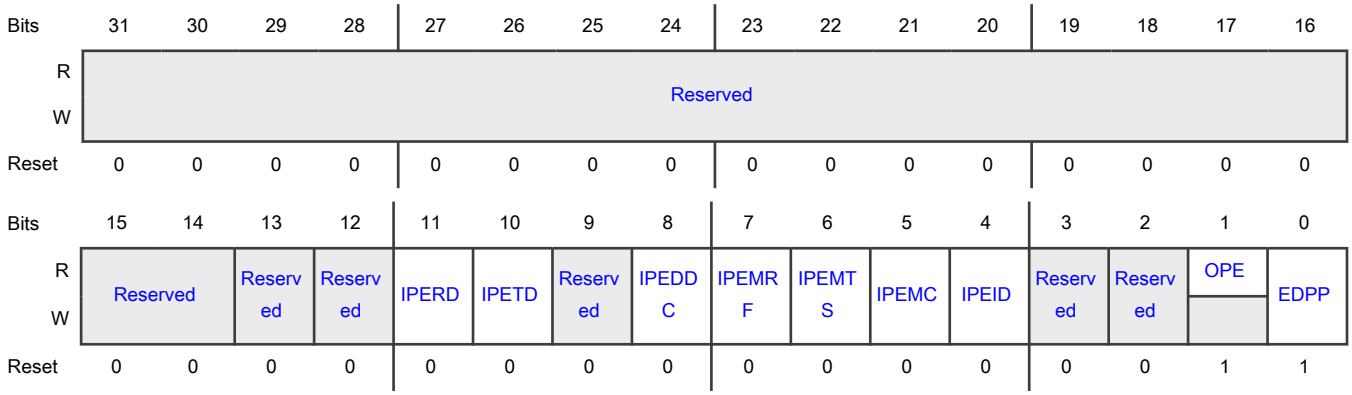
Offset

Register	Offset
MTL_DPP_Control	CE0h

Function

Establishes the operating mode of data parity protection and error injection.

Diagram



Fields

Field	Function
31-14 —	Reserved.
13 —	Reserved.
12 —	Reserved.
11 IPERD	Insert Parity error in Rx write-back Descriptor parity generator Indicates whether the insert parity error in receive write-back descriptor parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the DMA Rx write-back descriptor parity generator(or at PG8 as shown in Receive data path parity protection diagram) generates. 0b - Disabled 1b - Enabled
10 IPETD	Insert Parity error in Tx write-back Descriptor parity generator Indicates whether the insert parity error in transit write-back descriptor parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the DMA Tx write-back descriptor parity generator(or at PG4 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
9 —	Reserved.
8	Insert Parity Error in DMA DTX Control Word Parity Generator

Table continues on the next page...

Table continued from the previous page...

Field	Function
IPEDDC	Indicates whether the insert parity error in DMA DTX control word parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the DMA DTX Control word parity generator (or at PG2 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
7 IPEMRF	Insert Parity Error in MTL Rx FIFO Read Control Parity Generator Inserts parity Eerror in MTL receive FIFO read control parity generator. When this field is 1, it flips the parity bit of first valid data to which the MTL Rx FIFO read control parity generator (or at PG7 as shown in Receive data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
6 IPEMTS	Insert Parity Error in MTL Tx Status Parity Generator Indicates whether the insert parity error in MTL transit status parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the MTL Tx Status parity generator (or at PG6 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
5 IPEMC	Insert Parity Error in MTL Checksum Parity Generator Indicates whether the insert parity error in MTL checksum parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the MTL checksum parity generator (or at PG5 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
4 IPEID	Insert Parity Error in Interface Data Parity Generator Indicates whether the insert parity error in interface data parity generator is enabled. When this field is 1, it flips the parity bit of first valid input data to which the interface data parity generator (or at PG1 as shown in Transmit data path parity protection diagram) generates. Following are the input data bus on which parity bits are generated on the basis of configuration selected. In AHB Config, hrdata_i In AXI config, rdata_m_i

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In DMA Config, mdc_rdata_i In MTL Config, ati_data_i Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
3 —	Reserved.
2 —	Reserved.
1 OPE	Odd Parity Enable Indicates whether an odd parity protection is enabled. When this field is 1, it enables an odd parity protection on all the external interfaces and when this field is 0, it enables an even parity protection on all the external interfaces. 0b - Disabled 1b - Enabled
0 EDPP	Enable Data path Parity Protection Enables or disables the data path parity protection. When this field is 1, it indicates that by generating and checking the parity on EQOS datapath it enables the parity protection for EQOS datapath . When this field is 0, it disables the parity protection for EQOS datapath. 0b - Disable 1b - Enable

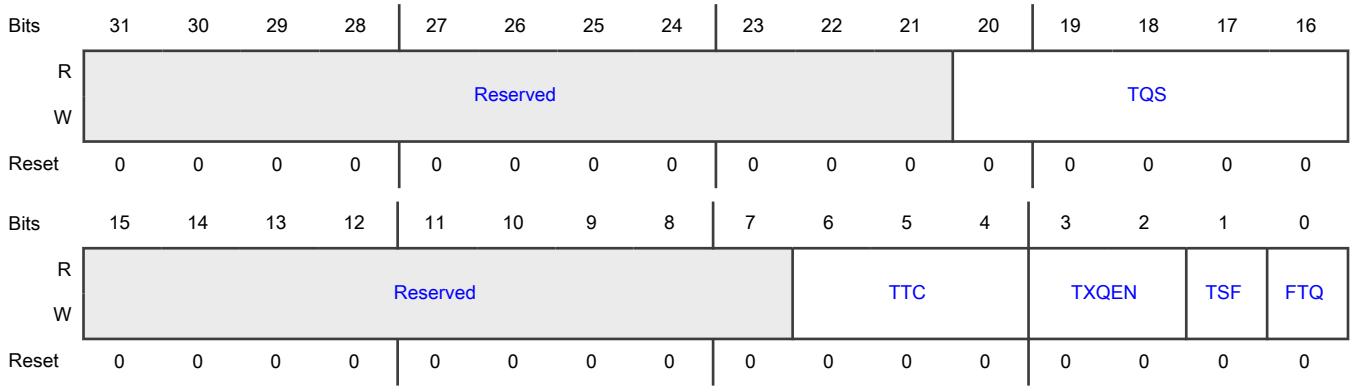
74.7.215 MTL Tx Queue 0 Operation Mode (MTL_TxQ0_Operation_Mode)

Offset

Register	Offset
MTL_TxQ0_Operation_Mode	D00h

Function
Establishes the transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-16 TQS	Transmit Queue Size Indicates the size of the allocated transmit queues in blocks of 256 bytes. This field is read-write only if the number of transit queues are more than one, the reset value is 0x0 and indicates 256 bytes size. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes . In general, the size of the Queue = (TQS+1)*256 bytes. When the number of transit queue is one, the field is read-only and the reset value reflects the configured TX FIFO size in blocks of 256 bytes. The field's width depends on the transit memory size selected in your configuration. For example, if the memory size is 2048, the field's width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved.
6-4 TTC	Transmit Threshold Control Controls the threshold level of the MTL transit queue. The transmission starts when the packet size within the MTL transit queue is larger than the threshold, also transmits full packets with length less than the threshold. These fields are used only when MTL_TxQ0_Operation_Mode[TSF] resets. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable Enables or disables the transmit queue 0. 2'b00 - Not enabled 2'b01 - Reserved 2'b10 - Enabled 2'b11 - Reserved This field is read only in single queue configurations and read write in multiple queue configurations. **NOTE** In multiple transit queue configuration, all the queues disables by default and programming this field enables the transit queue. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward Indicates whether the transmit store and forward is enabled. When this field is 1, it indicates that the transmission starts when a full packet resides in the MTL transit queue and the TTC values specified in Bits[6:4] of this register are ignored. This field must be changed only when you stop the transmission. 0b - Disabled 1b - Enabled
0 FTQ	Flush Transmit Queue Indicates whether the flush transmit queue is enabled. When this field is 1, it indicates that the transit queue controller logic resets to its default values. Therefore, all the data in the transit queue is lost or flushed. After the flushing operation completes this field resets internally. You must not write to the MTL_TxQ1_Operation_Mode until this field resets. The data to which the MAC transmitter has already accepted is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **NOTE** The flush operation completes only when the transit queue is empty and the application accepts the pending transit status of all the transmitted packets. To complete the flush operation, the PHY Tx clock (clk_tx_i) must be active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears automatically. Writing 1 sets this field and writing 0 has no effect. 0b - Disabled 1b - Enabled

74.7.216 MTL Tx Queue 0 Underflow (MTL_TxQ0_Underflow)

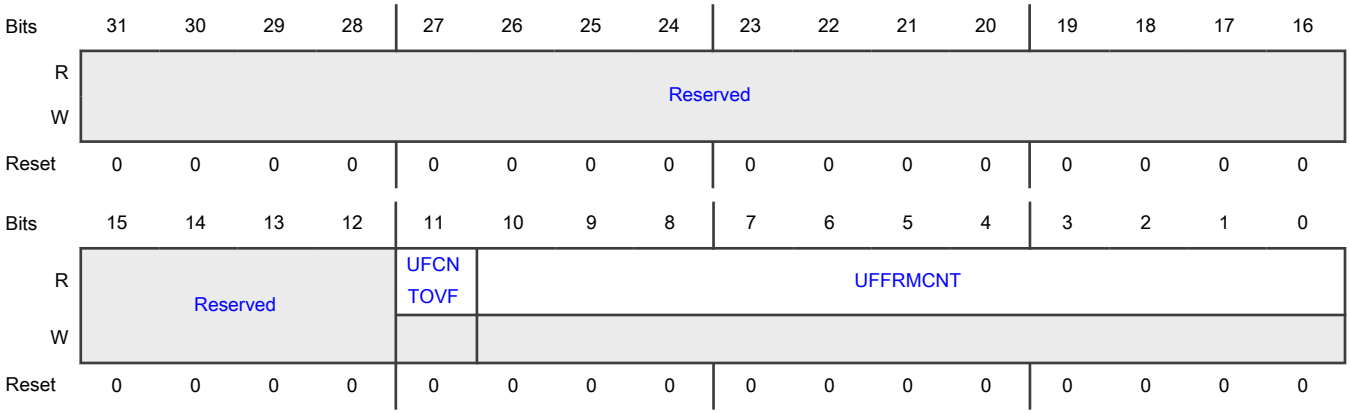
Offset

Register	Offset
MTL_TxQ0_Underflow	D04h

Function

Contains the counter for packets aborted because of transmit queue underflow and packets missed because of receive queue packet flush.

Diagram



Fields

Field	Function
31-12 —	Reserved.
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter Indicates whether the overflow is detected for underflow packet counter.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is 1, when the transit queue underflow packet counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter resets to all-zeros and this field indicates that the rollover occured. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10-0 UFFRMCNT	Underflow Packet Counter Indicates the number of packets aborted by the controller because of transit queue underflow. This counter increments each time the MAC aborts outgoing packet because of underflow. The counter clears when this register is read with mci_be_i[0] at 1'b1. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

74.7.217 MTL Tx Queue 0 Debug (MTL_TxQ0_Debug)

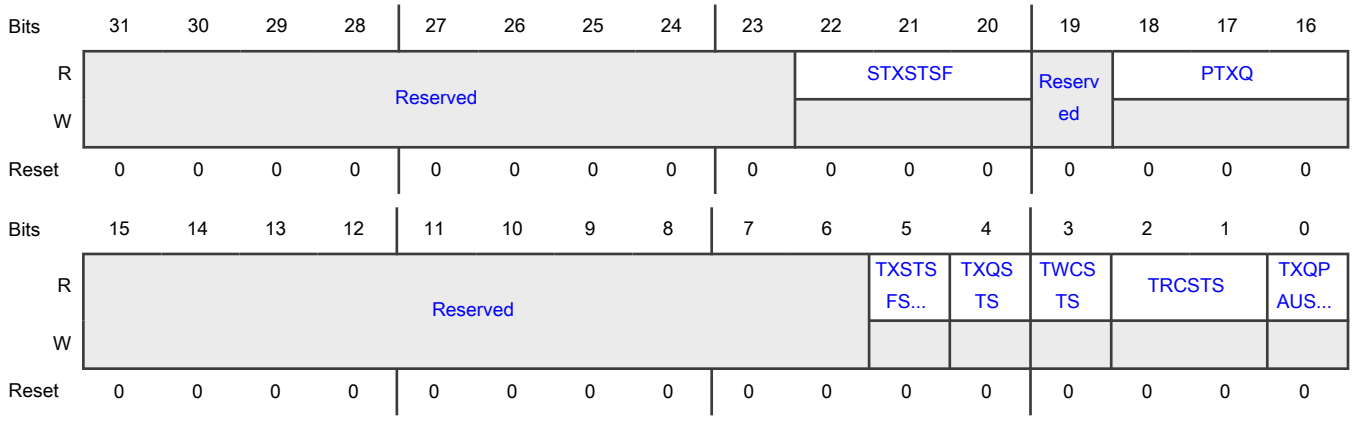
Offset

Register	Offset
MTL_TxQ0_Debug	D08h

Function

Provides the debug status of various blocks related to the transmit queue.

Diagram



Fields

Field	Function
31-23 —	Reserved.
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue Indicates the current number of status in the transit status FIFO of this queue. This field does not reflect the number of status words in transit status FIFO, when MTL_Operation_Mode[DTXSTS] = 1.
19 —	Reserved.
18-16 PTXQ	Number of Packets in the Transmit Queue Indicates the current number of packets in the transit queue. This field does not reflect the number of packets in the transmit queue, when MTL_Operation_Mode[DTXSTS] = 1.
15-6 —	Reserved.
5 TXSTSFSTS	MTL Tx Status FIFO Full Status Indicates whether the MTL transit status and FIFO full status is detected. When this field is 1, it indicates that the MTL transit status FIFO is full. Therefore, MTL cannot accept any more packets for transmission. 0b - Not detected 1b - Detected
4 TXQSTS	MTL Tx Queue Not Empty Status Indicates whether the MTL transit queue not empty status is detected. When this field is high, it indicates that the MTL transit queue is not empty and some data is left for transmission. 0b - Not detected 1b - Detected
3 TWCSTS	MTL Tx Queue Write Controller Status Indicates whether the MTL transit queue write controller status is detected. When high, this field indicates that the MTL transit queue write controller is active, and transfers the data to the transit queue. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-1 TRCSTS	MTL Tx Queue Read Controller Status Indicates the state of the transit queue read controller. 00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending transit status from the MAC transmitter 11b - Flushing the transit queue because of the packet abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause Indicates whether the transmit queue in pause is detected. When this field is 1 and the receive flow control is enabled, it indicates that the transit queue is in the pause condition (in the full-duplex only mode) because of the following scenario: • Receives PFC packet with the priorities assigned to the transit queue when PFC is enabled. • Receives 802.3x pause packet when PFC is disabled. 0b - Not detected 1b - Detected

74.7.218 MTL Tx Queue 0 ETS Status (MTL_TxQ0_ETS_Status)

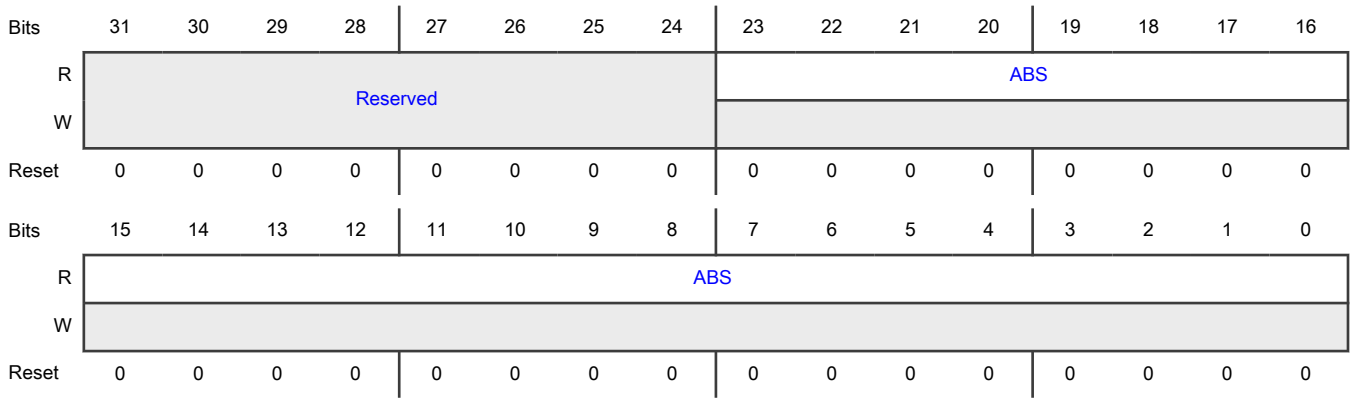
Offset

Register	Offset
MTL_TxQ0_ETS_Status	D14h

Function

Provides the average traffic transmitted in queue 0.

Diagram



Fields

Field	Function
31-24 —	Reserved.
23-0 ABS	Average Bits per Slot Contains the average transmitted bits per slot. Computes over every 10 million bit times slot (4 ms in 2500 Mbit/s; 10 ms in 1000 Mbit/s; 100 ms in 100 Mbit/s), when the DCB operation enables for queue 0. The maximum value is 0x989680.

74.7.219 MTL Tx Queue Quantum Weight (MTL_TxQ0_Quantum_Weight)

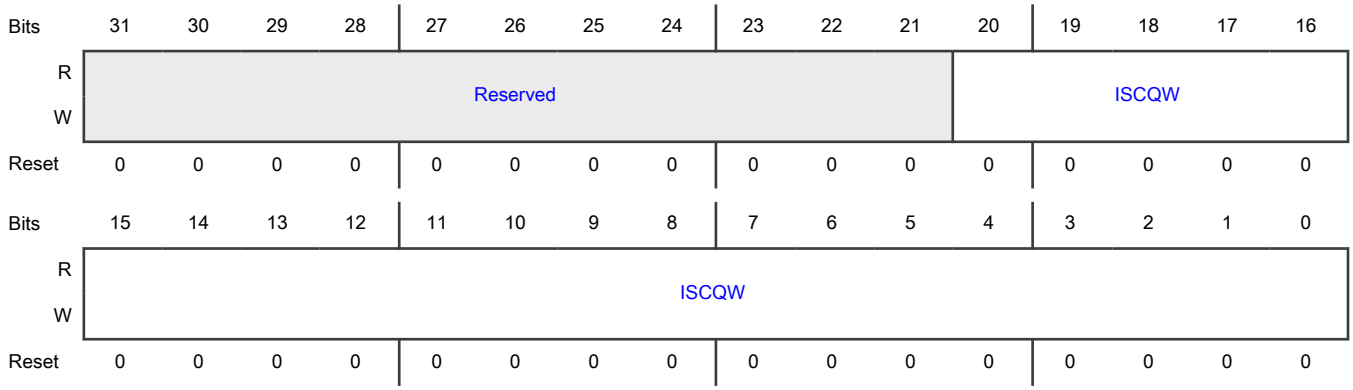
Offset

Register	Offset
MTL_TxQ0_Quantum_Weight	D18h

Function

Contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for queue 0.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-0	Quantum or Weights

Table continues on the next page...

Table continued from the previous page...

Field	Function
ISCQW	Contains the quantum value in bytes which is added to credit during every queue scanning cycle, when DCB operation enables with DWRR algorithm for queue 0 traffic. The maximum value is 0x1312D0 bytes. Contains the weight for this queue, when DCB operation enables with WFQ algorithm for queue 0 traffic. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Write 0 to bits[20:14]. The higher the programmed weights, the lesser is the bandwidth that is allocated for the particular transmit queue. This is because the weights compute the packet finish time (weights*packet_size). The lesser the finish time, the higher is the probability of the packet getting scheduled first and consuming more bandwidth. Contains the weight for this queue, when DCB operation or generic queuing operation enables with WRR algorithm for queue 0 traffic. The maximum value is 0x64. Write 0 to bits [20:7].

74.7.220 MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)

Offset

Register	Offset
MTL_Q0_Interrupt_Control_Status	D2Ch

Function

Contains the interrupt enable and status bits for the queue 0 interrupts.

Diagram

Fields

Field	Function
31-25 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 RXOIE	Receive Queue Overflow Interrupt Enable Enables or disables the receive queue overflow interrupt. When this field is 1, it enables the receive queue overflow interrupt. When this field becomes 0, it disables the receive queue overflow interrupt. 0b - Disabled 1b - Enabled
23-17 —	Reserved.
16 RXOVFIS	Receive Queue Overflow Interrupt Status Indicates whether the status of receive queue overflow interrupt is detected. This bit indicates that the receive queue had an overflow when you receive the packet. If you transfer a partial packet to the application, the overflow status sets in RDES3[21]. This fiels is 0 when the application writes 1 to it. Access restriction apply to this field. It becomes 0 automatically on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
15-10 —	Reserved.
9 ABPSIE	Average Bits Per Slot Interrupt Enable Enables or disables the average bits per slot interrupt. When this field is 1, it indicates that when you update the average bits per slot status, the MAC asserts the sbd_intr_o or mci_intr_o interrupt. When this field is 0, it indicates that the interrupt do not assert for such an event. 0b - Disabled 1b - Enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable Enables or disables transmit queue underflow interrupt. When this field is 1, it enables the transmit queue underflow interrupt. When this field becomes 0, it disables the transmit queue underflow interrupt. 0b - Disabled 1b - Enabled
7-2	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 ABPSIS	Average Bits Per Slot Interrupt Status Indicates whether the status of average bits per slot interrupt is detected. When this field is 1, it indicates that the MAC has updated the ABS value. This field is 0 when the application writes 1 it. Access restriction apply to this field. It becomes 0 automatically on an internal event occurrence. Writing 1 sets this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status Indicates whether the status of transmit queue underflow interrupt is detected. This field indicates that, when you transmit the packet,the transmit queue had an underflow. Suspend the transmission and write 1 to an underflow error TDES3[2]. This field is 0, when the application writes 1 to it. Access restriction apply to this field. It becomes 0 automatically on an internal event occurrence. Writing 1 sets this field and writing 0 has no effect. 0b - Not detected 1b - Detected

74.7.221 MTL Rx Queue 0 Operation Mode (MTL_RxQ0_Operation_Mode)

Offset

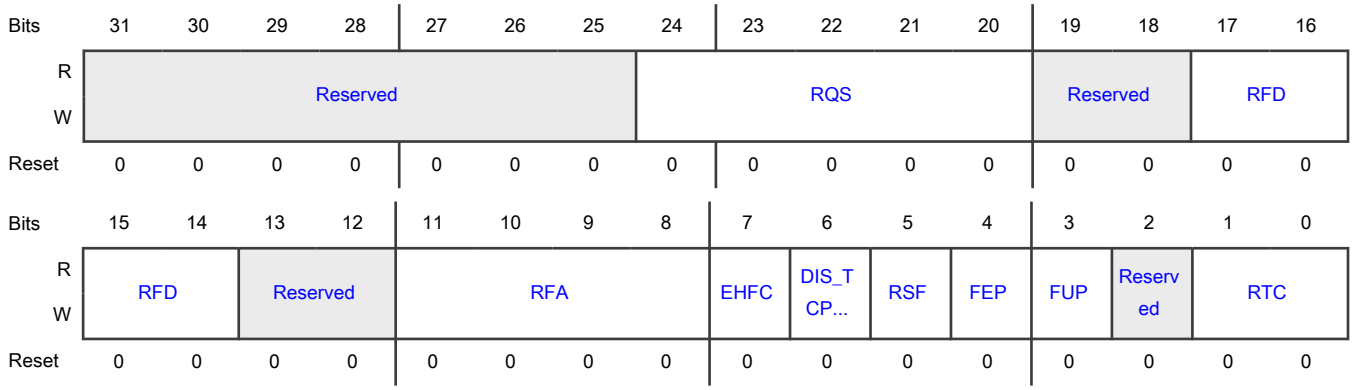
Register	Offset
MTL_RxQ0_Operation_Mode	D30h

Function

Establishes the receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-25 —	Reserved.
24-20 RQS	Receive Queue Size Indicates the size of the allocated receive queues in blocks of 256 bytes. The MTL_RxQ0_Operation_Mode[RQS] is read-write only if the number of receive queues are more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of receive queues is one, the field is read-only and the configured receive FIFO size in blocks of 256 bytes is reflected in the reset value. The field width depends on the receive memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved.
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) Controls the threshold (fill-level of Rx queue) at which the flow control is de-asserts after activation. 0 - Full minus 1 KB, that is, FULL 1 KB 1 - Full minus 1.5 KB, that is, FULL 1.5 KB 2 - Full minus 2 KB, that is, FULL 2 KB 3 - Full minus 2.5 KB, that is, FULL 2.5 KB ... 14 - Full minus 8 KB, that is, FULL 8 KB 15 - Full minus 8.5 KB, that is, FULL 8.5 KB

Table continues on the next page...

Table continued from the previous page...

Field	Function
	De-assertion is effective only after flow control is asserted. **NOTE** You must program the value in such a way that the threshold is a positive number. When MTL_RxQ0_Operation_Mode[EHFC] = 1, these values are applicable only when the receive queue size which the MTL_RxQ0_Operation_Mode[RQS] determines is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size which the MTL_RxQ0_Operation_Mode[RQS] determines. The field width depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved.
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex) Controls the threshold (fill-level of receive queue) at which the flow control is activated. See MTL_RxQ0_Operation_Mode[RFD] for more information on encoding for this field.
7 EHFC	Enable Hardware Flow Control Enables or disables hardware flow control. If this field is 1, it enables the flow control signal operation, on the basis of the fill-level of receive queue. When this field becomes 0, it disables the flow control operation. 0b - Disable 1b - Enable
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets Enables or disable dropping of TCP or IP checksum error packets. When this field is 1, it indicates that the MAC does not drop the packets which only have the errors which the receive checksum offload engine detects. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this field becomes 0, it indicates that all error packets are dropped if MTL_RxQ0_Operation_Mode[FEP] resets. 0b - Enable 1b - Disable
5 RSF	Receive Queue Store and Forward Indicates whether the receive queue store and forward is enabled. When this field is 1, it indicates that the module reads a packet from the receive queue only after the complete packet has been written to it, ignores the MTL_RxQ0_Operation_Mode[RTC].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, it indicates that the receive queue operates in the Threshold (cut-through) mode, subject to the threshold which the MTL_RxQ0_Operation_Mode[RTC] specifies. 0b - Disabled 1b - Enabled
4 FEP	Forward Error Packets Indicates whether the forward error packets are enabled. When this field becomes 0, it indicates that the receive queue drop packets with an error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, the packet does not drop if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode). When this field is 1, it indicates that all packets except the runt error packets are forwarded to the application or DMA. The packet is dropped irrespective of the setting of this field, if MTL_RxQ0_Operation_Mode[RSF] is 1 and the receive queue overflows when a partial packet is written. However, if MTL_RxQ0_Operation_Mode[RSF] becomes 0 and the receive queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Disabled 1b - Enabled
3 FUP	Forward Undersized Good Packets Indicates whether the forward undersized good packets are enabled. When this field is 1, it indicates that the receive queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this field becomes 0, it indicates that the receive queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of receive threshold, for example, MTL_RxQ0_Operation_Mode[RTC] = 01. 0b - Disabled 1b - Enabled
2 —	Reserved.
1-0 RTC	Receive Queue Threshold Control Controls the threshold level of the MTL receive queue (in bytes). The received packet is transferred to the application or DMA when the packet size within the MTL receive queue is larger than the threshold. In addition, automatically tranfer full packets with length less than the threshold. This field is valid only when MTL_RxQ0_Operation_Mode[RSF] = 0. This field is ignored when MTL_RxQ0_Operation_Mode[RSF] = 1. 00b - 64

Fields

Field	Function
31-28 —	Reserved.
27 MISCNTOVF	Missed Packet Counter Overflow Bit Indicates whether the missed packet counter overflow is detected. When this field is 1, it indicates that the receive queue missed packet counter has crossed the maximum limit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
26-16 MISPKTCNT	Missed Packet Counter Indicates the number of packets this module has missed because the application asserts ari_pkt_flush_i[] for this queue. This counter resets when this register reads with mci_be_i[0] at 1b1. This counter increments by 1 when the DMA discards the packet because of buffer unavailability. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.
15-12 —	Reserved.
11 OVFCNTOVF	Overflow Counter Overflow Bit Indicates whether the counter overflow is detected. When this field is 1, it indicates that the receive queue overflow packet counter field has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10-0 OVFPKTCNT	Overflow Packet Counter Indicates the number of packets which this module discards because of receive queue overflow. This counter increments each time the module discards an incoming packet because of overflow. This counter resets when this register reads with mci_be_i[0] at 1'b1. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

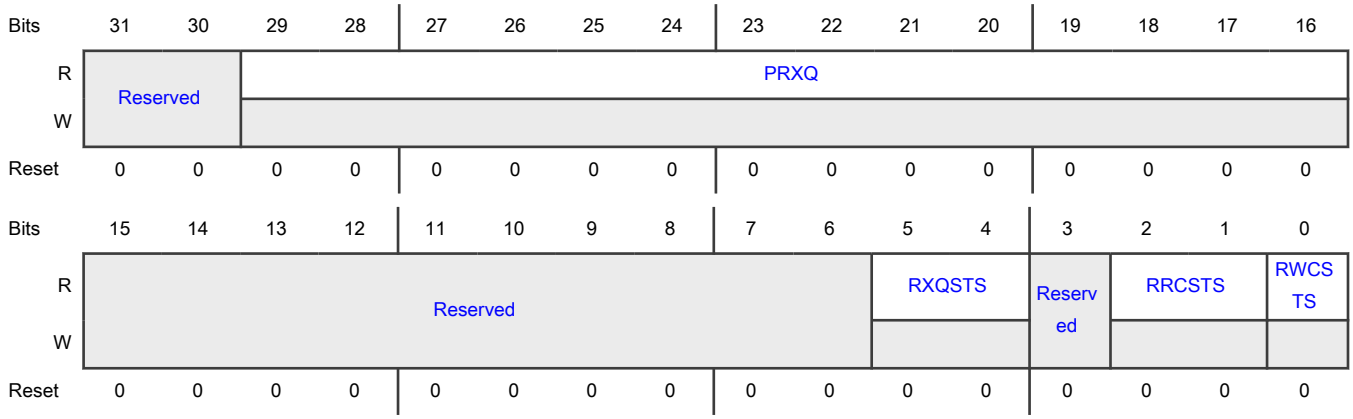
74.7.223 MTL Rx Queue 0 Debug (MTL_RxQ0_Debug)

Offset

Register	Offset
MTL_RxQ0_Debug	D38h

Function
Provides the debug status of various blocks related to the receive queue.

Diagram



Fields

Field	Function
31-30 —	Reserved.
29-16 PRXQ	Number of Packets in Receive Queue Indicates the current number of packets in the receive queue. The theoretical maximum value for this field is 256KB/16B = 16K packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved.
5-4 RXQSTS	MTL Rx Queue Fill-Level Status Provides the status of the receive queue fill-level. 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved.
2-1 RRCSTS	MTL Rx Queue Read Controller State Provides the state of the receive queue read controller. 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 RWCSTS	MTL Rx Queue Write Controller Active Status Indicates whether the MTL receive queue write controller active status is detected. When high, this bit indicates that the MTL receive queue write controller is active, and it is transferring a received packet to the receive queue. 0b - Not detected 1b - Detected

74.7.224 MTL Rx Queue 0 Control 0 (MTL_RxQ0_Control)

Offset

Register	Offset
MTL_RxQ0_Control	D3Ch

Function

Controls the receive arbitration and passing of received packets to the application.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved												RXQ_FRM...	RXQ_WEGT		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration Indicates whether the receive queue packet arbitration is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it indicates that the module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue transmits before switching to other queue. When this field becomes 0, it indicates that the module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue transmits before switching to other queue: • PBL amount of data (indicated by ari_qN_pbl_i[]), or • Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Disabled 1b - Enabled
2-0 RXQ_WEGT	Receive Queue Weight Indicates the weight assigned to receive queue 0. You must write a value to this field that is 1 less than the required queue weight. Therefore, if this field is 0, it indicates that the queue weight is 1, if this field is 1, it indicates that the queue weight is 2, and so on. You must use this weight to calculate the number of continuous PBL or packet requests, depending on the value of RXQ_FRM_ARBIT, allocated to the queue in an arbitration cycle. The field's value changes when the current service round completes or when there is a change from RAA=SP to RAA=WSP algorithm. This approach is required for a smooth transition. You must configure MTL Rx Queue 0 Control 0 (MTL_RxQ0_Control) before MTL Operation Mode (MTL_Operation_Mode) if you want to change the field's value before either of these two processes completes.

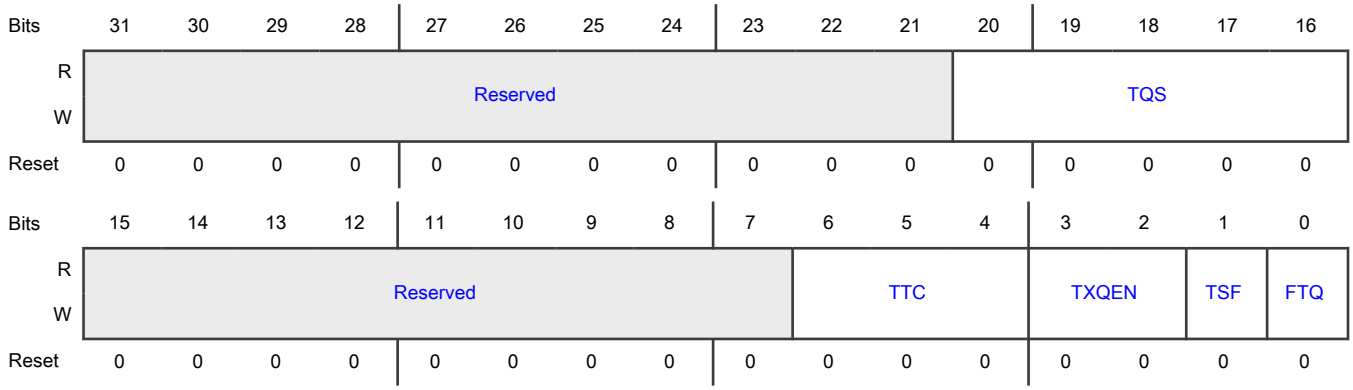
74.7.225 MTL Tx Queue 1 Operation Mode (MTL_TxQ1_Operation_Mode)

Offset

Register	Offset
MTL_TxQ1_Operation_Mode	D40h

Function
Establishes the transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-16 TQS	Transmit Queue Size Indicates the size of the allocated transmit queues in blocks of 256 bytes. This field is read-write only if the number of transit queues is more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (TQS+1)*256 bytes. When the number of transit queues is one, the field is read-only and the reset value reflects the configured TX FIFO size in blocks of 256 bytes. The field width depends on the transit memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved.
6-4 TTC	Transmit Threshold Control Controls the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, it also transmit full packets with length less than the threshold. These fields are used only when the MTL_TxQ1_Operation_Mode[TSF] resets. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable Enables or disables the transmit queue 0. 2'b00 - Not enabled 2'b01 - Enable in AV mode 2'b10 - Enabled 2'b11 - Reserved **NOTE** All the queues disables by default, in multiple transit queues configuration. You must program this field to enable the transit queue. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward Indicates whether the transmit store and forward is enabled. When this field is 1, it indicates that the transmission starts when full packet resides in the MTL transit queue and the TTC values specified in MTL_TxQ1_Operation_Mode[TTC] are ignored. This field must change only when the transmission stops. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue Indicates whether the flush transmit queue is enabled. When this field is 1, it indicates that the transmit queue controller logic resets to its default values. Therefore, all the data in the transit queue is lost or flushed. This field resets internally when the flushing operation completes. Until this field becomes 0, you must not write to MTL_TxQ1_Operation_Mode. The data which the MAC transmitter has already accepted is not flushed. It is scheduled for transmission and results in an underflow and runt packet transmission. **NOTE** The flush operation completes only when the transit queue is empty and the application has accepted the pending transit status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) must be active. Access restriction apply to this field. Writing 1 sets this field and it clears automatically. Writing 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled

74.7.226 MTL Tx Queue 1 Underflow (MTL_TxQ1_Underflow)

Offset

Register	Offset
MTL_TxQ1_Underflow	D44h

Function

Contains the counter for packets aborted because of transmit queue underflow and packets missed because of receive queue packet flush.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31-23	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue Indicates the current number of status in the transit status FIFO of this queue. When MTL_Operation_Mode[DTXSTS] = 1, this field does not reflect the number of status words in transit status FIFO.
19 —	Reserved.
18-16 PTXQ	Number of Packets in the Transmit Queue Indicates the current number of packets in the transit queue. When MTL_Operation_Mode[DTXSTS] = 1, this field does not reflect the number of packets in the transmit queue.
15-6 —	Reserved.
5 TXSTSFSTS	MTL Tx Status FIFO Full Status Indicates whether the MTL transit status FIFO full status is detected. When this field is 1, it indicates that the MTL transit status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - Not detected 1b - Detected
4 TXQSTS	MTL Tx Queue Not Empty Status Indicates whether the MTL transit queue not empty status is detected. When this field is 1, it indicates that the MTL transit queue is not empty and some data is left for transmission. 0b - Not detected 1b - Detected
3 TWCSTS	MTL Tx Queue Write Controller Status Indicates whether the MTL transit queue write controller status is detected. When this field is 1, it indicates that the MTL transit queue write controller is active, and it is transferring the data to the transit queue. 0b - Not detected 1b - Detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status Indicates the state of the transit queue read controller.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending transit status from the MAC transmitter 11b - Flushing the transit queue because of the packet abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause Indicates whether the transmit queue in pause status is detected. When this field is 1 and the receive flow control is enabled, it indicates that the transit queue is in the pause condition (in the full-duplex only mode) because of these scenarios: • Reception of the PFC packet for the priorities assigned to the transit queue when PFC is enabled. • Reception of 802.3x pause packet when PFC is disabled. 0b - Not detected 1b - Detected

74.7.228 MTL Tx Queue 1 ETS Control (MTL_TxQ1_ETS_Control)

Offset

Register	Offset
MTL_TxQ1_ETS_Control	D50h

Function

Controls the enhanced transmission selection operation.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-7 —	Reserved.
6-4 SLC	Slot Count If the credit-based shaper algorithm is enabled, then you can program the number of slots (of duration programmed in DMA_CH(#i)_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TxQ(#i)_ETS_Status register, is computed for queue. The encoding is as follows: 000b - 1 slot 001b - 2 slots 010b - 4 slots 011b - 8 slots 100b - 16 slots 101b - Reserved
3 CC	Credit Control Indicates whether the credit control is enabled. When this field is 1, it indicates that the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero, when there is positive credit and no packet to transmit in channel 1. The credit accumulates even when no packet is waiting in channel 1 and another channel is transmitting. When this field becomes 0, it indicates that the accumulated credit parameter in the credit-based shaper algorithm logic sets to zero, when there is positive credit and no packet to transmit in channel 1. No credit accumulates when no packet is waiting in channel 1 and other channel is transmitting. 0b - Disabled 1b - Enabled
2 AVALG	AV Algorithm Indicates whether the CBS algorithm is enabled. If you program queue 1 for AV, this field configures the scheduling algorithm for this queue. When this field is 1, it indicates that the credit based shaper algorithm (CBS) is selected for queue 1 traffic. If this field becomes 0, strict priority is selected. 0b - Disabled 1b - Enabled
1-0 —	Reserved.

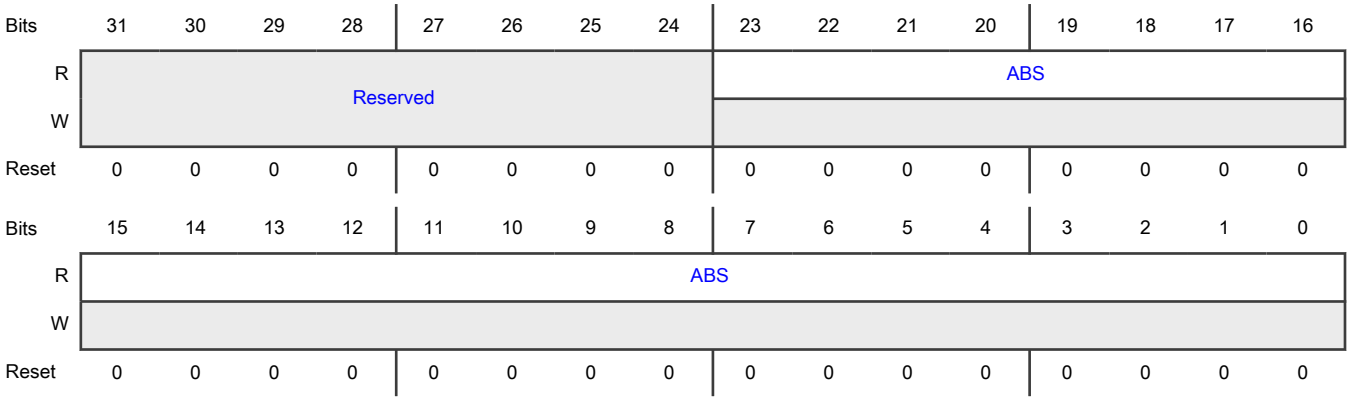
74.7.229 MTL Tx Queue 1 ETS Status (MTL_TxQ1_ETS_Status)

Offset

Register	Offset
MTL_TxQ1_ETS_Status	D54h

Function
Provides the average traffic transmitted in queue 1.

Diagram



Fields

Field	Function
31-24 —	Reserved.
23-0 ABS	Average Bits per Slot Contains the average transmitted bits per slot. Computes this field over number of slots programmed in the MTL_TxQ(#i)_ETS_CONTROL register's SLC field of, if you enables AV operation. This field's maximum value is 0x6_4000 in 100 Mbit/s, 0x3E_8000 in 1000 Mbit/s and 9C_4000 in 2500 Mbit/s mode respectively. Computes this field over every 10 million bit times slot (4 ms in 2500 Mbit/s; 10 ms in 1000 Mbit/s; 100 ms in 100 Mbit/s) when you enables DCB operation for queue. The maximum value is 0x989680.

74.7.230 MTL Tx Queue 1 Quantum Weight (MTL_TxQ1_Quantum_Weight)

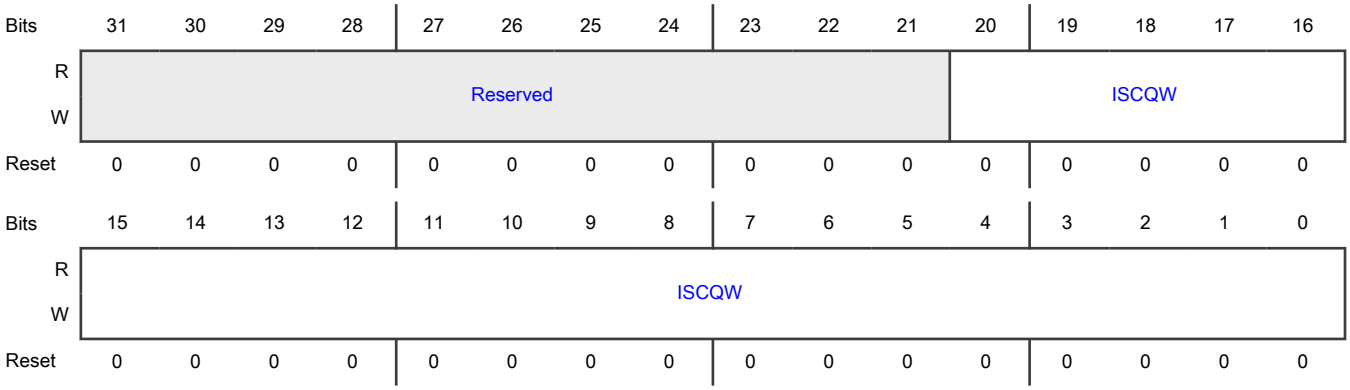
Offset

Register	Offset
MTL_TxQ1_Quantum_Weight	D58h

Function

Provides the average traffic transmitted in queue 1.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-0 ISCQW	idleSlopeCredit, Quantum or Weights idleSlopeCredit Contains the idleSlopeCredit value required for the credit-based shaper algorithm for queue 1, when you enables the AV feature. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbit/s; 8 ns for 1000 Mbit/s; 3.2 ns for 2500 Mbit/s) when the credit is increasing. You must program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbit/s mode and 0x1000 in 100 Mbit/s mode. Bits[20:14] must be written to zero. Quantum Contains the quantum value in bytes to be added to credit during every queue scanning cycle, when you enables the DCB operation with DWRR algorithm for queue 1 traffic. The maximum value is 0x1312D0 bytes. Weights Contains the weight for this queue, when you enables the DCB operation with WFQ algorithm for queue 1 traffic. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. Contains the weight for this queue, when you enables the DCB operation or generic queuing operation with WRR algorithm for queue 1 traffic. The maximum value is 0x64. Bits [20:7] must be written to zero.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE In multiple Queue configuration you must program this field in respective per queue register to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. You must not program this field when only Q0 is enabled. In general, you must program a non-zero value on both receive and transmit when WRR algorithm is selected. In receive, the register is MTL_Operation_Mode register. **NOTE** For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that transmit queue. The finish time is not a function of particular packet alone but it is according to the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) **NOTE** The programmed weights do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

74.7.231 MTL Tx Queue 1 Sendslope Credit (MTL_TxQ1_SendSlopeCredit)

Offset

Register	Offset
MTL_TxQ1_SendSlopeCredit	D5Ch

Function

Contains the sendSlope credit value required for the credit-based shaper algorithm for the queue.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-14 —	Reserved.
13-0 SSC	sendSlopeCredit Value Contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1, when you enables the AV operation. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbit/s, 1000 Mbit/s and 2500 Mbit/s respectively) when the credit is decreasing. You must program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbit/s mode and 0x1000 in 100 Mbit/s mode. You must program this fiels with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when channel 1 is selected for transmission.

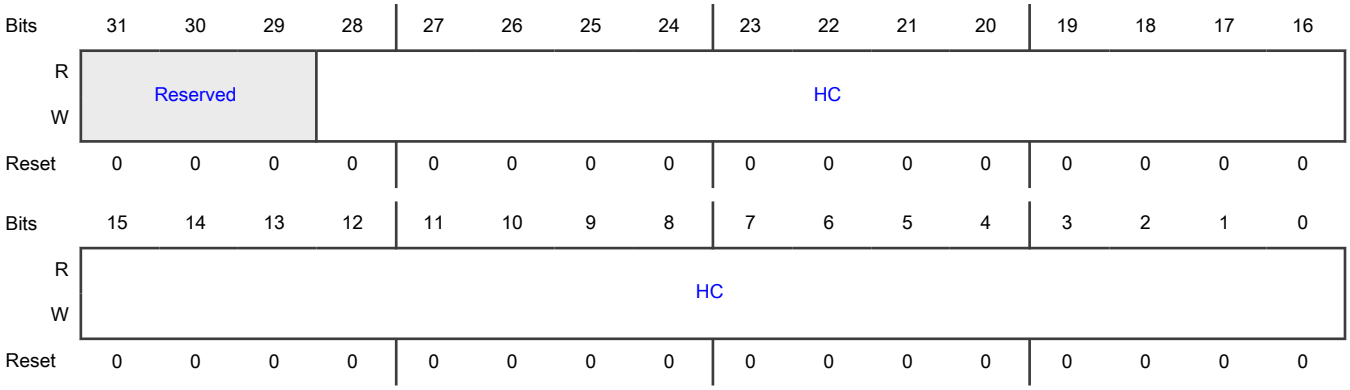
74.7.232 MTL Tx Queue 1 HiCredit (MTL_TxQ1_HiCredit)

Offset

Register	Offset
MTL_TxQ1_HiCredit	D60h

Function
Contains the hiCredit value required for the credit-based shaper algorithm for the queue.

Diagram



Fields

Field	Function
31-29 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
28-0 HC	hiCredit Value Contains the hiCredit value required for the credit-based shaper algorithm, when you enables the AV feature. This is the maximum value that you can accumulate in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The specified value is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

74.7.233 MTL Tx Queue 1 LoCredit (MTL_TxQ1_LoCredit)

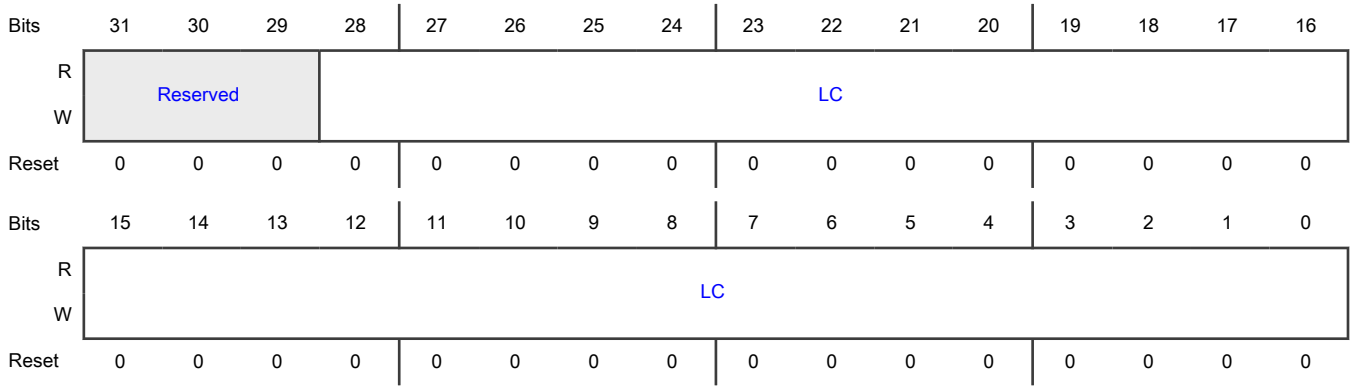
Offset

Register	Offset
MTL_TxQ1_LoCredit	D64h

Function

Contains the loCredit value required for the credit-based shaper algorithm for the queue.

Diagram



Fields

Field	Function
31-29 —	Reserved.
28-0 LC	loCredit Value Contains the loCredit value required for the credit-based shaper algorithm, when you enables the AV operation. This is the minimum value that you can accumulate in the credit parameter. This is specified in bits scaled by 1,024. The maximum value you can program corresponds to twice the maxFrameSize this queue transmits. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. The programmed value is 2's complement of the value, that is, 0x1800_0000 because it is a negative value.

74.7.234 MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)

Offset

Register	Offset
MTL_Q1_Interrupt_Control_Status	D6Ch

Function

Contains the interrupt enable and status bits for the queue 1 interrupts.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-25 —	Reserved.
24 RXOIE	Receive Queue Overflow Interrupt Enable Enables or disables the receive queue overflow interrupt. When this field is 1, it enables the receive queue overflow interrupt. When this field becomes 0, it disables the receive queue overflow interrupt. 0b - Disable 1b - Enable
23-17 —	Reserved.
16 RXOVFIS	Receive Queue Overflow Interrupt Status Indicates whether the status of receive queue overflow interrupt is detected. Indicates that the receive queue had an overflow when it receives the packet. If you transfers a partial packet to the application, the overflow status sets in RDES3[21]. This field is 0 when the application writes 1 to it.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
15-10 —	Reserved.
9 ABPSIE	Average Bits Per Slot Interrupt Enable Indicates whether an average bits per slot interrupt is enabled. When this field is 1, it indicates that the MAC asserts the sbd_intr_o or mci_intr_o interrupt when you update the average bits per slot status. When this field is 0, it indicates that the interrupt is not asserted for such an event. 0b - Disabled 1b - Enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable Enables or disables the transmit queue underflow interrupt. When this field is 1, it enables the transmit queue underflow interrupt. When this field becomes 0, it disables the transmit queue underflow interrupt. 0b - Disabled 1b - Enabled
7-2 —	Reserved.
1 ABPSIS	Average Bits Per Slot Interrupt Status Indicates whether the average bits per slot interrupt status is detected. When this field is 1, it indicates that the MAC has updated the ABS value. This field is 0 when the application writes 1 to it. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status Indicates whether the transmit queue underflow interrupt status is detected. Indicates that the transmit queue had an underflow when you transmits the packet. Suspends the transmission and sets an underflow error TDES3[2]. This field is 0 when the application writes 1 to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writting 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected

74.7.235 MTL Rx Queue 1 Operation Mode (MTL_RxQ1_Operation_Mode)

Offset

Register	Offset
MTL_RxQ1_Operation_Mode	D70h

Function

Establishes the receive queue operating modes and command.

The MTL_RxQ1_Operation_Mode[RFA] and MTL_RxQ1_Operation_Mode[RFD] are not backward compatible with the RFA and RFD fields of 4.00a release.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								RQS				Reserved		RFD	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Fields

Field	Function
31-25 —	Reserved.
24-20 RQS	Receive Queue Size Indicates the size of the allocated receive queues in blocks of 256 bytes. MTL_RxQ1_Operation_Mode[RQS] is read-write only if the number of receive queues is more than one, the

Table continues on the next page...

Table continued from the previous page...

Field	Function
	reset value is 0x0 and indicates 256 bytes size. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of receive queues is one, the field is read-only and the reset value reflects the configured RX FIFO size in blocks of 256 bytes. The field width depends on the receive memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved.
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) Controls the threshold (fill-level of Rx queue) at which the flow control de-asserts after activation 0 - Full minus 1 KB, that is, FULL 1 KB 1 - Full minus 1.5 KB, that is, FULL 1.5 KB 2 - Full minus 2 KB, that is, FULL 2 KB 3 -Full minus 2.5 KB, that is, FULL 2.5 KB ... 14 - Full minus 8 KB, that is, FULL 8 KB 15 - Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only when flow control asserts. **NOTE** Program the value in such a way that the threshold is a positive number. When MTL_RxQ1_Operation_Mode[EHFC] = 1, these values are applicable only when the receive queue size which MTL_RxQ1_Operation_Mode[RQS] determines, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size which MTL_RxQ1_Operation_Mode[RQS] determines. The field width depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved.
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex Controls the threshold (fill-level of Rx queue) at which the flow control activates. See MTL_RxQ1_Operation_Mode[RFD], for more information on encoding for this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 EHFC	Enable Hardware Flow Control Enables or disables hardware flow control. If this field is 1, it enables the flow control signal operation, based on the receive queue's fill-level. When this field becomes 0, it disables the flow control operation. 0b - Disable 1b - Enable
6 DIS_TCP_EF	Disable Dropping of TCP or IP Checksum Error Packets Indicates whether the dropping of TCP or IP checksum error packets is enabled. When this field is 1, it indicates that the MAC does not drop the packets which only have the errors that the receive checksum offload engine detects. Such packets have errors only in the encapsulated payload. MAC receives an Ethernet packet in which there are no errors (including FCS error). When this field becomes 0, it indicates that all the error packets drop if MTL_RxQ1_Operation_Mode[FEP] resets. 0b - Enabled 1b - Disabled
5 RSF	Receive Queue Store and Forward Indicates whether the receive queue store and forward is enabled. When this field is 1, it indicates that the module reads a packet from the receive queue only after the complete packet is written to it and ignores MTL_RxQ1_Operation_Mode[RTC]. When this field becomes 0, it indicates that the receive queue operates in the Threshold (cut-through) mode, subject to the threshold which MTL_RxQ1_Operation_Mode[RTC] specifies. 0b - Disabled 1b - Enabled
4 FEP	Forward Error Packets Indicates whether the forward error packets are enabled. If this field becomes 0, it indicates that the receive queue drops the packets with an error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, the packet does not drops, if the start byte (write) pointer of a packet is already transferred to the read controller side in Threshold mode. When this field is 1, it indicates that all the packets except the runt error packets forward to the application or DMA. If MTL_RxQ1_Operation_Mode[RSF] is 1 and the receive queue overflows when a partial packet is written, the packet drops irrespective of the setting of this field. However, if MTL_RxQ1_Operation_Mode[RSF] resets and the receive queue overflows when a partial packet is written, you may forward a partial packet to the application or DMA. 0b - Disabled 1b - Enabled
3	Forward Undersized Good Packets

Table continues on the next page...

Table continued from the previous page...

Field	Function
FUP	Indicates whether the forward undersized good packets are enabled. When this field is 1, it indicates that the receive queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this field becomes 0, it indicates that the receive queue drops all the packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Disabled 1b - Enabled
2 —	Reserved.
1-0 RTC	Receive Queue Threshold Control Controls the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL receive queue is larger than the threshold. Also, the full packets with length less than the threshold are automatically transferred. This field is valid only when MTL_RxQ1_Operation_Mode[RSF] = 0. This field is ignored when MTL_RxQ1_Operation_Mode[RSF] = 1. 00b - 64 01b - 32 10b - 96 11b - 128

74.7.236 MTL Rx Queue 1 Missed Packet Overflow Counter (MTL_RxQ1_Missed_Packet_Overflow_Cnt)

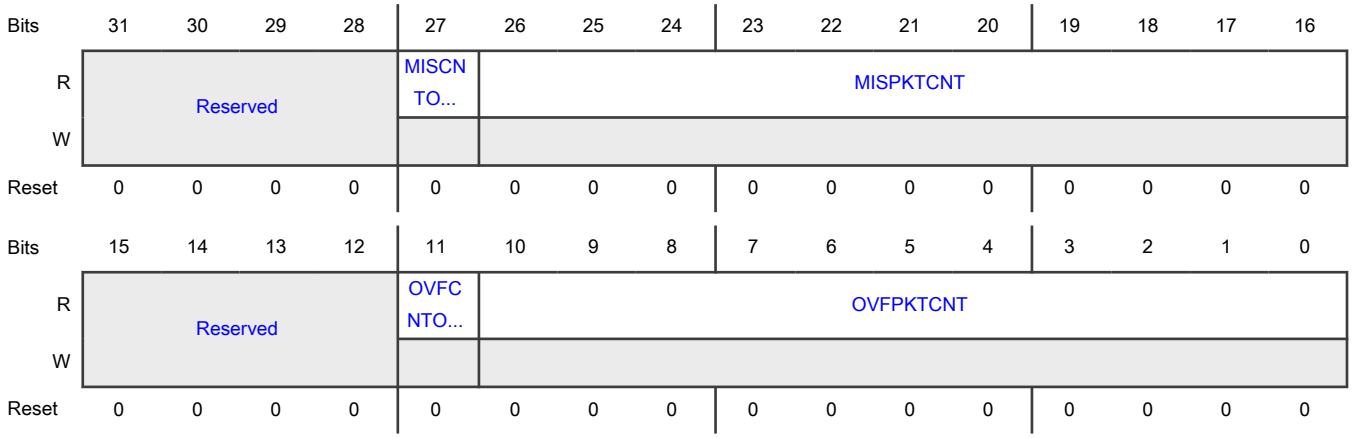
Offset

Register	Offset
MTL_RxQ1_Missed_Packet_Overflow_Cnt	D74h

Function

Contains the counter for packets missed because of receive queue packet flush and packets discarded because of receive queue overflow.

Diagram



Fields

Field	Function
31-28 —	Reserved.
27 MISCNTOVF	Missed Packet Counter Overflow Bit Indicates whether the missed packet counter overflow is detected. When this field is 1, it indicates that the receive queue missed packet counter has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
26-16 MISPKTCNT	Missed Packet Counter Indicates the number of packets the module has missed because the application asserted ari_pkt_flush_i[] for this queue. This counter resets when this register is read with mci_be_i[0] at 1b1. This counter increases by 1 when the DMA discards the packet because of buffer unavailability. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.
15-12 —	Reserved.
11 OVFCNTOVF	Overflow Counter Overflow Bit Indicates whether the counter overflow status is detected. When this field is 1, it indicates that the receive queue overflow packet counter field has crossed the maximum limit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10-0 OVFPKTCNT	Overflow Packet Counter Indicates the number of packets which the module discards because of receive queue overflow. This counter increments each time the module discards an incoming packet because of overflow. It resets when this register is read with mci_be_i[0] at 1'b1. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

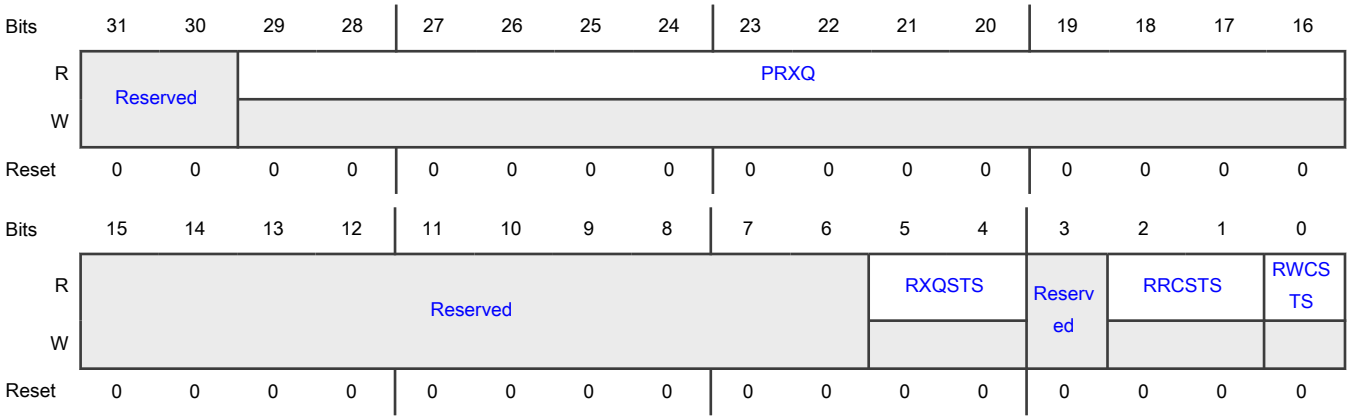
74.7.237 MTL Rx Queue 1 Debug (MTL_RxQ1_Debug)

Offset

Register	Offset
MTL_RxQ1_Debug	D78h

Function
Provides the debug status of various blocks related to the receive queue.

Diagram



Fields

Field	Function
31-30	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
29-16 PRXQ	Number of Packets in Receive Queue Indicates the current number of packets in the receive queue. The theoretical maximum field value is 256KB/16B = 16K packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved.
5-4 RXQSTS	MTL Rx Queue Fill-Level Status Provides the status of the receive queue fill-level. 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved.
2-1 RRCSTS	MTL Rx Queue Read Controller State Provides the state of the receive queue read controller. 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status Indicates whether the MTL receive queue write controller active status is detected. When this field is 1, it indicates that the MTL receive queue write controller is active, and it is transferring a received packet to the receive queue. 0b - Not detected 1b - Detected

74.7.238 MTL Rx Queue 1 Control (MTL_RxQ1_Control)

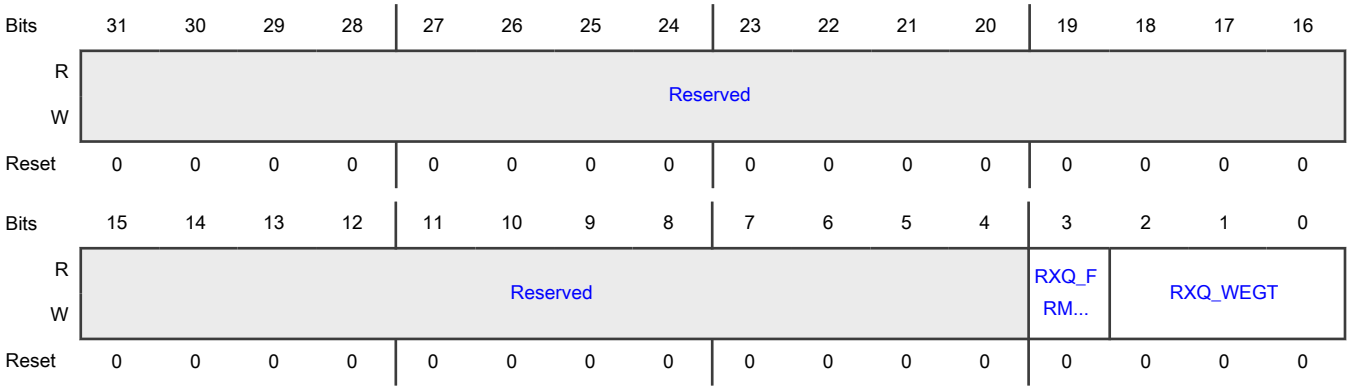
Offset

Register	Offset
MTL_RxQ1_Control	D7Ch

Function

Controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 —	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration Indicates whether the receive queue packet arbitration is enabled. When this field is 1, it indicates that the module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue transmits before switching to other queue. When this field becomes 0, it indicates that the module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue transmits before switching to other queue: • PBL amount of data (indicated by ari_qN_pbl_i[]), or • Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the module drives the complete status (including timestamp status) during the packet's first PBL request (in store-and-forward mode) or the last PBL request (in Threshold mode). 0b - Disabled 1b - Enabled
2-0 RXQ_WEGT	Receive Queue Weight Indicates the weight assigned to the receive queue 0. Program this field with one value less than the required weight, that is reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register.

74.7.239 DMA Mode (DMA_Mode)

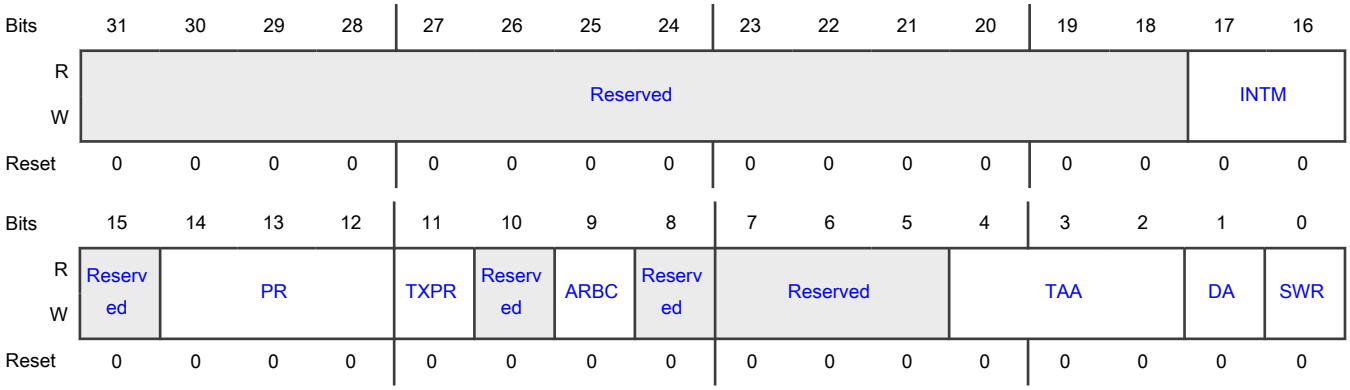
Offset

Register	Offset
DMA_Mode	1000h

Function

Establishes the bus operating modes for the DMA.

Diagram



Fields

Field	Function
31-18 —	Reserved.
17-16 INTM	Interrupt Mode Defines the interrupt mode of module. The behavior of the following outputs changes depending on these settings: sbd_perch_tx_intr_o[] (Transmit per channel interrupt) sbd_perch_rx_intr_o[] (Receive per channel interrupt) sbd_intr_o (Common interrupt) It also changes the behavior of the RI/TI bits in DMA_CH0_Status. 00 - sbd_perch_* are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. sbd_intr_o is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. 01 - sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10 - sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. 11 - Reserved See table "Transfer Complete Interrupt Behavior" for more information. 00b - See above description 01b - See above description 10b - See above description 11b - Reserved
15 —	Reserved.
14-12 PR	Priority Ratio Controls the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These fields are valid only when DMA_Mode[DA] resets. The priority ratio is Rx:Tx or Tx:Rx depending on whether DMA_Mode[TXPR] = 1 or it resets. 000b - The priority ratio is 1:1 001b - The priority ratio is 2:1 010b - The priority ratio is 3:1 011b - The priority ratio is 4:1 100b - The priority ratio is 5:1 101b - The priority ratio is 6:1 110b - The priority ratio is 7:1 111b - The priority ratio is 8:1
11 TXPR	Transmit Priority Indicates whether the transmit priority is enabled. When this field is 1, it indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus. 0b - Disabled 1b - Enabled
10 —	Reserved.
9 ARBC	Is reserved for NXP internal use. This field must always be 0 unless instructed by NXP. Writing 1 to this field may cause unexpected behavior.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - NXP reserved field disabled 1b - NXP reserved field enabled up on NXP request
8 —	Reserved.
7-5 —	Reserved.
4-2 TAA	Transmit Arbitration Algorithm Selects the arbitration algorithm for the transmit side when you select multiple transit DMAs. 000b - Fixed priority (Channel 0 has the lowest priority and the last channel has the highest priority) 001b - Weighted Strict Priority (WSP) 010b - Weighted Round-Robin (WRR) 011b - Reserved (for 3'b011 to 3'b111)
1 DA	DMA Tx or Rx Arbitration Scheme Specifies the arbitration scheme between the transmit and receive paths of all channels. 0 - Weighted round-robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in bits[14:12] and the priority weight is specified in DMA_Mode[TXPR]. 1 - Fixed Priority The transit path has priority over the receive path when DMA_Mode[TXPR] = 1. Otherwise, the receive path has priority over the transit path. 0b - Weighted Round-Robin with Rx:Tx or Tx:Rx 1b - Fixed Priority
0 SWR	Software Reset Indicates whether the software reset is enabled. When this field is 1, it indicates that the MAC and the DMA controller resets the logic and all internal registers of the DMA, MTL, and MAC. This field automatically clears after the reset operation completes in all module clock domains. A value of zero should be read in this field before reprogramming any module register. When this field is 1, it indicates that this field must read at least 4 CSR clock cycles. **NOTE** The reset operation completes only when all resets in all active clock domains de-assert. Therefore, to complete software reset, it is essential that all PHY input clocks (applicable for the selected PHY interface) are present. The time to complete the software reset operation depends on the frequency of the slowest active clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears automatically. Writing 1 sets this field and writting 0 has no effect. 0b - Disabled 1b - Enabled

74.7.240 DMA System Bus Mode (DMA_SysBus_Mode)

Offset

Register	Offset
DMA_SysBus_Mode	1004h

Function

Controls the behavior of the AHB or AXI master. It mainly controls burst splitting and the number of outstanding requests.

Diagram

Field	Function
—	
0 AXWHSTS	AHB Master Status Indicates whether the AXI master write channel or AHB master status is detected. When this field is 1, it indicates that the AHB master FSMs are in the non-idle state. 0b - Not detected 1b - detected

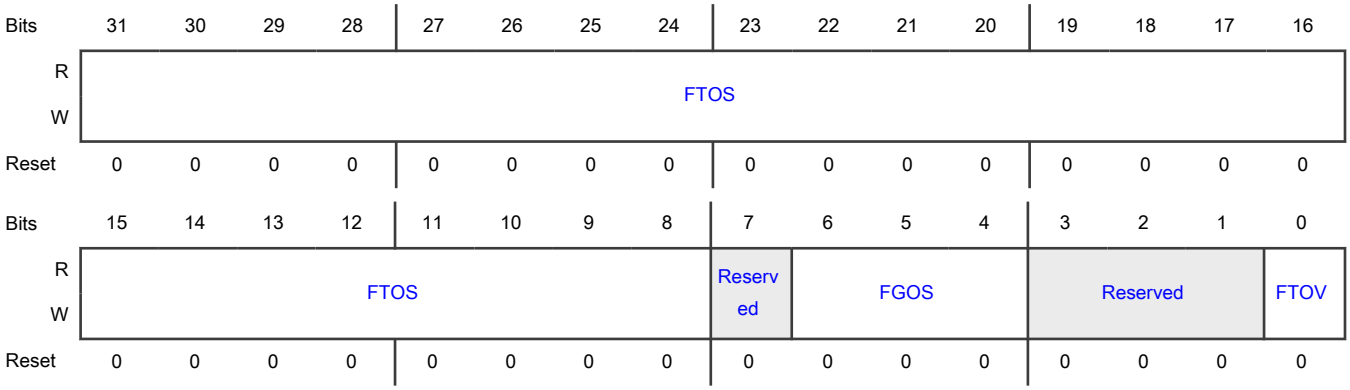
74.7.243 DMA TBS Control (DMA_TBS_CTRL)

Offset

Register	Offset
DMA_TBS_CTRL	1050h

Function
Controls the TBS attributes.

Diagram



Fields

Field	Function
31-8 FTOS	Fetch Time Offset Deduct the value in units of 256 nanoseconds, from the launch time to compute the fetch Time. Max value: 999,999,999 nanosecond, must be smaller than CTR-1 value when ESTM mode = 1, because this value is a modulo CTR value.
7	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6-4 FGOS	Fetch GSN Offset Deduct the number GSN slots from the launch GSN to compute the fetch GSN. The value is valid only when DMA_TBS_CTRL[FTOV] = 1.
3-1 —	Reserved.
0 FTOV	Fetch Time Offset Valid Indicates whether the fetch time offset is valid. When this field is 1, it indicates that DMA_TBS_CTRL[FTOS] is valid. When this field is not 1, it indicates that the fetch offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0b - Invalid 1b - Valid

74.7.244 DMA Safety Interrupt Status (DMA_Safety_Interrupt_Status)

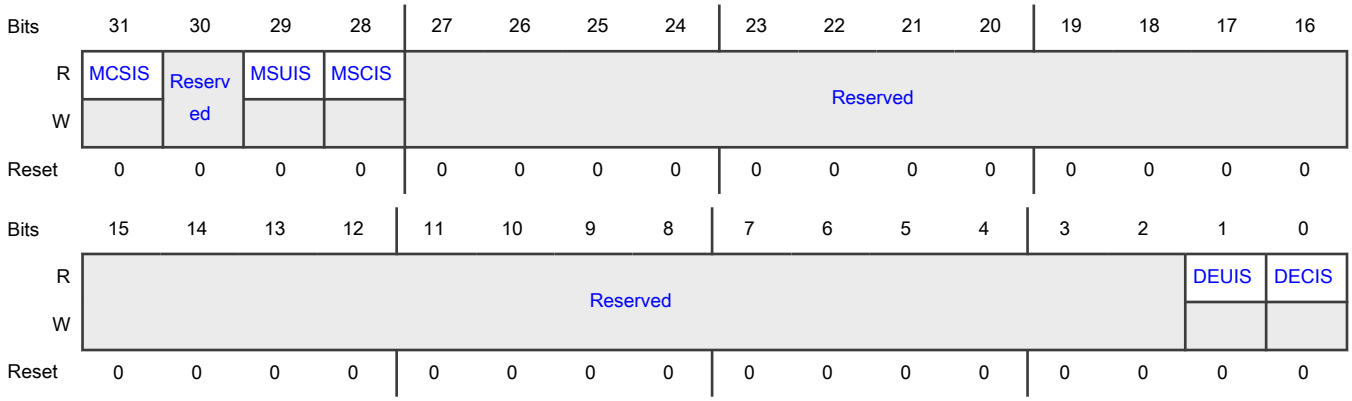
Offset

Register	Offset
DMA_Safety_Interrupt_Status	1080h

Function

Indicates summary (whether error occured in DMA/MTL/MAC and correctable/uncorrectable) of the automotive safety related error interrupts.

Diagram



Fields

Field	Function
31 MCSIS	MAC Safety Uncorrectable Interrupt Status Indicates whether the MAC safety uncorrectable interrupt status is detected. Indicates that an uncorrectable safety related interrupt is 1 in the MAC module. When this field is 1, it indicates that you must read the MAC_DPP_FSM_Interrupt_Status, to get the cause of the safety interrupt in MAC. 0b - Not detected 1b - Detected
30 —	Reserved.
29 MSUIS	MTL Safety Uncorrectable Error Interrupt Status Indicates whether the MTL safety uncorrectable error interrupt status is detected. Indicates an uncorrectable error interrupt event in MTL. To get exact cause of the interrupt you must read the MTL_Safety_Interrupt_Status. 0b - Not detected 1b - Detected
28 MSCIS	MTL Safety Correctable Error Interrupt Status Indicates whether the MTL safety correctable error interrupt status is detected. Indicates a correctable error interrupt event in MTL. To get the exact cause of the interrupt you must read the MTL_Safety_Interrupt_Status. 0b - Not detected 1b - Detected
27-2 —	Reserved.
1 DEUIS	DMA ECC Uncorrectable Error Interrupt Status Indicates whether the DMA ECC uncorrectable error interrupt status is deducted. Indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt the application must read the DMA_ECC_Interrupt_Status register. 0b - Not detected 1b - Detected
0 DECIS	DMA ECC Correctable Error Interrupt Status Indicates whether the DMA ECC correctable error interrupt status is detected. Indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt the application must read the DMA_ECC_Interrupt_Status register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not detected 1b - Detected

74.7.245 DMA Channel 0 Control (DMA_CH0_Control)

Offset

Register	Offset
DMA_CH0_Control	1100h

Function

Specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved							Reserved	Reserved				DSL			Reserved	PBLx8

Fields

Field	Function
31-25 —	Reserved.
24 —	Reserved.
23-21 —	Reserved.
20-18	Descriptor Skip Length

Table continues on the next page...

Table continued from the previous page...

Field	Function
DSL	Specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. The DMA assumes the descriptor table as contiguous, when the DSL value is equal to zero.
17 —	Reserved.
16 PBLx8	8xPBL mode Indicates whether 8xPBL mode is enabled. When this field is 1, it indicates that the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - Disabled 1b - Enabled
15-14 —	Reserved.
13-0 —	Reserved.

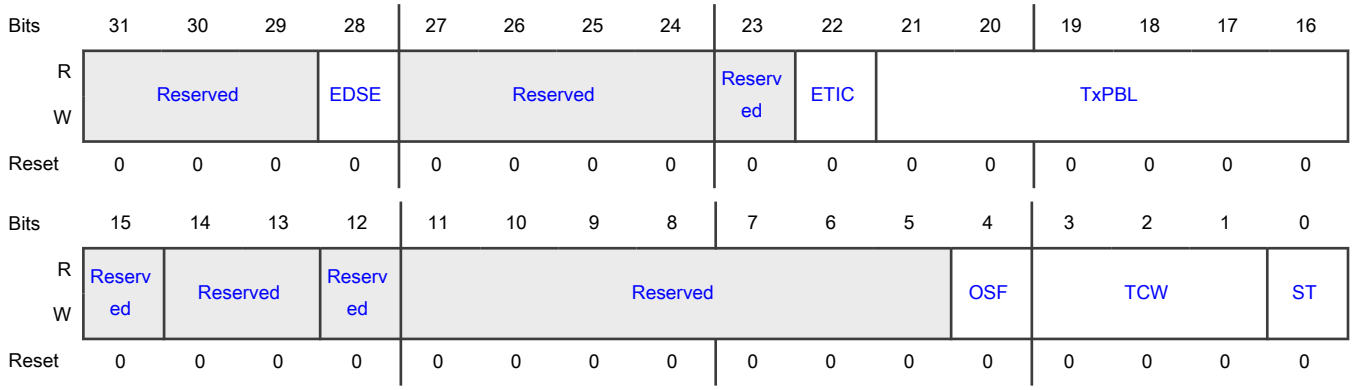
74.7.246 DMA Channel Tx Control (DMA_CH0_Tx_Control)

Offset

Register	Offset
DMA_CH0_Tx_Control	1104h

Function
Controls the transmit features such as PBL, TCP segmentation, and transmit channel weights.

Diagram



Fields

Field	Function
31-29 —	Reserved.
28 EDSE	Enhanced Descriptor Enable Indicates whether an enhanced descriptor is enabled. When this field is 1, it indicates that the corresponding channel uses 32 bytes enhanced descriptors for both normal and context descriptors. When this field becomes 0, it indicates that the corresponding channel uses the 16 bytes descriptors. 0b - Disabled 1b - Enabled
27-24 —	Reserved.
23 —	Reserved.
22 ETIC	Early Transmit Interrupt Control Indicates whether an early transmit interrupt is enabled. When this field is 1, it indicates that an early transmit interrupt (ETI) status = 1 after the data transfer from buffers of a transmit descriptor completes in which IOC bit (TDES2[31]) = 1. When this field becomes 1, it indicates that ETI = 1 only after a complete packet transfers to the MTL TX FIFO memory. 0b - Disabled 1b - Enabled
21-16 TxPBL	Transmit Programmable Burst Length

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the maximum number of beats to transfer in one DMA block data transfer. DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. Perform these steps to transfer more than 32 beats: 1. Set DMA_CH0_Control[PBLx8]. 2. Set the TxPBL. **NOTE** The maximum value of TxPBL must be less than or equal to half the transit queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the transit queue has space to store at least another TxPBL worth of data while the MTL Tx queue controller transfers data to MAC. For example, in 64-bit data width configurations the total locations in transit queue of size 512 bytes is 64. You must program TxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-13 —	Reserved.
12 —	Reserved.
11-5 —	Reserved.
4 OSF	Operate on Second Packet Indicates whether the operation on second packet is enabled. When this field is 1, it instructs DMA to process the second packet of the transmit data even before you receive the status for the first packet. 0b - Disabled 1b - Enabled
3-1 TCW	Transmit Channel Weight Indicates the weight assigned to the corresponding transmit channel. When reset completes, this field is 0 for all the channels by default, which results in equal weights to all channels.
0 ST	Start or Stop Transmission Command Indicates whether to start or stop the transmission command. When this field is 1, it indicates that the transmission is in the running state. DMA checks the transmit list at the current position for a packet to be transmitted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DMA tries to acquire descriptor from either of these positions: • The current position in the list. This is the base address of the transmit list to which DMA_CH0_TxDesc_List_Address sets. • The position at which the transmission was previously stopped. The transmission enters the suspended state and DMA_CH0_Status[TBU] = 1, if DMA does not own the current descriptor. The start transmission command is effective only when the transmission stops. If the command is issued before setting DMA_CH0_TxDesc_List_Address, you cannot predict the DMA behavior. When this field becomes 0, it indicates that the transmission process is placed in the stopped state when the transmission of the current packet completes . The next descriptor position in the transmit list is saved, and it becomes the current position when you restart the transmission. To change the list address, you must program DMA_CH0_TxDesc_List_Address with a new value when this field becomes 0.You can consider the new value when this field is 1 again. The stop transmission command is effective only when the transmission of the current packet completes or the transmission is in the suspended state. 0b - Stop 1b - Start

74.7.247 DMA Channel Rx Control (DMA_CH0_Rx_Control)

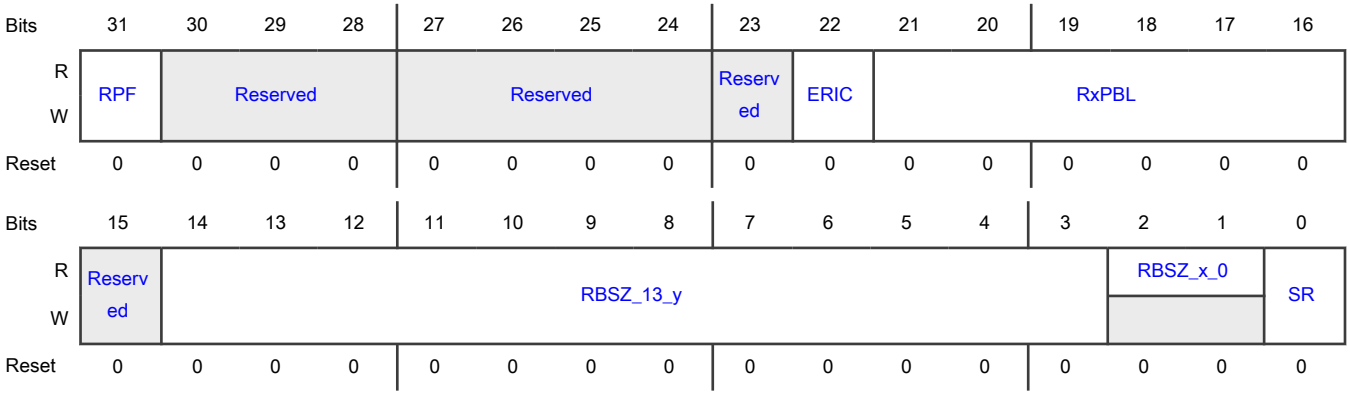
Offset

Register	Offset
DMA_CH0_Rx_Control	1108h

Function

Controls the receive features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush Indicates whether the receive packet flush is enabled. When this field is 1, it indicates that the module automatically flushes the packet from the receive queues destined to this DMA receive channel, when it stops. When this field remains 1 and the software driver re-starts DMA, the packets residing in the receive queues that were received when this RxDMA stops and flushes out. The packets that MAC receives after the RxDMA re-starts, route to the RxDMA. The flushing takes place on the read side of the receive queue. When this field is 0, it indicates that the module do not flush the packet in the receive queue destined to this RxDMA channel when it is in STOP state. This may cause head-of-line blocking in the corresponding receive queue. **NOTE** The packet flow from a receive DMA channel to the application by writing 1 to this field stops, only when there is one-to-one mapping of receive queue to receive DMA channels. In Dynamic mapping mode, writing 1 to this field in any DMA_CH(#i)_Rx_Control register might flush packets from an unintended receive queues which are destined to the stopped receive DMA channel. 0b - Disabled 1b - Enabled
30-28 —	Reserved.
27-24 —	Reserved.
23 —	Reserved.
22 ERIC	Early Receive Interrupt Control Indicates whether an early receive interrupt is enabled. When this field is 1, it indicates that the early receive interrupt (ERI) status sets after every burst transfer of data from the Rx DMA to the buffer completes. When this field becomes 0, it indicates that ERI sets only after a complete buffer is filled by the RxDMA. 0b - Disabled 1b - Enabled
21-16 RxPBL	Receive Programmable Burst Length Indicates the maximum number of beats to be transferred in one DMA block data transfer. DMA always attempts max burst as specified in PBL every time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Set DMA_CH0_Control[PBLx8]. 2. Set the RxPBL. **NOTE** The maximum value of RxPBL must be less than or equal to half the receive queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the receive queue has space to store at least another Rx PBL worth of data while the receive DMA transfers a block of data. For example, in 64-bit data width configurations the total locations in receive queue of size 512 bytes is 64. You must program RxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-3 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] splits into two fields, higher field is RBSZ_13_y and lower field is RBSZ_x_0. RBSZ[13:0] field indicates the receive buffers size specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. **NOTE** The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the buffer address pointer value is not aligned with data bus width. Hence the lower RBSZ_x_0 fields are read-only and the value is considered as all-zero. Thus RBSZ_13_y field indicates the buffer size in terms of locations (with the width same as bus-width).
2-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] splits into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. The field width is of 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive Indicates whether to start or stop receive. When this field is 1, it indicates that the DMA tries to acquire the descriptor from the receive list and processes the incoming packets. DMA tries to acquire descriptor from either of these positions: • The current position in the list. This is the address which DMA_CH0_RxDesc_List_Address sets. • The position at which the receive process was previously stopped. If DMA does not own the current descriptor, the reception is suspended and DMA_CH0_Status[RBU] = 1. The start receive command is effective only when the reception stops. If the command is issued before setting DMA_CH0_RxDesc_List_Address, the DMA behavior is unpredictable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, it indicates that the receive DMA operation stops after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the receive process restarts. The stop receive command is effective only when the receive process is in the running (waiting for receive packet) or suspended state. 0b - Stop 1b - Start

74.7.248 DMA Channel 0 Tx Descriptor List Address (DMA_CH0_TxDesc_List_Address)

Offset

Register	Offset
DMA_CH0_TxDesc_List_Address	1114h

Function

Specifies DMA to the start of transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA internally converts it to bus width aligned address by making the corresponding LSB low.

You can write to this register only when the transit DMA stops, that is, DMA_CH0_Tx_Control[ST] = 0. When stopped, write this register with a new descriptor list address. When DMA_CH0_Tx_Control[ST] = 1, DMA uses the newly-programmed descriptor base address. If this register does not change when DMA_CH0_Tx_Control[ST] = 0, DMA uses the descriptor address where it was stopped earlier.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-2	Start of Transmit List

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDESLA	Contains the base address of the first descriptor in the transmit descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

74.7.249 DMA Channel 0 Rx Descriptor List Address (DMA_CH0_RxDesc_List_Address)

Offset

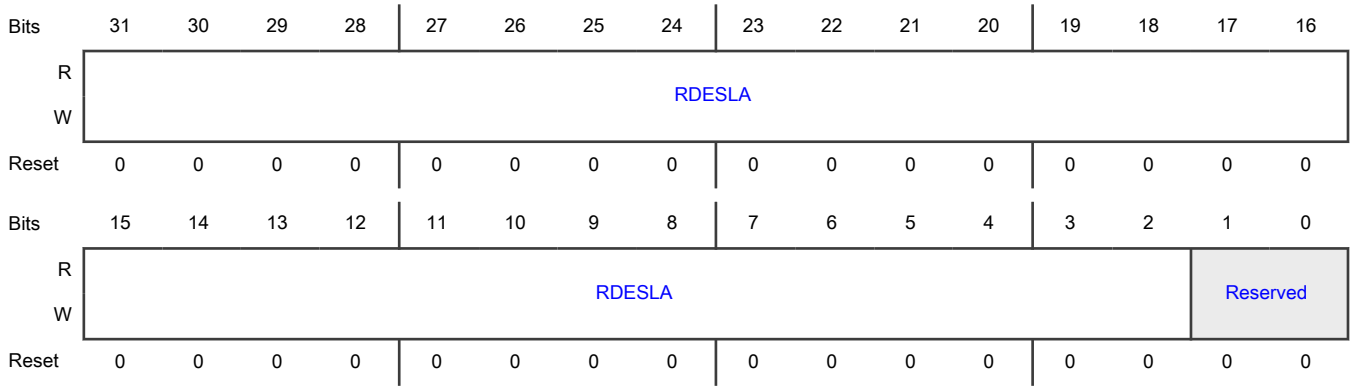
Register	Offset
DMA_CH0_RxDesc_List_Address	111Ch

Function

Specifies DMA to the start of receive descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA internally converts it to bus width aligned address by making the corresponding LS bits low. You can write to this register only when reception stops. When stopped, write this register before the receive start command is given. You can write to this register only when Rx DMA stops, that is, DMA_CH0_Rx_Control[SR] = 0. When stopped, write this register with a new descriptor list address.

When DMA_CH0_Rx_Control[SR] = 1, it indicates that DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-2 RDESLA	Start of Receive List Contains the base address of the first descriptor in the receive descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration

This field also enables the following interrupts in DMA_CH0_Status: -Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt When this field becomes 0, it disables the normal interrupt summary. 0b - Disable 1b - Enable
14	Abnormal Interrupt Summary Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
AIE	Enables or disables the abnormal interrupt summary. When this field is 1, it enables the abnormal interrupt summary. This field also enables the following interrupts in DMA_CH0_Status: Bit 1 - Transmit process stopped Bit 7 - Rx buffer unavailable Bit 8 - Receive process stopped Bit 9 - Receive watchdog timeout Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error When this field becomes 0, it disables the abnormal interrupt summary. 0b - Disable 1b - Enable
13 CDEE	Context Descriptor Error Enable Enables or disables the context descriptor error. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the descriptor error interrupt. When this field becomes 0, it disables the descriptor error interrupt. 0b - Disable 1b - Enable
12 FBEE	Fatal Bus Error Enable Enables or disables the fatal bus error. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the fatal bus error interrupt. When this field becomes 0, it disables the fatal bus error interrupt. 0b - Disable 1b - Enable
11 ERIE	Early Receive Interrupt Enable Enables or disables the early receive interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the early receive interrupt. When this field becomes 0, it disables the early receive interrupt. 0b - Disable 1b - Enable
10 ETIE	Early Transmit Interrupt Enable Enables or disables the early transmit interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the early transmit interrupt. When this field becomes 0, it disables the early transmit interrupt. 0b - Disable 1b - Enable
9 RWTE	Receive Watchdog Timeout Enable Enables or disables the receive watchdog timeout. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive watchdog timeout interrupt. When this field becomes 0, it disables the receive watchdog timeout interrupt. 0b - Disable 1b - Enable
8 RSE	Receive Stopped Enable Enables or disables the receive stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive stopped interrupt. When this field becomes 0, it disables the receive stopped interrupt. 0b - Disable 1b - Enable
7 RBUE	Receive Buffer Unavailable Enable Enables or disables the receive buffer unavailable interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive buffer unavailable interrupt. When this field becomes 0, it disables the receive buffer unavailable interrupt. 0b - Disable 1b - Enable
6 RIE	Receive Interrupt Enable Enables or disables the receive interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the receive interrupt. When this field becomes 0, it disables the receive interrupt. 0b - Disable 1b - Enable
5-3 —	Reserved.
2 TBUE	Transmit Buffer Unavailable Enable Enables or disables the transmit buffer unavailable interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit buffer unavailable interrupt. When this field becomes 0, it disables the transmit buffer unavailable interrupt. 0b - Disable 1b - Enable
1 TXSE	Transmit Stopped Enable Enables or disables the transmit stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the transmission stopped interrupt. When this field becomes 0, it disables the transmission stopped interrupt. 0b - Disable 1b - Enable
0 TIE	Transmit Interrupt Enable Enables or disables the transmit interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit interrupt. When this field becomes 0, it disables the transmit interrupt. 0b - Disable 1b - Enable

74.7.255 DMA Channel 0 Rx Interrupt Watchdog Timer (DMA_CH0_Rx_Interrupt_Watchdog_Timer)

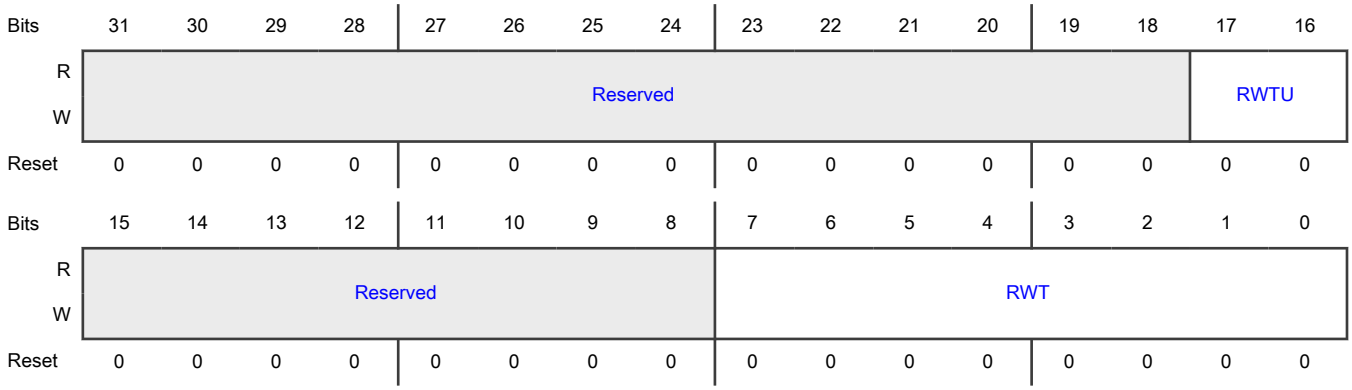
Offset

Register	Offset
DMA_CH0_Rx_Interrupt_Watchdog_Timer	1138h

Function

Indicates the watchdog timeout for receive interrupt (RI) from DMA. When you write this register with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 —	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units Indicates the system clock cycles number corresponding to one unit in DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWT]. 2'b00 - 256 2'b01 - 512 2'b10 - 1024 2'b11 - 2048 For example, when DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWT] = 2 and DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWTU] = 1, the watchdog timer sets for 2*512=1024 system clock cycles.
15-8 —	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count Indicates the number of system clock cycles, multiplied by factor which DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWTU] indicates, for which you set the watchdog timer. The watchdog timer triggers with the programmed value after the receive DMA completes the packet transfer for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of interrupt enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, it indicates that the RI bit is 1 and the timer stops. The watchdog timer resets when the RI bit is 1 because of automatic setting of RI per the interrupt enable bit RDES3[30] of any received packet.

74.7.256 DMA Channel 0 Slot Function Control Status (DMA_CH0_Slot_Function_Control_Status)

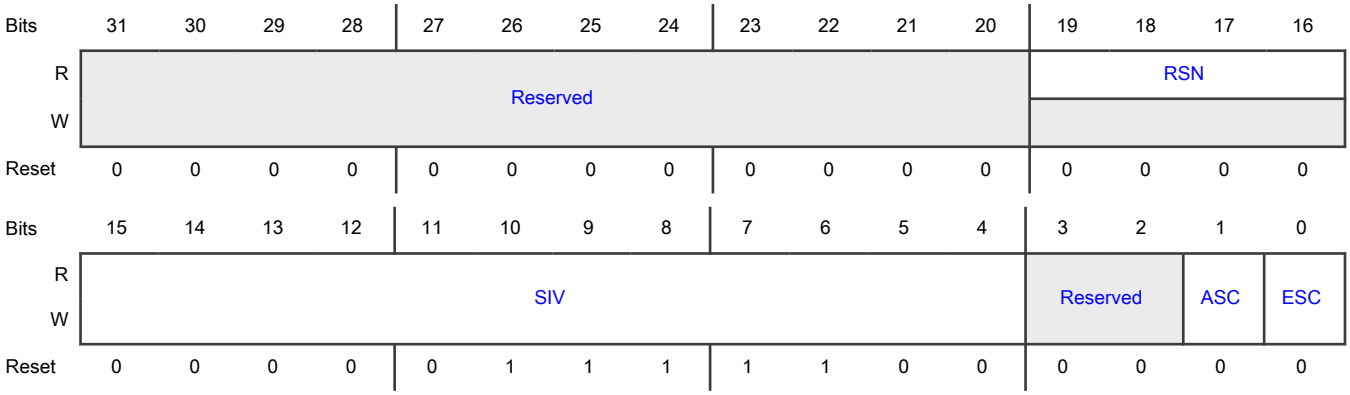
Offset

Register	Offset
DMA_CH0_Slot_Function_Control_Status	113Ch

Function

Contains the control bits for slot function and the status for transmit path.

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 RSN	Reference Slot Number Provides the current value of the reference slot number in DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value Controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default or reset value is 0x07C which corresponds to slot interval of 125 us
3-2 —	Reserved.
1 ASC	Advance Slot Check Indicates whether the advance slot check is enabled. When this field is 1, it enables DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transit descriptor is either:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Equal to the reference slot number given in DMA_CH0_Slot_Function_Control_Status[RSN], or Ahead of the reference slot number by up to two slots. This field is applicable only when DMA_CH0_Slot_Function_Control_Status[ESC] = 1. 0b - Disabled 1b - Enabled
0 ESC	Enable Slot Comparison Indicates whether the slot comparison is enabled. When this field is 1, it enables the checking of the slot numbers programmed in the transit descriptor with the current reference given in DMA_CH0_Slot_Function_Control_Status[RSN]. DMA fetches the data from the corresponding buffer only when the slot number is either: • Equal to the reference slot number, or • Ahead of the reference slot number by one slot. When this field becomes 0, it disables the checking of the slot numbers. DMA fetches the data immediately after you process the descriptor. **NOTE** You must not enable the UFO (UDP Fragmentation over IPv4)/TSO/USO along with TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets/segments/ fragments transmission for single packet received from application and the slot number check are applicable for fetching only first segment/fragment. As a result it might be difficult for you to specify slot number for subsequent packets. 0b - Disabled 1b - Enabled

74.7.257 DMA Channel 0 Current Application Transmit Descriptor (DMA_CH0_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH0_Current_App_TxDesc	1144h

Function
Specifies the current transmit descriptor which DMA reads.

Diagram

Field	Function
31-0 CURRDESAPTR	Application Receive Descriptor Address Pointer Indicates that the DMA updates this pointer during the receive operation. This pointer clears when reset.

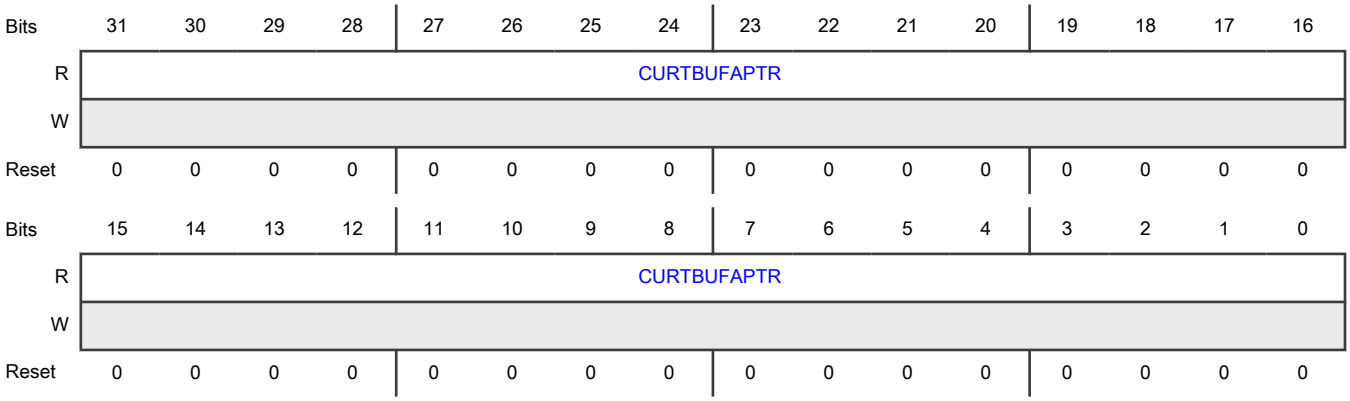
74.7.259 DMA Channel 0 Current Application Transmit Descriptor (DMA_CH0_Current_App_TxBuffer)

Offset

Register	Offset
DMA_CH0_Current_App_TxBuffer	1154h

Function
Specifies the current transit buffer address which DMA reads.

Diagram



Fields

Field	Function
31-0 CURTBUFAPTR	Application Transmit Buffer Address Pointer Indicates that DMA updates this pointer during the transit operation. This pointer clears when reset.

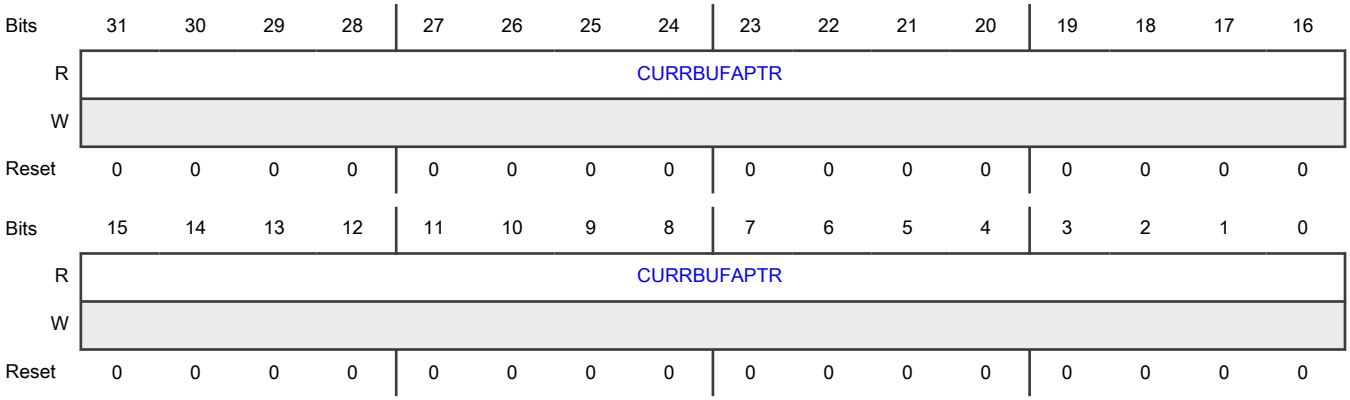
74.7.260 DMA Channel 0 Current Application Receive Buffer (DMA_CH0_Current_App_RxBuffer)

Offset

Register	Offset
DMA_CH0_Current_App_RxBuffer	115Ch

Function
Specifies the current receive buffer address which DMA read.

Diagram



Fields

Field	Function
31-0 CURRBUFAPTR	Application Receive Buffer Address Pointer Indicates that DMA updates this pointer during the receive operation. This pointer clears when reset.

74.7.261 DMA Channel 0 Status (DMA_CH0_Status)

Offset

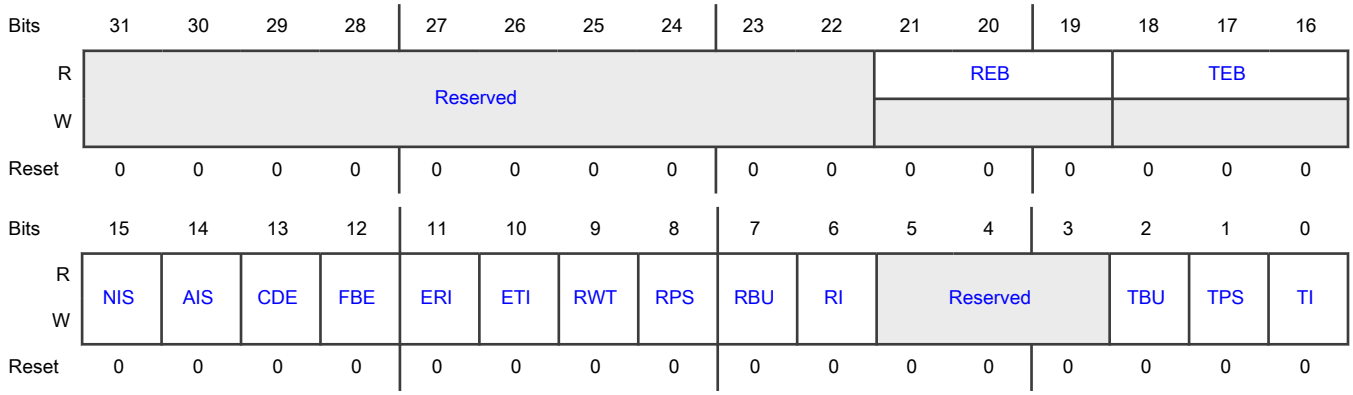
Register	Offset
DMA_CH0_Status	1160h

Function
Indicates that the software driver (application) reads the status register during an interrupt service routine or polling to determine the DMA status.

NOTE

The number of DMA_CH(#i)_Status register in the configuration is the higher of number of receive DMA channels and transit DMA channels.

Diagram



Fields

Field	Function
31-22 —	Reserved.
21-19 REB	Rx DMA Error Bits Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface. Bit 21 1'b1 - Error during data transfer by Rx DMA 1'b0 - No Error during data transfer by Rx DMA Bit 20 1'b1 - Error during descriptor access 1'b0 - Error during data buffer access Bit 19 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH0_Status[FBE] = 1. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface. Bit 18 1'b1 - Error during data transfer by Tx DMA 1'b0 - No Error during data transfer by Tx DMA Bit 17 1'b1 - Error during descriptor access 1'b0 - Error during data buffer access

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Bit 16 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH0_Status[FBE] = 1. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Indicates whether the normal interrupt summary status is detected. This field is the logical OR of the following bits when you enables the corresponding interrupt bits in DMA_CH0_Interrupt_Enable: Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt Only unmasked bits (interrupts for which interrupt enable sets in DMA_CH0_Interrupt_Enable) affect this field. This is a sticky bit. You must clear this field by writing 1 to it each time a corresponding field which sets this field clears. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
14 AIS	Abnormal Interrupt Summary Indicates whether an abnormal interrupt summary status is detected. This field is the logical OR of the following bits when you enables the corresponding interrupt bits in DMA_CH0_Interrupt_Enable: Bit 1 - Transmit process stopped Bit 7 - Receive buffer unavailable Bit 8 - Receive process stopped Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error Only unmasked bits affect this field. This is a sticky bit. You must clear this field by writing 1 to it each time a corresponding field, which sets this field, clears. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not detected 1b - Detected
13 CDE	Context Descriptor Error Indicates whether the context descriptor error status is detected. This field indicates that the DMA Tx/Rx engine receives a descriptor error, which indicates an invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in transit case and on receive side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
12 FBE	Fatal Bus Error Indicates whether the fatal bus error status is detected. This field indicates that a bus error occurred (as described in the EB field). When this field is 1, it indicates that the corresponding DMA channel engine disables all bus accesses. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
11 ERI	Early Receive Interrupt Indicates whether an early receive interrupt status is detected. When this field is 1, it indicates that the RxDMA completes the packet data transfer to the memory. In configs supporting ERIC, this field is 1 only after the receive DMA fills a complete receive buffer with packet data, when DMA_CH0_Rx_Control[ERIC] = 0. This field is 1 after every burst transfer of data from the receive DMA to the buffer, when DMA_CH0_Rx_Control[ERIC] = 1. Writing 1 to RI field automatically clears this field. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
10 ETI	Early Transmit Interrupt Indicates whether an early transmit interrupt status is detected. When this field is 1, it indicates that the TxDMA completes the packet data transfer to the MTL TXFIFO memory.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In configs supporting ERIC: this field is 1 only after the transit DMA transfers a complete packet to MTL, when DMA_CH0_Tx_Control[ETIC] = 0. This field is 1 after packet data transfers from buffer completes (partial) in the transmit descriptor in which IOC = 1, when DMA_CH0_Tx_Control[ETIC] = 1. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
9 RWT	Receive Watchdog Timeout Indicates whether the receive watchdog timeout status is detected. Asserts when you receives a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled). 0b - Not detected 1b - Detected
8 RPS	Receive Process Stopped Indicates whether the receive process stopped status is detected. Asserts when the receive process enters the stopped state. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
7 RBU	Receive Buffer Unavailable Indicates whether the receive buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the receive list, and DMA cannot acquire it. The receive process is suspended. To resume processing receive descriptors, the application must change the ownership of the descriptor and issue a receive poll demand command. If this command is not issued, the receive process resumes when you receive the next recognized incoming packet. In ring mode, the application must advance the receive descriptor tail pointer register of a channel. This field is 1 only when DMA owns the previous receive descriptor. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
6 RI	Receive Interrupt Indicates that the receive interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates that the packet reception is complete. When packet reception completes, bit 31 of RDES3 resets in the last descriptor, and you can update the specific packet status information in the descriptor. The reception remains in the running state. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
5-3 —	Reserved.
2 TBU	Transmit Buffer Unavailable Indicates whether the transmit buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the transmit list, and the DMA cannot acquire it. Transmission is suspended. DMA_Debug_Status0[TPS0] explains the transmit process state transitions. To resume processing the transmit descriptors, the application must perform these steps: 1. Change the ownership of the descriptor by writing 1 to bit 31 of TDES3. 2. Issue a transmit poll demand command. For Ring mode, the application must advance the transmit descriptor tail pointer register of a channel. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
1 TPS	Transmit Process Stopped Indicates whether the transmit process stopped status is detected. This field is 1 when the transmission stops. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TI	Transmit Interrupt Indicates whether the transmit interrupt status is detected. This field indicates that the packet transmission is complete. When transmission completes, Bit 31 of TDES3 resets in the last descriptor, and you can update the specific packet status information in the descriptor.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected

74.7.262 DMA Channel 0 Miss Frame Counter (DMA_CH0_Miss_Frame_Cnt)

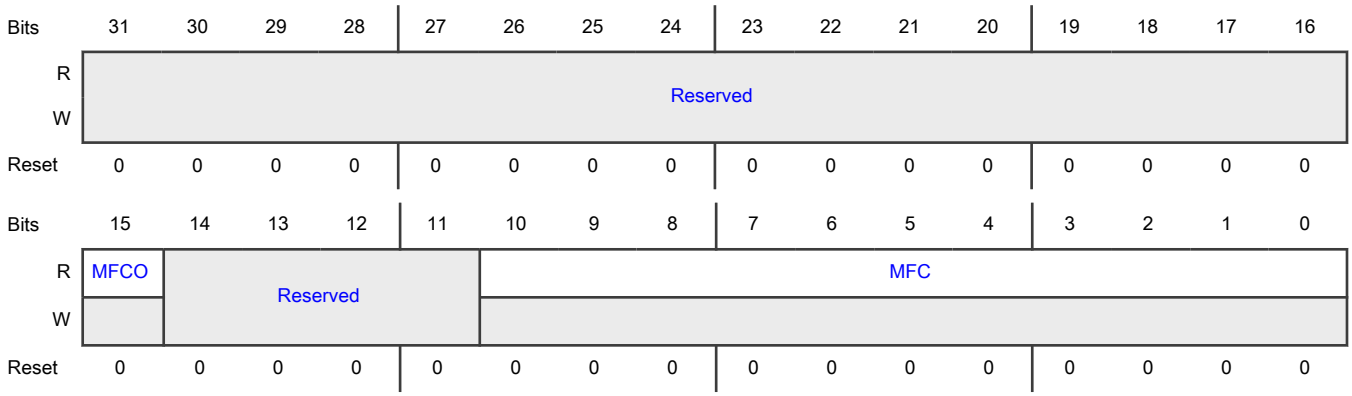
Offset

Register	Offset
DMA_CH0_Miss_Frame_Cnt	1164h

Function

Indicates the number of packet counter that DMA drops either due to bus error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Diagram



Fields

Field	Function
31-16 —	Reserved.
15 MFCO	Overflow status of the MFC Counter Indicates whether the miss frame counter overflow has occurred. When this field is 1, it indicates that the MFC counter does not increment further. This field is 0 when this register is read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
14-11 —	Reserved.
10-0 MFC	Dropped Packet Counters Indicates the number of packet counters that DMA drops either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. This field is 0 when this register is read. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

74.7.263 DMA Channel 0 Rx Parser Accept Count (DMA_CH0_RXP_Accept_Cnt)

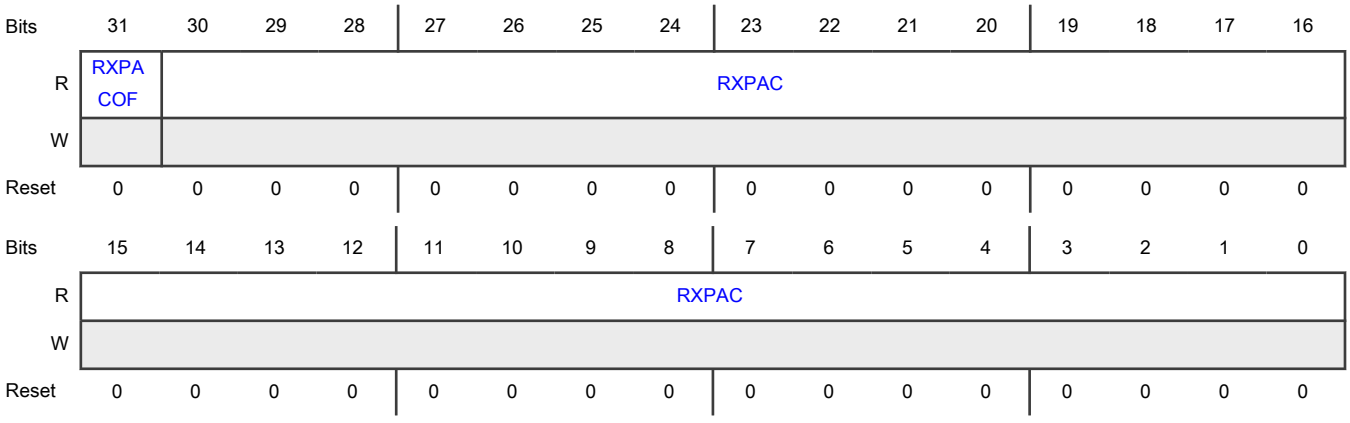
Offset

Register	Offset
DMA_CH0_RXP_Accept_Cnt	1168h

Function

Provides the count of the number of frames which the receive parser accept.

Diagram



Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit Indicates whether the receive parser accept counter overflow has occurred. When this field is 1, it indicates that the RXPAC counter field has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPAC	Rx Parser Accept Counter Implements whenever a receive parser accept a packet because AF = 1. The counter clears when the register is read.

74.7.264 DMA Channel 0 Rx ERI Count (DMA_CH0_RX_ERI_Cnt)

Offset

Register	Offset
DMA_CH0_RX_ERI_Cnt	116Ch

Function
Provides the count of the number of times ERI is asserted.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continued from the previous page...

Field	Function
—	
11-0 ECNT	ERI Counter Indicates that when ERIC bit of DMA_CH(#i)_RX_Control register is 1, this counter increments for burst transfer which the receive DMA completes from the start of packet transfer. This field becomes 0 at the start of new packet.

74.7.265 DMA Channel 1 Control (DMA_CH1_Control)

Offset

Register	Offset
DMA_CH1_Control	1180h

Function

Specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24 —	Reserved.
23-21	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
20-18 DSL	Descriptor Skip Length Specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When this field is 0, it indicates that DMA takes the descriptor table as contiguous.
17 —	Reserved.
16 PBLx8	8xPBL mode Indicates whether the 8xPBL mode is enabled. When this field is 1, it indicates that you must program the PBL value in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control and multiply it eight times. Therefore, DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - Disabled 1b - Enabled
15-14 —	Reserved.
13-0 —	Reserved.

74.7.266 DMA Channel 1 Tx Control (DMA_CH1_Tx_Control)

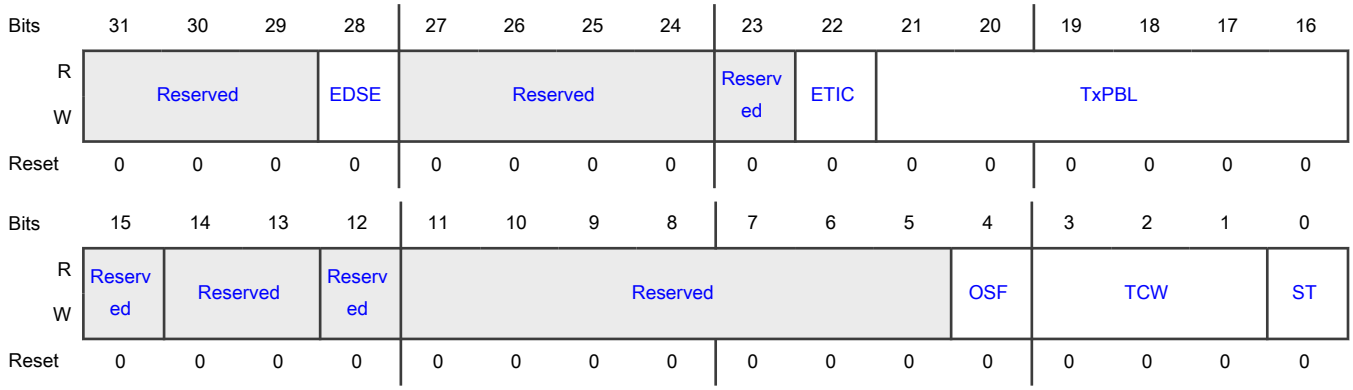
Offset

Register	Offset
DMA_CH1_Tx_Control	1184h

Function

Controls the transmit features such as PBL, TCP segmentation, and transmit channel weights.

Diagram



Fields

Field	Function
31-29 —	Reserved.
28 EDSE	Enhanced Descriptor Enable Indicates whether an enhanced descriptor is enabled. When this field is 1, it indicates that the corresponding channel uses enhanced descriptors that are 32 Bytes for both normal and context descriptors. When this field becomes 0, it indicates that the corresponding channel uses the descriptors that are 16 Bytes. 0b - Disabled 1b - Enabled
27-24 —	Reserved.
23 —	Reserved.
22 ETIC	Early Transmit Interrupt Control Indicates whether an early transmit interrupt is enabled. When this field is 1, it indicates that an early transmit interrupt (ETI) status sets after the data transfer completes from buffers of a transmit descriptor in which IOC bit (TDES2[31]) sets. When this field becomes 0, it indicates that the ETI sets only after a complete packet transfers to the MTL TX FIFO memory. 0b - Disabled 1b - Enabled
21-16	Transmit Programmable Burst Length

Table continues on the next page...

Table continued from the previous page...

Field	Function
TxPBL	Indicates the maximum number of beats to transfer in one DMA block data. DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in an undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Write 1 to DMA_CH0_Control[PBLx8]. 2. Write 1 to this field. **NOTE** The maximum value of this field must be less than or equal to half the transit queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the transit queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue controller transfers data to MAC. For example, in 64-bit data width configurations the total locations in transit queue of size 512 bytes is 64. You must program TxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-13 —	Reserved.
12 —	Reserved.
11-5 —	Reserved.
4 OSF	Operate on Second Packet Indicates whether an operation on second packet is enabled. When this field is 1, it instructs DMA to process the second packet of the transmit data even before the first packet status is obtained. 0b - Disabled 1b - Enabled
3-1 TCW	Transmit Channel Weight Indicates the weight assigned to the corresponding transmit channel. When reset completes, this field becomes 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command Indicates whether to start or stop transmission command. When this field is 1, it indicates that the transmission is placed in the running state. DMA checks the transmit list at the current position to transmit a packet.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DMA tries to acquire descriptor from either of the following positions: • The current position in the list. This is the base address of the transmit list which DMA_CH0_TxDesc_List_Address sets. • The position at which the transmission was previously stopped If DMA does not own the current descriptor, the transmission enters the suspended state and DMA_CH0_Status[TBU] = 1. The start transmission command is effective only when the transmission stops. If you issue the command before writing 1 to DMA_CH0_TxDesc_List_Address, then DMA behavior is unpredictable. When this field becomes 0, it indicates that the transmission process is placed in the stopped state after the transmission of the current packet completes. The next descriptor position in the transmit list is saved, and it becomes the current position when the transmission restarts. To change the list address, you must program DMA_CH0_TxDesc_List_Address with a new value when this field becomes 0. The new value is considered when this field is 1 again. The stop transmission command is effective only when the transmission of the current packet completes or the transmission is in the suspended state. 0b - Stop 1b - Start

74.7.267 DMA Channel 1 Rx Control (DMA_CH1_Rx_Control)

Offset

Register	Offset
DMA_CH1_Rx_Control	1188h

Function

Controls the receive features such as PBL, buffer size, and extended status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 RPF	Rx Packet Flush Indicates whether the receive packet flush is enabled. When this field is 1, it indicates that the module automatically flushes the packet from the receive queues destined to this DMA receive channel, when it stops. When this field remains 1 and the software driver re-starts DMA, the packets residing in the receive queues that were received when this RxDMA was stopped, flushes out. Route the packets to the RxDMA that the MAC receives after the RxDMA re-starts. The flushing takes place on the read side of the receive queue. When this field is 0, it indicates that the module do not flush the packet in the receive queue destined to this RxDMA channel when it is in stop state. This might in turn cause head-of-line blocking in the corresponding RxQueue. **NOTE** The stopping of packet flow from a Rx DMA Channel to the application by writing 1 to this field works only when there is one-to-one mapping of receive queue to the receive DMA channels. In Dynamic mapping mode, writing 1 to this field in any DMA_CH(#i)_Rx_Control register might flush packets from unintended receive queues which are destined to the stopped Rx DMA Channel. 0b - Disabled 1b - Enabled
30-28 —	Reserved.
27-24 —	Reserved.
23 —	Reserved.
22 ERIC	Early Receive Interrupt Control Indicates whether an early receive interrupt control status is enabled. When this field is 1, it indicates that an early receive interrupt (ERI) status sets after every burst transfer of data from the receive DMA to the buffer completes. When this field becomes 0, it indicates that ERI sets only after the RxDMA fills the complete buffer is filled. 0b - Disabled 1b - Enabled
21-16 RxPBL	Receive Programmable Burst Length Indicates the maximum number of beats to transfer in one DMA block data. DMA always attempts max burst as specified in PBL, each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in an undefined behavior. To transfer more than 32 beats, perform the following steps:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Write 1 to DMA_CH0_Control[PBLx8]. 2. Write 1 to RxPBL. **NOTE** The maximum value of RxPBL must be less than or equal to half the receive queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the receive queue has space to store at least another Rx PBL worth of data when the receive DMA transfers a block of data. For example, in 64-bit data width configurations the total locations in receive queue of size 512 bytes is 64, so you must program RxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-3 RBSZ_13_y	Receive Buffer size High Indicates that RBSZ[13:0] splits into two fields higher RBSZ_13_y and lower RBSZ_x_0. RBSZ[13:0] field indicates the size of the receive buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when you enable split headers. **NOTE** The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
2-1 RBSZ_x_0	Receive Buffer size Low Indicates that RBSZ[13:0] splits into two fields RBSZ_13_y and RBSZ_x_0. RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field width is of 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive Indicates whether to start or stop receive. When this field is 1, it indicates that DMA tries to acquire the descriptor from the receive list and processes the incoming packets. DMA tries to acquire descriptor from either of the following positions: • The current position in the list. This is the address that DMA_CH0_RxDesc_List_Address sets. • The position at which the receive process was previously stopped If DMA does not own the current descriptor, the reception suspends and DMA_CH0_Status[RBU] = 1. The start receive command is effective only when the reception stops. If the command is issued before writing 1 to DMA_CH0_RxDesc_List_Address, DMA behavior is unpredictable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, it indicates that the receive DMA operation stops after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the receive process restarts. The stop receive command is effective only when the receive process is in the running (waiting for Rx packet) or suspended state. 0b - Stop 1b - Start

74.7.268 DMA Channel 1 Tx Descriptor List Address (DMA_CH1_TxDesc_List_Address)

Offset

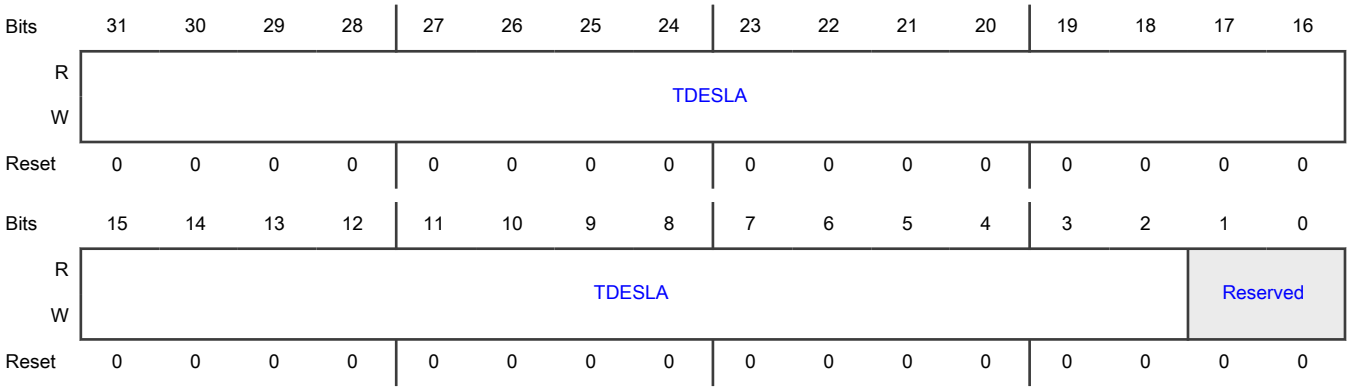
Register	Offset
DMA_CH1_TxDesc_List_Address	1194h

Function

Specifies DMA to the start of transmit descriptor list. The descriptor lists reside in the application's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA converts the corresponding LSB bits to low to internally convert the descriptor lists to bus width aligned address.

You can write to this register only when the transmit DMA stops, that is, DMA_CH0_Tx_Control[ST] = 0. When stopped, you can write this register with a new descriptor list address. When DMA_CH0_Tx_Control[ST] = 1, the DMA takes the newly-programmed descriptor base address. If this register do not change when DMA_CH0_Tx_Control[ST] = 0, DMA takes the descriptor address where it was stopped earlier.

Diagram



Fields

Field	Function
31-2	Start of Transmit List

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDESLA	Contains the first descriptor base address in the transmit descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally assumes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

74.7.269 DMA Channel 1 Rx Descriptor List Address (DMA_CH1_RxDesc_List_Address)

Offset

Register	Offset
DMA_CH1_RxDesc_List_Address	119Ch

Function

Specifies DMA to the start of receive descriptor list. The descriptor lists resides in the application's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA converts the correspondong LS bits low to internally convert the descriptor lists to bus width aligned address. You can write to this register only when reception stops. When stopped, you must write this register before the receive start command is given.

You can write to this register when receive DMA has stopped, that is, DMA_CH0_Rx_Control[SR] = 0. When stopped, you can this register with a new descriptor list address.

When DMA_CH0_Rx_Control[SR] = 1, DMA takes the newly programmed descriptor base address.

15 NIE	Normal Interrupt Summary Enable Enables or disables the normal interrupt summary. When this field is 1, it enables the normal interrupt summary. This field also enables the following interrupts in DMA_CH0_Status: Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt When this field becomes 0, it disables the normal interrupt summary. 0b - Disable 1b - Enable
14	Abnormal Interrupt Summary Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
AIE	Enables or disables the abnormal interrupt summary. When this field is 1, it enables the abnormal interrupt summary. This field also enables the following interrupts in DMA_CH0_Status: Bit 1 - Transmit process stopped Bit 7 - Rx buffer unavailable Bit 8 - Receive process stopped Bit 9 - Receive watchdog timeout Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error When this field becomes 0, it disables the abnormal interrupt summary. 0b - Disable 1b - Enable
13 CDEE	Context Descriptor Error Enable Enables or disables the context descriptor error. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the descriptor error interrupt. When this field becomes 0, it disables the descriptor error interrupt. 0b - Disable 1b - Enable
12 FBEE	Fatal Bus Error Enable Enables or disables fatal bus error. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the fatal bus error interrupt. When this field becomes 0, it disables the fatal bus error interrupt. 0b - Disable 1b - Enable
11 ERIE	Early Receive Interrupt Enable Enables or disables the early receive interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the early receive interrupt. When this field becomes 0, it disables the early receive interrupt. 0b - Disable 1b - Enable
10 ETIE	Early Transmit Interrupt Enable Enables or disables the early transmit interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the early transmit interrupt. When this field becomes 0, it disables the early transmit interrupt. 0b - Disable 1b - Enable
9 RWTE	Receive Watchdog Timeout Enable Enables or disables the receive watchdog timeout interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive watchdog timeout interrupt. When this field becomes 0, it disables the receive watchdog timeout interrupt. 0b - Disable 1b - Enable
8 RSE	Receive Stopped Enable Enables or disables the receive stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], It enables the receive stopped interrupt. When this field becomes 0, it disables the receive stopped interrupt. 0b - Disable 1b - Enable
7 RBUE	Receive Buffer Unavailable Enable Enables or disables the receive buffer unavailable interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive buffer unavailable interrupt. When this field becomes 0, it disables the receive buffer unavailable interrupt. 0b - Disable 1b - Enable
6 RIE	Receive Interrupt Enable Enables or disables the receive interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the receive interrupt. When this field becomes 0, it disables the receive interrupt. 0b - Disable 1b - Enable
5-3 —	Reserved.
2 TBUE	Transmit Buffer Unavailable Enable Enables or disables the transmit buffer unavailable interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit buffer unavailable interrupt. When this field becomes 0, it disables the transmit buffer unavailable interrupt. 0b - Disable 1b - Enable
1 TXSE	Transmit Stopped Enable Enables or disables the transmit stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the transmission stopped interrupt. When this field becomes 0, it disables the transmission Stopped interrupt. 0b - Disable 1b - Enable
0 TIE	Transmit Interrupt Enable Enables or disables the transmit interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit interrupt. When this field becomes 0, it disables the transmit interrupt. 0b - Disable 1b - Enable

74.7.275 DMA Channel 1 Rx Interrupt Watchdog Timer (DMA_CH1_Rx_Interrupt_Watchdog_Timer)

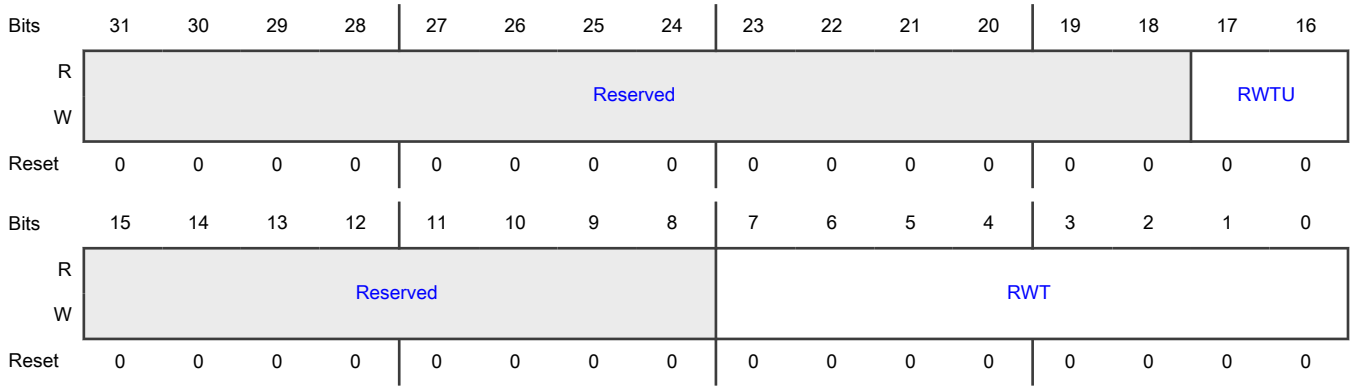
Offset

Register	Offset
DMA_CH1_Rx_Interrupt_Watchdog_Timer	11B8h

Function

Indicates the watchdog timeout for receive interrupt (RI) from DMA. When you write this register with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 —	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units Indicates the number of system clock cycles corresponding to one unit in DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWT]. 2'b00 - 256 2'b01 - 512 2'b10 - 1024 2'b11 - 2048 For example, the watchdog timer sets for 2*512=1024 system clock cycles, when DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWT] = 2 and DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWTU] = 1.
15-8 —	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count Indicates the number of system clock cycles, multiplied by factor indicated in DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWTU], for which the watchdog timer sets. The watchdog timer triggers with the programmed value after the receive DMA completes the packet transfer for which the RI bit is not 1 in DMA_CH(#i)_Status register, because of the setting of interrupt enable bit in the corresponding descriptor RDES3[30]. RI bit is 1 and the timer stops when the watchdog timer runs out. The watchdog timer becomes 0 when RI bit is 1 because RI sets automatically per the interrupt enable bit RDES3[30] of any received packet.

74.7.276 DMA Channel 1 Slot Function Control Status (DMA_CH1_Slot_Function_Control_Status)

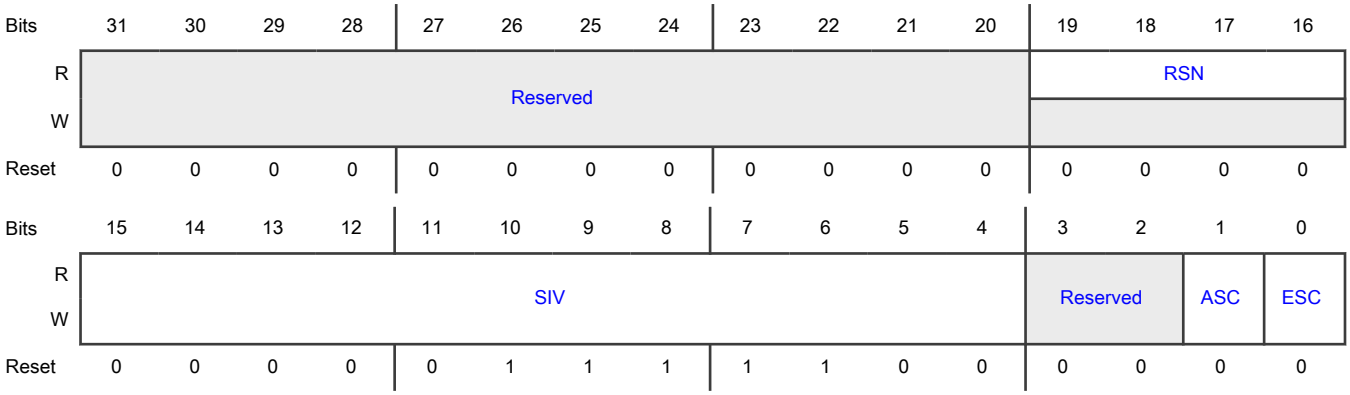
Offset

Register	Offset
DMA_CH1_Slot_Function_Control_Status	11BCh

Function

Contains the control field for slot function and the status for transmit path.

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 RSN	Reference Slot Number Provides the current value of the reference slot number in DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value Controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default or reset value is 0x07C which corresponds to slot interval of 125 us.
3-2 —	Reserved.
1 ASC	Advance Slot Check Indicates whether an advance slot check is enabled. When this field is 1, it enables DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor is:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Equal to the reference slot number given in DMA_CH1_Slot_Function_Control_Status[RSN], or • Ahead of the reference slot number by up to two slots. This field is applicable only when DMA_CH1_Slot_Function_Control_Status[ESC] = 1. 0b - Disabled 1b - Enabled
0 ESC	Enable Slot Comparison Enables slot comparison. When this field is 1, it enables the checking of the slot numbers programmed in the transmit descriptor with the current reference given in DMA_CH1_Slot_Function_Control_Status[RSN]. DMA fetches the data from the corresponding buffer only when the slot number is: • Equal to the reference slot number, or • Ahead of the reference slot number by one slot. When this field becomes 0, it disables the checking of the slot numbers. DMA fetches the data immediately after you process the descriptor. **NOTE** You must not enable the UFO (UDP Fragmentation over IPv4)/TSO/USO along with TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets or segments or fragments transmission for single packet received from application and the slot number check are applicable for fetching only first segment/fragment. As a result it might be difficult for you to specify slot number for subsequent packets. 0b - Disable 1b - Enable

74.7.277 DMA Channel 1 Current Application Transmit Descriptor (DMA_CH1_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH1_Current_App_TxDesc	11C4h

Function
Specifies the current transmit descriptor which DMA reads.

31-0 CURTBUFAPTR	Application Transmit Buffer Address Pointer Indicates that DMA updates this pointer during the transmit operation. This pointer is 0 on reset.

74.7.280 DMA Channel 1 Current Application Receive Buffer (DMA_CH1_Current_App_RxBuffer)

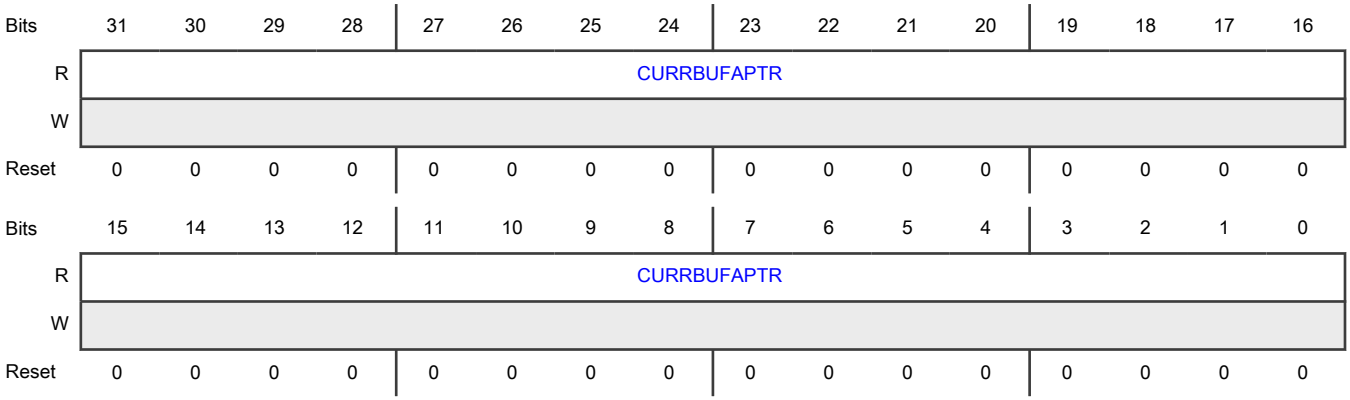
Offset

Register	Offset
DMA_CH1_Current_App_RxBuffer	11DCh

Function

Indicates that DMA_CH0_Current_App_RxBuffer points to the current receive buffer address which the DMA reads.

Diagram



Fields

Field	Function
31-0 CURRBUFAPTR	Application Receive Buffer Address Pointer Indicates that DMA update this pointer during the receive operation. This pointer is 0 on reset.

74.7.281 DMA Channel 1 Status (DMA_CH1_Status)

Offset

Register	Offset
DMA_CH1_Status	11E0h

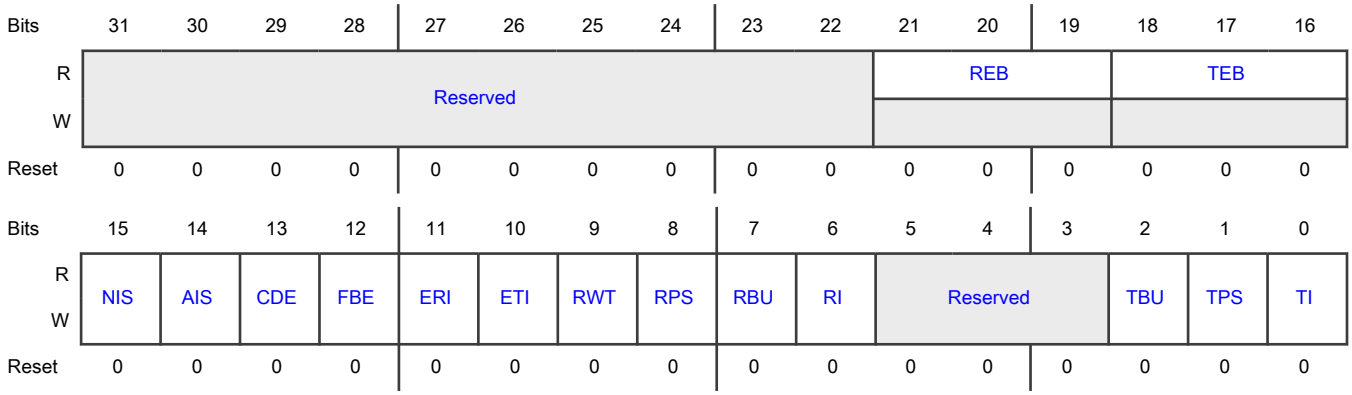
Function

Indicates that to determine the status of DMA, the application reads the status register during an interrupt service routine or polling.

NOTE

The number of DMA_CH(#i)_Status register in the configuration is the higher of number of receive DMA Channels and transmit DMA Channels.

Diagram



Fields

Field	Function
31-22 —	Reserved.
21-19 REB	Rx DMA Error Bits Indicates the type of error that causes a bus error. For example, an error response on the AHB or AXI interface. Bit 21 1'b1 - Error during data transfer by Rx DMA 1'b0 - No Error during data transfer by Rx DMA Bit 20 1'b1 - Error during descriptor access 1'b0 - Error during data buffer access Bit 19 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH1_Status[FBE] = 1. It does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface. Bit 18 1'b1 - Error during data transfer by Tx DMA 1'b0 - No Error during data transfer by Tx DMA Bit 17 1'b1 - Error during descriptor access

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1'b0 - Error during data buffer access Bit 16 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH1_Status[FBE] = 1. It does not generate an interrupt.
15 NIS	Normal Interrupt Summary Indicates whether the normal interrupt summary status is detected. The field value is the logical OR of the following bits when the corresponding interrupt bits enable in DMA_CH0_Interrupt_Enable: Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt Only unmasked bits (interrupts for which interrupt enable sets in DMA_CH0_Interrupt_Enable) affect this field. This is a sticky field. You must clear this field (by writing 1 to this field) each time a corresponding bit which sets it, clears. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
14 AIS	Abnormal Interrupt Summary Indicates whether an abnormal interrupt summary status is detected. The field value is the logical OR of the following bits when the corresponding interrupt bits enable in DMA_CH0_Interrupt_Enable: Bit 1 - Transmit process stopped Bit 7 - Receive buffer unavailable Bit 8 - Receive process stopped Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error Only unmasked bits affect this field. This is a sticky bit. You must clear this field (by writing 1 to this bit) each time a corresponding bit, which sets it, clears.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
13 CDE	Context Descriptor Error Indicates whether the context descriptor error status is detected. This field indicates that the DMA Tx/Rx engine receive a descriptor error, which indicates an invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in transmit case and on receive side. It indicates that DMA has read a descriptor with either of the buffer address as ones which you can consider invalid. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
12 FBE	Fatal Bus Error Indicates whether the fatal bus error status is detected. This field indicates that a bus error has occurred (as described in the EB field). When this field is 1, it indicates that the corresponding DMA channel engine disables all bus accesses. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
11 ERI	Early Receive Interrupt Indicates whether an early receive interrupt status is detected. When this field is 1, it indicates that the RxDMA has completed the packet data transfer to the memory. In configs supporting ERIC, When DMA_CH1_Rx_Control[ERIC] = 0, this field is 1 only after the Rx DMA fills a complete receive buffer with packet data. When DMA_CH1_Rx_Control[ERIC] = 1, this field is 1 after every burst data transfer from the receive DMA to the buffer. If DMA_CH1_Status[RI] = 1, this field clears automatically. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
10 ETI	Early Transmit Interrupt Indicates whether an early transmit interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it indicates that the TxDMA has completed the packet data transfer to the MTL TXFIFO memory. In configs supporting ERIC: When DMA_CH1_Tx_Control[ETIC] = 0, this fied is 1 only after the Tx DMA transfers a complete packet to MTL. When DMA_CH1_Tx_Control[ETIC] = 1, this field is 1 after the packet data transfer completes (partial) from buffers in the Transmit descriptor in which IOC=1. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
9 RWT	Receive Watchdog Timeout Indicates whether a receive watchdog timeout status is detected. This field asserts when it receives a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled). 0b - Not detected 1b - Detected
8 RPS	Receive Process Stopped Indicates whether a receive process stopped status is detected. This field asserts when the receive process enters the stopped state. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
7 RBU	Receive Buffer Unavailable Indicates whether a receive buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the receive list, and the DMA cannot acquire it. The receive process is suspended. To resume processing receive descriptors, the application must change the ownership of the descriptor and issue a receive poll demand command. If this command is not issued, the receive process resumes when you receives the next recognized incoming packet. In Ring mode, the application must advance the receive descriptor tail pointer register of a channel. This field is 1 only when the DMA owns the previous receive descriptor. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
6 RI	Receive Interrupt Indicates whether the receive interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates that the packet reception is complete. Bit 31 of RDES3 resets in the last descriptor, and updates the specific packet status information in the descriptor, when the packet reception is complete. The reception remains in the running state. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
5-3 —	Reserved.
2 TBU	Transmit Buffer Unavailable Indicates whether the transmit buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the transmit list, and the DMA cannot acquire it. Transmission is suspended. DMA_Debug_Status0[TPS0] explains the transmit process state transitions. The application must perform these actions, to resume the processing of transmit descriptors: 1. Write 1 to bit 31 of TDES3 to change the ownership of the descriptor. 2. Issue a transmit poll demand command. For Ring mode, the application must advance the transmit descriptor tail pointer register of a channel. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
1 TPS	Transmit Process Stopped Indicates that the transmit process stopped status is detected. This field is 1 when the transmission stops. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TI	Transmit Interrupt Indicates whether the transmit interrupt status is detected. This field indicates that the packet transmission is complete. When transmission completes, bit 31 of TDES3 resets in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.

74.8 Using PHY interfaces

This section is Synopsys Proprietary. Used with permission.

This module support the following modes:

- RMII 10/100 Mbps interface
- MII 10/100 Mbps interface

Phy_intf_sel input signal decides which mode is selected. Samples the Phy_intf_sel signal at reset. See Signal descriptions for more information. MAC_Configuration[PS] and MAC_Configuration[FES] selects the mode's speed.

The module supports the IEEE802.3-2015 specification for MII and RMII specification version 1.2 from RMII consortium.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports the access of the phy registers through SMA. It is a two wire Station management interface (MIM):

1. MDC
2. MDIO

According to IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which system clock derives using a divider. MAC_MDIO_Address[CR] programs to generate different MDC clock frequency.

SMA supports MDIO clause 45 and clause 22 frame structure per the IEEE802.3 specification. Writing 1 to MAC_MDIO_Address[C45E] enables the clause 45 frame structure.

The MII interface reduces the accuracy of the 1588 timestamp if it is overclocked to run at 200 Mbps. This happens because the MAC logic uses the MII interface speed,to adjust or compensate for the timestamps taken at MII, as compared to the time generated in the PTP clock domain as specified in MAC_Configuration[FES].

74.9 VLAN and double VLAN insertion, deletion, replacement and tagging

This section and all its sub-sections are Synopsys proprietary. These are used with permission.

The following sections describe the VLAN and double VLAN features.

74.9.1 Double VLAN processing

In the double VLAN tagging processing, the module supports the processing of two VLAN tags. The two VLAN tags are:

1. Inner VLAN tag (C-VLAN)
2. Outer VLAN tag (S-VLAN)

If there is only one tag in a packet then it is considered as an outer tag.

The module uses MAC_VLAN_Incl and MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers to support the following functions in a double VLAN processing feature.

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path.
- Packet filtering and stripping on the basis of any one of the two VLAN tags in the receive path. Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

74.9.1.1 Transmit path

Table 493. Double VLAN processing features in transmit path

Feature	Description
Support for C-VLAN and S-VLAN tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. MAC_VLAN_Incl[CSVL] and MAC_Inner_VLAN_Incl[CSVL] specifies the VLAN type. The module supports the processing of any sequence of outer and inner VLAN tags. The module does not support the C-VLAN and S-VLAN sequence. MAC does not examine whether the packet, which the application provides has a valid sequence of the VLAN tag types or the insertion or replacement operation results in an invalid sequence of VLAN tag type. Therefore, the application must provide a correct sequence of VLAN tag types and program the MAC in such a way that it results in correct sequence of VLAN tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when C-VLAN replaces the outer tag. • The outer tag should not be C-VLAN when S-VLAN replaces the inner tag.
VLAN tag deletion	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag deletion for an outer or inner tag. When you enable the VLAN deletion, MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If you enable the inner tag deletion and if there is only one tag in the packet, then the MAC does not delete the tag. NOTE
VLAN tag insertion or replacement	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag insertion or replacement for an outer or inner tag. When you enable the VLAN tag insertion or replacement, the MAC_VLAN_Incl[VLTI] or MAC_Inner_VLAN_Incl[VLTI] determines whether the VLAN tag must be fetched from the register or from the control word.

74.9.1.2 Receive path

Table 494. Double VLAN processing in receive path

Feature	Description
Outer or inner VLAN tag-based filtering	Mac can filter packets through the ERIVLT bit on the basis of the outer or inner VLAN tag.

Table continues on the next page...

Table 494. Double VLAN processing in receive path (continued)

C-VLAN or S-VLAN tag-based filtering	Mac can filter packets through the ERSVLM bit on the basis of the C-VLAN or S-VLAN type.
Outer and inner VLAN tag stripping	Mac can strip the outer and inner VLAN tags from received frame on the basis of the EVLS and EIVLS bits.
16-bit outer and inner VLAN tag and type in Rx status	Mac can provide the 16-bit outer and inner VLAN tag and type in the Rx status on the basis of the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN tag type	Mac can disable or skip checking of an outer VLAN tag type to match C-VLAN or S-VLAN on the basis of the DOVLTC bit.

74.9.1.3 Source address and VLAN insertion, replacement, or deletion

This module supports the SA, and VLAN insertion, replacement and deletion feature. The SA and VLAN fields are Tx packet-related control information that interfaces provide as part of the control word. IP supports the feature to insert or replace the source address on the basis of the information in the MAC address registers, and it also supports the feature to insert, replace, or delete the VLAN fields (VLAN type and VLAN tag) on the basis of the setting of the MAC_VLAN_Incl[VLTI]. SA insertion or replacement feature is enabled for all the transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature is enabled for all the Tx packets or selective packets.

74.9.1.4 Programming source address insertion or replacement

You can use the SA insertion or replacement feature to instruct MAC to perform the following actions for Tx packets:

- Insert the content of the MAC address registers in the SA field
- Replace the content of the SA field with the content of the MAC address registers

When SA insertion is enabled, the application must ensure that the packets sent to MAC do not have the SA field. The MAC does not check whether the SA field is present in the transmit packet and it inserts the content of MAC address registers in the SA field. Similarly, when the SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

MAC replaces the six bytes following the DA field in the transmit packet with the content of the MAC address registers.

- Configure MAC_Configuration[SARC] to enable the SA insertion or replacement for all Tx packets.
- Enable the SA insertion for selective packet by configuring the SA insertion control field (bits [25:23] of TDES3) in the first transmit descriptor of the packet. When you write 1 to bit 25 of TDES3, the SA insertion control field indicates insertion or replacement by MAC Address1 registers. When bit 25 of TDES3 resets, it indicates insertion or replacement by MAC Address 0 registers.

If you do not enable the MAC Address1 registers, then the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA insertion control field.

74.9.1.5 Programming VLAN insertion, replacement, or deletion

You can use the VLAN insertion, replacement, or deletion feature to instruct MAC to perform the following actions for the Tx packets:

- Delete the VLAN type and VLAN tag fields.
- Insert or replace the VLAN type and VLAN tag fields.

Insertion or replacement is done on the basis of the setting of the MAC_VLAN_Incl[VLTI] as described in theTable 495:

Table 495. VLAN insertion or replacement based on VLTI bit

Condition	Description
VLTI bit=1	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field depending on the content of the VT field of transmit context descriptor of the packet
VLTI bit resets	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field with the MAC_VLAN_Incl[VLT]

When the VLAN replacement or deletion is enabled, MAC checks whether the VLAN type field (0x8100 or 0x88a8) is present after the DA and SA fields in the transmit packet. The replace or delete operation does not occur if the VLAN type field is not detected in two bytes following the DA and SA fields. However, when the VLAN insertion is enabled, MAC does not check the presence of VLAN type field in the transmit packet and just inserts the VLAN type and VLAN tag fields.

Configuring MAC_VLAN_Incl[VLC] and MAC_VLAN_Incl[VLP] enables the VLAN insertion, replacement, or deletion feature for all Tx packets.

Configuring the VTIR field of TDES2 normal descriptor enables the VLAN insertion, replacement, or deletion for selective packets.

In addition, the VLP (VLAN Priority control) field must reset in MAC_VLAN_Incl (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for MAC to take the control inputs from the host, depending on the configuration.

74.10 Packet Filtering

This section and all its sub-sections are Synopsys proprietary. Used with permission.

MAC receiver contains various packet filtering scheme. Figure 2 shows the filtering sequence in their precedence order of received packet.

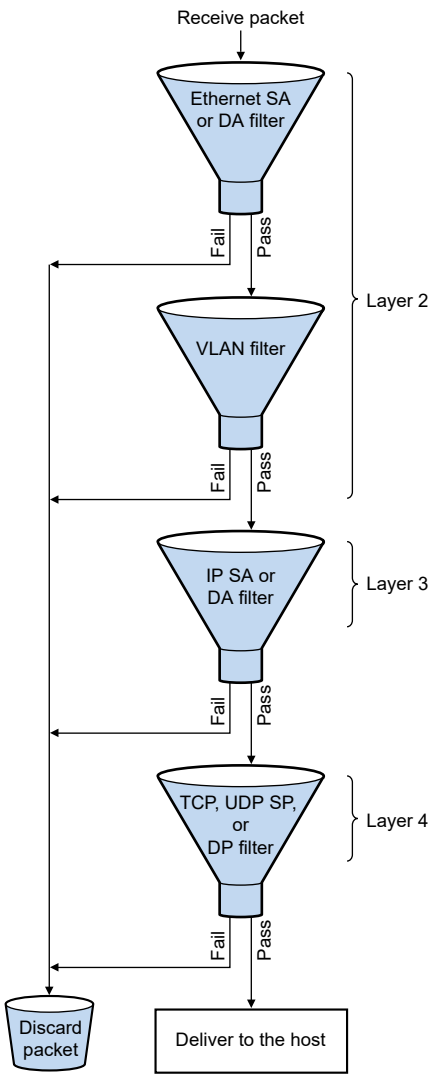

Figure 395. Packet filtering sequence

If you do not enable any of the layer filters, then that filter is bypassed and the subsequent filter is applied. Discard the packet that fails any of the filters. However, you can forward the discarded packet to the host on the basis of the register control.

74.10.1 Source address or destination address filtering

The address filtering module of MAC checks the SA and DA fields of each incoming packet. Programming of different types of address filtering is described in the sections that follows.

74.10.1.1 Unicast destination address filtering

MAC supports up to three MAC addresses for unicast perfect filtering. If perfect filtering is selected (MAC_Packet_Filter[HUC] resets), MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. MAC selects the MacAddr1 to MacAddr2 addresses with an individual enable field. Each byte of MacAddr1 to MacAddr2 can be masked when you compare them with corresponding received DA byte by writing 1 to the corresponding Mask byte control field in the register. This enables group address filtering for the DA.

In hash filtering mode (when you write 1 to HUC bit), MAC performs imperfect filtering by using a 64-bit hash table for unicast addresses . For hash filtering, MAC uses the upper 6 bits CRC of the received destination address to index the content of the hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of hash table register. If the value of

the corresponding bit (indicated by the 6-bit CRC) is 1, the unicast packet is considered to have passed the hash filter, otherwise, the packet is considered to have failed the hash filter.

74.10.1.2 Multicast destination address filtering

Enable MAC_Packet_Filter[PM] to pass all the multicast packets or disable to do multicast addresses filtering on the basis of MAC_Packet_Filter[HMC]. Compare the multicast address with the configured MAC destination address registers (1–2), also supports the group address filtering.

In Hash filtering mode, MAC performs imperfect filtering using a 64-bit hash table. MAC uses the upper 6-bits CRC of received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the hash table register. The multicast packet is considered to have passed the hash filter if the value of the corresponding bit is equal to 1. Otherwise, the packet is considered to have failed the hash filter.

74.10.1.3 Hash or perfect address filtering

Configure MAC_Packet_Filter[HPF] to enable or disable the destination address filtering either by hash filter or perfect filter. Also configure MAC_Packet_Filter[HUC] and MAC_Packet_Filter[HMC] to select the hash filtering or perfect filtering for unicast or multicast packet.

74.10.1.4 Broadcast address filtering

MAC does not filter any broadcast packets by default. You must write 1 to MAC_Packet_Filter[DBF] to reject the broadcast packets.

74.10.1.5 Unicast source address filtering

MAC by default compares the source address field with the value configured in the source address registers. Configure bit 30 of MAC address register [1-2] to use it for source address instead of destination address comparison. MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. MAC drop the packets that fail the SA filter if you write 1 to MAC_Packet_Filter[SAF] field. Otherwise, the result of the SA filter is given as a status bit in the receive status word. When you write 1 to the SAF field, the SA filter and DA filter results ends to decide whether you can forward the packets. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

74.10.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by writing 1 to the DAIF and SAIF fields of MAC_Packet_Filter register. The DAIF field is applicable for both the unicast and multicast DA packets. The unicast or multicast destination address filter result is inverted in this mode. Similarly, writing 1 to the SAIF field reverses the result of unicast SA filter.

Table 496 and Table 497 summarize the DA and SA filtering on the basis of the type of packets received.

Table 496. Destination address filtering

Packet type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA filter operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	All packets pass
	0	X	0	0	X	X	X	Pass on perfect or group filter match

Table continues on the next page...

Table 496. Destination address filtering (continued)

	0	X	0	1	X	X	X	Fail on perfect or group filter match
	0	0	1	0	X	X	X	Pass on hash filter match
	0	0	1	1	X	X	X	Fail on hash filter match
	0	1	1	0	X	X	X	Pass on hash or perfect or group filter match
	0	1	1	1	X	X	X	Fail on hash or perfect or group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on hash filter match and drop pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on hash or perfect or group filter match and drop pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on hash filter match and drop pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on hash or perfect/group filter match and drop pause packets if PCF = 0x

Table 497. Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on perfect or group filter match but do not drop packets that fail
	0	1	0	Fail status on perfect or group filter match but do not drop packet
	0	0	1	Pass status on perfect or group filter match and drop packets that fail
	0	1	1	Fail status on perfect or group filter match and drop packets that fail

NOTE

When you write 1 to the MAC_Packet_Filter[RA] field, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

74.10.2 VLAN filtering

VLAN tag filter can be done either by perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forward the VLAN tagged packet with match status when it drop all the packets which do not match.

MAC uses 16-bit VLAN hash table for group address filtering on the basis of the VLAN tag. If MAC enables the hash filtering then the most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the MAC_VLAN_Hash_Table. A value of 1 in the VLAN hash table register, corresponding to the index indicates that the VLAN tag of the packet has matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

MAC supports the inverse matching for VLAN packets. In the Inverse matching mode, the packet must be dropped when the VLAN tag of a packet matches the perfect or hash filter. If MAC enables the VLAN perfect and VLAN hash match, then a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, MAC forwards a packet only when both the perfect and hash filters indicate mismatch.

Table 498 specifies the different possibilities for VLAN matching and the final VLAN match status. When you write 1 to MAC_Packet_Filter[RA] all packets are received and it indicates the VLAN match status in the VF field of RDES2 normal descriptor (write-back format). When the RA field is not set and when you write 1 to MAC_Packet_Filter[VTFE] the packet drops if the final VLAN match status fails

When VLAN VID programs to 0 in the VL field of MAC_VLAN_Tag register, consider that all the VLAN-tagged packets are perfectly matched but the status of the VLAN hash match depends on the VTHM and VTIM fields in MAC_VLAN_Tag register.

Table 498. VLAN match status

VID	VLAN perfect filter match result	VTHM bit	VLAN hash filter match result	VTIM bit	Final VLAN match status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID1= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In Table 498, X represents any value.

74.10.3 VLAN filter fail packets queue

When you enable VLAN filtering, route the VLAN filter fail packets to a programmable queue (VFFQ) when the value of MAC_Packet_Filter[RA] = 1 or MAC_Packet_Filter[VTFE] = 0 and write 1 to MAC_RxQ_Ctrl4[VFFQE] for the queue.

Route the packets that passes the VLAN filtering to Rx queues on the basis of the VLAN tag priority field by configuring the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. Discard the packets that fail the VLAN filter if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, forward the VLAN filter fail packets to the application. In such case, when you write 1 to the VLAN filter fail queue enable (VFFQE) field, the VLAN filter fail packets forward to the Rx queue number programmed in the VFFQ field. If the value of VFFQE=0, the VLAN priority mapping determines the Rx queue number per the PSRQ fields.

Table 499 shows the Rx queue routing table for unicast tagged packets, with DA or SA filter enabled.

Table 499. Rx queue routing table for unicast tagged packets

RA	VFTE	SA or DA filter result	VLAN filter result	VFFQE	Queue routing
X	X	Pass	Pass	X	PSRQ
0	0	Pass	Fail	0	PSRQ
0	0	Pass	Fail	1	VFFQ
0	X	Fail	X	X	Dropped
0	1	Pass	Fail	X	Dropped
1	X	Fail	X	0	UFFQ*/PSRQ
1	X	Fail	X	1	UFFQ*/VFFQ
1	X	Pass	Fail	0	PSRQ
1	X	Pass	Fail	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ.

74.10.4 Extended receive VLAN filtering and routing

When the extended Rx VLAN filtering and routing is enabled then both the perfect filtering and hash filtering can be enabled. The overall VLAN filter result is based on the perfect filter result and hash filter result (if enabled). Filter result is passed to application as part of the status bit. Extended routing will take place only if VLAN filter has passed. Routing is only based on perfect filter result. Each perfect filter has a DMA channel enable and DMA channel number filed which must be programmed for routing.

See the extended VLAN based DMA selection in Dynamic (per packet) mapping for more information about routing.

74.10.4.1 Comparison mode

Application has these comparison option for each VLAN tag filter:

- Programs MAC to compare the inner or outer VLAN tag either with 12 bits or 16 bits programmed VID.
- Selects whether the VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

74.10.4.2 Filtering

Perfect filtering is done on the basis of the MAC_VLAN_Tag_Filter registers. MAC compares the relevant VLAN tag ID and gives a result for each VLAN tag filter.

The results for each VLAN tag filter are:

- Pass- If any one of the VLAN tag filters gives a match.
- Fail- If the frame mismatches all the filters.

This behavior is applicable only when the inverse filtering is not enabled in MAC_VLAN_Tag_Ctrl.

If inverse filtering is enabled and the frame mis-matches all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered to have failed. The frame is bypassed to the application if none of the enabled filters can perform a comparison or if none of the filters are enabled.

The overall filter result and the programming on MAC_Packet_Filter[VTFE] and MAC_Packet_Filter[RA] determines if the frame will drop or it is forwarded to the application. If the value of RA = 1 or VTFE = 0, then the frame is always forwarded whether the filter result is a pass or fail, . If the value of RA = 0 and VTFE = 1, only then, if the VLAN tag filter result is a pass the MAC forwards the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the status bits.

74.10.4.3 Filter status

The extended receive VLAN filtering and routing feature provides two status fields to show the comparison result of the VLAN tags.

By default, MAC indicates the VLAN filter status through one bit in the status VF field in RDES2. When you enable the extended RX VLAN filtering and routing, two status fields will show the comparison result of the VLAN tags. The outer VLAN tag filter pass and inner VLAN tag filter pass bits are defined in the following positions. The status indicated through these fields depends on the programming as described below.

In RDES2:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In ARI status: MAC filter status:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In MRI status:

- Bit 47 – Outer VLAN tag filter status
- Bit 46 – Inner VLAN tag filter status

Outer VLAN tag filter status (OTS)

- In perfect filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's outer VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's outer VLAN tag has either failed the relevant outer VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for outer VLAN tag comparison.
- If inverse filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it is resets, then it has failed at least one filter or bypassed all the filters programmed for outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN tag filter status (ITS)

- In perfect Filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's inner VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's inner VLAN tag has either failed the relevant inner VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for inner VLAN tag comparison.
- If Inverse Filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it resets, then it has failed at least one filter or bypassed all the filters programmed for inner VLAN tag comparison.

- This bit is valid for only double VLAN tagged frames, when double VLAN processing is enabled.

The application must observe the status fields and the program to determine if the frame has passed or failed the VLAN filter.

Table 500 and Table 501 describes the possible filter combinations and the corresponding filter results and they also explain the scenarios when the double VLAN processing and the hash VLAN filter are enabled in the design.

Legend for the table OTS and ITS Bit Values with at least 1 perfect filter enabled

- VTIM: VLAN tag inverse match enable – bit 17 in VLAN_Tag_Ctrl register.
- HFO: Hash filter enabled for outer VLAN tag comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- HFI: Hash filter enabled for inner VLAN tag comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- PFO – Perfect filter comparison enabled for outer VLAN tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for outer VLAN tag comparison (write 0 to bit 20).
- PFI – Perfect filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for inner VLAN tag comparison (write 1 to bit 20).
- OTS – Outer VLAN tag filter status
- ITS – Inner VLAN tag filter status

Table 500 shows the possible values of status bits (OTS and ITS) when at least one perfect filter is enabled.

Table 500. OTS and ITS bit values with at least 1 perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0

Table continues on the next page...

Table 500. OTS and ITS bit values with at least 1 perfect filter enabled (continued)

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 501 shows the possible values of status bits (OTS and ITS) when no perfect filters are enabled except the VLAN hash filter is enabled.

Table 501. OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of OTS and ITS bit values with only VLAN hash filter enabled indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes atleast one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: The last row of table "OTS and ITS bit values with only VLAN hash filter enabled" indicates that the inverse filtering is enabled, hash filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

74.10.4.4 Stripping

Each VLAN tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or outer VLAN tag stripping is based on the pass or fail results of the individual tag. If all the relevant filters bypasses a tag, stripping is not applicable for the tag.

- If strip on pass is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has passed the relevant filters. The outer VLAN tag filter result field will be 1.
- If strip on fail is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has failed relevant filters. The outer VLAN tag filter result field will reset.
- If the outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the status bit is 0.

- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of thefilters. The VLAN Tag's value is not always deterministic from the filter status bits.

If an application strips the VLAN tag on the basis of the filter result, it might lose the VID. You can use it, if stripping is enabled for any of the tags, place the tag in the status. For this the software or application will enable the respective VLAN tag in status bit - 24 or 31 in the MAC VLAN tag control register.

See section Programming guidelines for extended VLAN filtering and routing on receive for more information.

74.10.5 Layer 3 and layer 4 filtering

IP supports the layer 3 based packet filtering which is an IP source or destination address filtering in the IPv4 or IPv6 packets, and layer 4 based packet filtering which is a source or destination port number filtering in TCP or UDP. When you enable layer 3 and layer 4 packet filtering then packets are filtered in the following manner.

- Matched packets: MAC forward the packets that match all enabled fields to the application along with the status. It gives the matched field status only if MAC_Configuration[IPC] = 1 and if one of the following conditions is true:
  - All enabled layer 3 and layer 4 fields match
  - At least one enabled field matches and other fields are bypassed or disabled

When you enable multiple layer 3 and layer 4 filters, any filter match is considered as a match. If more than one filter matches, MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter.

- Unmatched packets: MAC drop the packets that do not match any enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP packets: By default, all the non-TCP or UDP IP packets bypasses the layer 3 and layer 4 filters. You can optionally program MAC to drop all the non-TCP or UDP packets over IP packets.
- IP has a control register MAC_L3_L4_Control to control the layer L3 and L4 packet filtering along with address registers to program the layer L3 and L4 fields to be matched.

74.10.6 Flexible receive parser

When you enable this function, all incoming packets are parsed per the programmable instruction stored in memory. It perform these functions:

- Packet filter (Accept or reject)
- DMA channel selection

Flexible receive parser block operates over the first 128 bytes data of receive packet on the basis of 64 bytes of instruction on each packet. Figure 396 shows the functional block diagram of flexible receive parser.

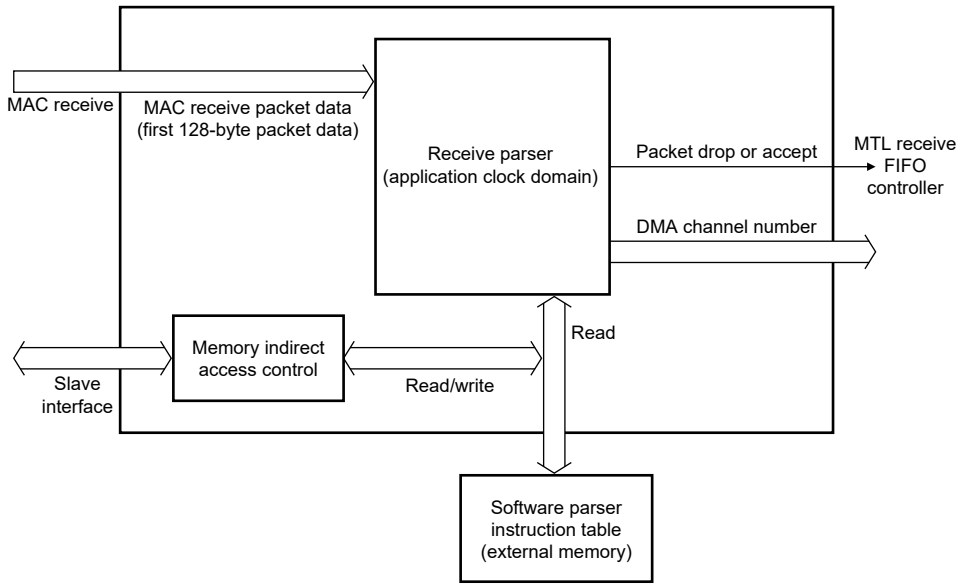

Figure 396. Functional block diagram of flexible recieve parser

74.10.6.1 Instruction table format of the flexible receive parser

You must build the 96-bit wide instruction before enabling the receive parser feature and program each instruction as an entry in the instruction memory.

Table 502 shows the format of each entry in the instruction table .

Table 502. Rx parser instruction entry format

Field	Field Name	Description
31:0	MATCH_DATA	This is a 4-byte data. You can use it to compare with incoming packet data which starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are 1 (MATCH_EN bits of [63:32]). See the notes (below this table) on the byte order relative to Ethernet arrival data and endianness which the QoS IP supports on the slave interface. The programming of this instruction table must adhere to the same.
62:32	MATCH_EN	When the MATCH_EN = 1, you can use the corresponding packet data bit for comparing. Otherwise, corresponding data bit is don’t care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NC	Next instruction control
71:68	Reserved	-

Table continues on the next page...

Table 502. Rx parser instruction entry format (continued)

Field	Field Name	Description
79:72	Frame offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0) Conpare the frame offset in the packet data for Match.This is in terms of 4 bytes. The value of actual frame offset in bytes are 0 01 42 8… ..63 252 The max value programmed in this instruction table is 128 B. The 'Actual frame offset' must not cross this limit.
87:80	OK index	If (NIC==0) the memory index you can use next when ENTRY_MATCH==1 and neither AF or RF = 1. If (NIC==1) the memory index you can use next when ENTRY_MATCH==0
95:88	DMA Ch No	Indicates the DMA channel number (1-bit for each). You can use this when ENTRY_MATCH ==1 and AF = 1 (Accept frame). The following bits give the encoding: bit[0]- DMA channel number o, bit[1]- DMA channel number , 1bit[2]- DMA channel number 2… bit[7]- DMA channel number 7. **NOTE** You can encode the DMA channel number using bit wise as QoS IP support multicasting or broadcast across DMA channels. See section 3.3.12 for more information and proper usage.
128:96	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 96-bits).

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the current entry parser result. Flexible receive parser flow chart shows the detailed flow.

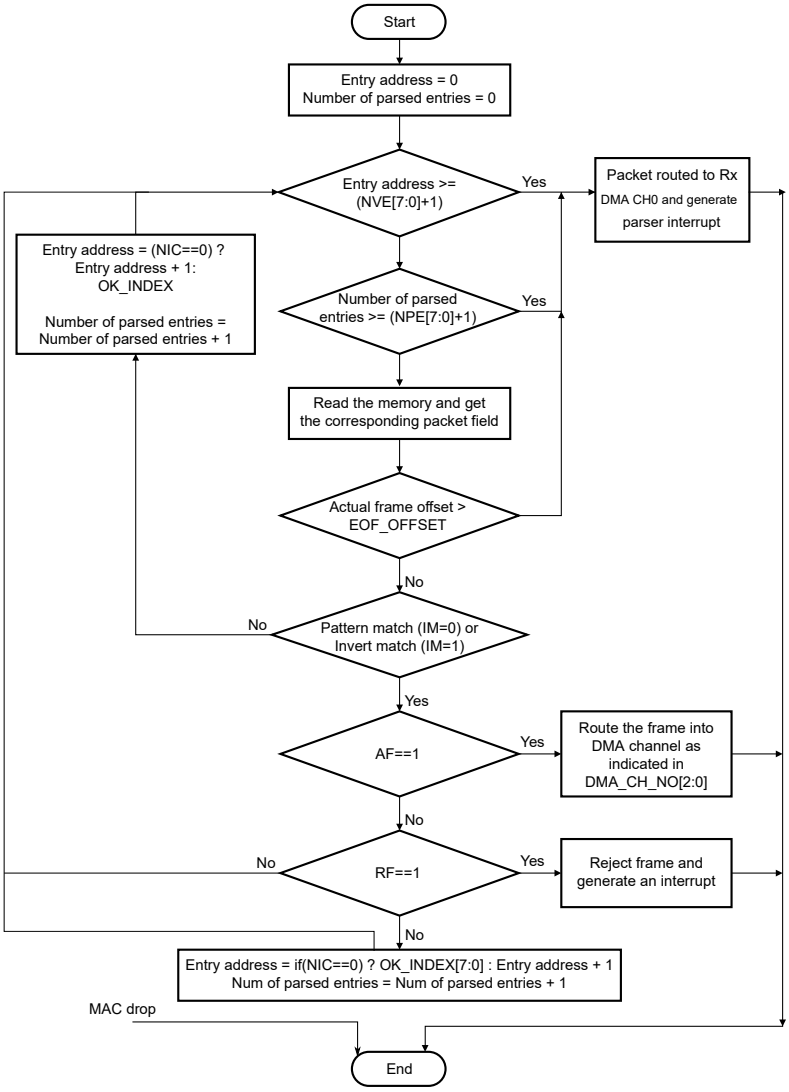

Figure 397. Flexible recieve parser flow chart

The EOF_OFFSET shown in the figure is the least among the following:

- Actual packet size
- 128 Byte when frame pre-emption feature is not enabled or configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible
- 64 Byte when frame pre-emption feature is enabled and packet is express packet

74.10.6.2 Number of valid entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. You can change this value by writing into MTL_RXP_Control_Status[NVE].

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NVEOVIS], if the entry address is greater than MTL_RXP_Control_Status[NVE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

74.10.6.3 Number of parsable entries (NPE)

NPE indicates the number of entries that you can parse on an incoming packet. The default value is 64. Write into MTL_RXP_Control_Status[NPE] to change this value.

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NPEOVIS], if the number of parsed of parsed entries is more than MTL_RXP_Control_Status[NPE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

NVE[] indicates the number of valid entries in the receive parser memory which you have built and NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

74.10.6.4 Frame offset

It indicates the frame offset, in terms of 4 bytes which you use when comparing against the current table entry.

In an entry, an error is flagged in MTL_RXP_Interrupt_Control_Status[FOOVIS] in any of the following cases:

When frame offset is more than:

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an express packet

IP generates an interrupt status (<xref href="DWC_ether_qos.dita#MTL_Interrupt_Status/MTL_Interrupt_Status.MTLPIS" >MTL_Interrupt_Status[MTLPIS]</xref>).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the receive parser declares a frame offset error if you enable comparison (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

74.10.6.5 Frame reject

You can drop the frame in cases, where an entry matches (considering the inverse match, IM bit in the instruction table) and frame accept bit is not 1, and frame reject bit (RF) = 1.

When a frame drops because RF = 1, IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

74.10.6.6 Out of order processing

The Rx parser flow can be out of order. The decision tree is not based on the order in which packet arrives. This implies that the next entry and next frame offset (OK_INDEX[] and FRAME_OFFSET[]) can be less than the current entry address and current frame offset.

74.10.6.7 DMA channel selection

When you enables the receive parser (MTL_Operation_Mode[FRPE] = 1) it overrides the MAC DMA selection criteria.

When you disables the receive parser (MTL_Operation_Mode[FRPE] = 0) the MAC/MTL determines the DMA channel number.

74.10.6.8 Receive queue selection

The existing MAC functionality determines the receive queue, irrespective of whether the receive parser is enabled or disabled. This is because the receive parser is mainly designed to select the DMA channel and the MAC decides the receive queuing to enable the proper functioning of the pause or PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on receive parser.

74.10.6.9 MAC packet filtering/drop/error handling

Packet filtering is done on the basis of the received packet fields. You must disable the packet filtering features inside the MAC when the receive parser is enabled. Follow these steps to disable the packet filtering features inside the MAC :

1. Write 1 to the Promiscuous mode (MAC_Packet_Filter[PR]).
2. Write 1 to all other fields in MAC_Packet_Filter to its default values.

When MAC decides to drop the packet due to the receive MAC dependent error such as:

- GMII error
- Receive watchdog error
- CRC error
- Giant frame error

the packet drops irrespective of the receive parser decision.

74.10.6.10 Pad strip or CRC strip handling

Software controls the pad strip and CRC strip and it is applicable to all the received packets. Also,software must build the receive parser instructions accordingly, when you enable these features.

NOTE

Enable pad and CRC stripping in real use case.

74.10.6.11 VLAN strip handling

MAC supports stripping the outer VLAN as well as inner VLAN. When you program MAC to strip the VLAN, the receive parser considers those VLAN tags to be part of the incoming packet.

74.10.6.12 Multicast and broadcast support

IP supports multicast and broadcast packet and the packet route to the highest queue number.

When you enables the receive parser, the DMA channel numbers (DMA CH NO, Bits [95:88]) in the instruction table, decide the packet routing.

When you disables the receive parser, DCS (DMA Channel Select) field of the MAC_AddressX_High register determines the packet routing. See the Broadcast/multicast packet duplication.

NOTE

You can select multiple DMA channels for the packet routing because the DCS/DMA CH NO field is per the DMA channel control.

74.10.6.13 Pre-emption support

IP supports the frame pre-emption feature when the flexible receive parser feature is enabled. It has the following limitations:

- Number of bytes would be 64, so that the receive parser can operate on an express traffic
- Number of bytes would be 128, so that receive parser can operate on a pre-emptible traffic.

74.10.6.14 Software access to the flexible receive parser memory

Software can read and write into the receive parser memory. It uses the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_Data

For more details, see EMAC register descriptions.

74.10.6.15 Statistical counters

IP supports these statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see EMAC register descriptions.

74.10.6.16 Changing the instruction table by software

Software can update the instruction table in the memory in the following ways:

- Disables the MAC receiver and receive parser by writing 0 to MAC_Configuration[RE] and MTL_Operation_Mode[FRPE]. It waits for receive parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Programs in the entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory), where you can program it to reject or accept all the packets.

74.10.6.17 Receive cut-through functionality

In the Cut-Through mode, the receive controller transfer the received packets to DMA just after it receives the cut-through threshold amount of packet data (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the receive controller delays the packet transfer to DMA accordingly, and the cut-through functionality is re-defined as follows:

The receive controller transfers packet to DMA after at least RTC number of bytes have been received and receive parser results are available.

74.10.6.18 Receive packet drop indication

In most cases, the packet drops internally in the receive queue. However, back-to-back packets can arrive for the same queue and the first packet's receive parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the application interface and indicates the status accordingly. See RDES2, bit 16(RXPD) in Receive normal descriptor (write-back format) for more information.

74.10.6.19 Runt packet handling

The receive parser can performs the operation with 64B minimum size packet. If the runt packet is received (MAC must indicate it), the receive parser assumes that it is dropped in the MAC, this is because, the back-to-back runt packets (< 64B) cannot be handled in the receive parser.

74.10.6.20 Uncorrectable ECC error handling

The packet does not drops when the parser detects an uncorrectable ECC error while parsing the parser memory. The packet is sent to the application with an error indication. The RXPI (RX parser incomplete) sets in the packet status along with error summary (ES) bit.

See the Receive normal descriptor (write-back format) for more information.

74.11 IEEE 1588 timestamp support

This section and all its sub-sections are Synopsys proprietary. Used with permission.

IP supports the IEEE 1588 precision time protocol (PTP). It is also able to do precise time stamping and captures incoming and outgoing frame because of the PTP protocol implementation in the IP. It supports all the clock types defined in IEEE 1588-2008. The typical frequency of PTP timestamp clock is 125 MHz.

IP supports these features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

74.11.1 Delay request-response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 398 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

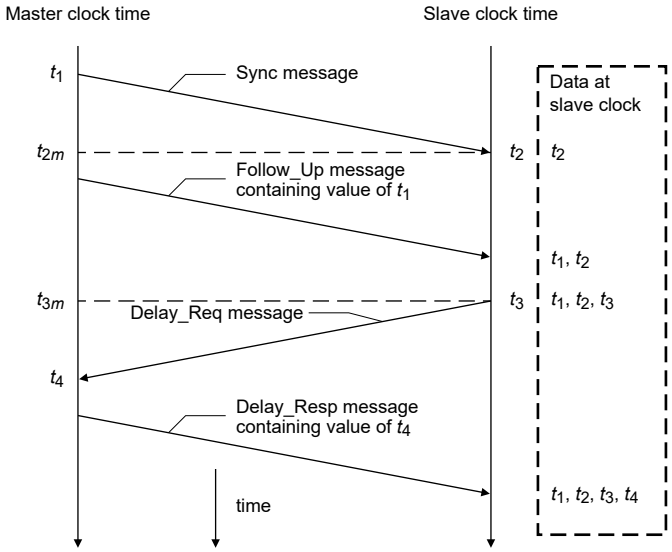

Figure 398. Networked time synchronization

As shown in the figure, PTP uses this process:

1. The master broadcast the PTP sync messages to all its nodes. The sync message contains the reference time information of the master. This message leaves the system of the master at t1. You must capture this time for Ethernet ports at GMII or MII.
2. The slave receives the sync message and it also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and note the exact time, t3, at which this packet leaves the GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave use the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware captures the exact time when specific PTP packets enter into or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

74.11.2 Peer-to-peer PTP transparent clock (P2P TC) message support

The IEEE 1588-2008 supports the peer-to-peer PTP (Pdelay) message in addition to the sync, delay request, follow-up, and delay response messages. Figure 399 shows the method to calculate the propagation delay in clocks supporting the peer-to-peer path correction.

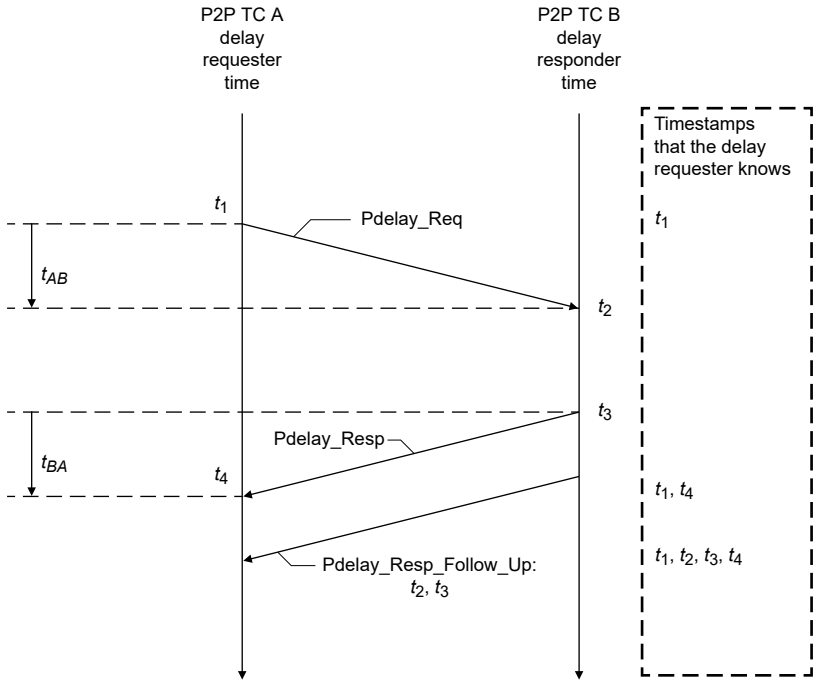

Figure 399. Propagation delay calculation in clocks supporting peer-to-peer path correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives a Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message, to minimize the errors because of any frequency offset between the two ports. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) after receiving the Pdelay_Resp message.
5. Port 1 uses all the four timestamps t1, t2, t3, and t4 to compute the mean link delay.

74.11.3 Timestamp correction

According to the IEEE 1588 specification, you must capture a timestamp when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the start frame delimiter octet) crosses the boundary between the node and the network. As MAC takes the timestamp at an internal point far from the actual boundary of the node and network, you must correct or update the captured timestamp for the ingress or egress path latency (including the delay in the PHY layers). Further

correction is done for the inaccuracies or errors introduced because the clock (MII Tx, Rx clock) is different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that generates the time. The resultant CDC (Clock domain crossing) circuits add an error depending on the clock period of the MII and PTP clocks.

74.11.3.1 Ingress correction

The timestamp captured at the internal snapshot point In the receive side is delayed (later in time) as compared to the time at which the packet's SFD bit is received at the port's boundary. Therefore, the ingress latency and the errors in CDC sampling reduces the captured timestamp. You must determine or calculate the correction value and write into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum ingress latency. You can read these registers and determines the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the ingress latency from its datasheet or timing characteristics.

2. Internal latency from the core's input to the internal capture point.

   You can read the internal ingress latency from MAC_Timestamp_Ingress_Latency. This is a read-only register and provides the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC, to determine the current internal latency.

3. CDC synchronization

   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_pt-p_ref_i).

You must add the values that these three components determine and must write into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written into the register must be negative (two's complement as explained below), because it is subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When MAC_Timestamp_Control[TSCTRLSSR] is 1, it indicates that the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be 1 (for negative value) and bits[30:0] must write with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When MAC_Timestamp_Control[TSCTRLSSR] becomes 0, it indicates that the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must write with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

74.11.3.2 Egress correction

The timestamp captured at the internal snapshot point in the transmit side is earlier (advanced in time) as compared to the time at which the packet's SFD bit is output at the port's boundary. Therefore, the egress latency and the errors in CDC sampling must compensate the captured timestamp. You must determine or calculate this correction value and write into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between the core output and the port and the network boundary

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum egress latency. You can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), you must dertermine the egress latency from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the core output of the c

   You can read this internal egress latency from MAC_Timestamp_Egress_Latency. This is a read-only register and gives the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

74.11.3.3 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains that is from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between the two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between the two captured timestamp is less than this delay, MAC does not take a timestamp snapshot for the second packet.

74.11.3.4 PTP processing and control

Table 503 shows the common message header for the PTP messages. This format is defined in the IEEE 1588-2008.

Table 503. Message format defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2 message type field is used for detecting different message types.

There are some fields in the Ethernet payload that detects the PTP packet type and controls the snapshot to be taken. These fields are specified in Table 504 for PTP packets over Ethernet.

Following table provides the information about the fields that match to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and version 2. The octet positions are offset by 4 for the tagged packets. This is based on the IEEE 1588-2008, Annex D, and the message format.

Table 504. Ethernet PTP packet fields required for control And status

Field matched	Octet position	Matched value	Description
MAC destination multicast address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC packet type	12, 13	0x88F7	PTP Ethernet packet
PTP control field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP message type field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), which is programmed in MAC address 0 to 31, is used if MAC_Timestamp_Control[TSENMACADDR] = 1.
2. IEEE 1588-2008, Annex F
3. MAC does not consider the PTP version 1 messages with peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

74.11.4 Transmit path functions

MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. You can control the packets, for which the timestamps are captured on a per-packet basis and mark each transmit packet to indicate whether to capture a timestamp for it. MAC does not process the transmitted packets to identify the PTP packets. You can use the control bits in the transmit descriptor to specify the packets. MAC returns the timestamp to the software inside the corresponding transmit descriptor and therefore connects the timestamp automatically to the specific PTP packet. You must write the 64-bit timestamp information to TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

74.11.5 Receive path functions

You can program MAC to capture the timestamp of all packets received on the MII interface or to process the packets to identify the valid PTP messages.

You can use these options of MAC_Timestamp_Control to control the snapshot of the time sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 505. Timestamp snapshot dependency on register bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

DMA returns the timestamp to the software inside the corresponding receive descriptor. The extended status, contains the timestamp message status and the IPC status. You must write the extended status in the normal descriptor RDES1 and the snapshot of the timestamp in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

See the System time correction for programming guidelines for IEEE 1588 timestamping (System time correction).

74.11.6 IEEE 1588 system time source

IP supports both the external and internal time source for reference timestamping.

- External time source uses the 64-bit external time reference and clock as an input in IP. The clock input synchronizes the external timing reference into the MAC clock domain. Upper 32-bit indicates the time in seconds and the lower 32-bit indicates the time in nanoseconds.
- Internal time source uses the only clock input to generate timing reference internally for snapshot and capture timestamps. Internal time reference has two fields.
  - UInteger48 seconds field: The seconds field is the integer portion of the timestamp in seconds units. It is 48-bit wide.

    For example, 2.000000001 seconds are represented as seconds field = 0x0000_0000_0002.

— UInteger32 nanoseconds field The nanoseconds field is the fractional portion of the timestamp in nanoseconds units.

For example, 2.000000001 seconds are represented as nanoseconds field = 0x0000_0001. The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after 0x7FFF_FFFF value . Accuracy is ~0.466 ns per bit.

There is a system time register module, it is used when you use an internal time reference. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets which is transmitted or received at the MII interface.

Initialize or correct the system time counter using the coarse correction method. In this method, write the initial value or the offset value to the timestamp update register. For initialization, write the system time counter with the value in the timestamp update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, correct the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) over a period of time instead of in one clock, as in coarse correction. This maintains linear time and does not introduce drastic changes (or a large jitter) in the reference time between the PTP sync message intervals.

See Initialization guidelines for system time generation for programming guidelines for IEEE 1588 timestamping (For internal timestamp source configuration).

74.11.7 IEEE 1588 higher word register

You can invoke the higher word register if system time source is internal. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field are read from the CSR register.

74.11.8 Flexible pulse-per-second output

IP supports the flexibility of programming the start or stop time, generates pulse width and interval on pulse-per-second output. It also support four such output signals. By default, IP is in fixed pulse-per-second output mode with interval of 1 second.

Initially you must program the start time in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired or enabled pps output. If you re-programs start or stop time then you must do it after the synchronization of earlier programmed value. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, MAC sets an error status bit which indicates the programming error. If enabled, MAC also sets the target time reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

Program the PPS width and interval in terms of granularity of system time, that is, the number of units of sub-second increment value.

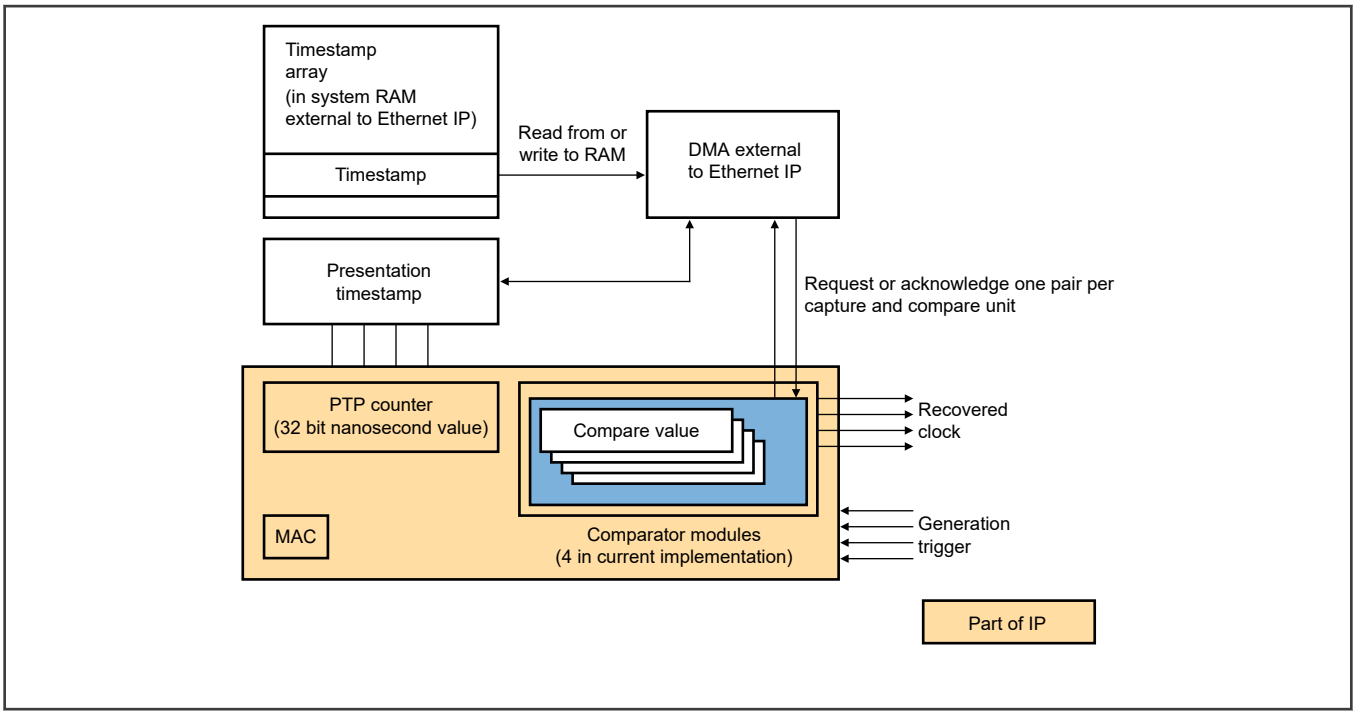
See Programming guidelines for flexible pulse-per-second output for more information.

74.11.9 Media clock generation and recovery

Media clock recovery and generation requires a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of a dedicated hardware which multiplies to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and program these values into CSR registers so that IP can read them for media clock recovery.

Figure 400 shows that the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that completes at the full 32-bit value to match with 1722 presentation time format and an handshake mechanism with an external application (such as DMA) to program the presentation time into CSR register.

Figure 400. Media clock generation and recovery block diagram



74.11.9.1 Presentation time counter

Presentation time counter provides an another perspective of the PTP system time (1588 timer). For a given PTP system time (PTP[63:32] represents time in seconds Comparator modules and PTP[31:0] represents time in nanoseconds), there exists a corresponding presentation time (32-bit value in nanosecond). The presentation time computed is referred to as current presentation time (CPT).

CPT derives from 64-bit PTP system time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64-bit nanosecond value.

Current presentation time[31:0] = PTPNS[31:0]

Media clock recovery is possible when the system time is internally generated in IP and compute the CPT in the same way as the internal PTP system time generation. The increment cycle of CPT and system time are same because the values of both the timers are in nanoseconds and they are synchronous. The timer updates at the same instance, but the updated value could be different. You must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input generates media clock timestamps that are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

74.11.9.2 Comparator modules

Figure 400 shows that the module supports four comparator modules to handle multiple media clocks that it may require. When MAC_Timestamp_Control[PTGE] is 1, it indicates that the comparator modules handshake with the application to program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register.

Write 1 to presentation time control fields of the particular instance for recovery mode.

The timestamps received from the application are referred as target presentation time (TPT).

When MCGREN#i field of MAC_PPS_Control is 1, it indicates that the IP operates in MCGR mode. The comparator module sends upto two requests to the application for TPT write, when MAC_Timestamp_Control[PTGE] and the presentation time control bits of the particular instance are 1 for MCGR mode. Subsequent requests are generated each time a presentation time match occurs. CPT transitions from a value less than TPT, to a value greater than or equal to CPT. The first request asserts when a specific comparator instance sets to MCGR mode with a non-zero presentation time control and an additional request is made when the comparator receives the first data. This allows the application to write the next TPT value when IP processes the previous TPT value for a match.

TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle or pulse is generated in the next cycle when a match is detected. Also,the mcgr_dma_req_o#i request for that comparator asserts (to obtain next TPT) until the corresponding application acknowledgment is set, when a match is detected.

The presentation control fields (PPSCMD#i field of MAC_PPS_Control) determine the shape of the generated waveform. You can program these fields to either toggle or generate a high/low pulse for one PTP clock cycle, when matched.

Media clock recovery: A match occurs, when the free-running CPT value matches the received TPT value. An output signal, EMAC_TMR signal as shown in the IO mux sheet asserts (toggle, low pulse, or high pulse) on the basis of the programmed presentation control value.

Media clock generation: On the basis of the presentation control value programmed in MAC_PPS_Control, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. The captured timestamp is read when a request is raised to the application. No new timestamps are captured, until the read operation is complete acknowledgment is received from the application.

74.11.9.3 Media clock generation and recovery flow

Figure 401 shows the media clock generation and recovery flow. Write 1 to MAC_Timestamp_Control[PTGE] for CPT generation and write 1 to MAC_PPS_Control MCGREN#i field to enable the corresponding instance in the MCGR mode, for both media clock generation and recovery.

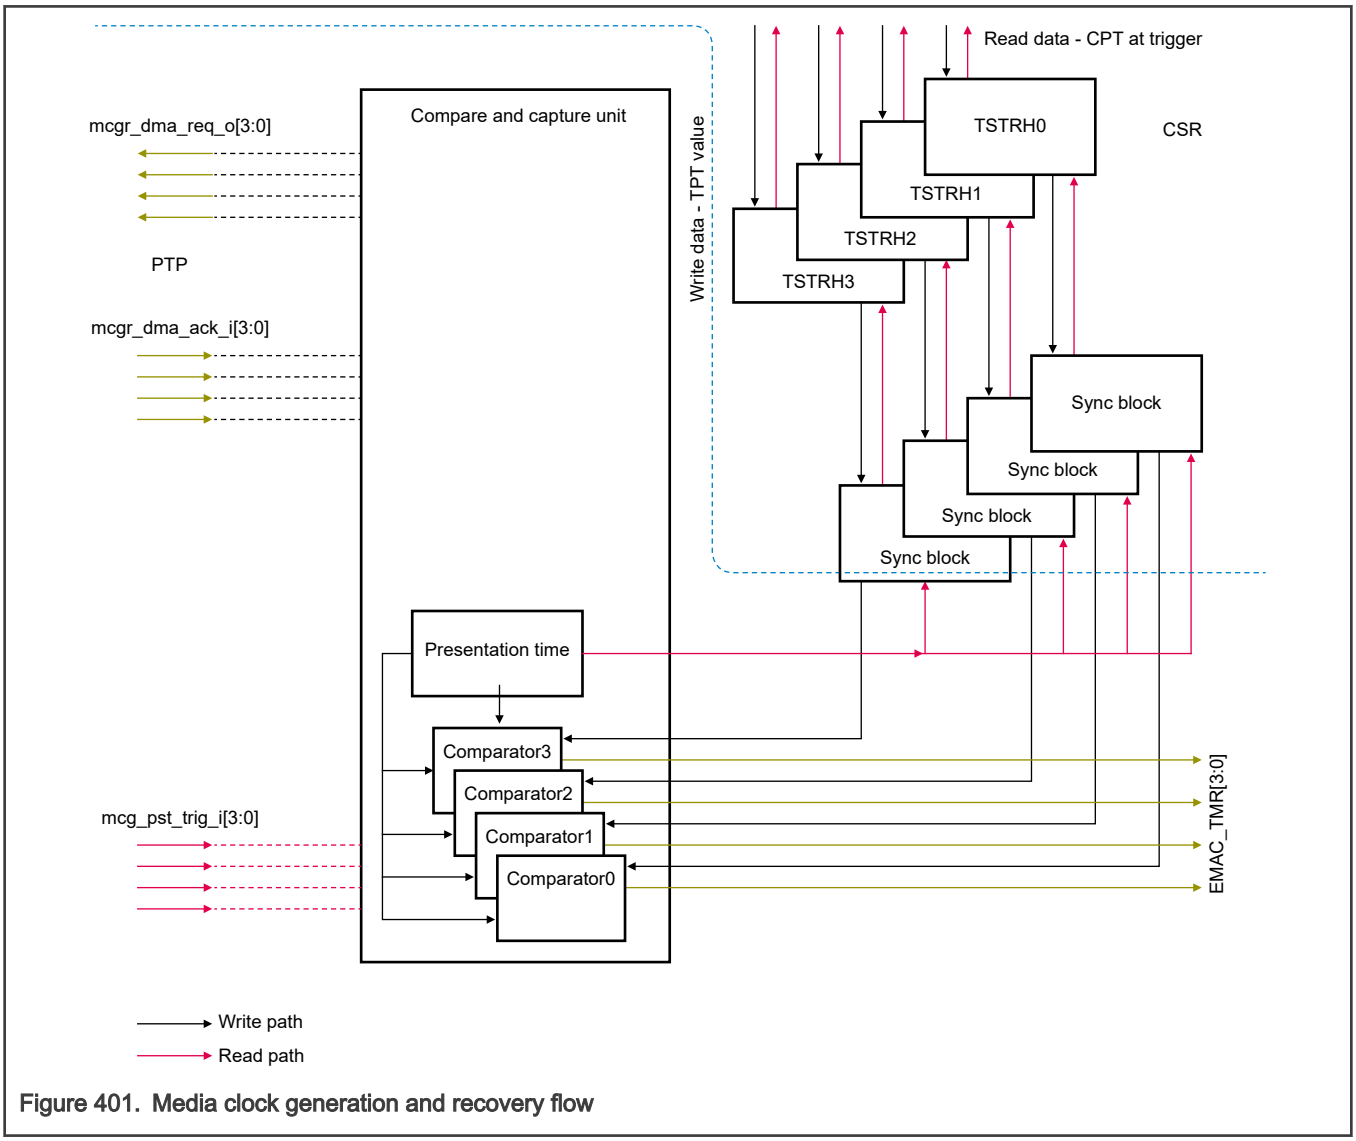


Figure 401. Media clock generation and recovery flow

NOTE

1. The consecutive triggers to sample the presentation time must assert after a few PTP clock cycles so as to allow synchronization delays. (There is no such issue when the input trigger maximum frequency is 8 KHz and the PTP clock runs at least at 1MHz)
2. In the Media Clock Recovery mode, the DMA acknowledgment is both posted as well as non-posted.

See Programming guidelines for media clock generation and recovery for more information.

74.11.10 One step timestamp

IP supports the one step timestamp feature. Writing 1 to bit 20 (OSTC) in the control word, enables the one step timestamp feature for a packet.

See the Programming guidelines for IEEE 1588 timestamping for more information.

74.11.11 IEEE 1588 sub nanoseconds timestamp

IP supports the ingress and egress correction accuracy in sub nanoseconds. It is programmed in MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS], respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. You must program the least significant 8 bits of the value in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Egress_Corr_Nanosecond[TSEC] must be 0x3 and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS] must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Ingress_Corr_Nanosecond[TSIC] must be 0xBB9A_C9FC and MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] must be 0x66 (fractional part of (10^9 - 3.6) * 256).

74.12 Multiple channels and queues support

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP support two queues and channel on Tx and Rx paths. Figure 402 shows the architecture of IP with two queues and channel.

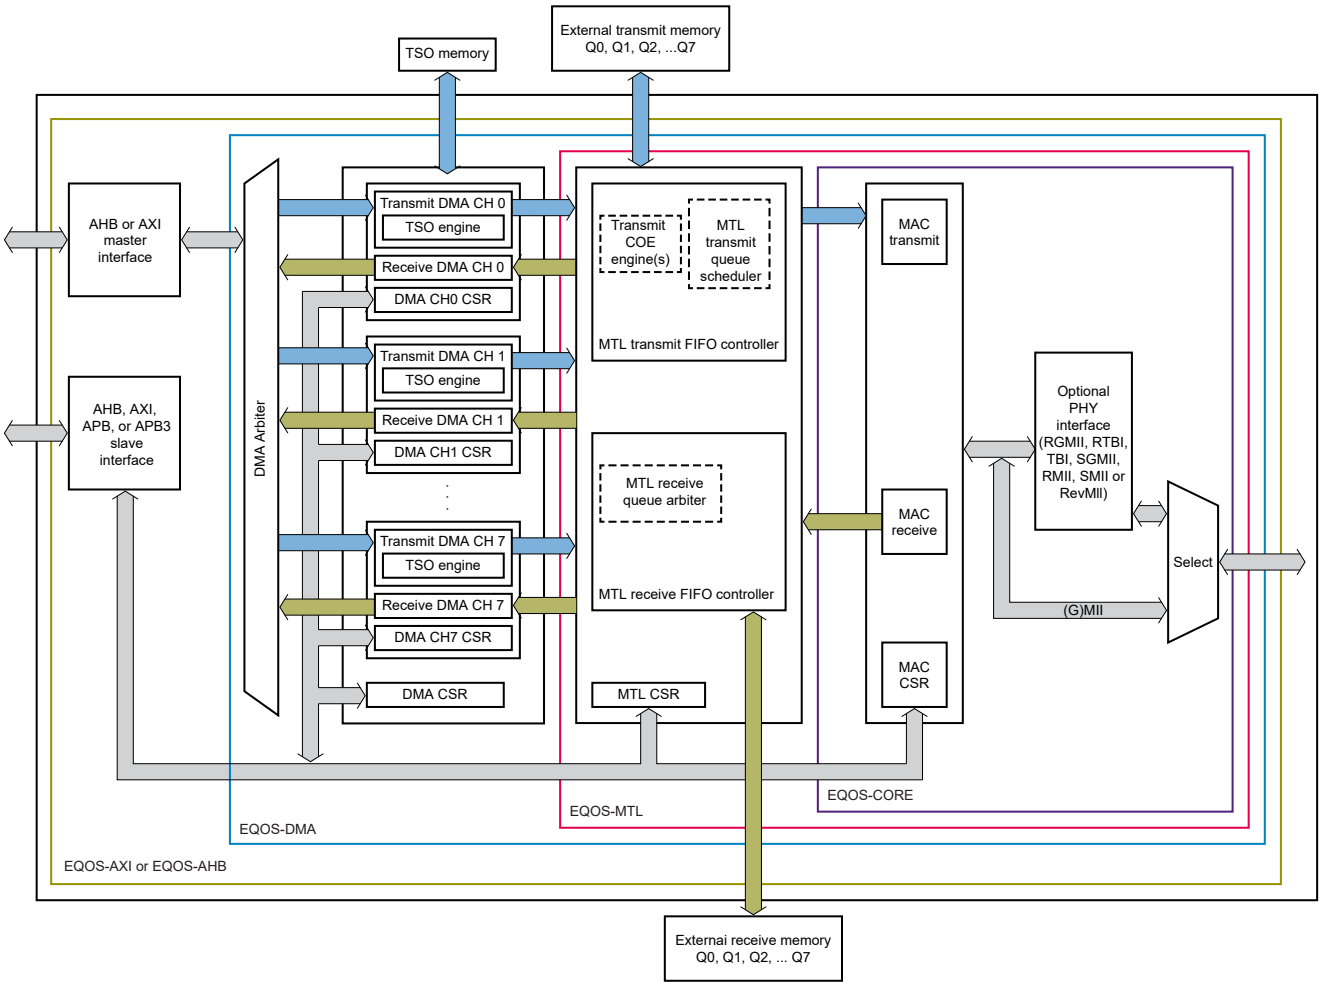

Figure 402. Module with multiple channels and queues block diagram

The above block diagram, support only two queues.

IP DMA arbiter support two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels to access descriptors and data buffers. DMA_Mode[DA] specifies the arbitration scheme (fixed or weighted round-robin) between the channel Tx and Rx DMA.

DMA_Mode[TXPR] sets the priority between the corresponding Tx DMA and Rx DMA. Writing 1 to DMA_Mode[PR] specifies the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Table 506 provides an information about the priority scheme between Tx DMA and Rx DMA.

Table 506. Priority scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1

Table continues on the next page...

Table 506. Priority scheme for Tx DMA and Rx DMA (continued)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

74.12.1 Multiple queues and channels support in the transmit path

IP support two transmit queues and two channels.

Fixed priority scheme is the default priority scheme for the DMA channels and channel with highest priority always wins the arbitration when it requests for the bus. Channel 0 is always of lowest priority and channel 1 is always of highest priority.

In weighted strict priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. Reallocate the unused burst transfers of one or more channels on the basis of the priority. The channel with highest priority receives the unused burst transfer time before it is allocated to a channel with the next highest priority. You can process the next lower priority, when a channel uses the allocated burst transfers. After processing the allocated bandwidth of all the channels that have packets to transmit, allocate any unused burst transfer time to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

In weighted round robin (WRR) priority scheme, program the weight through TCW field of DMA_CH#_Tx_Control register. IN WRR scheme, service all channels in round-robin order according to the weights settings. Table 507 shows that the TCW field of DMA_CH#_Tx_Control register provides the weight for each transmit channel.

Table 507. Weight for DMA channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

See Programming guidelines for multi-channel multi-queuing for more information.

74.12.2 Multiple queues and channels support in the receive path

IP support two receive channels and two queues.

In the receive direction, the MTL Rx controller selects the Rx DMA for which it transfers or reads the data from the receive FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it will transfer. The scheduler checks whether sufficient data (of requested burst length) is available to transfer to these DMAs and then selects the receive DMA that is serviced using the programmed priorities.

See Programming guidelines for multi-channel multi-queuing for more information.

74.12.3 Rx queue to DMA mapping

You can program MTL_RxQ_DMA_Map0 (for queues 0 and 1) to route the packets in the MTL receive queues to any one of the multiple DMA channels.

The following types of receive queue to DMA mapping is possible through programming.

74.12.3.1 Static mapping

In this mode, you can connect all the packets of the receive queue to a specific DMA channel. For example, all the packets from the receive queue 0 program MTL_RxQ_DMA_Map0[Q0MDMACH] (bit[3:0]) and MTL_RxQ_DMA_Map0[Q0DDMACH] (bit[7] = 0) to route to a DMA channel.

Similarly, packets from other receive queues program register fields corresponding to each queue to route to any DMA channel.

74.12.3.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet read from a Rx queue is not constant but it is decided independently for each packet. For example, if you write 1 to MTL_RxQ_DMA_Map0[Q1DDMACH], it indicates that the static mapping disables for receive queue 1 and ignores the value in MTL_RxQ_DMA_Map0[Q1MDMACH]. The MAC receiver decides the destination DMA channel for each packet, depending on the following in decreasing order of priority:

1. **L3-L4 filter based DMA selection**: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number, if DMCHEN field of the same register is 1. If none of the L3-L4 registers give a comparison match, then the module proceeds to the next step below.
2. **Extended VLAN based DMA selection**: Extended routing is applicable only if the VLAN filter has passed. Routing is done only on the basis of the perfect filter result. Each perfect filter has a DMA channel enable and a DMA channel number field which you can program. Routing is applicable for a filter, only if the DMA channel enable field is 1. The frame routes to the smallest matching filter's DMA channel, if it is enabled. If the filter's DMA channel number is not enabled, the frame route to channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1, then the MAC checks if DMA channel number of filter 1 is enabled through programming. If yes, the frame route to the programmed value; otherwise it route to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame routes on the basis of the DA based addressing or to channel 0.

   If hash filter is also enabled, it is determines the filter result only. Routing will still depends on the enabled perfect filters. Routing based on the VLAN filter will not occur if none of the perfect filters are enabled or if all of them are bypassed. The frame will route via DA based addressing or to channel 0. If all the perfect filters fails and the hash filter has passed, then the VLAN filter result is a pass but routing will be based on DA based addressing or to channel 0. Similar behavior is seen when you enables inverse filtering as well.
3. **Ethernet DA-based DMA selection**: The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations make a successful match or decision, then the packet routes to the DMA channel 0 by default.

74.12.3.2.1 Broadcast/multicast packet duplication

This feature provides a mechanism to send the received broadcast or multicast packets to multiple DMA channels.

MAC_Address0_High[DCS] and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC address present in that register) must route.

DMA channel routing mechanisms such as extended VLAN, or L3-L4 based routing does not support the packet duplication.

The packet duplication feature is supported only on the highest MTL queue configured. Therefore, you must program MAC_RxQ_Ctrl1[MCBCQ] to the highest RxQ present in the configuration for the packet duplication for broadcast or multicast packets.

74.12.4 Selection of tag priorities assigned to receive queues

Program the PSRQ field in the corresponding MAC_RxQ_Ctrl2 to assign the VLAN tag priorities to receive queues. The bit corresponding to the VLAN tag priority can be set in the PSRQ field for assigning that priority to the receive queue. For example, if you want to assign VLAN tag priority of 3 to receive queue 0, write 1 to bit [3] in PSRQ field of MAC_RxQ_Ctrl2. The VLAN tag priority assigned to particular receive queue must be unique, that is, you cannot assign more than one receive queue to the same VLAN tag priority. However, more than one VLAN tag priorities can be assigned to same receive queue.

The settings in the PSRQ field is used for VLAN tagged receive packet routing to receive queues as well as for PFC based transit flow control. The received VLAN tagged receive packet route to receive queue that has the VLAN tag priority match. In PFC based transit flow control, PSRQ field corresponding to a particular receive queue enables VLAN tag priorities in the PFC packet transmitted when corresponding receive queue reach the threshold level.

74.12.5 Receive side routing from MAC to queues

IP supports receive side routing from MAC to queues. MAC route the receive packets to the receive queues on the basis of the these packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter

- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN tag priority field in VLAN tagged AV data packets
- AV control packets
- VLAN tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN tag priority field in VLAN tagged packets
- Untagged packets

You can route the outer C-VLAN tagged AV data receive packets on the basis of the priorities assigned to receive queues through PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature enables (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with an inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of Rx packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the AV control receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[AVCPQ] and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature is enabled (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of receive packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the VLAN tagged receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue for DCB/generic. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged IEEE 1588 PTP over Ethernet receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[PTPQ] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. Also, you can route the VLAN tagged IEEE 1588 PTP over Ethernet receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 or the receive queue number specified in the MAC_RxQ_Ctrl1[PTPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 register enables the corresponding Rx queue. Programming MAC_RxQ_Ctrl1[TPQC] determines this. This type of receive packet routing is available when IEEE 1588 timestamp feature supports and the multiple receive queues are selected in the configuration. The VLAN tagged IEEE 1588 PTP over Ethernet receive packets are detected only when you disables 802.1AS mode (MAC_Timestamp_Control[AV8021ASMEN] = 0), otherwise this type of receive packets are routed as generic VLAN tagged Rx packets.

You can route the multicast or broadcast destination address receive packets that passes the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[MCBCQ]the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MAC_RxQ_Ctrl1[MCBCQEN] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of Rx packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[UPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The unicast destination address receive packets that fail the destination address filter can be routed based on the receive queue number specified in MAC_RxQ_Ctrl4[UFFQ] when enabled through MAC_RxQ_Ctrl4[UFFQE]UFFQE, MAC_Packet_Filter[RA] = 1 and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the multicast destination address receive packets that fails the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl4[MFFQ] when MAC_RxQ_Ctrl4[MFFQE] enables it. MAC_Packet_Filter[RA] = 1 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The receive packet will route through the receive queue 0, if it is not classified in any of the defined packet type for routing.

74.12.6 Receive side arbitration between DMA and MTL

IP controller supports receive side arbitration between DMA and MTL.

After the current packet processing completes, the DMA channel controller fetches the next descriptor and after the descriptor fetching completes, the DMA channel controller evaluates the amount of data to transfer to the Rx buffer on the basis of the programmed PBL and receive buffer length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL receive queue arbitration scheme selects receive queue on the basis of the arbitration scheme (MTL_Operation_Mode[RAA]) and the weights programmed in queue <n> receive control register. The arbitration is done among queues for which DMA is ready to service. After the receive queue is selected, PBL amount of data is read out from that queue and route to the receive DMA channel on the basis of the receive channel selection criteria.

The arbitration occur after every PBL data transfer completes and descriptors are ready for processing from at least one DMA channel.

74.12.7 Transit side arbitration between DMA and MTL

IP supports transit side arbitration between DMA and MTL. Transit DMA channels and transit queues are always mapped directly because the number of transit DMA channels are always equal to the number of transit queues in MTL. For instance, each transit DMA pushes data into its respective transit queue assigned to it.

The data inside each transit queue is stored in packets. Therefore, if two DMAs are allowed to transfer data into the same queue, when a transit DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding transit queue.

74.12.8 Audio video bridging

IP supports the audio video bridging in 100 Mbps mode only, which allows the transmission of time sensitive traffic over network. IP implements these protocol for supporting the AVB feature:

- IEEE 802.1Qbv-2015 (Enhancements to scheduling traffic)
- IEEE 802.3br (Interspersing traffic)
- IEEE 802.1Qbu (Frame preemption)

The queue 0 transmit path supports the strict priority algorithm, and it is used for best-effort traffic when transmit paths of additional queues use the credit-based shaper algorithm to support traffic management. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if these conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive per the algorithm
- AV traffic is received on all queues. IP can also receive untagged PTP packets in addition to AV traffic on any queue.

74.12.9 Queue modes

Transit and receive queues both handles the AV traffic.

Queueing is based on WRR (Weighted round robin) or WSP (Weighted strict priority) algorithm for generic traffic. It is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

The receive queue is configured for generic or AV based routing, which depends on the RXQ#EN field of corresponding queue. Queueing is done on the basis of the VLAN tag priority. The VLAN tag priority must match the PSRQ field of MAC_RxQ_Ctrl2. The receive packets can route to a particular DMA channel on the basis of the DCS field of perfectly-matched MAC address register.

By default, the untagged packets in a generic traffic route to the receive queue specified in MAC_RxQ_Ctrl1[UPQ]. Queue 0 is the default value of MAC_RxQ_Ctrl1[UPQ]. You can override the default value with any other value, for the MAC_RxQ_Ctrl1[UPQ].

The AV control packets (tagged or untagged) route on the basis of MAC_RxQ_Ctrl1[AVCPQ]. The PTP over Ethernet packets route on the basis of MAC_RxQ_Ctrl1[PTPQ].

74.12.10 Queue priorities

You can program the priority of an receive queue in the corresponding field of MAC_RxQ_Ctrl2. Also, you must program the AV queue (high priority) as an higher priority than the best-effort queue (low priority).

74.12.11 Enhancements to scheduled traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each queues on every egress port which makes the implementation aware of traffic arrival schedule. This information blocks the lower priority traffic from transmission in this time window or slot. This ensures that the sender forward the scheduled traffic to receiver through all the network nodes with a deterministic delay.

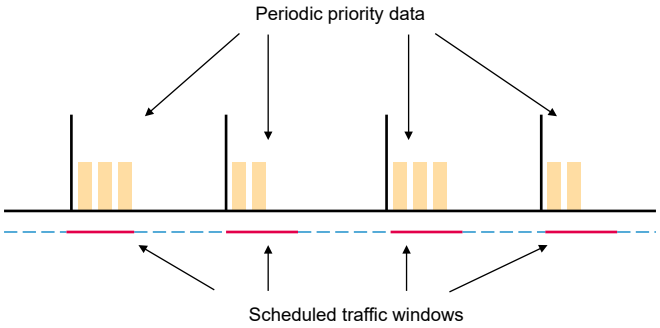

Figure 403. Time aware shaper implementation for traffic scheduling

An important requirement to achieve a low latency is to ensure that there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations when a transmission starts.

As shown in Figure 404 , if an interfering frame begins transmission just before the reserved time period starts, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

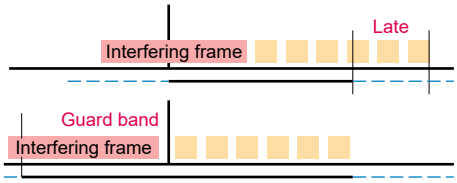

Figure 404. Implementing a guard band to avoid delays due to interfering frames

A larger guard band equates to a less efficient use of network bandwidth. However, this issue is addressed with the implementation of IEEE802.1Qbu (frame preemption). Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band must be as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

74.12.11.1 Frequently used terms in EST

These are some of the frequently used terms in the EST support and their definitions.

- Gate control list: The list in the hardware memory that hold the gate controls and the associated time intervals.
- Gate controls: For a given schedule (row in gate control list) there is a gate open (O) and gate close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the gate controls. Example: CCOCOOCO means TC7=C, TC6=C, TC5=O and so on.

- Time interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the gate control list that indicates the time for which the associated gate controls are valid.
- Base time register: Each gate control list is associated with a 64-bit base time register that holds the start time (in PTP format) for the list.

74.12.11.2 Updates to the transmit scheduling to support EST

To support EST, these updates are required to transmit scheduling:

- Implementation of gate control list (GCL)
- Enforcing gate controls in the scheduler
- Utilizing gate open (O) duty cycle in the computation of idleSlope (CBS)

74.12.11.2.1 Implementation of gate control list (GCL)

Figure 405 shows how the gate control list governs the gate close(C) and open(O) events on the basis of the schedule provided for each event. GCL has two parts:

- Time interval: Defines the time in nanoseconds for which the gate controls are valid and must apply before reading the next gate controls from the list. The configurable width of 16, 20 or 24-bit represents a maximum of 64us, 1ms, or 16ms schedule interval respectively. It supports left shift of the time interval upto 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate control: Defines the open (O) represented by logic 1 or close (C) represented by logic 0 state for the gate of each TC.

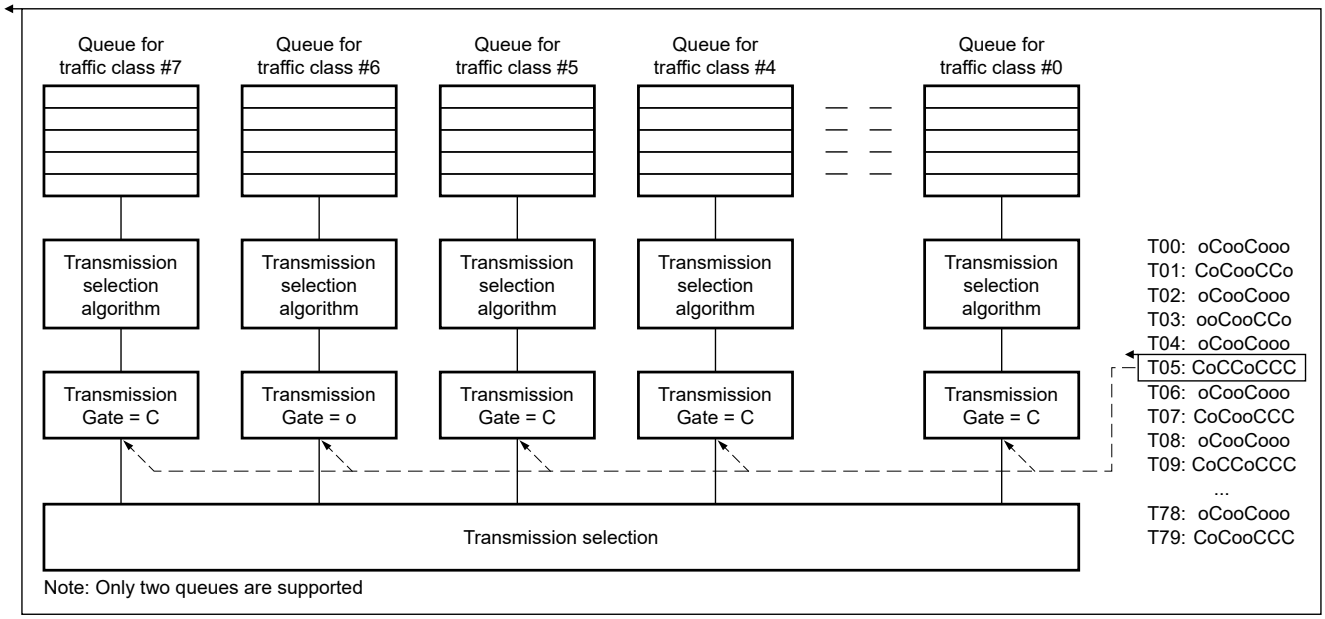

Figure 405. Block diagram from IEEE 802.1 Qbv specification - GCL governing gate close and open events

The implementation of GCL consists of these two gate control lists:

- HWOL - Hardware owned list which is a list for hardware access.
- SWOL - Software owned list which is a list for software access.

The access to these lists is mutually exclusive. Hardware sets the ownership to the list in MTL_EST_Status[SWOL]. Table 508 provides the implementation details of GCL.

Table 508. External memory used for holding the two gate-control lists

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
I	I	
I	I	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
I	I	
I	I	
OCOCCCCC		
OOCCCCCC	T last	

74.12.11.2.2 Registers related to gate control list

The following are the set of four registers (one for each GCL) related to GCL. These registers are implemented through Indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data registers.

1. 64-bit Base time register (BTR)

2. 40-bit Cycle time register (CTR)

3. m-bit Time extension register (TER)

4. n-bit [Gate control] List length register (LLR) (n depends of the configured GCL depth)

74.12.11.2.2.1 Base time register (BTR)

This is a 64-bit register that specifies the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nanoseconds). After the execution of a given list starts, the implementation can update the value in BTR to indicate the next list execution start time.

74.12.11.2.2.2 Cycle time register (CTR)

This is a 40-bit register that specifies the time at which the execution of the GCL must repeat. This register consists of an 8-bit value in seconds, and a 32-bit value in nanoseconds (similar to the PTP time format with truncated seconds register). For a given GCL, the start time is "Base Time" + N * "Cycle Time" where N is an integer value that represents the iteration number starting with 0 for first iteration. If the GCL execution takes longer than the cycle time, then the list is truncated at the cycle time and the subsequent loop begins at cycle time.

74.12.11.2.2.3 Time extension register (TER)

This is a m-bit (where m = Configured time interval width + 7) register that specifies the amount of time (in nano seconds) the current GCL can extend before switching to the new GCL. This helps to avoid the execution of the small fragments of the current list before switching to a new list.

74.12.11.2.2.4 List length register (LLR)

This is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that specifies the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

74.12.11.2.3 Transmission gating implementation

A bridge or an end station can enhance to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if you can select the queued frames for transmission.

For a TC, the transmission gate can be in one of these two states:

1. Open: Select queued frames for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. Closed: Does not select queued frames for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that you can avoid the transmission overruns and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by MTL_EST_Control[CTOV]). This ensures that the schedule provided is always accurately implemented at the line.

You must ensure that the GCL slot interval is always greater than the expected packet size and overhead (scheduler delay, inter frame gap (IFG), and preamble, all combined).

74.12.11.3 Idle slope computation updates

When EST is enabled, credit accumulates only when the gate is open therefore, the effective data rate of the idleSlope must increase to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed on the basis of the gate open time and oper cycle time values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient field width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

74.12.11.3.1 Operational details of GCL

Write 1 to MTL_EST_Control[SSWL], so that the hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the base time register (BTR) and is held until the programmed "time interval" value.

One additional gate control event is always read ahead from the list, to avoid the transmission overruns. This enables the GCL to determine the next gate close events (if any) for the open TCs.

The scheduling is done on the basis of the gate open state and time interval of only the current and subsequent schedule. An internal accumulator adds the time intervals when gate controls are applied. BTR + Accumulator specifies the time at which the next set of gate controls are applied.

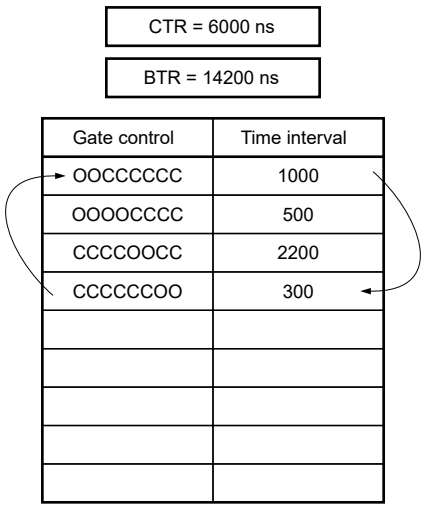

Figure 406. GCL and associated registers - basetime and cycletime

GCL is read progressively from the first row adhering to the schedule. The read operations continue until the list length (from LLR register) is reached and the execution of the list restarts at BTR + CTR time. At this point the value in CTR increments BTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are in open state, during the execution of the list.

In cases where the execution time of the list is greater than the cycletime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 509. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

Table 509 describes an example in which the execution starts at 14200 and the first set of gate controls "OOCCCCCC" are applied immediately. The time interval is 1000 ns, so the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . The above table shows that there are no gate controls available after the execution of the last gate control and before the next iteration of the loop. The gates are deemed in open state during that time period as depicted at 18200 current time.

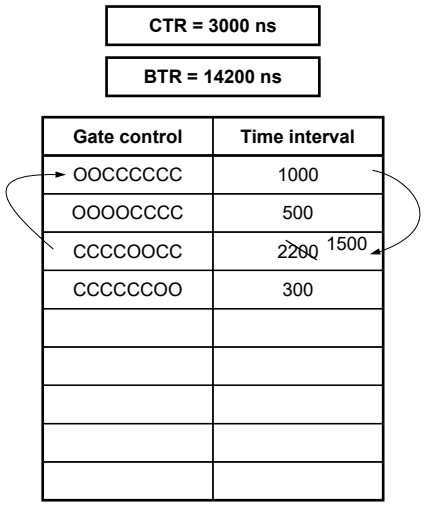

Figure 407. GCL and associated registers - BaseTime and CycleTime list execution time > CycleTime

Table 510 indicates that the list execution takes longer than the allocated CycleTime, so the list is truncated and the list starts from the BTR+CTR.

Table 510. GCL and associated registers - BTR and CTR, execution time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

When you apply the third set of gate controls, BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

74.12.11.3.2 Installing a new GCL

The switch to the new GCL can happen in one of the following ways when a new software programmed GCL is available and executed at the new BTR value:

- New base time aligned with current schedule
- New base time unaligned with current schedule

74.12.11.3.2.1 New base time aligned with current schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New base time > = Current time)

ConfigChangeTime = New BaseTime

Else If (New base time < Current time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is true.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requires the software to reprogram the new base time.

Figure 408 illustrates the installation of the new GCL along with the timelines.

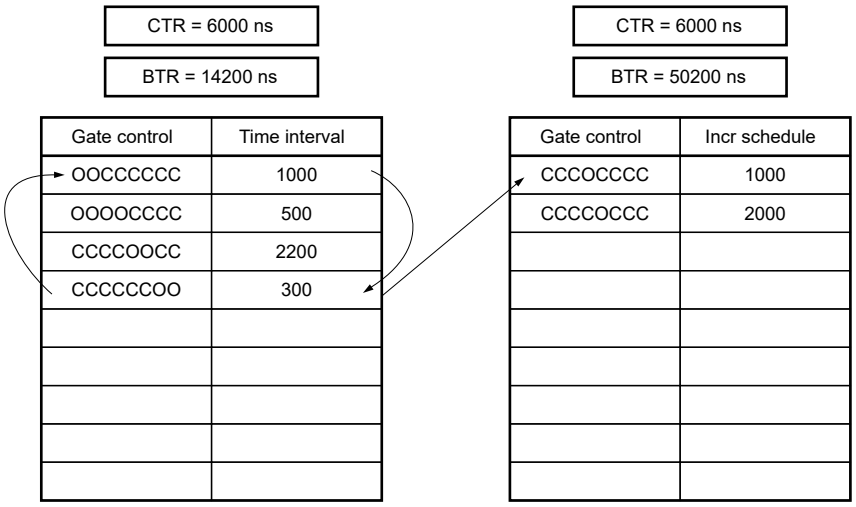

Figure 408. Switching to a new configuration that is aligned with the existing configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 511. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200

Table continues on the next page...

Table 511. GCL and associated registers - BTR and CTR (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

74.12.11.3.2.2 New base time unaligned with current schedule

If the new cycletime differs from the current cycletime or new basetime in the future and is not an integer multiple of current cycletime, then the old and new cycles do not line up. When new basetime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

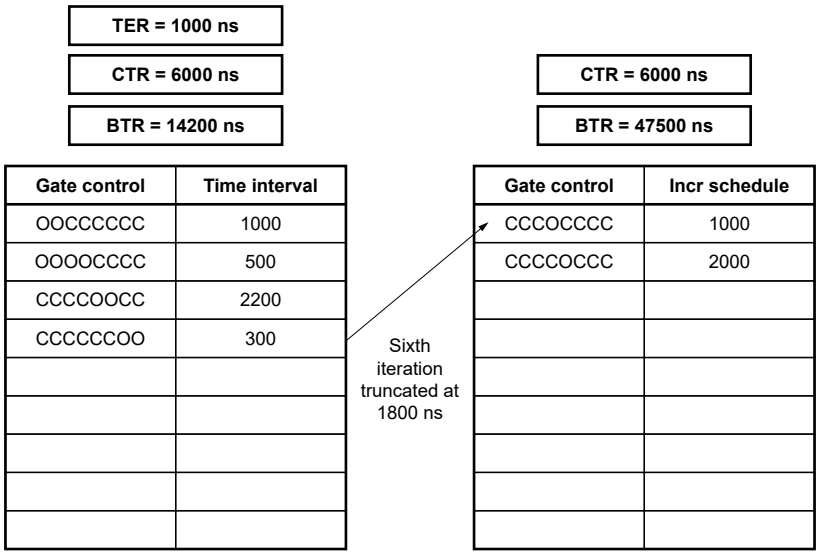

Figure 409. Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 512. Extending to new list by truncating the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200

Table continues on the next page...

Table 512. Extending to new list by truncating the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

Figure 410. Switching to new list by extending the current list

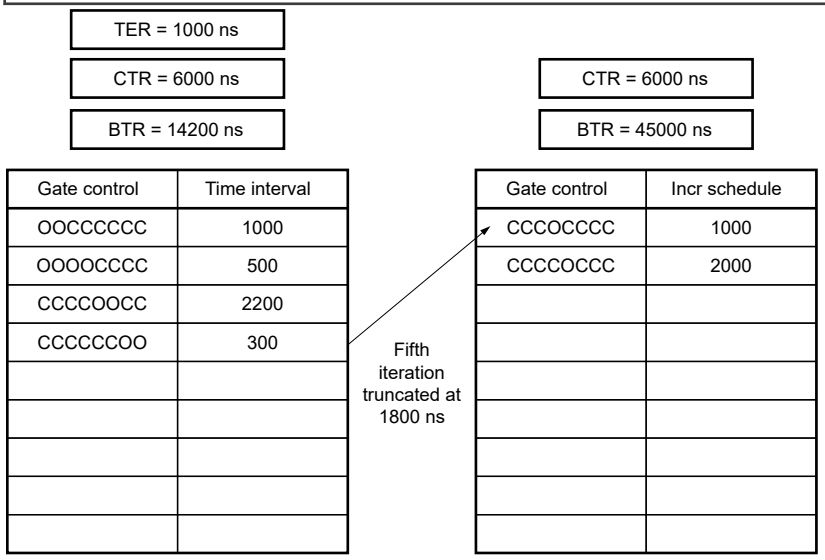

Table 513. Switching to new list by extending the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000

Table continues on the next page...

Table 513. Switching to new list by extending the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

74.12.11.4 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming guidelines for EST

74.12.12 Frame preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemtable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.

- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

If you are unable to schedule fragmented packets after a certain number of attempts because of some reason, there is a possibility that the remaining fragmented packets are dropped. For this, software can program MTL_EST_Control[LCSE] to increase number of iterations or MTL_EST_Control[DFBS] to disable dropping of packet.

NOTE

EST and FPE cannot be used at the same time.

74.12.12.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate control (up to 8 bits)	Time interval (ns) 16, 20 or 24 bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
|	|
|	|
OCOCOCOO	T126
OOOOCCCC	T127

Figure 411. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate control (up to 7 bits)	Release or hold indication	Time interval (ns) 16, 20 or 24 bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

Figure 412. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

74.12.12.2 Impact of Preemption on CBS

In Credit Base Shaper(CBS), the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

74.12.12.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 514. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C

Table continues on the next page...

Table 514. Possible SMD Values of mPacket (continued)

mPacket Type	Notation	Frame Count	Value
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 515. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC

- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

74.12.12.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

All the PTP packets should be transmitted as express packets

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 518. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

74.12.12.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

74.12.12.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

74.12.12.5 Receive Preemption

74.12.12.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 519. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

74.12.12.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

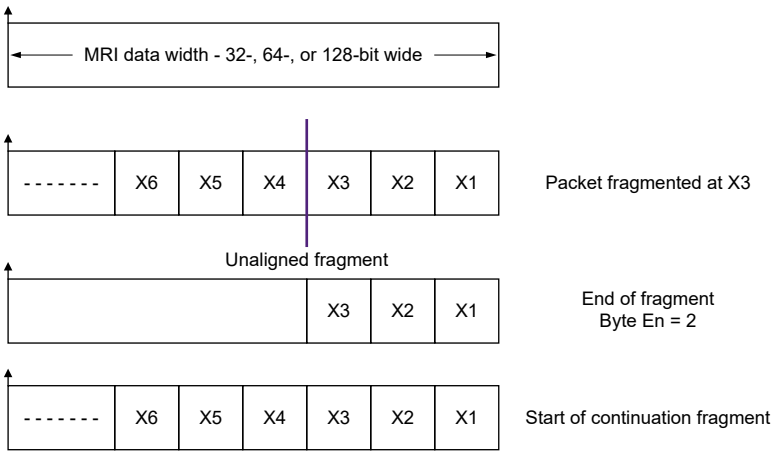

Figure 413. Data Alignment Feature of MAC

74.12.12.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 520. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

74.12.12.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

74.12.12.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Software must ensure that frame preemption verify and response packet are not triggered at the same time. Trigger either of the packets and then wait for its completion before triggering another packet.

74.12.12.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 521. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr

Table continues on the next page...

Table 521. MMC Counters and Associated Interrupt Registers (continued)

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

74.12.12.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

74.12.13 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

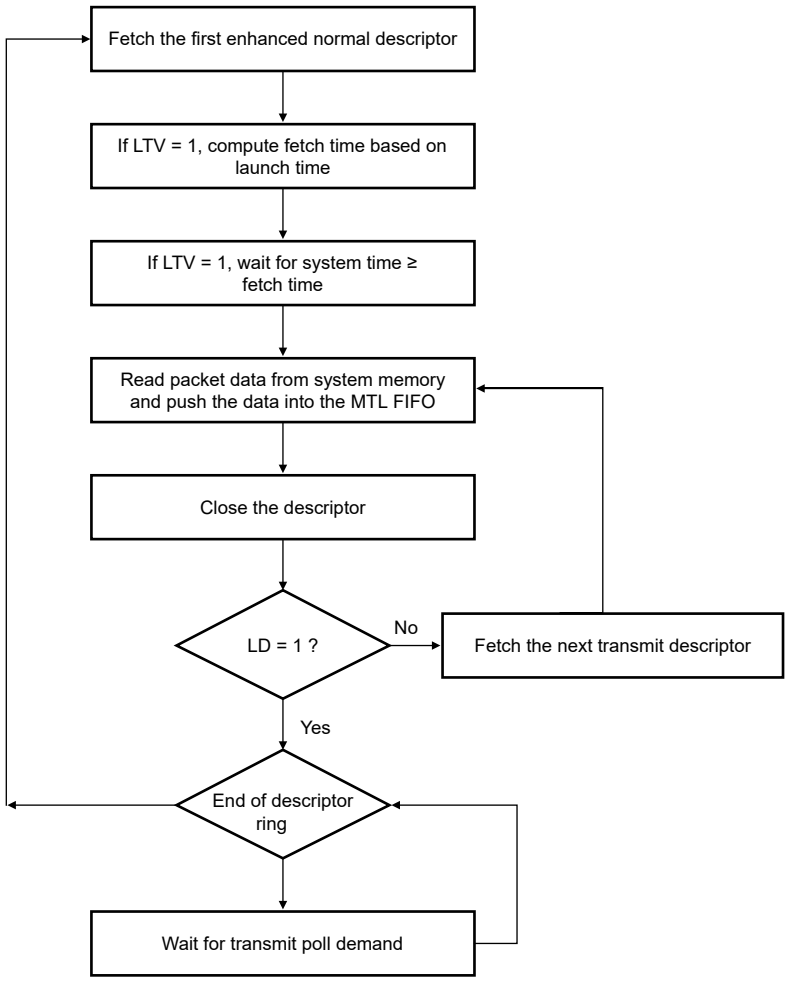

Figure 414. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

74.12.13.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time resets after the transmission of one frame. These are the two formats of the launch time.

Normal or absolute format:

In this format, the launch time is interpreted in the normal or absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24-bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based system or PTP time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of system time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24-bits of the launch time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of launch time is 256 seconds,

- Launch time is greater than current system time when its value is between system time[39:8] and System time[39:8] + 128 sec.

- Launch time is less than current system time when its value is between System Time[39:8] + 128sec and System Time[39:8] + 256 sec, because this is a modulo 256 computation.

EST or offset format

In this format, the launch time is a offset value relative to the time which the BTR of the GCL list provided in the GCL slot number (GSN) indicates. The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the launch time value are specified in the enhanced transmit descriptor in the DMA configurations, or as control word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL slot number. The value of the launch time offset must be smaller than the value of the cycle time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of launch time offset must be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch time = Launch GSN BTR[63:0] + (Launch time offset[31:0] << 8), which is compared with the system time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL slot number (GSN) A modulo 16 count of the GCL loop count is implemented and it is known as GSN. The count is incremented for every new GCL loop. Installation of new GCL list does not impact the count. Read MTL_EST_Status[CGSN] to obtain the current GCL slot number.

The maximum value of GSN is 15. Therefore the GSN values between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8 represent current or future slots and all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8.

74.12.13.2 Launch expiry time

Normal or Absolute Mode

In this mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch expiry time = (Launch time[39:8] + LEOS[32:8]) * 256 ns

The packet with a specific launch time is considered as eligible for transmission when the launch time is less than the system time and (if MTL_TBS_CTRL[LEOV] = 1) the system time is less than the launch expiry time.

When the system time is greater than the launch expiry time, the frame is categorized as expired and it drops from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the fetch, launch, and launch expiry time must never set to a value larger than the Current system time + 128 sec; such a value is interpreted as time that has already elapsed.
- In Full Duplex mode, the frames dropped from the MTL FIFO have error summary (Bit 15) and excessive deferral (bit 3) of TxStatus set.

EST/Offset Mode

In EST mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEGOS] and MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999 ns or CTR-1 ns.

The Launch expiry GSN is computed as follows:

Launch expiry GSN = (Launch GSN + LEGOS + CCMA) where, CCMA is the CTR carry due to modulo addition. This value is 1 if ((Launch time offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch expiry offset = (Launch time offset+ LEOS) - CTR

When CCMA = 0,

Launch expiry offset = (Launch time offset + LEOS).

Launch expiry time = Launch expiry GSN BTR [63:0] + Launch expiry time offset.

When MTL_TBS_CTRL[LEOV] is not 1, the launch expiry time is not checked.

When MTL_TBS_CTRL[LEOV] = 1, and

- the system time is greater than the launch expiry time, the frame drops from MTL FIFO. Then the frame is considered as expired.
- the launch time is smaller than the system time and the launch expiry time is greater than the system time, then the frame is considered eligible for launch.

NOTE

- Max value of MTL_TBS_CTRL[LEGOS] is 7. This indicates that when MTL_TBS_CTRL[LEOV] = 1, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for launch.
- The slot number of the first GCL list that executes each time after EST is enabled, is zero.

74.12.13.3 Fetch time

This accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If DMA_TBS_CTRL[FTOV] is 1, it indicates the fetch time for each packet. If DMA_TBS_CTRL[FTOV] is not 1, it indicates that the fetch time offset is not valid and DMA fetches packets without any time constraints.

Normal/Absolute mode

In this mode fetch time is derived or calculated by reducing the time specified in DMA_TBS_CTRL[FTOS] from the given launch time.

In Normal mode, the fetch launch time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The fetch time is 32-bits and is compared against the system time[39:8] to determine whether it is eligible for fetching the frame:

- The fetch time is defined as greater than system time if the fetch time is in the range of system time[39:8]" and system time[39:8] + 128 sec. The frame is considered as not-eligible for fetch.
- The fetch time is defined as smaller than the system time if the fetch time is in the range of system time[39:8] + 128 sec and system time[39:8] + 256 sec. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset mode

In this mode, the fetch GSN offset (DMA_TBS_CTRL[FGOS]) provides the slot number offset to deduct from the launch GSN. In this case the FTOS value must be smaller than 999,999,999 ns or CTR-1 ns.

If (Launch time offset >= FTOS):

Fetch time offset = ((Launch time offset - FTOS) * 256ns)

CBFS(CTR borrow for fetch subtraction) = 0

If (Launch time offset < FTOS) Fetch time offset = CTR + ((Launch time offset - FTOS) * 256ns)

CBFS (CTR borrow for fetch subtraction) = 1

The fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch time = Fetch GSN BTR[63:0] + Fetch time offset

The frame is eligible for DMA fetch when the fetch time is smaller than the system time.

DMA operations sequence

This is the sequence of operation when FTOV = 1:

1. Fetch the first enhanced normal descriptor (FD = 1).
2. Compute the fetch time on the basis of the launch time and wait for the system time to be greater than fetch time, if LTV = 1 and fetch is enabled.
3. Read the frame (data) from the host memory and transfer to MTL FIFO.
4. Close the normal descriptor.
5. Fetch the next normal descriptor (if the previous descriptor was not the last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD = 1).

After the last descriptor of a frame, program the next enhanced normal descriptor with a new launch time and with LTV = 1. Otherwise, process the subsequent frames without any time restrictions.

See Programming the launch time in time-based scheduling for more information.

74.13 TCP/IP Offloading Features

This section and all other sections, along with respective sub-sections are Synopsys Proprietary. Used with permission.

74.13.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

74.13.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0 in Table 19-12 on page 1330). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corre-sponding Header Length field in an extension header) is completely received.

74.13.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in Table 19-3 on page 1324). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. Following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 522. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes

Table continues on the next page...

Table 522. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not applicable • Not applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

74.13.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 523. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No

Table continues on the next page...

Table 523. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No

Table continues on the next page...

Table 523. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

74.14 MAC Management Counters

This section is Synopsys Proprietary. Used with permission.

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in EMAC register descriptions.

74.15 Flow Control

This section and its sub-sections are Synopsys Proprietary. Used with permission.

74.15.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

74.15.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 524. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

74.15.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

74.15.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 525. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

74.15.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

74.15.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 526. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

74.15.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

74.16 Loopback Mode

This section is Synopsys Proprietary. Used with permission.

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

74.17 Automotive Safety Features

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP supports the automotive safety feature.

74.17.1 Error Correction Code (ECC) Protection for Memories

The Error Correction Code (ECC) block can correct single-bit error and detect double-bit error.

At the write interface, ECC checkbits are generated by computing ECC on the contents of the data bus and respective address is appended with the data that is written to the memory.

At the read interface, ECC checkbits are recomputed on the content of the read data and the respective address is compared with the received checkbits in the memory.

Following figure shows the block diagram of ECC protection for memories

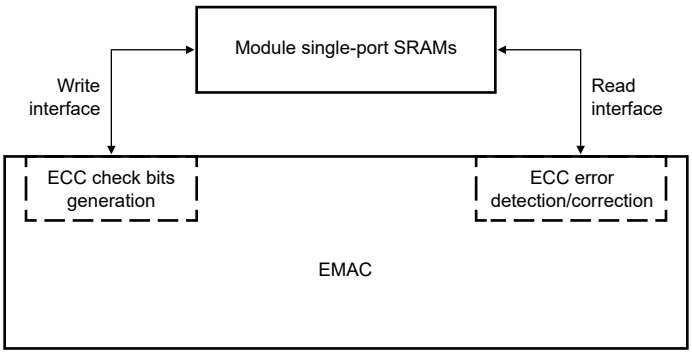

Figure 415. Block Diagram of ECC Protection for Memories

74.17.1.1 Handling the Address Mismatch

The ECC is calculated over the sum of memory data and memory location address. However only data is written in the memory along with the ECC(address is excluded).

On the read interface, the ECC is checked over the sum of memory DATA, memory ECC, and Internally generated address. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

74.17.1.2 Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_EC-C_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first errored memory address is reported or the latest errored memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected. The module sets the respective interrupt enable bits (in the DMA/MTL_ECC_Interrupt_enable register).
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Inter-rupt_Status registers.

NOTE

- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

74.17.1.3 ECC Error Injection Capabilities

IP supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection
- Two bits to indicate the type of error to be injected ❑ 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for

- MTL Tx/Rx and DMA TSO memory are specified in the MTL_DBG_CTL register, for and for R.
- MTL EST memory are specified in the MTL_EST_GCL_Control register
- Rx parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register

NOTE

While using debug mode for ECC error injection:

- There should be no traffic in the module
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write main-tains the same value for the error injection control word.
- See Programming guidelines for ECC protection for memories

74.17.2 Finite State Machine(FSM) Parity and Timeout Protection

The FSM protection feature supports FSM parity and time out protection.

74.17.2.1 FSM State Parity Protection

Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control Register.

74.17.2.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of CSR cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1us, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on the programmable bits NTMRMD, LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

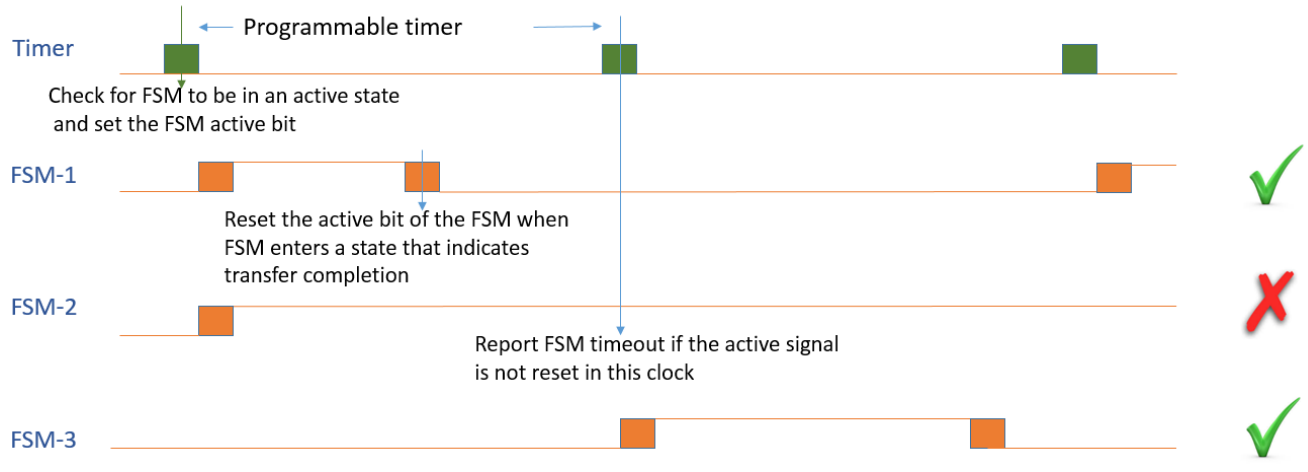

Figure 416. FSM Timeout Timing Diagram

In the above figure, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains. IP does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting IP).

74.17.2.3 Enabling FSM Parity and Timeout Protection

FSM timeout feature is enabled by setting the TMOUTEN field of MAC_FSM_Control register.

NOTE

See Programming guidelines for FSM parity and timeout

74.17.3 Application/CSR Interface Timeout Protection

This feature provides timeout protection to the application/CSR Interface. All the interfaces which has the handshake mechanism monitored for potential hangs due to the external agent (Master/Slave/Interconnect/Application client) not responding to the requests/transfers initiated by the QoS. After the request is initiated the response arrival interval is monitored. If the response does not arrive within a programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered, using similar trigger generation as explained in the Section FSM protection.

The timeout is triggered when IP initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register. The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when application timeout status is set.

The hardware does not attempt to recover from Application/CSR Interface hangs and relies on software to take appropriate corrective action.

NOTE

- Protection is not needed for APB3 Slave interfaces because potential hangs can be only when IP does not respond to the requests. In such cases the IP internal protection logic (FSM timeout) detects such defects.
- Based on the time at which the transfer is initiated relative to the timer ticks, the timeout period could be any value between the programmed timeout and 2x times the programmed timeout.
- When an uncorrectable safety interrupt is issued and the read of the Interrupt status register returns all zeros, it implies that the CSR read is not functional. As soft reset of IP is not possible without the CSR access, and therefore, a hard reset of IP is recommended.
- See Programming guidelines for FSM parity and timeout .

74.18 Descriptors

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

74.18.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

74.18.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

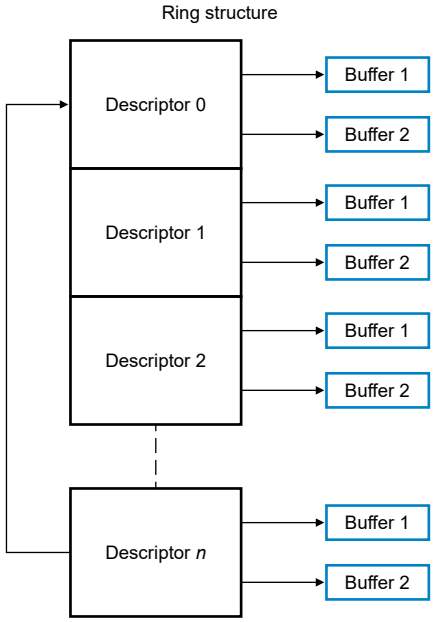

Figure 417. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

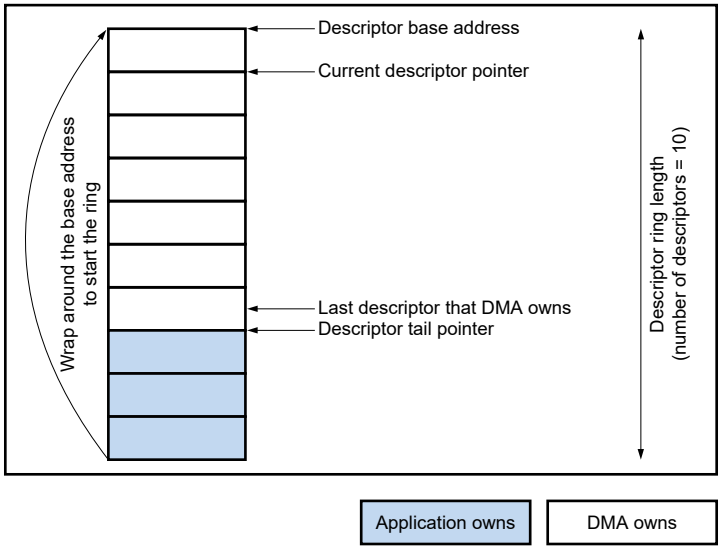

Figure 418. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

74.18.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

NOTE

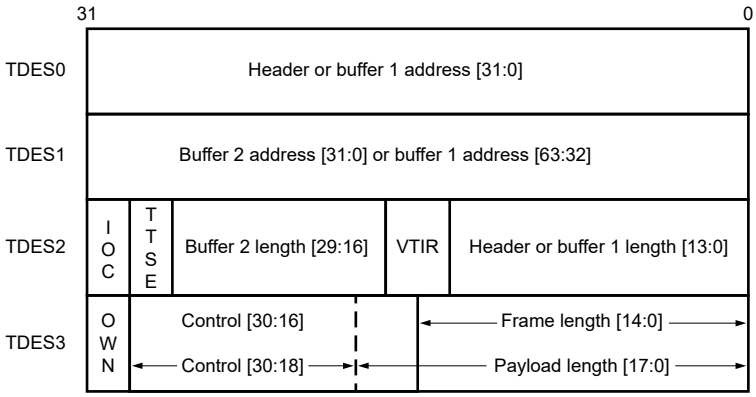
TSO Split header is not supported.

Software must not write same tail pointer addresses when DMA is in Suspended state before setting new descriptor(s) for further processing.

74.18.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 419. Transmit Descriptor Read Format



74.18.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 527. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

74.18.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 528. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

74.18.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 529. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 530. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/ TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

74.18.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 531. TDES2 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 532. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet.

Table continues on the next page...

Table 532. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support.

Table continues on the next page...

Table 532. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

74.18.3.1.5 Transmit normal descriptor (write-back format)

The transmit descriptor write-back format includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. Write 1 to the LD bit (TDES3[28]) in the descriptor where DMA writes back the status and timestamp information for the corresponding transmit packet.

Figure 420 shows the transmit descriptor write-back format.

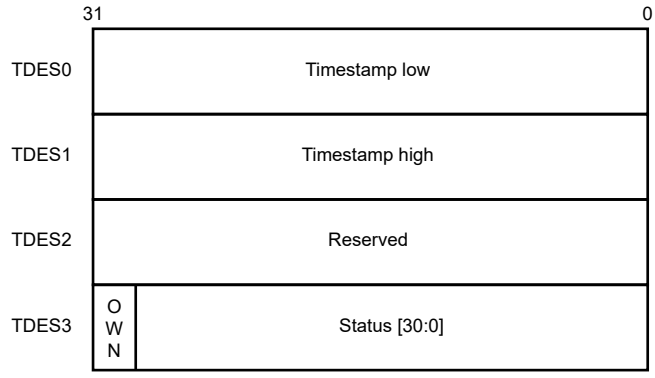


Figure 420. Transmit descriptor write-back format

TDES0 normal descriptor (write-back format)

Table 533 shows that this format is only applicable to the last descriptor of a packet.

Table 533. TDES0 normal descriptor (write-back format)TDES0 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding transmit packet. DMA writes the timestamp only if TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and the Timestamp status (TTSS) bit.

TDES1 normal descriptor (write-back format)

Table 534 shows that this format is only applicable to the last descriptor of a packet.

Table 534. TDES1 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High DMA updates this field with the most significant 32 bits of the timestamp captured for a corresponding transmit packet. DMA writes the timestamp only if the TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and Timestamp status (TTSS) bit.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 535. TDES2 normal descriptor (write-back format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 536. TDES3 normal descriptor (write-back format)

31	30	29	28	27:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 537. TDES3 normal descriptor (write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. DMA write 0 to this field when it completes the packet transmission. After the write-back is complete, this field is set to 'b0.
30	CTXT	Context Type

Table continues on the next page...

Table 537. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
		This field must be set to 'b0 for normal descriptor.
29	FD	First Descriptor This field indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This field is set to 'b1 for last descriptor of a packet. DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when the descriptor is closed. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT is 1 along with LD or FD bits as 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA write 1 to TI bit in the DMA_CH#_Status register **NOTE** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might consider as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This field indicates that a timestamp has been captured for the corresponding transmit packet. When this field is 1, it indicates that TDES0 and TDES1 have timestamp values that were captured for the transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is 1. This field is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. **NOTE** An uncorrectable error in the transmit FIFO memory is reported with (Bit 13) FF = 1. This is because the module flushes all such packets.

Table continues on the next page...

Table 537. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
15	ES	Error Summary This field indicates the logical OR of the following bits: • TDES3[0]: IP header error • TDES3[14]: Jabber timeout • TDES3[13]: Packet flush • TDES3[12]: Payload checksum error • TDES3[11]: Loss of carrier • TDES3[10]: No carrier • TDES3[9]: Late collision • TDES3[8]: Excessive collision • TDES3[3]: Excessive deferral • TDES3[2]: Underflow error This field is 1 when EUE (bit 16) = 1.
14	JT	Jabber Timeout This field indicates that the MAC transmitter experiences a jabber time-out. This field is 1 only when MAC_Configuration[JD] is not 1.
13	FF	Packet Flushed This field indicates that DMA or MTL flushes the packet because the CPU gives a software flush command.
12	PCE	Payload Checksum Error This field indicates that the checksum offload engine had a failure and does not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can either because of insufficient bytes, as the payload length field of the IP header indicates or the MTL starting to forward the packet to the MAC transmitter in Store-and-forward mode without calculating the checksum. This second error condition only occurs when the transmit FIFO depth is less than the length of the Ethernet packet that is transmitted to avoid deadlock. The MTL starts forwarding the packet when the FIFO is full, even in the Store-and-forward mode. This error can also occur when you detects a bus error during packet transfer. When the full checksum offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This field indicates that a loss of carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This field is valid only for the packets transmitted without collision and when MAC operates in the Half-duplex mode.
10	NC	No Carrier This field indicates that the carrier sense signal from the PHY was not asserted during transmission.

Table continues on the next page...

Table 537. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This field indicates that the transmission was aborted after 16 successive collisions when you transmits the current packet. If MAC_Configuration[DR] = 1, this field is 1 after first collision and abort the packet transmission.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before transmitting the packet. The count is not valid when the EC bit = 1.
3	ED	Excessive Deferral This field indicates that the transmission ends because of an excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode or Jumbo packet enabled mode) if MAC_Configuration[DC] = 1. When TBS is enabled in Full duplex mode and this field is 1, it indicates that the frame drops after the expiry time is reached.
2	UF	Underflow Error This field indicates that MAC aborts the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • DMA encounters an empty transmit buffer when it transmits the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the Suspended state and sets the underflow bit corresponding to a queue in MTL_Interrupt_Status.
1	DB	Deferred Bit This field indicates that MAC defers before transmitting because of presence of carrier. This field is valid only in the Half-Duplex mode.
0	IHE	IP Header Error When IP Header Error is 1, this field indicates that the checksum offload engine detects an IP header error. This field is valid only when transit checksum offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload. In Full-Duplex mode, when EST/Qbv is enabled and this field is 1, it indicates the frame drop status due to the frame size error or schedule error.

74.18.3.2 Transmit context descriptor

The transmit context descriptor can provide any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor provide the timestamps for one-step timestamp correction and VLAN tag ID for VLAN insertion feature. Write back is done on a context descriptor only to write 0 to OWN bit.

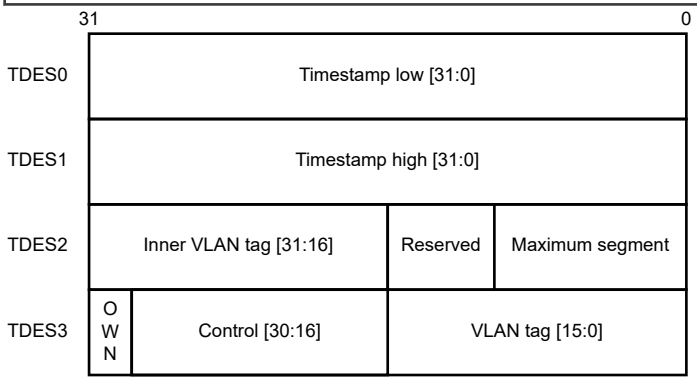
NOTE

DMA internally store the VLAN tag IDs and MSS values which the application provides in a context descriptor with their corresponding valid bits set. DMA always passes the last valid VLAN tag to the MTL, when the outer or inner VLAN tag is provided with the valid bit set. The application cannot invalidate the valid VLAN tag which DMA stores. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The inner VLAN tag control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which DMA must use the inner VLAN tag control input.

Figure 421 shows the transmit context descriptor format.

Figure 421. Transmit context descriptor format



74.18.3.2.1 TDES0 context descriptor

Table 538 describes the TDES0 context descriptor format.

Table 538. TDES0 context descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

74.18.3.2.2 TDES1 context descriptor

Table 539 describes the TDES1 context descriptor format.

Table 539. TDES1 context descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

74.18.3.2.3 TDES2 context descriptor

Table 540 shows the TDES2 context descriptor format.

Table 540. TDES2 context descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is 1 and the TCMSSV and OSTC bits of TDES3 context descriptor becomes 0, it indicates that the TDES2[31:16] contains the inner VLAN tag to insert in the subsequent transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO split header is not supported. The value of this bit is always zero.

74.18.3.2.4 TDES3 context descriptor

Table 541. TDES3 context descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Table 542 shows the TDES3 context descriptor format.

Table 542. TDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field immediately after the read.
30	CTXT	Context Type This field must set to 1'b1 for context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this field is 1, it indicates that DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this field and the OSTC field are 1, it indicates that the timestamp correction input provided in TDES0 and TDES1 is valid. When the OSTC field becomes 0 and this field and the TSE bit of TDES3 are 1 in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved

Table continues on the next page...

Table 542. TDES3 context descriptor (continued)

Bit	Name	Description
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when it closes the context descriptor. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All ones. • CD, LD, and FD bits = 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits are 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA writes 1 to TI bit in the DMA_CH#_Status register **NOTE** On the basis of CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might considered as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this field is 1, it requests MAC to perform inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. You must use this option only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. You must use this option only with the VLAN frames.. These fields are valid when you select the enable SA and VLAN insertion on transit and enable double VLAN processing options.
17	IVLTV	Inner VLAN Tag Valid When this field is 1, it indicates that IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this field is 1, it indicates that VT field of TDES3 is valid.
15:0	VT	VLAN Tag

Table continues on the next page...

Table 542. TDES3 context descriptor (continued)

Bit	Name	Description
		Contains the VLAN tag to insert or replace in the packet. This field is used as VLAN tag only when MAC_VLAN_Incl[VLTI] becomes 0.

74.18.4 Receive descriptor

DMA in the module reads a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that accommodates at least two complete packets which MAC receives. Otherwise, the performance of DMA is impacted because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following receive descriptors are present:

- Normal descriptors
- Context descriptors

You can prepare all the receive descriptors and give to DMA as normal descriptors with the content as shown in receive normal descriptor (read format). DMA reads this descriptor and the receive DMA closes the descriptor with the corresponding packet status after transferring a received packet (or part of) to the buffers indicated by the descriptor. The receive normal descriptor (write-back format) describes the format of this status.

For some packets, only the normal descriptor bits cannot write the complete status. For such packets, the receive DMA writes the extended status to the next descriptor (without processing or using the buffers or pointers embedded in that descriptor). Receive context descriptor describes the descriptor write back format and content.

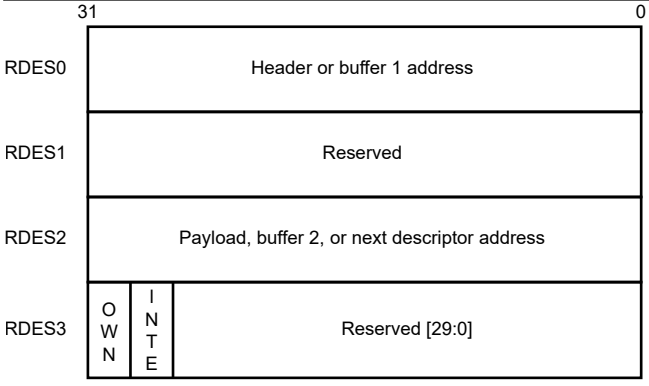
74.18.4.1 Receive normal descriptor (read format)

The read format for a receive normal descriptor is made up of the following:

- A header or buffer 1 address
- Reserved field
- Payload or buffer 2 or next descriptor address
- A 30-bit reserved field
- OWN bit
- An interrupt field

Figure 422 shows the read format for a receive normal descriptor.

Figure 422. Receive normal descriptor read format



NOTE

In the receive descriptor (read format), if the buffer address field is all zeros, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

74.18.4.1.1 RDES0 normal descriptor (read format)

Table 543 shows the RDES0 normal descriptor read format.

Table 543. RDES0 normal descriptor (read format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH field of control register of a channel becomes 0, these field indicates the physical address of buffer 1. When the SPH field is 1, these field indicates the physical address of header buffer where the receive DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, DMA performs a write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero, when the start of packet is transfered. However, the packet data shifts per the actual offset which the buffer address pointer provides. If the address pointer points to a buffer where the middle or last part of the packet is stored, DMA ignores the offset address and writes to the full location which the data-width indicates .

74.18.4.1.2 RDES1 normal descriptor (read format)

Table 544 shows the RDES1 normal descriptor read format.

Table 544. RDES1 normal descriptor (read format)

Bit	Name	Description
31:0	Reserved or BUF1AP	Contains the most-significant 32 bits of the buffer 1 address pointer in 64-bit Addressing mode. Otherwise, this field is reserved.

74.18.4.1.3 RDES2 normal descriptor (read format)

Table 545 shows the RDES2 normal descriptor read format.

Table 545. RDES2 normal descriptor (read format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer Indicates the physical address of buffer 2. When the SPH bit of the DMA_CH#_Control register = 1, it indicates that the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register becomes 0, it indicates that there is no limitations on the RDES2 value. However, the RxDMA uses the LS fields of the pointer address only when it transfers the start bytes of a packet. If the BUF2AP provides the address of a buffer in which the middle or last part of a packet is stored, DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

74.18.4.1.4 RDES3 normal descriptor (read format)

#unique_3312/unique_3312_Connect_42_id_1746ef2a-ecdf-425a-a0eb-74c5a5b90e21 describes the RDES3 normal descriptor read format.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

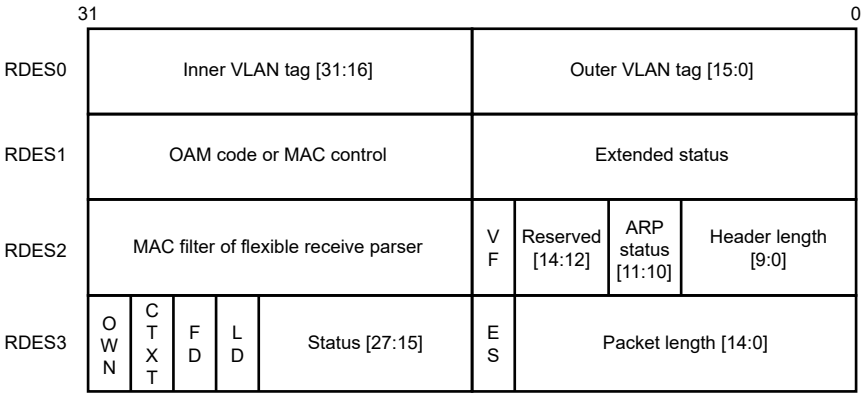
Table 546. RDES3 normal descriptor (read format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA write 0 this field when either of the following conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	IOC	Interrupt Enabled on Completion When this field is 1, it indicates that an interrupt is issued to the application when DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this field is 1, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must write 1 to this field so that DMA can use the address, to which the buffer 2 address in RDES2 points to write received packet data.
24	BUF1V	Buffer 1 Address Valid When this field is 1, it indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must write 1 to this field, if DMA uses the address to which the buffer 1 address in RDES1 points to write the received packet data.
23:0	Rsvd	Reserved

74.18.4.1.5 Receive normal descriptor (write-back format)

Figure 423 shows the write-back format for a receive normal descriptor.

Figure 423. Receive normal descriptor (write-back format)



NOTE

When you enables the flexible receive parser, RDES2[31:16] indicates the parser status, and not the MAC filter status. The MAC filter status is not available when flexible receive parser is enabled.

74.18.4.1.5.1 RDES0 normal descriptor (write-back format)

Table 547 shows the write-back format for the RDES0 normal descriptor.

Table 547. RDES0 normal descriptor (write-back format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag Contains the inner VLAN tag of the received packet if the RS0V bit of RDES3 = 1. This field is valid only when you enables the double VLAN tag processing and VLAN tag stripping.
15:0	OVT	Outer VLAN Tag Contains the outer VLAN tag of the received packet if the RS0V bit of RDES3 = 1.

74.18.4.1.5.2 RDES1 normal descriptor (write-back format)

The status fields in the write-back format are valid only for the last descriptor (RDES3[28] = 1). #unique_3314/unique_3314_Connect_42_table_18e086e2-bda5-4002-b444-4d7ac47c01e8 provide the details of the write-back format for RDES1 normal descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 548. RDES1 normal descriptor (write-back format)

Bit	Name	Description
31:16	OPC	Indicates any one of the following: • OAM sub-type code: If bits [18:16] of RDES3 as described in RDES3 normal descriptor (read format) are 111b, this field contains the OAM sub-type and code fields.

Table continues on the next page...

Table 548. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• MAC control packet opcode: Bits 15:8 of RDES3 as described in RDES3 normal descriptor (read format) contain the subtype and bits 7:0 contain the code.
15	TD	Timestamp Dropped Indicates that the timestamp was captured for this packet but it dropped in the MTL Rx FIFO because of overflow. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
14	TSA	Timestamp Available Indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1) when timestamp is present. This is valid only when the last descriptor field (RDES3 [28]) = 1 You can write the context descriptor in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version Indicates that the received PTP message has the IEEE 1588 version 2 format. When this field becomes 0, it indicates the IEEE 1588 version 1 format. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
12	PFT	PTP Packet Type Indicates that the PTP message is sent directly over Ethernet. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
11:8	PMT	PTP Message Type Encodes to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with reserved message type These fields are available only when you select the timestamp feature.

Table continues on the next page...

Table 548. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
7	IPCE	IP Payload Error When this field is 1, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) which MAC calculates does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this field is 1.
6	IPCB	IP Checksum Bypassed Indicates that the checksum offload engine is bypassed. This field is available when you select the enable receive TCP/IP checksum check feature.
5	IPV6	IPv6 header Present Indicates that an IPV6 header is detected. When you select the enable split header feature option and the SPH bit of control register of a channel is 1, the IPV6 header is available in the header buffer area to which RDES0 points.
4	IPV4	IPV4 Header Present Indicates that an IPV4 header is detected. When the SPH bit of RDES3 is 1, the IPV4 header is available in the header buffer area to which RDES0 points.
3	IPHE	IP Header Error When this field is 1, it indicates either of the following: • The 16-bit IPv4 header checksum which MAC calculates does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet type value. • Ethernet packet does not have the expected number of IP header bytes. This field is valid when either bit 5 or bit 4 is 1. This field is available when you select the enable receive TCP/IP checksum check feature.
2:0	PT	Payload Type Indicates the type of payload encapsulated in the IP datagram that the receive checksum offload engine (COE) process. • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV tagged data packet • 3'b111: AV tagged control packet

Table continues on the next page...

Table 548. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• 3'b101: AV untagged control packet • 3'b100: IGMP, if IPV4 header present field = 1, else DCB (LLDP) control packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these fields to 3'b000.

74.18.4.1.5.3 RDES2 normal descriptor (Write-back format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 549. RDES2 normal descriptor (Write-back format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched Indicates the number of the layer 3 and layer 4 filter that matches the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when bit 28 or bit 27 = 1. When more than one filter matches, these fields provide the number of lowest filter. **NOTE** This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of these conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match • All enabled layer 3 and layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].

Table continues on the next page...

Table 549. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		NOTE This status is not available when the flexible receive parser is enabled.
27	L3FM	Layer 3 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 3 IP address fields. This status is given only when one of these conditions is true: • All enabled layer 3 fields match and bypasses all enabled layer 4 fields. • All enabled filter fields match. When more than one filter matches, this field gives the layer 3 filter status of filter which bits[31:29] indicate. **NOTE** This status is not available when the flexible receive parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When HF becomes 0, it indicates that this field contains the MAC address register number that matches the received packet destination address. This field is valid only if the DAF field becomes 0. When HF = 1, it indicates that this field contains the hash value that MAC computes. A packet passes the hash filter when the field corresponding to the hash value is 1 in the hash filter register. **NOTE** This status is not available when the flexible receive parser is enabled.
18	HF	Hash Filter Status When this field is 1, it indicates that the packet passes the MAC address hash filter. Bits[26:19] indicate the hash value. **NOTE** This status is not available when the flexible receive parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the DA filter in MAC. When flexible receive parser is enabled, and this field is 1, it indicates that the packet parsing is incomplete (RXPI) due to ECC error. **NOTE** When this field is 1, RDES3 ES field is also 1.
16	SAF/RXPD	SA Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the SA filter in MAC.

Table continues on the next page...

Table 549. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		When flexible receive parser is enabled and this field is 1, it indicates that the parser drops the RXPD packet. **NOTE** When this field is 1, RDES3 ES field is also 1.
15	OTS	VLAN Filter Status When this field is 1, it indicates that the received packet VLAN tag passes the VLAN filter. This field redefines as an outer VLAN tag filter status (OTS). This field is valid for both single and double VLAN tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS) This field is valid only for double VLAN tagged frames, when double VLAN processing is enabled. See Filter status for more information.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this field is 1, it indicates that MAC did not generate the ARP reply for the ARP request packet it receives.. This field is 1 when MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This field is reserved when you do not select the enable IPv4 ARP offload option.
9:0	HL	L3/L4 Header Length Contains the length of the packet header which MAC splits at L3 or L4 header boundary which the MAC receiver identifies. This field is valid only when the first descriptor bit = 1 (FD = 1). You can write the header data to the buffer 1 address of corresponding descriptor. If the header length is zero, this field is not valid. It implies that MAC does not identify and split the header. This field is valid when you select the enable split header feature option.

74.18.4.1.5.4 RDES3 normal descriptor (Write-back format)

#unique_3316/unique_3316_Connect_42_id_9cde4392-a0c2-4731-bcb2-bf9dcd789aae describes the write-back format for the RDES3 normal descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 550. RDES3 normal descriptor (Write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. If this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor When this field is 1, it indicates that the current descriptor is a context type descriptor. DMA writes 1'b0 to this field for a normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 2’b00: Intermediate descriptor • 2’b01: First descriptor • 2’b10: Reserved • 2’b11: Descriptor error (due to all 1s) **NOTE** When descriptor error occurs, the receive DMA closes the receive descriptor indicating a descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA will write 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, as this is not marked as the last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	FD	First Descriptor When this field is 1, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet and if the size of the second buffer is also 0, the next descriptor will contain the beginning of the packet. See the CTXT bit description for more information on how to use the CTXT bit and FD bit together.
28	LD	Last Descriptor When this field is 1, it indicates that this descriptor buffers points to the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this field is 1, it indicates that the status in RDES2 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
26	RS1V	Receive Status RDES1 Valid When this field is 1, it indicates that the status in RDES1 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
25	RS0V	Receive Status RDES0 Valid When this field is 1, it indicates that the status in RDES0 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.

Table continues on the next page...

Table 550. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
24	CE	CRC Error When this field is 1, it indicates that a cyclic redundancy check (CRC) error occurs on the received packet. This field is valid only when the LD bit of RDES3 = 1.
23	GP	Giant Packet When this field is 1, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable = 1). **NOTE** Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this field is 1, it indicates that the receive watchdog timer expires when it receives the current packet. The current packet truncates after watchdog timeout.
21	OE	Overflow Error When this field is 1, it indicates that the received packet is damaged because of buffer overflow in receive FIFO. **NOTE** This field is 1 only when DMA transfers a partial packet to the application. This happens only when the receive FIFO operates in the Threshold mode. In the Store-and-Forward mode, all the partial packets drops completely in the receive FIFO.
20	RE	Receive Error When this field is 1, it indicates that the gmii_rxer_i signal asserts when the gmii_rxdv_i signal asserts during the packet reception. This error also includes carrier extension error in the GMII and Half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this field is 1, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This field is valid only in the MII mode.
18:16	LT	Length/Type Field Indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet. • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP request packet type • 3'b100: The packet is a type packet with VLAN tag • 3'b101: The packet is a type packet with double VLAN tag • 3'b110: The packet is a MAC control packet type • 3'b111: The packet is a OAM packet type

Table continues on the next page...

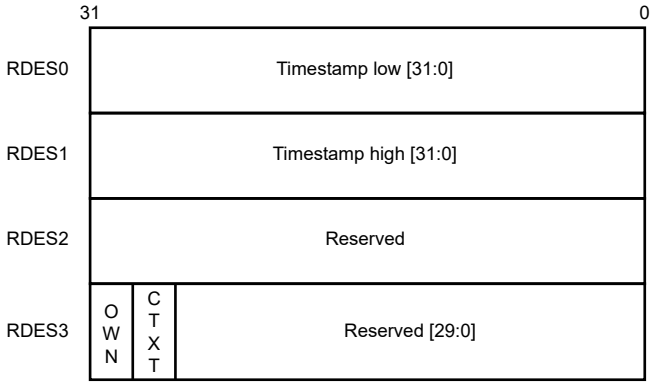
Table 550. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		• 3'b010: Reserved
15	ES	Error Summary When this field is 1, it indicates the logical OR of these bits, : • RDES3[24]: CRC error • RDES3[19]: Dribble error • RDES3[20]: Receive error • RDES3[22]: Watchdog timeout • RDES3[21]: Overflow error • RDES3[23]: Giant packet • RDES2[17]: Destination address filter fail, when the flexible receive parser is enabled • RDES2[16]: SA address filter fail, when flexible receive parser is enabled This field is valid only when the LD bit of RDES3 = 1.
14:0	PL	Packet Length Indicates the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 = 1 and overflow error bits becomes 0. The packet length also includes the two bytes that appends to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 = 1. When the last descriptor and error summary bits are not 1, this field indicates the accumulated number of bytes that are transferred for the current packet.

74.18.4.1.6 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

Figure 424. Receive context descriptor format



74.18.4.1.6.1 RDES0 context descriptor

Table 551. RDES0 context descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low DMA updates this field with least significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSH field of RDES1 show all-ones value, you must consider the timestamp as corrupt.

74.18.4.1.6.2 RDES1 context descriptor

Table 552. RDES1 context descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High DMA updates this field with the most significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, you must consider the timestamp as corrupt.

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA clears this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor

Table continues on the next page...

Table 554. RDES3 context descriptor (continued)

Bit	Name	Description
		When this field is 1, it indicates that the current descriptor is a context descriptor. DMA writes 1'b1 to this field for context descriptor. DMA writes 2'b11 to indicate a descriptor error due to all = 1. When CTXT and DE bits are used together {CTXT, DE} • 2'b00: Reserved • 2'b01: Reserved • 2'b10: Context descriptor • 2'b11: Descriptor error Note: When descriptor error occurs, the receive DMA closes the receive descriptor indicating descriptor error. This receive descriptor is skipped and the buffer addresses does not write the packet data. The receive DMA writes 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, because this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	DE	Descriptor Error See the CTXT bit description for more information about how to use the DE bit along with CTXT bit.
28:0	Rsvd	Reserved

74.18.5 Enhanced descriptor for time-based scheduling

This feature needs 32 bytes enhanced descriptors to enable on all the DMA channels that uses this feature (write 1 to EDSE bit of DMA_CH(#i)_TX_Control register).

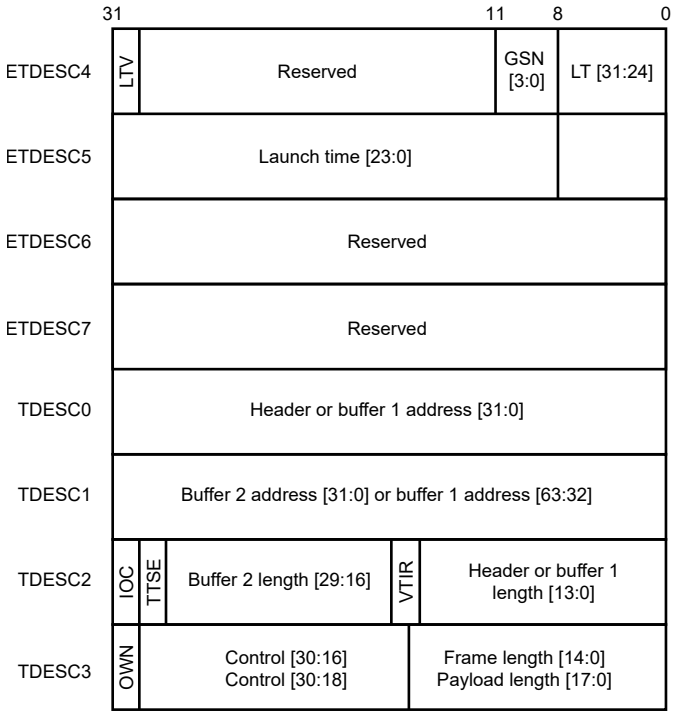
The structure of 32-byte descriptor for the context and the normal descriptor in read and write formats are described in the upcoming sections.

74.18.5.1 Enhanced normal descriptor - Read (32-bit mode)

These fields are present in the first 16 bytes of the enhanced descriptor format of normal descriptor:

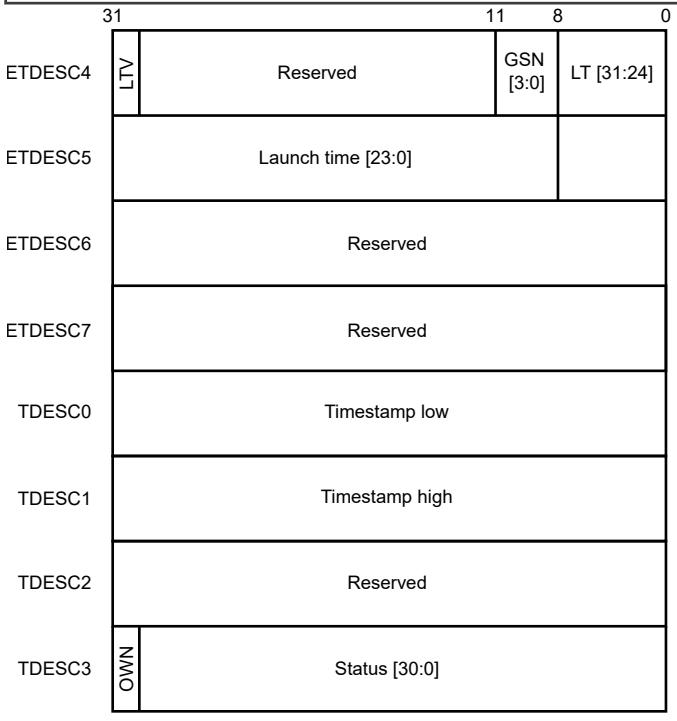
- LTV- Indicates that the launch time (LT) and GSN fields present in the descriptor are valid. The LTV must be = 1 only if the FD bit of the descriptor is not.
- GSN- Indicates the GCL slot number associated with the packet.
- LT- Indicates the launch time associated with the packet.

Figure 425. Enhanced normal descriptor - Read (32-bit mode)



74.18.5.2 Enhanced normal descriptor (Write, 32-bit mode)

Figure 426. Enhanced normal descriptor write (32-bit mode)



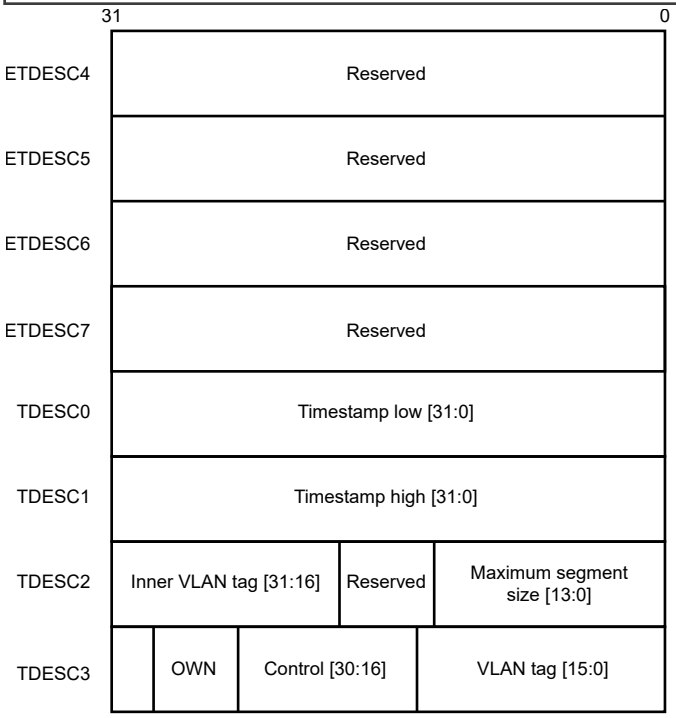
NOTE

- All the enhanced descriptors, example, assumes a 32-bit data width configurations. However, the same definitions are valid in 64-bit and 128-bit configurations.
- In both the write back formats, you cannot modify the extended 16 bytes. The remaining 16 bytes (TDESC0 to TDESC3) are written back per the previous 16 bytes descriptor format.
- When you enable the fetch time it overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding fetch, launch, and launch expiry because the CTR and BTR values get updated when the frame is processed

74.18.5.3 Enhanced context descriptor (Read, 32-bit mode)

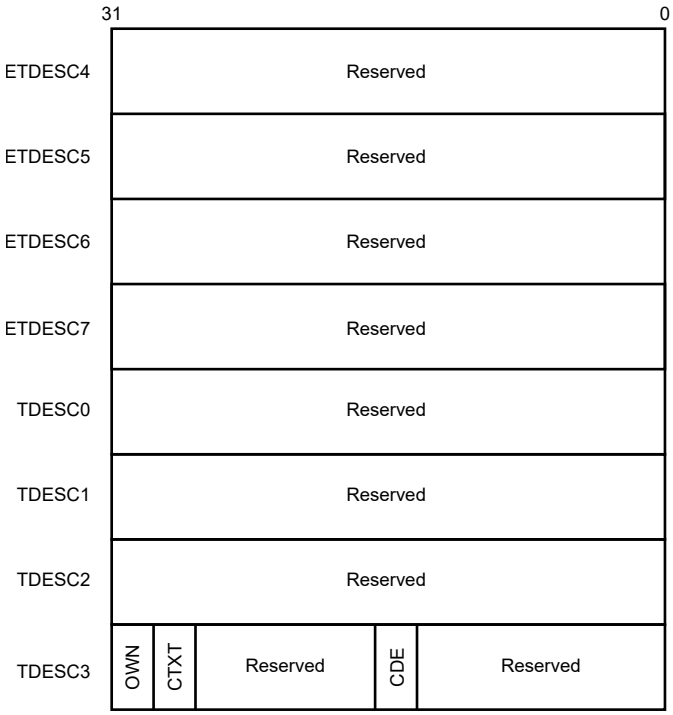
The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be = 0. The fields present in the last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

Figure 427. Enhanced context descriptor - Read



74.18.5.4 Enhanced context descriptor (Write, 32-bit mode)

Figure 428. Enhanced context descriptor - Write



74.19 Programming

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

74.19.1 Initializing DMA

Perform these steps to initialize DMA:

1. Provide a software reset. This resets all the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the reset process (poll bit 0 of DMA_Mode which is only clears after the reset operation completes) to complete.
3. Program these fields to initialize DMA_SysBus_Mode:
   a. DMA_SysBus_Mode[AAL]
   b. Fixed burst or undefined burst
   c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
   d. Select the maximum burst length possible on the AXI bus (bits [7:1]), if fixed length value is enabled.
4. Create a descriptor list for a transmit and receive. Also, ensure that DMA (write 1 to bit 31 of descriptor TDES3/RDES3) owns the descriptors. See Descriptors for more information about descriptors.
5. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= 1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= 1)). The programmed ring length must be at least 4.

   NOTE

   The descriptor address from the start to the end of the ring must not cross the 4 GB boundary.

6. Initialize the receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program the transmit and receive tail pointer registers that indicates DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer

(for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)).

NOTE

For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).

The tailpointer registers must advance to the location immediately after the descriptors that are set so that DMA is aware that the additional descriptors are available.

7. Program the settings of these registers for the parameters like maximum burst-length (PBL) which DMA initiates, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Program the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to enable the interrupts.
9. Write 1 to SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to start the receive and transmit DMAs.
10. Repeat steps 4 to 9 for all the transit DMA and receive DMA channels selected in the hardware.

74.19.2 Initializing MTL registers

The transaction layer (MTL) registers must initialize to establish the transmit and receive operating modes and commands.

Perform these steps to initialize the MTL registers:

1. Program MTL_Operation_Mode[SCHALG] and MTL_Operation_Mode[RAA] to initialize the MTL operation in case of multiple transit and receive queues.
2. Program the receive queue to DMA mapping in MTL_RxQ_DMA_Map0.
3. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode.
   a. MTL_TxQ0_Operation_Mode[TSF] or MTL_TxQ0_Operation_Mode[TTC] in case of Threshold mode.
   b. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0.
   c. MTL_TxQ0_Operation_Mode[TQS]
4. Program these fields to initialize the mode of operation in MTL_RxQ0_Operation_Mode:
   a. MTL_RxQ0_Operation_Mode[RSF] or MTL_RxQ0_Operation_Mode[RTC] in case of Threshold mode.
   b. Flow control activation and de-activation thresholds for MTL receive FIFO (MTL_RxQ0_Operation_Mode[RFA] and MTL_RxQ0_Operation_Mode[RFD]).
   c. Error Packet and undersized good Packet forwarding enable (MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]).
   d. MTL_RxQ0_Operation_Mode[RQS]
5. Repeat previous two steps for all MTL transit and receive queues selected in the configuration.

74.19.3 Initializing MAC

The MAC configuration registers establish the operating mode of MAC. These registers must initialize before initializing DMA.

You can perform these MAC initialization operations after DMA initialization. If the MAC initialization completes before DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, the received frames fill the receive FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled, , program the MAC addresses appropriately.

2. Program these fields to set the appropriate filters for the incoming frames in MAC_Packet_Filter:

a. Receive all

b. Promiscuous mode

c. Hash or perfect filter

d. Unicast, multicast, broadcast, and control frames filter settings

3. Program these fields for proper flow control in MAC_Q0_Tx_Flow_Ctrl:

a. Pause time and other Pause frame control bits

b. Transmit flow control bits

c. Flow control busy

4. Program MAC_Interrupt_Enable as required, and if applicable, for your configuration.

5. Program the appropriate fields in MAC_Configuration. For example Inter-packet gap when transmission and jabber disable.

6. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to start the MAC transmitter and receiver.

74.19.4 Performing normal receive and transmit operation

During normal operation of the module, read the normal and transmit interrupts, poll the descriptors, suspend the DMA (if it does not own descriptors), and read the values of the current host transmitter or receiver descriptor pointers for debugging.

For normal operation, perform these steps:

1. Read the interrupt status for normal transmit and receive interrupts. Then poll the descriptors, read the status of the descriptor which the host owns (either transmit or receive).

2. Set appropriate values for the descriptors, ensure that the DMA owns the transmit and receive descriptors to resume the data transmission and reception.

3. If DMA does not own the descriptors (or no descriptor is available), DMA enters into SUSPEND state. The transmission or reception can resume by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).

4. Read the current host transmitter or receiver descriptor address pointer values for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc regsiter).

5. Read the current host transmit buffer address pointer and receive buffer address pointer values for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Cur-rent_App_RxBuffer).

74.19.5 Stopping and starting transmission

Perform these steps to pause the transmission for some time. The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable) .

2. Wait for any previous frame transmissions to complete. Read the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01 and MTL_TxQ0_Debug[TXQSTS] = 0) to check this.

3. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and MAC receiver.

4. Disable the receive DMA (if applicable), after you ensure that the data in the receive FIFO transfers to the system memory (read the appropriate fields MTL_RxQ0_Debug[PRXQ] = 0 and MTL_RxQ0_Debug[RXQSTS] = 00).

5. Ensure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] = 0 and MTL_RxQ0_Debug[RXQSTS] = 0).

6. Restart the operation by first starting the DMAs, and then enable the MAC transmitter and receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. You can change these parameters only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA related configuration when transmit and receive DMA are active.

74.19.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the receive DMA as compared to the transit DMA. It is permitted when the RxDMA is in SUSPEND state as described below:

- RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND state because the descriptors are not available, a major failure occurs (you are not able to free the filled-up descriptors or buffers). If this issue does not rectify immediately, frames will be lost because of an RxFIFO overflow. Therefore, you can create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

74.19.7 Programming guidelines for multi-channel multi-queuing

74.19.7.1 Transmit

1. Program the transmit queue size in TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in TQS field, you can determine the queue size.

In the transmit operation, the number of channels is equal to the number of the queues, because of this reason, the channel-to-queue mapping is fixed.

2. Enable the queue in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode register to use the queue. In DMA configurations, enable the ST field of DMA_CH[n]_Tx_Con-trol register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode register.

3. Program the scheduling method in MTL_Operation_Mode[SCHALG].

4. Program MTL_TxQ[n]_Quantum_Weight register for DCB queue per the selected algorithm. In case of CBS algorithm in AVB queues program the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit, and MTL_TxQ[n]_LoCredit registers as required.

5. Program the MAC_TxQ_Prty_Map0 register to assign a fixed priority to the queue, if DCB is enabled and PFC function is required. You can use this assigned priority to determine if the corresponding queue must stop transmitting packet on the basis of the received PFC packet.

74.19.7.2 Receive

1. Program the receive queue size in RQS field of MTL_RxQ[n]_Operation_Mode register. Determine the size of the queue, based on the value programmed in RQS field.
2. Enable the receive queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 for AV or DCB. In DMA configurations, SR bit of statically or dynamically map DMA_CH[n]_Rx_Control register and the corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 is enabled.
3. Based on these packet types MAC routes the receive packets to the receive queues :
    a. AV PTP packets: Based on the programming of MAC_RxQ_Ctrl1[PTPQ].
    b. AV untagged control packets: Based on the programming of MAC_RxQ_Ctrl1[AVCPQ].

c. Data center bridging (DCB) related link layer discovery protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 to indicate MAC which queue should get the DCB packets.

d. VLAN tag priority field in VLAN tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 register for routing the tagged packets based on the received packets USP (user priority) field to the receive queues 0 to 7.

e. Route the AV tagged control and data packets based on PSRQ field of MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.

NOTE

The priorities set in PSRQ7-0 must be unique.

4. If multiple receive DMA channels are enabled, you must perform the following programming for proper arbitration and mapping:

a. Program MTL_Operation_Mode[RAA] to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.

b. Program the MTL_RxQ[n]_Control register to decide the weights and the packet arbitration for each RxQ.

c. If you program the static mapping in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH becomes 0), fields RXQx2DMA and others are programmed to select the channel to map each queue.

d. Write 1 to RXQ[n]DADMACH field in MTL_RxQ_DMA_Map0 to select the dynamic mapping of packets in each receive queue.

e. In dynamic channel mapping, the value of DCS field in the lowest MAC address registerthe decides the routing of a packet to a specific RxDMA channel.

74.19.7.2.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the receive DMA channel failure.

Perform these steps if you get bus error in the receive DMA channel:

1. Write 1 to DMA_CH0_Rx_Control[RPF]. This flushes all the packets one after the other.

This step is optional. However, writing 1 to this field prevents head-of-line blocking in the receive queues when packets sent to the RXDMA are stopped due to the bus error.

2. Re-program the specific registers of the DMA channel.

3. Start the DMA channel.

Recovering from the transmit DMA channel failure.

1. Stop the specific DMA channel, even if it is in active state.

2. Flush the corresponding MTL queue.

3. Re-program the specific registers of the DMA channel.

4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not be always successful in recovering from a bus error. If the module is not fully functional after reprogramming the DMA, you can issue a soft reset to recover from the bus error.

74.19.8 Programming guidelines for GMII link state transitions

74.19.8.1 Transmit and receive clocks running when link down

Perform these steps when the link is down but the transmit and receive clocks are running:

NOTE

The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable).

2. Write 0 to MAC_Configuration[RE] to disable the MAC receiver.

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01) or, flush the Tx FIFO for faster empty operation.

4. Write 0 to MAC_Configuration[TE] to disable the MAC transmitter.

5. Make sure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] and MTL_RxQ0_Debug[RXQSTS] are 0).

6. Read the PHY registers to know the latest configuration and accordingly program the MAC registers, after the link is up.

7. Start the transit DMA to restart the operation, and then enable the MAC transmitter and receiver.

You do not disable the receive DMA because the receiver is disabled and the FIFO does not get any data in the receive FIFO.

74.19.8.2 Transmit and receive clocks stopped when link down

Perform these steps when the link is down and the transmit and receive clocks are stopped:

NOTE

The steps are provided for channel 0.

1. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and receiver. This does not take effect immediately as the clocks are absent.

2. Wait until the link is up and the clocks are restored.

3. Wait for the transfer of any partial frame, if any to complete at time of stopping of the transmit or receive clock. To check this, read MAC_Debug (should be all-zero). Some old packets may still remain in the TXFIFO because the MAC transmitter is stopped.

4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.

5. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to restart the MAC transmitter and receiver.

74.19.9 Programming guidelines for IEEE 1588 timestamping

74.19.9.1 Initialization guidelines for system time generation

Write 1 MAC_Timestamp_Control[TSENA] to enable the timestamp feature. However, it is essential to initialize the timestamp counter after MAC_Timestamp_Control[TSENA] = 1. Perform these steps during the module initialization:

1. Write 0 to the bit 16 of MAC_Interrupt_Enable to mask the timestamp trigger interrupt.
2. Write 1 to MAC_Timestamp_Control[TSENA] to enable timestamping.
3. Program MAC_Sub_Second_Increment based on the PTP clock frequency.
4. Program MAC_Timestamp_Addend and write 1 to MAC_Timestamp_Control[TSADDREG], if you are using the fine correction approach.
5. Poll MAC_Timestamp_Control until MAC_Timestamp_Control[TSADDREG] = 0.
6. Program MAC_Timestamp_Control[TSCFUPDT] to select the fine update method (if required).

7. Program MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update with the appropriate time value.
8. Write 1 to MAC_Timestamp_Control[TSINIT].
9. Initialize the timestamp counter with the value written in the timestamp update registers so that the timestamp counter can start operation. If one-step timestamping is enabled
    a. Program Bit 27 of the TDES3 context descriptor, to enable one-step timestamping.
    b. Program MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If the timestamp operation is disabled by writing 0 to MAC_Timestamp_Control[TSENA], repeat all these steps to restart the timestamp operation.

74.19.9.2 System time correction

74.19.9.2.1 Coarse correction method

Perform these steps to synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the timestamp registers that is MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update.

2. Write 1 to MAC_Timestamp_Control[TSUPDT].

The value in the timestamp update registers is added to or subtracted from the system time when MAC_Timestamp_Control[TSUPDT] = 0.

74.19.9.2.2 Fine correction method

Perform these steps to synchronize or update the system time to reduce system-time jitter (fine correction method):

1. Calculate the rate by which you want to increment the system time slower or faster, with the help of the algorithm.

2. Update MAC_Timestamp_Addend with the new value and write 1 to MAC_Timestamp_Control[TSADDREG].

3. Wait for the time for which you want the new value of the addend register to be active. You can do this by enabling the timestamp trigger interrupt after the system time reaches the target value.

4. Program the required target time in MAC_PPS[n]_Target_Time_Seconds register and MAC_PPS[n]_Target_Time_Nanoseconds register.

5. Enable the timestamp interrupt in MAC_Interrupt_Enable[TSIE].

6. Write 1 to bit 4 in MAC_Timestamp_Control.

7. Read MAC_Interrupt_Status when this trigger causes an interrupt.

8. Reprogram MAC_Timestamp_Addend with the old value and write 1 to MAC_Timestamp_Control[TSADDREG] again.

74.19.10 Programming guidelines for AV feature

After you enable the AV feature in the module controller, follow these programming tasks:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

74.19.10.1 Initializing the DMA in audio video feature

The first step to program the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI/QOS-AXI4 configurations with AV feature.

1. Provide a software reset to reset all the QOS internal registers and logic (DMA_Mode[SWR]).

2. Wait for the reset process to complete. Poll DMA_Mode[SWR], which clears only after the reset operation completes.

3. Set the values in DMA_Mode to program the fields to initialize the DMA register.

4. Create a descriptor list for transmit and receive. In addition, ensure that the DMA owns the transmit and receive descriptors. When you use OSF mode, at least two transmit descriptors are required.

See Descriptors for more information about descriptors.

5. Ensure that you create three or more different transmit or receive descriptors in the list before reusing any descriptors.

6. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the transmit and receive tail pointer registers to indicate the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode:

a. MTL_TxQ0_Operation_Mode[TSF]

b. MTL_TxQ0_Operation_Mode[TTC]

c. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0

d. MTL_TxQ0_Operation_Mode[TQS]

9. Enable the interrupts by programming DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

10. Repeat steps 4 through 9 for all the additional channels of AV feature.

11. Program the AV queues CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers.

12. Write 1 to bit 0 of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register to start the receive and transmit DMA.

74.19.10.2 Enabling slot number checking

You can enable slot number checking feature if you specifies the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus.

You must complete these steps after step 11 and before step 12 of Initializing the DMA in audio video feature .

You can use the slot number check feature to specify the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus. This feature is useful for an uniform and periodic transfer of the AV traffic from the host memory and it is available only when you enable timestamping and programs MAC_Sub_Second_Increment. Perform these steps to enable the slot number checking:

1. Follow the steps described in Initialization guidelines for system time generation to enable timestamping.

2. Ensure that the SLOTNUM field (bits 22:19) of TDES3 normal descriptor (Read format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Func-tion_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

3. Write 1 to bit 0 (ESC) of the slot function control and status register of a channel to enable the slot number checking.

74.19.10.3 Enabling average bits per slot reporting

You can enable the reporting of average bits transmitted in a slot.

The CBS status register of the additional AV channels provide information about the average bits that are transmitted in a slot. You can asynchronously read this register to retrieve information about the average bits transmitted per slot. Perform these steps to enable average bits per slot reporting:

1. Follow the steps as described in the Initialization guidelines for system time generation to enable timestamping.

2. Program SLC bits [6:4], of the MTL_TxQ[n]_ETS_Control register of a channel with the number of slots over which the average transmitted bits per slot are computed.

3. Enable bit 9(ABPSSIE) of the MTL_Q[n]_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt generates at every 125 microsecond.
- You can disable this interrupt to stop the interrupt flooding, when it is not required.

4. Read ABS bits [16:0], of the MTL_TxQ[n]_ETS_Status register of a channel on each interrupt.

NOTE

You can read the ABS fields in the polling mode even if ABPSIE bit is not enabled. When bit 1 (ABPSIS) of the MTL_TxQ[n]_ETS_Status register is 1, it indicates that a new value is updated in the ABS field.

74.19.10.4 Disabling flow control for AV enabled queues

74.19.10.4.1 Transmit flow

Program the EHFC (Enable Hardware Flow Control) field of the corresponding receive queue's MTL_RxQ[n]_Operation_Mode register to 0.

74.19.10.4.2 Receive flow control

Program PSTQ[n] field, corresponding to AV enabled transit queue in MAC_TxQ_Prty_Map0/1 register to 0.

74.19.10.5 Programming guidelines for flexible pulse-per-second output

After you enable the flexible pulse-per-second output feature in the module controller, you can perform these tasks:

- Generating single pulse on PPS
- Generating next pulse on PPS
- Generating a pulse train on PPS
- Generating an interrupt without affecting the PPS

74.19.10.5.1 Generating single pulse on PPS

Perform these steps to generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5], of MAC_PPS_Control. This instructs MAC to use the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for a start time of the PPS signal output.
2. Program the start time value in the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= 3) register.

4. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0001. This instructs MAC to generate single pulse on the PPS signal output at the time programmed in the target time registers.

74.19.10.5.2 Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can give the cancel start command (PPSCMD=0011) before the programmed start time elapses to cancel the pulse generation. You can also program the behavior of the next pulse in advance.

Follow these steps to program the next pulse:

1. Program the start time for the next pulse in the target time registers. This time must be more than the time at which the falling edge occurs for the previous pulse.

2. Program the next PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

3. Program PPSCMD bits [3:0], of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs MAC to generate single pulse on the PPS signal output, at the time programmed in target time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

74.19.10.5.3 Generating a pulse train on PPS

Perform these steps to generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5] , of MAC_PPS_Control. This instructs MAC to use the target time registers for the start time of the PPS signal output.

2. Program the start time value in the target time registers.

3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_Interval (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

4. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

5. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0010. This instructs MAC to generate train of pulses on the PPS signal output with start time programmed in target time registers.

By default, the PPS pulse train is free-running unless the STOP pulse train at time or STOP pulse train immediately commands stop it.

6. Program the stop value in the target time registers. Ensure that bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register becomes 0 before programming the target time registers again.

7. Program PPSCMD field [bit 3:0] of MAC_PPS_Control to 0100. This stops the train of pulses on the PPS signal output after the programmed stop time specified in step 6 elapses.

You can program 0101 in PPSCMD field [bit 3:0] of MAC_PPS_Control to stop the pulse train at any time. Similarly, you can program 0110 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the time (programmed in step 6) elapses to cancel the stop pulse train command (given in Step 7). Also, program 0011 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the programmed start time (in Step 2) elapses to cancel the pulse train generation.

74.19.10.5.4 Generating an interrupt without affecting the PPS

MAC_PPS_Control TRGTMODSEL bits [6:5] enables you to program the target time registers to perform any one of these actions:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Perform these steps to program the target time registers to generate only interrupt event:

1. Program 00 (for interrupt) in MAC_PPS_Control TRGTMODSEL bits [6:5]. This instructs the MAC to use the target time registers for target time interrupt.

2. Program a target time value in the target time registers. This instructs the MAC to generate an interrupt when the target time elapses.

If TRGTMODSEL bits [6:5], are changed (for example, to control the PPS) then over-write the interrupt generation with the new mode and new programmed target time register value.

74.19.10.6 Programming guidelines for VLAN filtering on receive

Perform these steps to program VLAN filtering on receive:

1. Program MAC_VLAN_Tag register for the following fields to select the filtering method:

a. ETV: Enables 12-Bit VLAN tag comparison or 16-bit VLAN tag comparison.

b. VTHM: VLAN tag hash table match enable.

c. ERIVLT: Enables inner VLAN tag or outer VLAN Tag (to enable the inner or outer VLAN tag filtering, writing 1 to MAC_VLAN_Tag_Ctrl[EDVLP] enables the double VLAN processing).

d. ERSVLM: Enables receive S-VLAN match or C-VLAN match (write 1 to MAC_VLAN_Tag_Ctrl[ESVL] to enable S-VLAN processing).

e. DOVLTC: Ignores VLAN type for tag match

f. VTIM: Enables VLAN tag inverse match instead of the normal VLAN tag matching

2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.

3. Program MAC_VLAN_Hash_Table, if hash filtering of VLAN tag is enabled. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0, it indicates that the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and index the content of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] is 1, it indicates that the upper 4 bits of calculated CRC-32 of VLAN Tag index the content of MAC_VLAN_Hash_Table. For example, when MAC_VLAN_Tag_Ctrl[ETV] is 1, a hash value of 4b'1000 selects bit 8 of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0 a hash value of 4'b1000 selects bit 7 of MAC_VLAN_Hash_Table.

74.19.10.7 Programming guidelines for extended VLAN filtering and routing on receive

Perform these steps, for the indirect access of the per VLAN tag registers:

- Write
  - Write the required data into MAC_VLAN_Tag_Data.
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required filter register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a write command, set this field to 0.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0 to do the next write. This will guarantee that you have programmed the appropriate VLAN Tag Filter register.
- Read
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a read command, set this field to 1.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0. The appropriate value of the VLAN Tag Filter register is available in MAC_VLAN_Tag_Data.

74.19.10.8 Programming sequence for queue/channel based VLAN inclusion register

Perform these steps to program the queue/channel-based VLAN inclusion register:

NOTE

When MAC_VLAN_Incl[CBTI] = 1 you cannot access the indirect VLAN include registers.

1. Write 1 to MAC_VLAN_Incl[CBTI], to enable queue or channel based VLAN tag insertion on all the transmitted packets. This field must be 1 before any indirect access to the queue or channel specific MAC_VLAN_Incl(#i) register.

2. Program the VLAN tag and VLAN type to insert in packets from a particular queue or channel in MAC_VLAN_Incl[VLT] and MAC_VLAN_Incl[CSVL], corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Write 0 to MAC_VLAN_Incl[RDWR] to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_Incl initiates access to indirect access MAC_VLAN_Incl(#i) register.

3. Write 1 to MAC_VLAN_Incl[BUSY] via the module to indicate the progress of access to indirect access MAC_VLAN_Incl(#i) register. After the access completes, MAC_VLAN_Incl[BUSY] = 0. The application must not attempt subsequent access to MAC_VLAN_Incl(#i) register when the MAC_VLAN_Incl[BUSY] is 1.

4. Repeat step 2 and step 3 to program VLAN tag and VLAN type to insert in packets from the remaining queues or channels. The application must ensure that the required VLAN tag and VLAN type for all the queues or channels are programmed, otherwise an unintended VLAN tag and VLAN type might be inserted.

74.19.11 Programming guidelines for EST

Program the gate control values and time intervals in MTL_EST_Status[SWOL] along with the other EST related registers that are described in EMAC register descriptions to appropriate values. The upcoming sub-sections provide step by step details for programming the GCL and the other EST related registers.

74.19.11.1 Programming the GCL and GCL linked registers

Perform these steps to program the GCL and the four other registers implemented per GCL:

1. Access the GCL and the four other GCL-linked registers via indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data. MTL_EST_Status[SWOL] indicates whether the software owns GCL0 or GCL1.
2. Write the 32-bit write data to MTL_EST_GCL_Data, to program the GCL. Then program MTL_EST_GCL_Control to write the write address and other control information.
3. In MTL_EST_GCL_Data, write data consists of up to 8 bits (configurable) of gate controls and up to 24 bits (configurable) of time interval. Programming a 0 indicates gate close and programming a 1 indicates gate open. For a 4-TC and 20-bit time interval configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. You must write the data in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. Program MTL_EST_GCL_Control[SRWO] to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check that the hardware clears MTL_EST_GCL_Control[SRWO] to indicate that the previous operation completes before initiating a new read-write operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL completes.
7. Program the BTR, CTR, TER and LLR registers, using the same indirect addressing method as described above. Write 1 to MTL_EST_GCL_Control[GCRR] appropriately. MTL_EST_GCL_Control[GCRR] interprets the address field as belonging to these registers (instead of the GCL).

After the GCL and the related registers are programmed, program MTL_EST_GCL_Control to allow hardware to own and process the GCL. When the list length (as indicated in LLR) is 1, the associated time interval must be smaller than the cycle time register value. Otherwise, an error is reported (as described in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP system time is used, you must program the nanoseconds field to use the Digital Rollover mode. (The value of MAC_Timestamp_Control[TSCTRLSSR]must be 1)

74.19.11.2 Programming the EST registers

After the steps mentioned in "Programming the GCL and GCL Linked Registers" completes, program MTL_EST_Control

1. Write 1 to MTL_EST_Control[CTOV] and MTL_EST_Control[TILS]. Also, write 1 to MTL_EST_Control[EEST] and MTL_EST_Control[SWOL].

   NOTE

   The CTOV recommendations for GMII for SPRAM configurations are:

   - 96 * Tx clock period, for 32 and 64 bit data width configurations.
   - 128 * Tx clock period for 128 bit data width configurations.

   The CTOV recommendations for GMII for non-SPRAM configurations are:

   - 30 * Tx clock period, when SA/VLAN insertion is enabled.
   - 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. Enables the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Performs an appropriate action to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Write 1 to MTL_EST_Control[SSWL] to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when MTL_EST_Control[SSWL] = 1, because the hardware might be using the new GCL.

The hardware resets or clears MTL_EST_Control[SSWL] when it successfully switches to the new list. The hardware also flips MTL_EST_Status[SWOL] to indicate the new GCL that the software owns.

Program the GCL that software owns (MTL_EST_Status[SWOL] indicates) as described in "Programming the GCL and GCL Linked Registers" and then program MTL_EST_Control as described above, to install a new GCL. Ensure that the new BTR is set to an appropriate value to avoid BTR Error that may require software intervention in some cases.

The packet length (frame size) information must be available at all times, to avoid transmission overruns. Therefore, in the DMA configurations, program the packet length in the first descriptor of every transmit frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

The packet length provided in the transmit descriptor must account for the SA and VLAN insertion, to avoid transmission overruns, if applicable, that is, packet length must represent the actual packet length on the Ethernet line.

74.19.12 Programming the launch time in time-based scheduling

Configure the launch time in the enhanced normal transmit descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and launch time features are mutually exclusive and must not be used together. In case of a conflict (if OSTC = LTV = 1 in MTL configuration), give priority to OSTC and ignore the launch time.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV = 1, then the LTV is ignored.

74.19.13 Programming guidelines for media clock generation and recovery

74.19.13.1 Programming guidelines for media clock generation

These are the guidelines for the media clock generation:

1. Program the appropriate presentation time control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control, to define the PPS instance in Media clock generation mode.

2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].

3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_Target_Time_Seconds register. Then, mcgr_dma_req_o[#i] is set.

4. For every request which DUT generates, the module reads the corresponding MAC_PPS(#i)_Target_Time_Seconds register and asserts the corresponding mcgr_d-ma_ack_i[#i] to acknowledge the read request.

74.19.13.2 Programming guidelines for media clock recovery

These are the guidelines for the media clock recovery:

- Writing 1 to MAC_Timestamp_Control[PTGE] enables the CPT counter. In addition to configuring the initialization values for the system time, update MAC_Presn_Time_Updt with the equivalent presentation time initialization value, then MAC_Timestamp_Control[TSINIT] = 1.
- Use the increment values for the system time and also for the CPT because the increment value is in sub-seconds and sub-nanoseconds.
- Update MAC_Presn_Time_Updt with the equivalent presentation time update value (32 bit ns), when an update is requred, and also configure the updated values for the system time. Finally, MAC_Timestamp_Control[TSUPDT] must be 1 for the update.
- Program the MCGREN#i field of MAC_PPS_Control to enable the PPS instance to operate in MCGR mode.
- Program the appropriate presentation time control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance) or PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register, to set the PPS instance in Media clock recovery mode.
- After the PPS instance is set in Recovery mode, DUT sets the corresponding mcgr_dma_req_o[#i]. For every request which DUT generates, program the target presentation time into the MAC_PPS(#i)_Target_Time_Seconds register and assert the corresponding mcgr_dma_ack_i[#i] to acknowledge the request. Acknowledgment can be given before/after programming the Target presentation time.
- Observe the recovered media clock on the corresponding ptp_pps_o[#i].

74.19.14 Programming guidelines for ECC protection for memories

These are the guidelines for the ECC protection for memories:

- Write 1 to the appropriate field of MTL_ECC_Control to enable the ECC features for the respective memory.
- Generate a correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application, if any correctable, uncorrectable, or address errors are detected. DMA_Interrupt_Status or MTL_ECC_Interrupt_Status indicates an appropriate status.
- Provide debug mode for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise the false interrupts may trigger.

74.19.14.1 Programming guidelines for ECC hardware error injection (Debug mode)

Follow these steps for ECC hardware error injection:

- Write 1 to the appropriate field in MTL_DBG_CTL to enable the ECC error injection feature for MTL TX/RX and DMA TSO.
- Write 1 to the appropriate field in MTL_EST_GCL_Control to enable the ECC error injection feature for the EST memory.
- Write 1 to the appropriate field in MTL_RXP_Indirect_Acc_Control_Status to enable the ECC error injection for the receive parser memory. To access the receive parser memory in Debug mode, write 0 to MTL_RXP_Indirect_Acc_Control_Status[FRPE] to disable the receive parser feature.
- Ensure that all the CSR writes corresponding to one memory write must have the same value for the error injection control word, where multiple CSR writes are required for writing single data word into the memory.

74.19.15 Programming guidelines for on-chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Writing 1 to MTL_DPP_Control[EDPP] enables the parity generation and parity detection mismatch on datapath.
- Generates an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application if any parity mismatch is detected. DMA_Safety_Interrupt_Status or MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status indicates the appropriate status.
- Supports Debug mode for each parity generator to insert an error.

NOTE

Enable the datapath parity protection before the receive or transit traffic starts, to avoid the false safety interrupts.

74.19.16 Programming guidelines for FSM parity and timeout

Follow these steps to configure the FSM parity and timeout:

- Write 1 to MAC_FSM_Control[PRTYEN] and MAC_FSM_Control[TMOUTEN] to enable the FSM parity and timeout feature respectively.
- Force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to define with MAC_DPP_FSM_Interrupt_Status[FSMPES] for a parity error detection.
- Write 1 to the parity error injection using the [23:16] bits of MAC_FSM_Control to select the appropriate clock domain, for Error injection mode in FSM parity. Wait for the safety uncorrectable interrupt to be defined with MAC_DPP_FSM_Interrupt_Status[FSMPES].
- Configure the large and normal mode values which MAC_FSM_ACT_Timer[LTMRMD] and MAC_FSM_ACT_Timer[NTMRMD] indicates , for FSM timeouts.
- Use the [31:24] bits of MAC_FSM_Control to select the large or normal mode tic generation per clock domain.
- Write 1 to MAC_FSM_ACT_Timer[TMR] with the appropriate number of CSR clock cycles to generate 1us tic.
- Force the FSM in a particular clock domain to remain in an active state for timeout duration (for example, T-2T). You can check the safety interrupt and the status field for the corresponding clock domain that sets in the [15:8] bits of the MAC_DPP_FSM_Interrupt_Status .
- Select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control, for Error injection mode in FSM timeout. Wait for the safety uncorrectable interrupt to define with the corresponding error status in the MAC_DPP_FSM_Interrupt_Status .
- Use only normal mode tic generation, for application or CSR interface timeout. On the basis of the time-outs of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_Interrupt_Status is defined with the safety interrupt.

74.20 Glossary

AFM Address filtering module

ARI Application receive interface

ATI	Application transmit interface
AVB	Audio video bridging
AXI	Advanced extensible interface
BTR	Base time register
CPT	Current presentation time
CRC	Cyclic redundancy check
DA	Destination address
DCB	Data center bridging
DUT	Device under test
EOP	End of packet
FCS	A 32-bit cyclic redundancy check used to detect an in-transit corruption of data. Also marks the end of an Ethernet frame.
FIFO	First in first out
GCL	Gate control list
GMII	Gigabit media independent interface
MAC	Media access controller
MCI	MAC control tnterface
MDC	Management data clock
MDIO	Management data input/output
MII	Media independent interface
MRI	MAC receive interface
MTI	MAC transmit interface
MTL	MAC transmit layer
PBL	Programmable burst length
PHY	The physical interface transceiver that implements the OSI physical layer for an ethernet network. The IEEE 802.3 standard defines it.
RGMII	Reduced gigabit media independent interface
RMII	Reduced media independent interface
RMON	Remote network monitoring
SA	Source address
SFD	Start frame delimiter
SGMII	Serial gigabit media independent interface
SMA	Station management agent
TCP	Transmission control protocol
UDP	User datagram protocol
VLAN	Virtual local area network

Chapter 75
Gigabit Ethernet Media Access Controller (GMAC)

75.1 Chip-specific GMAC information

75.1.1 GMAC instances and configuration

This chip supports up to 1 instance of GMAC IP.

Table 555. GMAC instances

Instance	K3x1 / K3x2 / K3x4	K358
GMAC	No	Yes

NOTE

DWC_EQOS refer to the Synopsys GMAC IP.

NOTE

The description for some GMAC registers include references to configurations of the Synopsis Ethernet MAC IP. Refer to MAC_HW_Feature registers for the specific features available in this chip.

NOTE

GMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

Following key features are supported:

- This chip supports MII/RMII/RGMII interfaces.
- 4 bit MII interface operating at 2.5/25/50 Mhz, MII can run at 10/100/200 Mbps.
- 2 bit RMII interface operating at 50 MHz, RMII can run at 10/100 Mbps
- 4 bit MII-Lite interface operating at 2.5/25 MHz
- 4 bit RGMII interface operation at 125 MHz in DDR mode
- 4 PPS are supported using DMA trigger
- Supports 4-bit Reduced Gigabit MII (RGMII) operating at 125 MHz
- The Ethernet module supports a data rate of 1Gbps (1000 Mbps)
- MTL Receive FIFO size 16384 bytes
- MTL Transmit FIFO size 16384 bytes

NOTE

The DMA referred within GMAC chapter refers to the internal GMAC DMA engine and not the device AXBS master DMA.

NOTE

Register access beyond 8k address space is not supported and will generate a transfer error.

NOTE

Always use store and forward mode if possible. In cut through mode, if multiple masters are active then there is chance (even in round robin arbitration mode) that GMAC DMA may starve for data resulting in insufficient data in TX FIFO leading to Tx underflow. To avoid this, increase MTL_TxQ0_Operation_Mode[TTC] value as needed.

The table below provides the information on the specific configuration utilized for the S32K3x4 and K342 devices.

Table 556. Specific configuration information

Application Interface		
	Application interface configuration	EQOS-AHB
	Data width	64
	Endian mode	Little Endian
	Address width	32
	CSR interfcae	APB3 interface
General feature		
	Mode of operation	10/100/1000
	Enable double VLAN processing	Yes
	Enable Que/channel based VLAN tag inertion on Tx	Yes
	Enable SA and VLAN insertion on Tx	Enabled by default
Buffer management		
	MTL Receive FIFO size in bytes	16384
	MTL Receive FIFO size in bytes	16384
	Enable debug memory access	Yes
	Use single port memory	Yes
PHY interface		
	Enable RGMII, RMII only	Enable RGMII, Enable RMII, GMII/MII default
	Enabled signel phy interface	No
	Enable MDIO interface	Yes
Filtering		
	Enable Additional 1-31 MAC address registers	2
	Enable Address Filter Hash Table	Yes
	Hash Table Size	256
	Enable VLAN Hash table based filtering	Yes
	Extended Rx VLAN Filter Enable	Yes
	Number of VLAN tag Filters	32
	Enable Layer3 and Layer4 Packet Filter	Yes
	Number of layer3 and Layer 4 packet filters	8

Table continues on the next page...

Table 556. Specific configuration information (continued)

	Enable Flexible Programmable Receive Parser	Yes
	Maximum Packet Header Size for Parsing	256
	Maximum Entries of Parser Look up table	64
	Packet duplication support	Yes
IEEE 1588 timestamp		
	Enable IEEE 1588 Time stamp support	Enabled by default
	IEEE 1588 System Time Support	Both option
	Add IEEE 1588 Higher word register	Yes
	Enable IEEE 1588 sub nanoseconds time stamp support	Yes
	Add IEEE 1588 Auxilary snapshot	No
	Enable Flexible Pulse Per Seconds Output	Yes
	Number of pulse per Second outputs	4
	Enable PTP Timestamp offload feature	No
	Enable One Step timestamp for PTP over UDP/IP feature	No
	Enable One Step timestamp feature	Yes
Multiple queue support		
	Number of transmit Queue	3
	Number of recieve Queue	3
	Enable data center Bridging	Yes
	Enable Audo Video Bridging	Yes
	Enable support for AV in Tx queue 1	Yes
	Enable support for AV in Tx queue 2	Yes
	Enable support for AV in Tx queue 3	No
	Enable support for AV in Tx queue 4	No
	Number of DMA Channel on the receive side	3
Time sensitive networking		
	Enable Enhancement to Schedule traffic(EST)	Yes
	Width of Time Interval Field in the Gate Control List	24

Table continues on the next page...

Table 556. Specific configuration information (continued)

	Depth of Gate Control List	256
	Enable Frame Pre-emption support	Yes
Time based scheduling		
	Enable time based Scheduling	Yes
TCP/IP offloading features		
	Enable receive TCP/IP Checksum Check	Enabled by default
	Enable transmit TCP/IP Checksum offload	Enabled by default
	Enable support for Tx COE in Tx queue 0	Yes
	Enable support for Tx COE in Tx queue 1	Yes
	Enable support for Tx COE in Tx queue 2	Yes
	Enable support for Tx COE in Tx queue 3	No
	Enable support for Tx COE in Tx queue 4	No
	Enable TCP Segmentation offloading for TCP/IP	No
	Enable Split Header Feature	Yes
	Enable IPv4 ARP offload	Yes
RMON counters		
	Enable MAC Management Counters(MMC)	Yes
	Enable the MAC Management Counters for Reciever TCP/IP Checksum offload	No
Automotive safety feature		
	Enable all automotive safety feature	Yes

75.4 Introduction

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

GMAC:

- Supports the 10/100/1000 Mbps application in compliance with IEEE802.3-2015 specifications
- Can support advanced applications such as time-sensitive networking and AVB
- Supports a MAC core that has prominent features such as a flexible receive parser, media clock recovery and generation, and safety

75.4.1 Features

GMAC supports these features in addition to the default feature defined in the IEEE802.3 specification:

- MII (10/100 Mbps), RMII (10/100 Mbps), and RGMII (1000 Mbps)

- Time-aware shaper (IEEE802.1bv), time synchronization (IEEE802.1AS-rev), and frame preemption (IEEE802.1Qbu) for time-sensitive networking
- Media clock recovery and generation for AVB
- AMBA 2.0 for AHB master and APB3 interface
- RMII specification version 1.2 from RMII consortium
- RGMII specification version 2.6 from HP/Marvell
- Separate interface for transmit, receive, and control paths
- Two-buffer ring
- Broadcast and multicast packet duplication
- Full-duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the pulse per second (PPS) output signal
- MDIO clause 22 and clause 45 interface for configuration and management of the PHY device
- Preamble and SFD insertion and deletion
- Automatic CRC and pad generation/stripping option
- Option to disable CRC checking
- Programmable insert packet gap
- Source address insertion or replacement
- VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control, insertion, replacement, and deletion of up to two VLAN tags, insertion, replacement, and deletion of queue or channel-based VLAN tags
- IEEE802.1Q VLAN tag detection and an option to delete the tags in the receive packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes that allow:
  - Up to two additional 48-bit perfect DA filters with masks for each byte
  - Up to two 48-bit SA comparison checks with masks for each byte
  - 64-bit hash filter for multicast and unicast DA addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Passing of all incoming packets (according to filter) with a status report
- Additional packet filtering that is based on:
  - Virtual local area network (VLAN) tag—perfect match and hash-based filtering, which is based on either outer or inner VLAN tag, is possible
  - Layer 3 and layer 4—TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag—filtering based on four filter selections

75.4.2 Functional block diagram

This figure shows the GMAC block diagram. GMAC has four main blocks to perform all the functions.

- The AHB interface is connected to all DMA channels.
- The DMA arbiter helps in the arbitration of all paths (transmit and receive) in DMA channels.

- Each channel has a separate set of control and status registers (CSRs) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

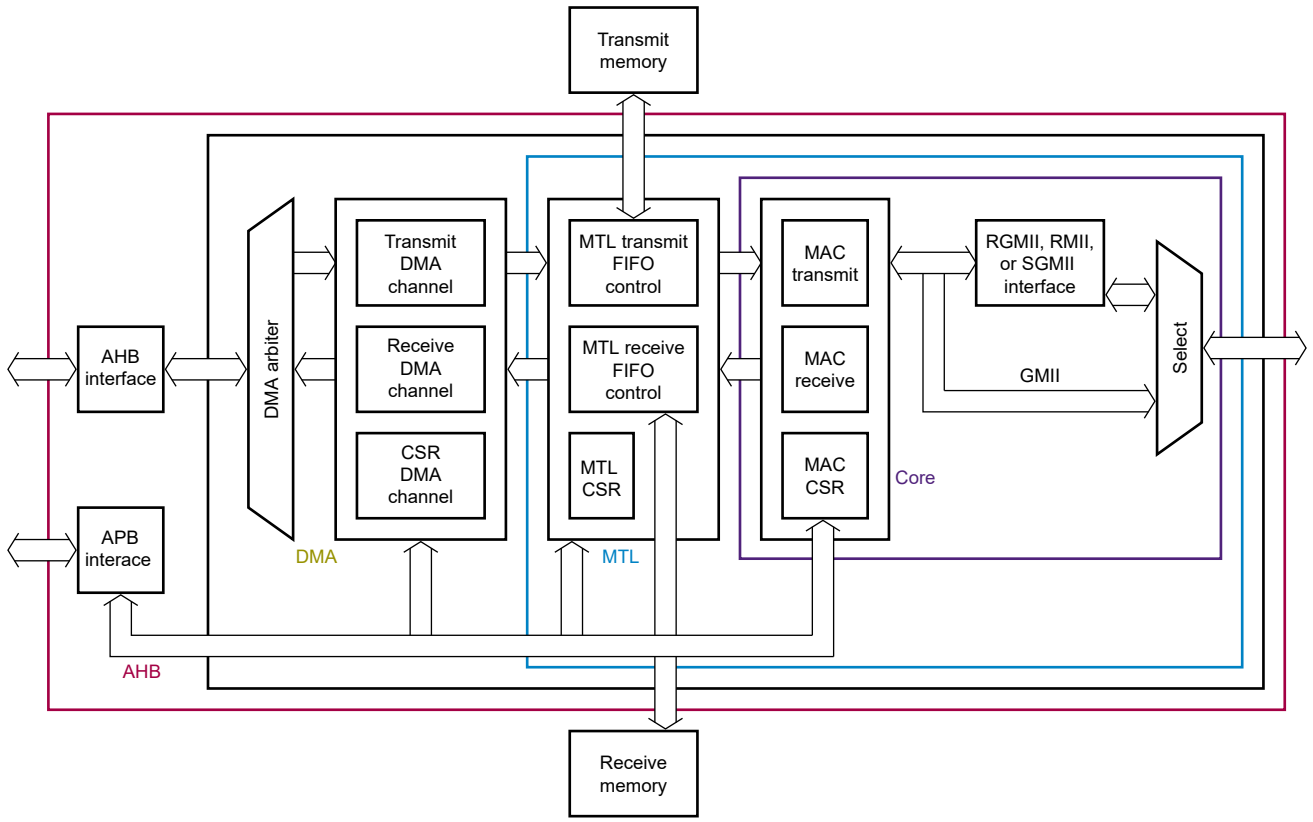


Figure 429. System-level block diagram

75.5 Architecture

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The section describes GMAC interfaces, protocols, and functionality. These are its main blocks:

- AHB master and APB3 slave interface
- DMA controller
- MTL
- MAC
- Interrupts

75.5.1 AHB master and CSR slave (APB3) interface

The 32-bit APB3 slave interface:

- Provides access to DMA, MTL, and MAC control and status registers (CSRs)
- Supports the 32-bit write and read transfers to these CSRs
- Supports single- and all-burst transfers, and an OKAY response

The DMA block uses the AHB master interface to interact with the external world. The AHB master interface:

- Controls data transfer

- Is AMBA 2.0-compliant with no restrictions
- Supports 64-bit data transfer
- Supports single and INCR transfers
- Supports burst-length modes such as Fixed, Unspecified, and Mixed

75.5.2 DMA inclusions

DMA controller:

- Includes independent transmit (Tx) and receive (Rx) engines, and a CSR space. The transmit engine transfers data from the system memory to the MTL interface, whereas the receive engine transfers data from the MTL interface to the system memory.
- Is designed for packet-oriented data transfers such as packets in Ethernet.
- Communicates with the host through CSR, descriptor lists, and data buffers.

DMA descriptors

DMA supports up to three transmit and three receive descriptor lists (or DMA channels). The base address of each list is written to the respective transmit and receive descriptor list address registers. A descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one, and DMA_CH0_Control[DSL] contols the offset. The number of descriptors in the list is programmed using the respective DMA_CH0_TxDesc_Ring_Length and DMA_CH0_RxDesc_Ring_Length registers. After the DMA processes the last descriptor in the list, it automatically jumps to the descriptor in the list address register to create a descriptor ring.

GMAC supports the ring structure for DMA descriptors. For more information, see Descriptors .

The DMA engine uses descriptors to efficiently move data from source to destination with minimal host intervention, and the DMA controller can be programmed to interrupt the host in certain situations. These situations may include packet transmit and receive transfer completion and other normal or error conditions.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory, enabling two buffers to be used and physically addressed rather than contiguous buffers in the memory.

Data buffers

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of the next packet when an EOP is detected.

The next few sections discuss DMA controller.

75.5.2.1 DMA controller bus burst access

DMA engines attempt to transfer data in a burst of the maximum size programmed using DMA_CH0_Tx_Control[TxPBL] and DMA_CH0_Rx_Control[RxPBL] of the respective DMAs, which always access the receive and transmit descriptors in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers that the DMA initates can be split into multiple burst transfers according to the AHB requirements and settings specified in (DMA_SysBus_Mode).

The transmit DMA initiates a data transfer only when sufficient space is available in the MTL transmit queue to accommodate either of these:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in the transmit buffer without EOP
- Number of bytes till EOP

The receive DMA initiates a data transfer in these conditions:

- Sufficient data is available in the MTL receive queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the receive queue

DMA indicates the start address and the number of transfers required to the AHB master interface. When the interface is configured for fixed-length burst, it transfers data by using the best combination of the INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed burst ends on the AHB interface, DMA performs dummy transfers to complete the fixed burst. Otherwise, DMA_SysBus_Mode[FB] becomes 0. The DMA transfers the data using undefined length (INCR) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first-burst transfer that AHB initates is less than or equal to the size of the configured PBL value, and the subsequent beats start at an address aligned to this value. The DMA can only align the address for beats up to size 16 (for PBL > 16) for the AHB interface because it does not support more than INCR16.

75.5.2.2 DMA application data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with an address aligned to the bus width and dummy data (old data) in the invalid byte lanes. The process of write transfer typically happens during the beginning or end of an Ethernet packet transfer. The software driver must discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 557. Data buffer alignment examples

Examples	
Buffer read	If the transmit buffer address is FF2h (for a 32-bit data bus) and 15 bytes need to be transferred, the DMA reads five full words from address FF0h. However, when DMA transfers data to the MTL transmit queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL transmit queue, unless it is the end of the packet.
Buffer write	If the receive buffer address is FF2h (for a 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address FF0h. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first receive buffer of the packet. It ignores the offset address and performs full-word writes for the middle and last receive buffers of the packet.

75.5.2.3 DMA buffer size calculations

DMA does not update the size fields in the transmit and receive descriptors. It updates only the status fields (RDES and TDES) of the descriptors. The driver performs the size calculations.

The transmit DMA transfers the exact number of bytes (as the buffer size field of TDES2 indicates) to MAC. If a descriptor is marked as first (TDES3[FD] = 1), the DMA marks the first transfer from the buffer as SOP, and if the descriptor is marked as last (TDES3[LD]), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or MTL sends the end of packet. When TDES3[FD] = 1, the amount of valid data in a buffer is accurately indicated by the buffer size fields in (DMA_CH0_Rx_Control) minus the data buffer pointer offset. The offset is 0 when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by DMA_CH0_Rx_Control[RBSZ_13_y] and DMA_CH0_Rx_Control[RBSZ_x_0]). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL fields of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The receive DMA always transfers the start of the next packet with a new descriptor.

75.5.2.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB master interface. These two types of arbitrations are supported:

- Round-robin: If DMA_Mode[DA] = 0 and both transmit and receive DMAs simultaneously request access, the arbiter allocates the data bus in ratio sets defined in DMA_Mode[PR].
- Fixed-priority: If DMA_Mode[DA] = 1, receive DMA is always prioritized over transmit DMA for data access by default. If DMA_Mode[TXPR] = 1, transmit DMA is prioritized over receive DMA as explained in Table 574.

75.5.3 MTL

MTL provides the FIFO memory interface to buffer and regulate the packets between system memory and MAC. It also enables data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: transmit path and receive path. MTL communicates with the host through ATI on the transmit path and through ARI on the receive path.

75.5.3.1 Transmit path

The internal DMA:

- Handles all transactions for the transmit path through ATI.
- Pushes the Ethernet packet reads from system memory to the corresponding queue.

The Ethernet packet, then, pops out and is transfered to MAC when the queue reaches its threshold (Threshold mode) or if the complete packet is in the queue (Store-and-Forward mode). When EOP is transferred, the status of the transmission is taken from MAC and transferred back to the internal DMA.

75.5.3.1.1 Transmit control word

This control information related to packet transmission is provided as part of the control word through the ATI interface:

- Packet length (if DCB is enabled with WFQ scheduling algorithm)
- CRC pad control
- Source address insertion control
- VLAN insertion and replacement control and VLAN tag for outer and inner VLAN tags
- TCP/IP checksum insertion control
- One-step timestamping control correction
- Transmit timestamp enable

75.5.3.1.2 Transmit operation

These two modes of operation trigger data read towards MAC:

- Threshold (or cut-through) mode: This is the default mode. In this mode, as soon as the number of bytes in the queue crosses the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to MAC. The threshold level is configured by using MTL_TxQ0_Operation_Mode[TTC].
- Store-and-Forward mode: In this mode, MTL pops the packet out to MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the queue.
  - The transmit FIFO becomes almost full.
  - The ATI watermark becomes low.

The watermark becomes low when the requested queue is not spacious enough to accommodate the requested burst length on ATI. Therefore, MTL, when operating in Store-and-Forward mode, allows packet transmission even if the packet length is bigger than the transmit queue size.

You can flush the complete content of the transmit queue by writing 1 to MTL_TxQ0_Operation_Mode[FTQ] or MTL_TxQ1_Operation_Mode[FTQ], depending on the queue. Doing so initializes the queue pointers to the default state. The FTQ field returns to 0 by itself. If you write 1 to the FTQ field during a packet transfer from MTL to MAC, MTL stops further transfers because MTL considers the queue to be empty. Therefore, an underflow event occurs at the MAC transmitter.

75.5.3.1.3 Initialization flow

After reset, MTL is ready to manage the data flow between DMA and MAC.

- With single-transmit queue configurations, there are no initialization requirements for enabling MTL.
- With multiple-transmit queue configurations, initialize the queue size for each of the queues by programming MTL_TxQ0_Operation_Mode[TQS] corresponding to a transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

75.5.3.2 Receive path

MAC sends packets to the MTL receive module and pushes them into the receive queue. MTL indicates the status (fill level) of the queue to the application or DMA when it crosses the configured receive threshold (MTL_RxQ0_Operation_Mode[RTC]), or when the MTL receive module receives the complete packet in Store-and-Forward mode. MTL also indicates the fill level of the queue so that DMA can initiate preconfigured burst transfers to the AHB interface.

75.5.3.2.1 Receive operation

During a receive operation, MTL is MAC's slave. This is the general sequence of events:

1. When MAC receives a packet, it indicates the availability of receive data.
2. MAC indicates the SOP and EOP delimiters.
3. MTL accepts the data and pushes it into the corresponding receive queue.
4. When MAC transfers EOP to the MTL receive module, MAC also drives the status word that MTL pushes into the corresponding receive queue.
5. MTL takes the data out of the queue and sends it to DMA depending on these modes:
   - Threshold mode
   - Store-and-Forward mode

   The sections that follow discuss these modes.

75.5.3.2.1.1 Threshold mode

In Threshold (default) mode, MTL reads the data and indicates its availability to the application or DMA when one of these occurs:

- Data bytes equal to the threshold amount are written to the receive queue (to MTL_RxQ0_Operation_Mode[RTC] and MTL_RxQ1_Operation_Mode[RTC]).
- A full packet of data is received into the queue.

75.5.3.2.1.2 Store-and-Forward mode

In this mode (when MTL_RxQ0_Operation_Mode[RSF] = 1), the initial receive queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the receive queue. In this mode, all error packets are dropped (if configured through MTL_RxQ0_Operation_Mode[FEP]) in such a way that only valid packets are read and forwarded to the application.

75.5.3.2.2 Multi-packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In Store-and-Forward mode, the packet data is available after the packet status. MTL is capable of storing any number of packets in the queue as long as it is not full.

If MAC receives a packet when the corresponding receive queue is full, MTL ignores that packet and overflow pulse generates on the corresponding receive queue. In addition, MTL increments the overflow counter in (MTL_RxQ0_Missed_Packet_Overflow_Cnt) for the corresponding queue.

75.5.3.2.3 Error handling in receive operation

MTL performs these actions if the MTL receive queue is full before it receives the EOP data from MAC:

1. Declares an overflow
2. Drops the whole packet (including the status word)
3. Increments the overflow counter in DMA ((MTL_RxQ0_Missed_Packet_Overflow_Cnt))

This is true even if MTL_RxQ0_Operation_Mode[FEP] is 1.

If the start address of such a packet is already transferred to the read controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL receive queue is configured to operate in the Store-and-Forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL receive control logic can filter errors and undersized packets, if enabled by using MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]. If the start address of one such packet is already transferred to the receive queue read controller, the packet is not filtered. The start address of the packet is transferred to the read controller after the packet crosses the receive threshold defined using MTL_RxQ0_Operation_Mode[RTC].

If the MTL receive queue is configured to operate in Store-and-Forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. MTL then starts transferring the next packet, if it's available.

75.5.4 MAC

MAC can support the MII and RMII PHY interface and it consists of:

- MTI
- MRI
- MCI

75.5.4.1 MAC transmission

The MAC transmission process is as follows:

1. The transmission initiates when MTL pushes in data with the SOP signal asserted.
2. After the SOP signal is detected, MAC accepts the data and begins transmitting to RMII or MII.
3. After the EOP signal is transferred to MAC, it performs one of these steps:
   - Completes normal packet transmission and sends the transmission status to MTL
   - Sends retry requests if a normal collision (in Half-Duplex mode) occurs during transmission, and until one of the following is true:
     - Packet is successfully transmitted.
     - Maximum retry requests have expired. When this happens, MAC aborts the packet transmission with "excessive collision transmit" status. MAC accepts and drops all further data until it receives the next SOP.

The MTL block must retransmit the same packet from SOP on observing a retry request (in the status) from MAC.

- If any one of the following happens, MAC aborts the packet transmission:
  - No carrier (Half-Duplex mode)
  - Loss of carrier (Half-Duplex mode)
  - Excessive deferral (Half-Duplex mode)
  - Late collisions (Half-Duplex mode)
  - Jabber
  - MAC accepts and drops all further data until it receives the next SOP

4. MAC issues an underflow status if MTL is not able to provide data continuously during transmission. Until the next SOP is received, MAC accepts and drops all further data.
5. During the normal transfer of a packet from MTL, if MAC receives an SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as a continuation of the previous packet.

75.5.4.2 MAC reception

The receive operation initiates as follows:

1. MAC detects a state-of-frame data on RMII or MII.
2. MAC strips the preamble and SFD before processing an Ethernet packet.
3. The MAC AFM:
   - Checks the header fields (SA and DA) of an incoming packet for filtering
   - Verifies the CRC contained in the packet's FCS field
4. MAC's AFM checks the header fields (SA and DA) of an incoming packet for filtering.
5. FCS verifies the CRC of the received packet.
6. MAC stores the received packet in a shallow buffer until address filtering is performed.
7. AFM drops the packet if it fails the address filter.

75.5.5 Interrupts

GMAC supports interrupt coalescing, which reduces the number of interrupts generated by the module and reduces the CPU load. (MAC_Interrupt_Status) captures various interrupt events. If the interrupt enable field of an interrupt is 1, the corresponding interrupt generates based on the event status in the Status registers. The Interrupt mode (INTM) field decides whether the interrupt signal is a level signal or pulse signal. See the following table and interrupt map file attached to this document for details.

Table 558. Interrupt request

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Common interrupt	(MAC_Interrupt_Enable)	(MAC_Interrupt_Status)
	(MMC_Rx_Interrupt_Mask)	(MMC_Rx_Interrupt)
	(MMC_Tx_Interrupt_Mask)	(MMC_Tx_Interrupt)
	(MMC_FPE_Tx_Interrupt_Mask)	(MMC_FPE_Tx_Interrupt)
	(MMC_FPE_Rx_Interrupt_Mask)	(MMC_FPE_Rx_Interrupt)
	(MTL_DBG_CTL)	(MTL_DBG_STS)

Table continues on the next page...

Table 558. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
	(MTL_EST_Intr_Enable)	(MTL_EST_Status)
	(MTL_RXP_Interrupt_Control_Status)	(MTL_RXP_Interrupt_Control_Status)
	(MTL_Q0_Interrupt_Control_Status)	(MTL_Q0_Interrupt_Control_Status)
	(MTL_Q1_Interrupt_Control_Status)	(MTL_Q1_Interrupt_Control_Status)
	(DMA_CH0_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH0_Interrupt_Status
	(DMA_CH1_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH1_Interrupt_Status
		(DMA_Interrupt_Status) (First level status. Indicates major block event source: DMA channel, MTL or MAC)
		(MTL_Interrupt_Status) (Status summary for MTL block interrupts: Rx Parser, EST, FIFO Debug, Queue 1/Queue 0)
Tx interrupt 0/1	(DMA_CH0_Tx_Control)	(DMA_CH0_Status)
	(DMA_CH0_Interrupt_Enable)	
	(DMA_CH1_Tx_Control)	(DMA_CH1_Status)
	(DMA_CH1_Interrupt_Enable)	
Rx interrupt 0/1	(DMA_CH0_Rx_Control)	(DMA_CH0_Status)
	(DMA_CH0_Interrupt_Enable)	
	(DMA_CH1_Rx_Control)	(DMA_CH1_Status)
	(DMA_CH1_Interrupt_Enable)	
Safety interrupt	(MTL_ECC_Interrupt_Enable)	(MTL_ECC_Interrupt_Status)
		(MTL_Safety_Interrupt_Status)
	(MTL_DPP_Control)	(MAC_DPP_FSM_Interrupt_Status)
	(MAC_FSM_Control)	

These are the interrupt output signals that are synchronous to the CSR clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – interrupt per transmit channel
- Sbd_perch_rx_intr_o [max_dma_ch] – interrupt per receive channel

NOTE

max_dma_ch = number of transmit/receive queues, which is 2

The sbd_intr_o common interrupt is a level signal. When it is asserted, a corresponding interrupt event source can be found in (DMA_Interrupt_Status), which is a read-only register that contains the event source fields corresponding to each DMA channel

(transmit and receive queue pair), MAC transaction layer, and MAC blocks. You must then read the following registers and look for the fields that are 1:

- (MAC_Interrupt_Status)
- (MTL_Interrupt_Status)
- (DMA_CH0_Status)

The sbd_intr_o interrupt deasserts only when all the enabled interrupt events are clear in their respective status registers, and correspondingly, all the fields in (DMA_Interrupt_Status) are 0. (DMA_CH0_Status) captures all the interrupt events of that transmit DMA and receive DMA channel pair.

(DMA_CH0_Interrupt_Enable) contains the corresponding enable fields for each of the interrupt events. These are the two groups of interrupts in the DMA channel:

- Normal—DMA_CH0_Status[NIS] indicates this interrupt, which is used for events that occur during the normal transfer of packets (TI, RI, TBU).
- Abnormal—DMA_CH0_Status[AIS] indicates this interrupt, which is used for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts generate.

The common sbd_intr_o output signal asserts for the transfer complete interrupts only when the corresponding interrupts are enabled in (DMA_CH0_Interrupt_Enable).

GMAC also supports these per-channel transfer-complete interrupt signals:

- sbd_perch_tx_intr_o[max_dma_ch] (transmit per channel interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (receive per channel interrupts)

The behavior of the RI/TI/sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depends on the configuration specified in DMA_Mode[INTM]. This table explains the transfer complete interrupt behavior.

Table 559. Transfer complete interrupt behavior

Interrupt mode	Behavior of sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of the TI/RI interrupts and sbd_intr_o
INTM = 1	In this mode, these signals indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are 1, respectively. Therefore, they are level signals that you clear by writing 1 to these fields. The signals do not assert when DMA_CH0_Status[RI] or DMA_CH0_Status[TI] is 0.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are configured as explained. For any RI/TI events: • The sbd_intr_o signal does not assert. • DMA_CH0_Status[NIS] remains 0.
INTM = 2	In this mode, RI/TI are queued and indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when any of these fields is 1. RI and TI are level signals that you clear by writing 1 to these fields. However, the fields become 1 again if another TI/RI event is detected before DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 for the previous event.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 whenever the transfer complete event is detected and are reset whenever the software driver changes them to 0 by writing 1. However, if another transfer complete event is

Table continues on the next page...

Table 559. Transfer complete interrupt behavior (continued)

		detected before the software changes it to 0 (services it), GMAC automatically writes 1 to these fields again. The generation of the sbd_intr_o signal; however, is not based on DMA_CH0_Status[RI] or DMA_CH0_Status[TI].

75.6 Signal descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

75.6.1 Module signals

This table provides port/signal names and their descriptions. See the IOMUX file attached to this document for details.

Table 560. Module signals

Port Name	I/O	Description
clk_tx_i	I	MAC Transmitter Clock. The external PHY or PLL provides this transmission clock. This is 312.5 MHz in 2.5 Gbps mode, 125 MHz in 1 Gbps mode, 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. All transmission signals generated by the MAC are synchronous to this clock. This clock is required for all PHY interfaces.
clk_rx_i	I	MAC Receiver Clock. The external PHY provides this receive clock for RGMII, GMII, MII, and RMII interfaces. This clock is 312.5 MHz in 2.5 Gbps mode, 125 MHz in 1 Gbps mode, 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. All RGMII, GMII, and MII receive signals received by the MAC are synchronous to this clock. This clock input is required for all PHY interfaces.
clk_rmii_i	I	RMII Clock. This is the 50-MHz clock used by the RMII interface. When the RMII interface is selected, the clk_rx_i clock should be 25 or 2.5 MHz and it should be derived from this clock.
clk_ptp_ref_i	I	PTP Reference Clock. This reference clock, provided by an external oscillator or a timing source, is used for the timestamp logic.
ptp_pps_o[3:0]	O	Pulse Per Second. This signal is high based on the PPS mode selected in the MAC_PPS_Control register. When PPS is programmed in Media Clock recovery Mode, this port indicates the recovered clock. See the device IOMUX sheet for details on the number of these signals available.
mcg_pst_trig_i[3:0]	I	Media Clock Generation Trigger Input

Table continues on the next page...

Table 560. Module signals (continued)

Port Name	I/O	Description
		Trigger Input to the DUT to capture presentation time. Based on presentation control value of MAC_PPS_Control register, this signal can be pulse or level signal. Width of this IO changes with the configured number of PPS instances. See the device IOMUX sheet for details on the number of these signals available.
phy_intf_sel_i[2:0]	I	PHY Interface Select. This signal selects the PHY interface of the MAC: • 000: GMII or MII • 001: RGMII • 100: RMII This signal is sampled only during reset assertion, and it is ignored after that. The reset is generated internally in the IP, and it gets activated when either the input reset (pwr_on_rst_n) or the software reset is asserted.
phy_txen_o	O	PHY Transmit Data Enable. The MAC drives this signal. This signal has multiple functions depending on the selected PHY interface as described in the following list: • GMII/MII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to: clk_tx_i • RMII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to: clk_rmii_i • RGMII: This signal is the control signal (rgmii_tctl) for the Transmit data, and it is driven on both edges of the clock. Synchronous to: clk_tx_i, clk_tx_180_i
phy_txer_o	O	PHY Transmit Error. The MAC drives this signal. It has multiple functions depending on the selected PHY interface as described in the following list: • GMII: When this signal is high, it indicates a Transmit error or carrier extension on the phy_txd_o bus. Synchronous to:clk_tx_i • MII, RMII, RGMII: Not used and tied to low. According to the IEEE standard, the TX_ER signal (phy_txer_o signal in the GMAC) is optional in the MII mode. However, if you have enabled the Energy Efficient Ethernet feature, the phy_txer_o signal is required.
phy_txd_o[7:0]	O	PHY Transmit Data. This is a group of transmit data signals driven by the MAC. It has multiple functions depending on the selected PHY interface as described in the following list: • GMII: All eight bits provide the GMII transmit data byte. The data is valid only when the phy_txen_o and phy_txer_o signals are high. Synchronous to: clk_tx_i

Table continues on the next page...

Table 560. Module signals (continued)

Port Name	I/O	Description
		• MII: Bits[3:0] provide the MII transmit data nibble. The data is valid only when the phy_txen_o and phy_txer_o signals are high. Synchro-nous to: clk_tx_i • RGMII: Bits[3:0] provide the RGMII transmit data. The data bus changes with both rising and falling edges of the transmit clock (clk_tx_i). The data is valid only when the phy_txen_o signal is high. Synchronous to: clk_tx_i and clk_tx_180_i • RMII: Bits[1:0] provide the RMII transmit data. The data is valid only when the phy_txen_o signal is high. Synchronous to: clk_rmii_i
phy_crs_i	I	PHY CRS. This signal is valid only in the GMII or MII mode. The PHY drives this signal high when the Transmit or Receive medium is not idle. The PHY drives this signal low when both Transmit and Receive mediums are idle. This signal is not synchronous to any clock.
phy_col_i	I	PHY Collision. This signal is valid only in the GMII or MII mode. The PHY drives this signal high when a collision is detected on the medium. This signal is not synchronous to any clock.
phy_rxdv_i	I	PHY Receive Data Valid. The PHY drives this signal. It has multiple functions depending on the selected PHY interface as described in the following list: • GMII or MII: Indicates that the data on the phy_rxd_i bus is valid. It remains high continuously from the first recovered byte or nibble of the packet through the final recovered byte or nibble of the packet. Synchronous to: clk_rx_i • RGMII: This is the Receive control signal that is used to qualify the data received phy_rxd_i. This signal is sampled both edges of the clock. Synchronous to: clk_rx_i, clk_rx_180_i • RMII: Contains the crs and data valid information of the Receive interface. Synchronous to: clk_rmii_i
phy_rxer_i	I	PHY Receive Error. The PHY drives this signal. It has multiple functions depending on the selected PHY interface as described in the following list: • GMII or MII: Indicates an error or carrier extension (in GMII) in the received packet the phy_rxd_i bus. Synchronous to: clk_rx_i • RGMII, RMII: This signal is not used.
phy_rxd_i[7:0]	I	PHY Receive Data.

Table continues on the next page...

Table 560. Module signals (continued)

Port Name	I/O	Description
		This is a group of data signals received from the PHY. It has multiple functions depending on the selected PHY interface as described in the following list: • GMII: All eight bits provide the GMII receive data byte. The data is valid only when the phy_rxdv_i and phy_rxer_i signals are high. Synchronous to: clk_rx_i • MII: Bits [3:0] provide the MII receive data nibble. The data is valid only when the phy_rxdv_i and phy_rxer_i signals are high. Synchro-nous to: clk_rx_i • RGMII: Bits [3:0] provide the RGMII receive data. The data bus is sampled with both rising and falling edges of the receive clock (clk_rx_i). The data is valid only when the phy_rxdv_i signal is high. Synchronous to: clk_rx_i, clk_rx_180_i • RMII: Bits [1:0] provide the RMII receive data. he data is valid only when the phy_rxdv_i signal is high. Synchronous to: clk_rmii_i
gmii_mdc_o	O	Management Data Clock. The MAC provides timing reference for the gmii_mdi_i and gmii_mdo_o signals on GMII or MII through this aperiodic clock. This clock is generated from the application clock through a clock divider controlled by CR field of MAC_MDIO_Address register.
gmii_mdi_i	I	Management Data In. The PHY generates this signal to transfer register data during a read operation. This signal is driven synchronously with the gmii_mdc_o clock.
gmii_mdo_o	O	Management Data Out. The MAC uses this signal to transfer control and data information to the PHY.

75.7 GMAC register descriptions

75.7.1 GMAC memory map

NOTE

This chip has 16 KB allocated per Ethernet controller for configuration space. GMAC uses only 8 KB of this memory and the remaining 8 KB is reserved for future use. Writing to the reserved memory may lead to unintended behavior.

GMAC base address: 4048_4000h

75.7.2 (MAC_Configuration)

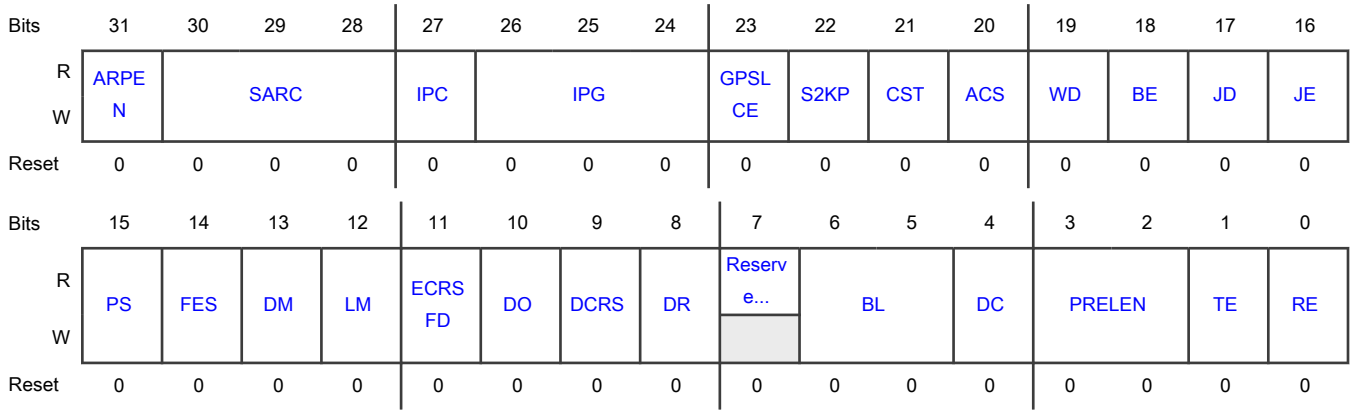
Offset

Register	Offset
MAC_Configuration	0h

Function

The MAC Configuration Register establishes the operating mode of the MAC.

Diagram



Fields

Field	Function
31 ARPEN	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus. This bit is available only when the Enable IPv4 ARP Offload is selected. 0b - ARP Offload is disabled 1b - ARP Offload is enabled
30-28 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the IP, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010b - Contents of MAC Addr-0 inserted in SA field 011b - Contents of MAC Addr-0 replaces SA field 110b - Contents of MAC Addr-1 inserted in SA field 111b - Contents of MAC Addr-1 replaces SA field
27 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically

Table continues on the next page...

Table continued from the previous page...

Field	Function
	selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0b - IP header/payload checksum checking is disabled 1b - IP header/payload checksum checking is enabled
26-24 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. This function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. 000b - 96 bit times IPG 001b - 88 bit times IPG 010b - 80 bit times IPG 011b - 72 bit times IPG 100b - 64 bit times IPG 101b - 56 bit times IPG 110b - 48 bit times IPG 111b - 40 bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0b - Giant Packet Size Limit Control is disabled 1b - Giant Packet Size Limit Control is enabled
22 S2KP	IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Giant Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0b - Support upto 2K packet is disabled 1b - Support upto 2K packet is Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. 0b - CRC stripping for Type packets is disabled 1b - CRC stripping for Type packets is enabled
20 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . 0b - Automatic Pad or CRC Stripping is disabled 1b - Automatic Pad or CRC Stripping is enabled
19 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0b - Watchdog is enabled 1b - Watchdog is disabled
18 BE	Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0b - Packet Burst is disabled 1b - Packet Burst is enabled
17 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0b - Jabber is enabled 1b - Jabber is disabled
16 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0b - Jumbo packet is disabled 1b - Jumbo packet is enabled
15 PS	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - For 1000 or 2500 Mbps operations 1b - For 10 or 100 Mbps operations
14 FES	Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. 0b - 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1b - 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0b - Half-duplex mode 1b - Full-duplex mode
12 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0b - Loopback is disabled 1b - Loopback is enabled
11 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0b - ECRSFD is disabled 1b - ECRSFD is enabled
10 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0b - Enable Receive Own 1b - Disable Receive Own
9 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0b - Enable Carrier Sense During Transmission 1b - Disable Carrier Sense During Transmission
8 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0b - Enable Retry

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Disable Retry
7 Reserved_7	Reserved.
6-5 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 00b - k = min(n,10) 01b - k = min(n,8) 10b - k = min(n,4) 11b - k = min(n,1)
4 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0b - Deferral check function is disabled 1b - Deferral check function is enabled
3-2 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00b - 7 bytes of preamble 01b - 5 bytes of preamble 10b - 3 bytes of preamble 11b - Reserved
1 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0b - Transmitter is disabled 1b - Transmitter is enabled
0	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it

Table continues on the next page...

Table continued from the previous page...

Field	Function
RE	completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. 0b - Receiver is disabled 1b - Receiver is enabled

75.7.3 (MAC_Ext_Configuration)

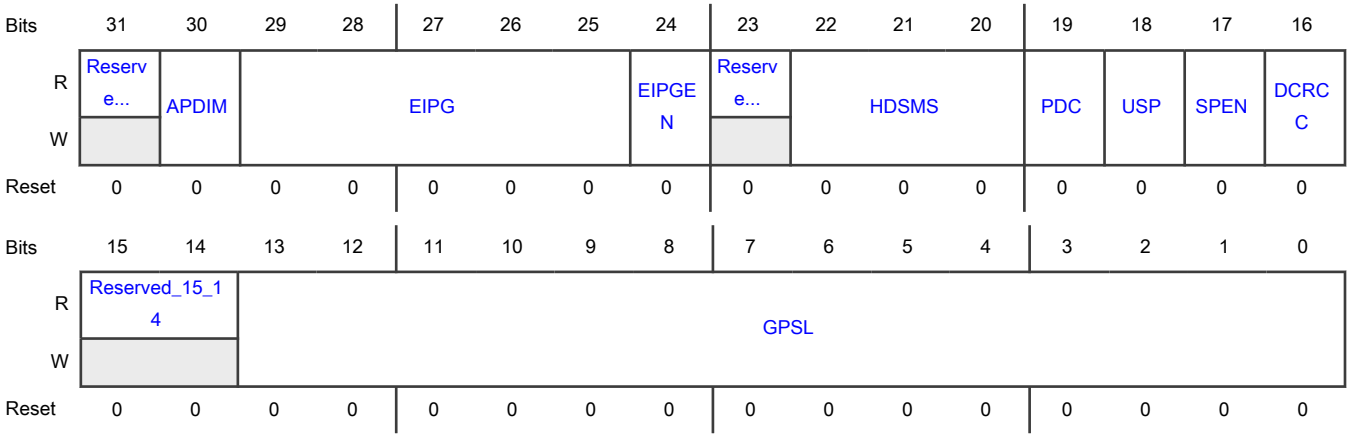
Offset

Register	Offset
MAC_Ext_Configuration	4h

Function

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Diagram



Fields

Field	Function
31 Reserved_FHE	Reserved.
30 APDIM	ARP Packet Drop if IP Address Mismatch When this bit is set, Packet for which Target Protocol Address does not match IPv4 address is dropped in the MTL layer. When this bit is reset, when target Protocol Address does not match, packet is forwarded to MTL maintaining backward compatibility 0b - mux select to drop the arp packet if target protocol address mismatches IPv4 address disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - mux select to drop the arp packet if target protocol address mismatches IPv4 address enabled
29-25 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: Enable the extended Inter-Packet Gap feature only when operating in Full-Duplex mode. There might be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0b - Extended Inter-Packet Gap is disabled 1b - Extended Inter-Packet Gap is enabled
23 Reserved_23	Reserved.
22-20 HDSMS	Maximum Size for Splitting the Header Data These bits indicate the maximum header size allowed for splitting the header data in the received packet. 000b - Maximum Size for Splitting the Header Data is 64 bytes 001b - Maximum Size for Splitting the Header Data is 128 bytes 010b - Maximum Size for Splitting the Header Data is 256 bytes 011b - Maximum Size for Splitting the Header Data is 512 bytes 100b - Maximum Size for Splitting the Header Data is 1024 bytes 101b - Reserved
19 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_Address(#i)_High register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of MAC_Address(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. 0b - Packet Duplication Control is disabled 1b - Packet Duplication Control is enabled
18 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Unicast Slow Protocol Packet Detection is disabled 1b - Unicast Slow Protocol Packet Detection is enabled
17 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Slow Protocol Sub-Type and Code fields in Rx status. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0b - Slow Protocol Detection is disabled 1b - Slow Protocol Detection is enabled
16 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0b - CRC Checking is enabled 1b - CRC Checking is disabled
15-14 Reserved_15_14	Reserved.
13-0 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

75.7.4 (MAC_Packet_Filter)

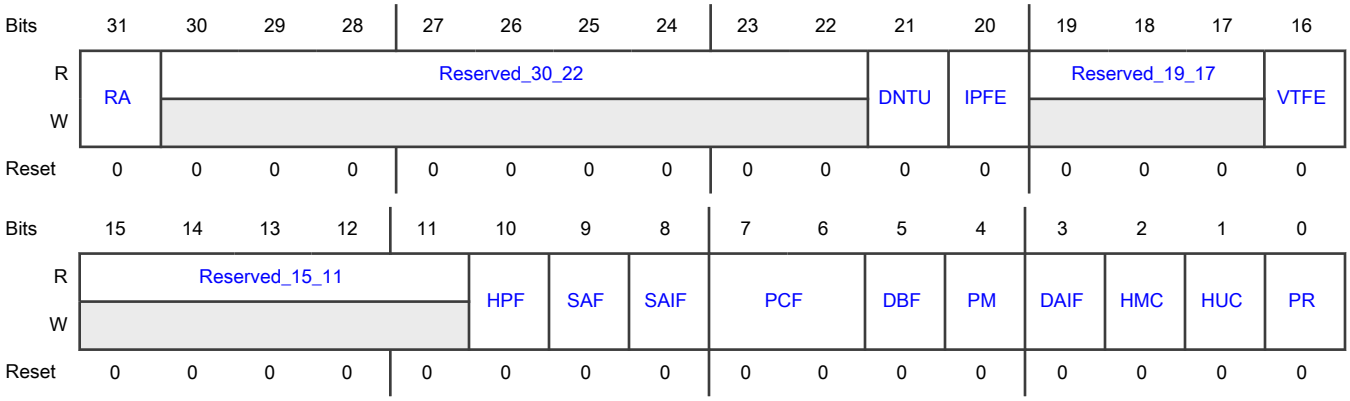
Offset

Register	Offset
MAC_Packet_Filter	8h

Function

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Diagram



Fields

Field	Function
31 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0b - Receive All is disabled 1b - Receive All is enabled
30-22 Reserved_30_22	Reserved.
21 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0b - Forward Non-TCP/UDP over IP Packets 1b - Drop Non-TCP/UDP over IP Packets
20 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0b - Layer 3 and Layer 4 Filters are disabled 1b - Layer 3 and Layer 4 Filters are enabled
19-17 Reserved_19_17	Reserved.
16 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - VLAN Tag Filter is disabled 1b - VLAN Tag Filter is enabled
15-11 Reserved_15_11	Reserved.
10 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0b - Hash or Perfect Filter is disabled 1b - Hash or Perfect Filter is enabled
9 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0b - SA Filtering is disabled 1b - SA Filtering is enabled
8 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0b - SA Inverse Filtering is disabled 1b - SA Inverse Filtering is enabled
7-6 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00b - MAC filters all control packets from reaching the application 01b - MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 10b - MAC forwards all control packets to the application even if they fail the Address filter 11b - MAC forwards the control packets that pass the Address filter
5 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all the incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0b - Enable Broadcast Packets 1b - Disable Broadcast Packets

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 PM	Pass All Multicast When this bit is set, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0b - Pass All Multicast is disabled 1b - Pass All Multicast is enabled
3 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0b - DA Inverse Filtering is disabled 1b - DA Inverse Filtering is enabled
2 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Hash Multicast is disabled 1b - Hash Multicast is enabled
1 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Hash Unicast is disabled 1b - Hash Unicast is enabled
0 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0b - Promiscuous Mode is disabled 1b - Promiscuous Mode is enabled

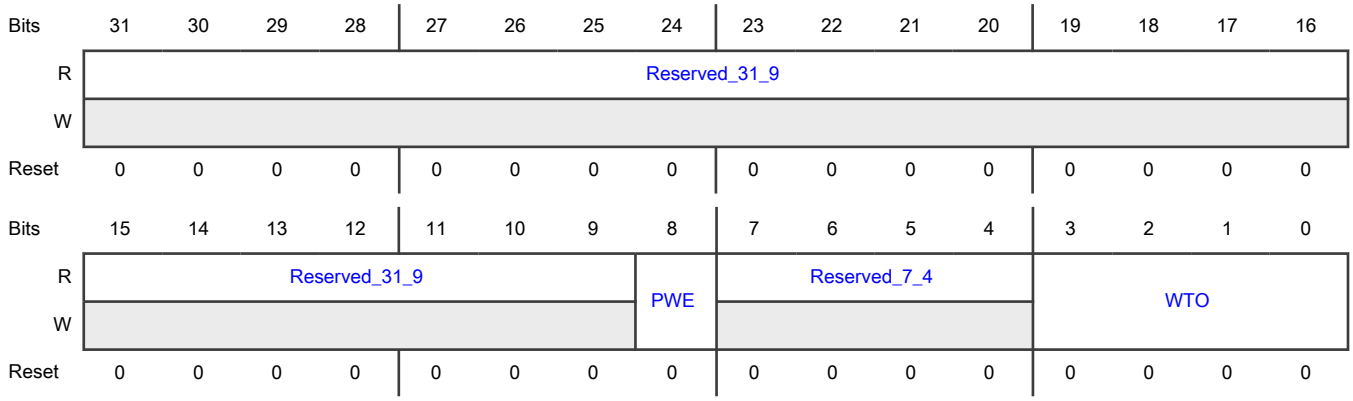
75.7.5 (MAC_Watchdog_Timeout)

Offset

Register	Offset
MAC_Watchdog_Timeout	Ch

Function
The Watchdog Timeout register controls the watchdog timeout for received packets.

Diagram



Fields

Field	Function
31-9 Reserved_31_9	Reserved.
8 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register. 0b - Programmable Watchdog is disabled 1b - Programmable Watchdog is enabled
7-4 Reserved_7_4	Reserved.
3-0 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. 0000b - 2 KB 0001b - 3 KB 0010b - 4 KB 0011b - 5 KB 0100b - 6 KB 0101b - 7 KB 0110b - 8 KB 0111b - 9 KB 1000b - 10 KB

75.7.6 (MAC_Hash_Table_Reg0)

Offset

Register	Offset
MAC_Hash_Table_Reg0	10h

Function

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: - Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). - Perform bitwise reversal for the value obtained in Step 1. - Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

75.7.7 (MAC_Hash_Table_Reg1)

Offset

Register	Offset
MAC_Hash_Table_Reg1	14h

Function

The Hash Table Register 1 contains the second 32 bits of the hash table. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: - Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). - Perform bitwise reversal for the value obtained in Step 1. - Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Function
31 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0b - Inner VLAN Tag in Rx status is disabled 1b - Inner VLAN Tag in Rx status is enabled
30 Reserved_30	Reserved.
29-28 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	Enable Inner VLAN Tag Comparison When this bit, VTHM bit and the EDVLP field are set, the MAC receiver enables VLAN Hash filtering operation on the inner VLAN Tag (if present). When this bit is reset and VTHM bit is set, the MAC receiver enables VLAN Hash filtering operation on the outer VLAN Tag (if present). The ERSVLM bit and DOVLTC bit determines which VLAN type is enabled for filtering. 0b - Inner VLAN tag is disabled 1b - Inner VLAN tag is enabled
26 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0b - Double VLAN Processing is disabled 1b - Double VLAN Processing is enabled
25 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed. 0b - VLAN Tag Hash Table Match is disabled 1b - VLAN Tag Hash Table Match is enabled
24 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. 0b - VLAN Tag in Rx status is disabled 1b - VLAN Tag in Rx status is enabled
23	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
Reserved_23	
22-21 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20 DOVLTC	Disable VLAN Type Check for VLAN Hash Filtering When this bit is set, the MAC VLAN Hash Filter does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC VLAN Hash Filter filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit. 0b - VLAN Type Check is enabled 1b - VLAN Type Check is disabled
19 ERSVLM	Enable Receive S-VLAN Match for VLAN Hash Filtering When this bit is set, the MAC receiver enables VLAN Hash filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables VLAN Hash filtering or matching for C-VLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for VLAN Hash filtering or matching. 0b - Receive S-VLAN Match is disabled 1b - Receive S-VLAN Match is enabled
18 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0b - S-VLAN is disabled 1b - S-VLAN is enabled
17 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0b - VLAN Tag Inverse Match is disabled 1b - VLAN Tag Inverse Match is enabled
16 ETV	Enable 12-Bit VLAN Tag Comparison for VLAN Hash Filtering When this bit is set, a 12-bit VLAN identifier is used for VLAN Hash filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - 12-Bit VLAN Tag Comparison is disabled 1b - 12-Bit VLAN Tag Comparison is enabled
15-7 Reserved_15_y	Reserved.

Table continued from the previous page...

Field	Function
6-2 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
1 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation. 0b - Write operation 1b - Read operation
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the MAC_VLAN_Tag_Data register only after this bit is reset. 0b - Operation Busy is disabled 1b - Operation Busy is enabled

75.7.15 (MAC_VLAN_Tag_Data)

Offset

Register	Offset
MAC_VLAN_Tag_Data	54h

Function

This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

Fields

Field	Function
31-27 Reserved_31_y	Reserved.
26-25 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0b - DMA Channel Number is disabled 1b - DMA Channel Number is enabled
23-21 Reserved_23_21	Reserved.
20 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when Double VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0b - Inner VLAN tag comparison is disabled 1b - Inner VLAN tag comparison is enabled
19 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0b - Receive S-VLAN Match is disabled 1b - Receive S-VLAN Match is enabled
18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0b - VLAN type comparison is enabled 1b - VLAN type comparison is disabled
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16 bit VLAN comparison 1b - 12 bit VLAN comparison

Table continues on the next page...

Field	Function
18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0b - VLAN type comparison is enabled 1b - VLAN type comparison is disabled
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16 bit VLAN comparison 1b - 12 bit VLAN comparison
16 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0b - VLAN Tag is disabled 1b - VLAN Tag is enabled
15-0 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

26-25 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0b - DMA Channel Number is disabled 1b - DMA Channel Number is enabled
23-21 Reserved_23_21	Reserved.
20 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when Double VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0b - Inner VLAN tag comparison is disabled 1b - Inner VLAN tag comparison is enabled
19 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0b - Receive S-VLAN Match is disabled 1b - Receive S-VLAN Match is enabled

18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0b - VLAN type comparison is enabled 1b - VLAN type comparison is disabled
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16 bit VLAN comparison 1b - 12 bit VLAN comparison
16 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0b - VLAN Tag is disabled 1b - VLAN Tag is enabled
15-0 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

75.7.48 (MAC_VLAN_Hash_Table)

Offset

Register	Offset
MAC_VLAN_Hash_Table	58h

Function

When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC value are used to index the contents of the VLAN Hash table. For example, hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: - Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3). - Perform bitwise reversal for the value obtained in step 1. - Take the upper four bits from the value obtained in step 2. If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. - If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

75.7.49 (MAC_VLAN_Incl)

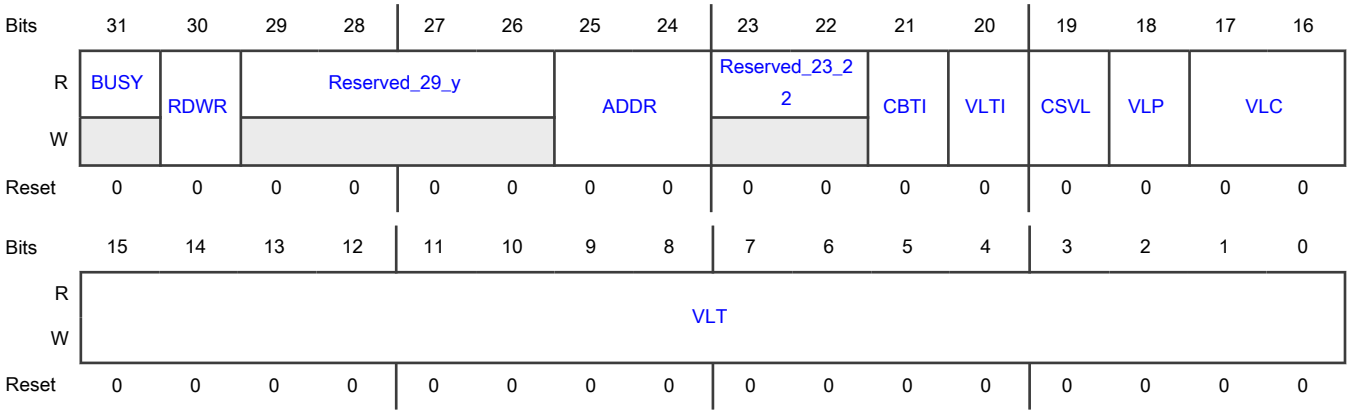
Offset

Register	Offset
MAC_VLAN_Incl	60h

Function

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

Diagram



Fields

Field	Function
31 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0b - Busy status not detected 1b - Busy status detected
30 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0b - Read operation of indirect access 1b - Write operation of indirect access
29-26 Reserved_29_y	Reserved.
25-24 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
23-22 Reserved_23_22	Reserved.
21 CBTI	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0b - Channel based tag insertion is disabled 1b - Channel based tag insertion is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0b - VLAN Tag Input is disabled 1b - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0b - C-VLAN type (0x8100) is inserted or replaced 1b - S-VLAN type (0x88A8) is inserted or replaced
18 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0b - VLAN Priority Control is disabled 1b - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

75.7.59 (MAC_Q0_Tx_Flow_Ctrl)

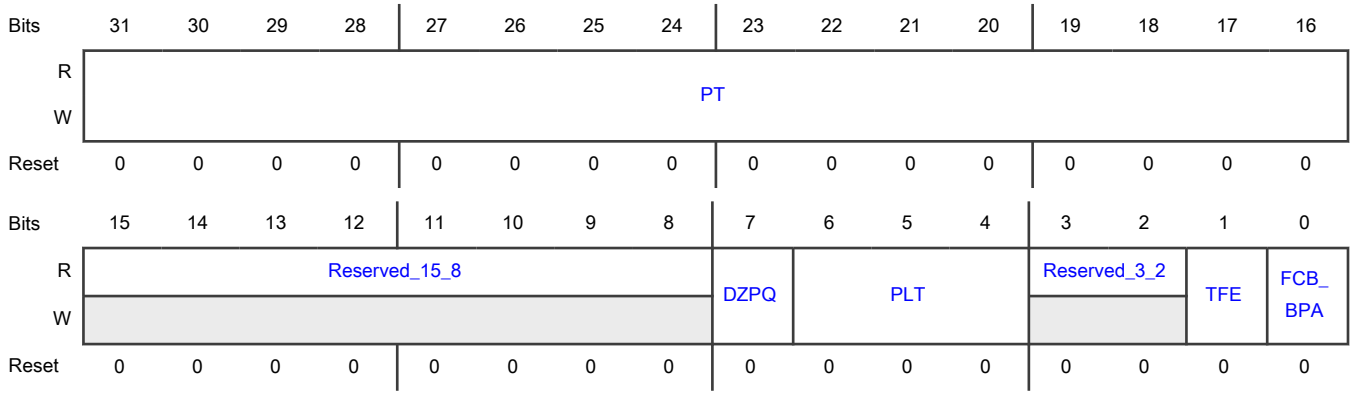
Offset

Register	Offset
MAC_Q0_Tx_Flow_Ctrl	70h

Function

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register. When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

Diagram



Fields

Field	Function
31-16 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 Reserved_15_8	Reserved.
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0b - Zero-Quanta Pause packet generation is enabled 1b - Zero-Quanta Pause packet generation is disabled
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000b - Pause Time minus 4 Slot Times (PT -4 slot times) 001b - Pause Time minus 28 Slot Times (PT -28 slot times) 010b - Pause Time minus 36 Slot Times (PT -36 slot times) 011b - Pause Time minus 144 Slot Times (PT -144 slot times) 100b - Pause Time minus 256 Slot Times (PT -256 slot times) 101b - Pause Time minus 512 Slot Times (PT -512 slot times) 110b - Reserved
3-2 Reserved_3_2	Reserved.
1 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0b - Transmit Flow Control is disabled 1b - Transmit Flow Control is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flow Control Busy or Backpressure Activate is disabled 1b - Flow Control Busy or Backpressure Activate is enabled

Table continued from the previous page...

Field	Function
	VLAN Tagged packet (based on PSRQ for DCB/Generic enabled Rx Queues). - 1'b1: VLAN Tagged PTPoE packets are routed to Rx Queues specified by PTPQ field.
21 TACPQE	Tagged AV Control Packets Queuing Enable. When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. 0b - Tagged AV Control Packets Queuing is disabled 1b - Tagged AV Control Packets Queuing is enabled
20 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field. 0b - Multicast and Broadcast Queue is disabled 1b - Multicast and Broadcast Queue is enabled
19 Reserved_19	Reserved.
18-16 MCBCQ	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Receive Queue 5 110b - Receive Queue 6 111b - Receive Queue 7
15 Reserved_15	Reserved.
14-12 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Untagged Packets. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4

Table continues on the next page...

Table continued from the previous page...

Field	Function
	101b - Receive Queue 5 110b - Receive Queue 6 111b - Receive Queue 7
11 Reserved_11	Reserved.
10-8 DCBCPQ	DCB Control Packets Queue This field specifies the Rx queue on which the received DCB control packets are routed. The DCB data packets are routed based on the PSRQ field of the Transmit Flow Control Register of corresponding queue. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Receive Queue 5 110b - Receive Queue 6 111b - Receive Queue 7
7 Reserved_7	Reserved.
6-4 PTPQ	PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When the AV8021ASMEN bit of MAC_Timestamp_Control register is set, only untagged PTP over Ethernet packets are routed on an Rx Queue. If the bit is not set, then based on programming of TPQC field, both tagged and untagged PTPoE packets can be routed to this Rx Queue. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Receive Queue 5 110b - Receive Queue 6 111b - Receive Queue 7
3 Reserved_3	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-0 AVCPQ	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field. 000b - Receive Queue 0 001b - Receive Queue 1 010b - Receive Queue 2 011b - Receive Queue 3 100b - Receive Queue 4 101b - Receive Queue 5 110b - Receive Queue 6 111b - Receive Queue 7

75.7.67 (MAC_RxQ_Ctrl2)

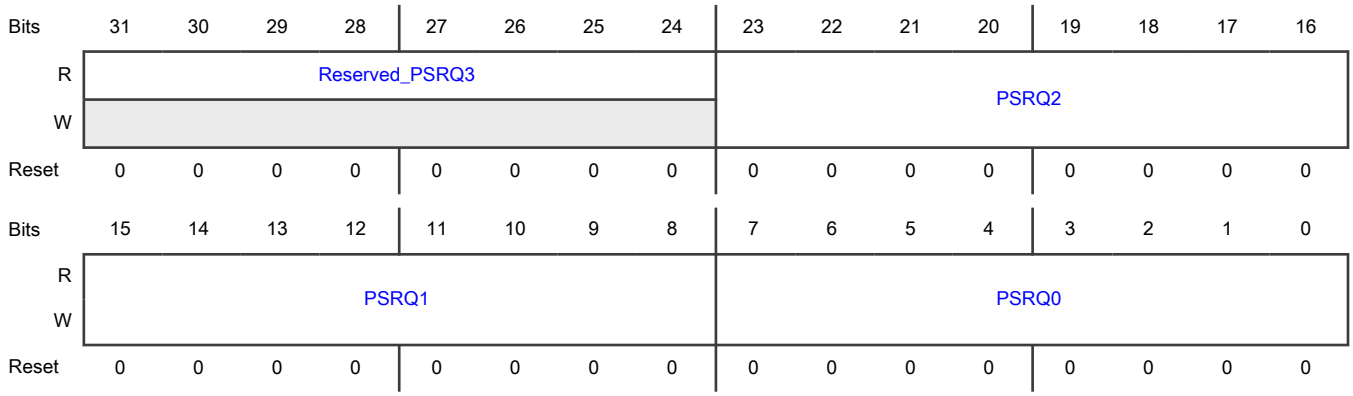
Offset

Register	Offset
MAC_RxQ_Ctrl2	A8h

Function

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3.

Diagram



Fields

Field	Function
31-24 Reserved_PSRQ3	Reserved.
23-16 PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 2 crosses the flow control threshold settings.
15-8 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 1 crosses the flow control threshold settings.
7-0 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 0 crosses the flow control threshold settings.

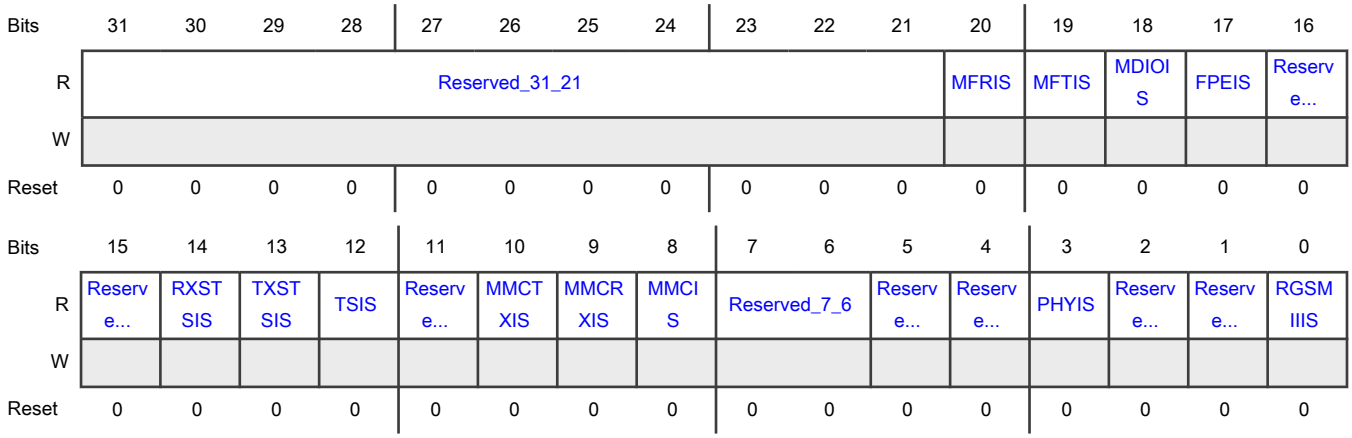
75.7.68 (MAC_Interrupt_Status)

Offset

Register	Offset
MAC_Interrupt_Status	B0h

Function
The Interrupt Status register contains the status of interrupts.

Diagram



Fields

Field	Function
31-21 Reserved_31_21	Reserved.
20 MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0b - MMC FPE Receive Interrupt status not active 1b - MMC FPE Receive Interrupt status active
19 MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0b - MMC FPE Transmit Interrupt status not active 1b - MMC FPE Transmit Interrupt status active
18 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of MAC_CSR_SW_Ctrl register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - MDIO Interrupt status not active 1b - MDIO Interrupt status active
17 FPEIS	Frame Preemption Interrupt Status This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt. 0b - Frame Preemption Interrupt status not active

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Frame Preemption Interrupt status active
16 Reserved_16	Reserved.
15 Reserved_GPIIS	Reserved.
14 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. 0b - Receive Interrupt status not active 1b - Receive Interrupt status active
13 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. 0b - Transmit Interrupt status not active 1b - Transmit Interrupt status active
12 TSIS	Timestamp Interrupt Status If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Timestamp_Status register. 0b - Timestamp Interrupt status not active 1b - Timestamp Interrupt status active
11 Reserved_MMCRXIPIS	Reserved.
10 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - MMC Transmit Interrupt status not active 1b - MMC Transmit Interrupt status active
9 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - MMC Receive Interrupt status not active 1b - MMC Receive Interrupt status active
8 MMCIS	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - MMC Interrupt status not active 1b - MMC Interrupt status active
7-6 Reserved_7_6	Reserved.
5 Reserved_LPIIS	Reserved.
4 Reserved_PMTIS	Reserved.
3 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0b - PHY Interrupt not detected 1b - PHY Interrupt detected
2 Reserved_PCSANCIS	Reserved.
1 Reserved_PCSLCHGIS	Reserved.
0 RGSMIIIS	RGMII or SMII Interrupt Status This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_Control_Status register). This bit is cleared when the MAC_PHYIF_Control_Status register is read (or LNKSTS bit of MAC_PHYIF_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). This bit is valid only when you select the optional RGMII or SMII PHY interface.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - RGMII or SMII Interrupt Status is not active 1b - RGMII or SMII Interrupt Status is active

75.7.69 (MAC_Interrupt_Enable)

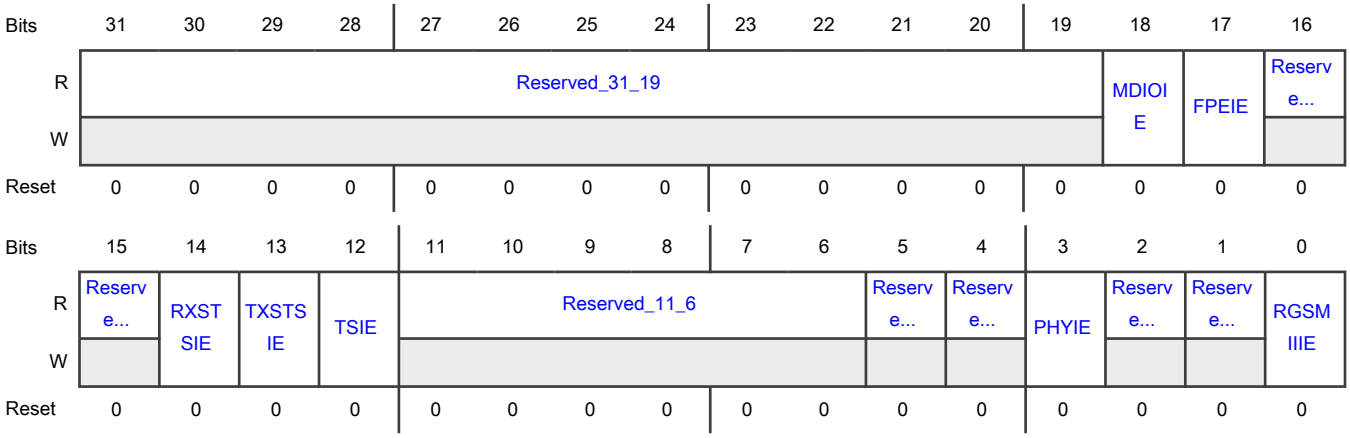
Offset

Register	Offset
MAC_Interrupt_Enable	B4h

Function

The Interrupt Enable register contains the masks for generating the interrupts.

Diagram



Fields

Field	Function
31-19 Reserved_31_19	Reserved.
18 MDIOIE	MDIO Interrupt Enable When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_Interrupt_Status register. 0b - MDIO Interrupt is disabled 1b - MDIO Interrupt is enabled
17	Frame Preemption Interrupt Enable When this bit is set, it enables the assertion of the interrupt when FPEIS field is set in the MAC_Interrupt_Status register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
FPEIE	0b - Frame Preemption Interrupt is disabled 1b - Frame Preemption Interrupt is enabled
16 Reserved_16	Reserved.
15 Reserved_15	Reserved.
14 RXSTSIE	Receive Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the MAC_Interrupt_Status register. 0b - Receive Status Interrupt is disabled 1b - Receive Status Interrupt is enabled
13 TXSTSIE	Transmit Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the MAC_Interrupt_Status register. 0b - Timestamp Status Interrupt is disabled 1b - Timestamp Status Interrupt is enabled
12 TSIE	Timestamp Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in MAC_Interrupt_Status register. 0b - Timestamp Interrupt is disabled 1b - Timestamp Interrupt is enabled
11-6 Reserved_11_6	Reserved.
5 Reserved_LPIIE	Reserved.
4 Reserved_PMTIE	Reserved.
3 PHYIE	PHY Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in MAC_Interrupt_Status register. 0b - PHY Interrupt is disabled 1b - PHY Interrupt is enabled
2 Reserved_PCSANCIE	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 Reserved_PCSLCHGIE	Reserved.
0 RGSMIIIE	RGMII or SMII Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RGSMIIIS bit in MAC_Interrupt_Status register. 0b - RGMII or SMII Interrupt is disabled 1b - RGMII or SMII Interrupt is enabled

75.7.70 (MAC_Rx_Tx_Status)

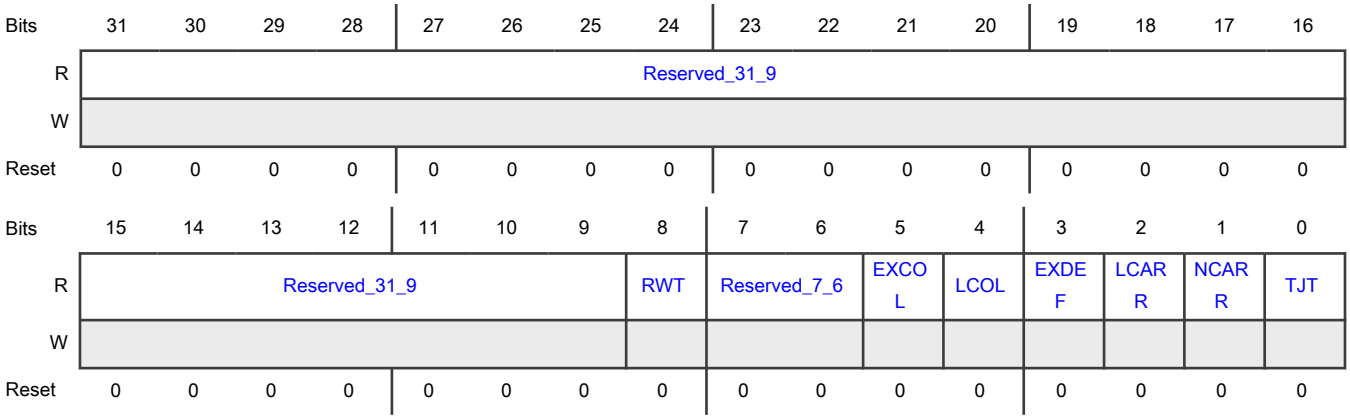
Offset

Register	Offset
MAC_Rx_Tx_Status	B8h

Function

The Receive Transmit Status register contains the Receive and Transmit Error status.

Diagram



Fields

Field	Function
31-9 Reserved_31_9	Reserved.
8	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
RWT	register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No receive watchdog timeout 1b - Receive watchdog timed out
7-6 Reserved_7_6	Reserved.
5 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No collision 1b - Excessive collision is sensed
4 LCOL	Late Collision When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No collision 1b - Late collision is sensed
3 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No Excessive deferral 1b - Excessive deferral
2 LCARR	Loss of Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Carrier is present 1b - Loss of carrier
1 NCARR	No Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Carrier is present 1b - No carrier
0 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No Transmit Jabber Timeout 1b - Transmit Jabber Timeout occurred

75.7.71 (MAC_PHYIF_Control_Status)

Offset

Register	Offset
MAC_PHYIF_Control_Status	F8h

Function

The PHY Interface Control and Status register indicates the status signals received by the SGMII, RGMII, or SMII interface (selected at reset) from the PHY. This register is optional.

Diagram

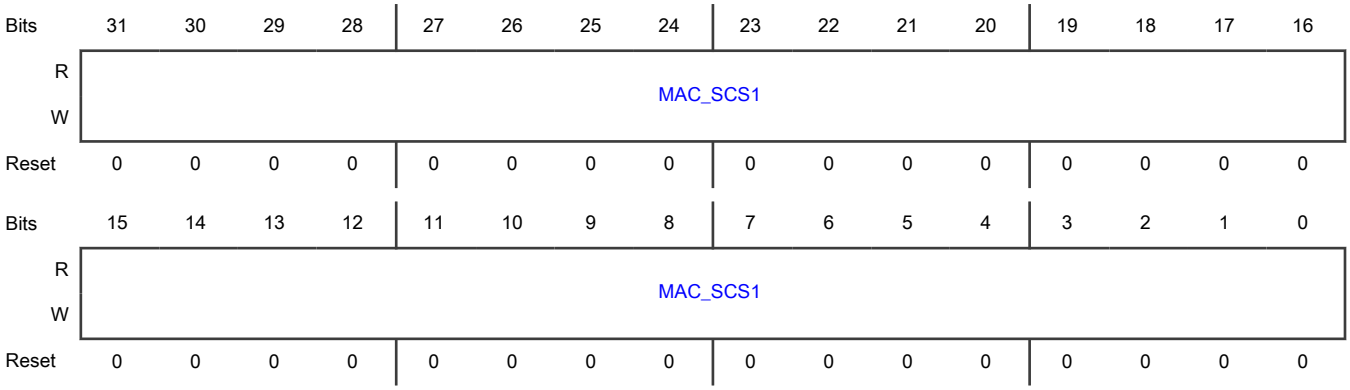
75.7.81 (SCS_REG1)

Offset

Register	Offset
SCS_REG1	150h

Function
NXP Reserved Register

Diagram



Fields

Field	Function
31-0 MAC_SCS1	NXP Reserved, All the bits must be set to "0". This field is reserved for NXP Internal use, and must always be set to "0" unless instructed by NXP. Setting any bit to "1" might cause unexpected behavior in the IP.

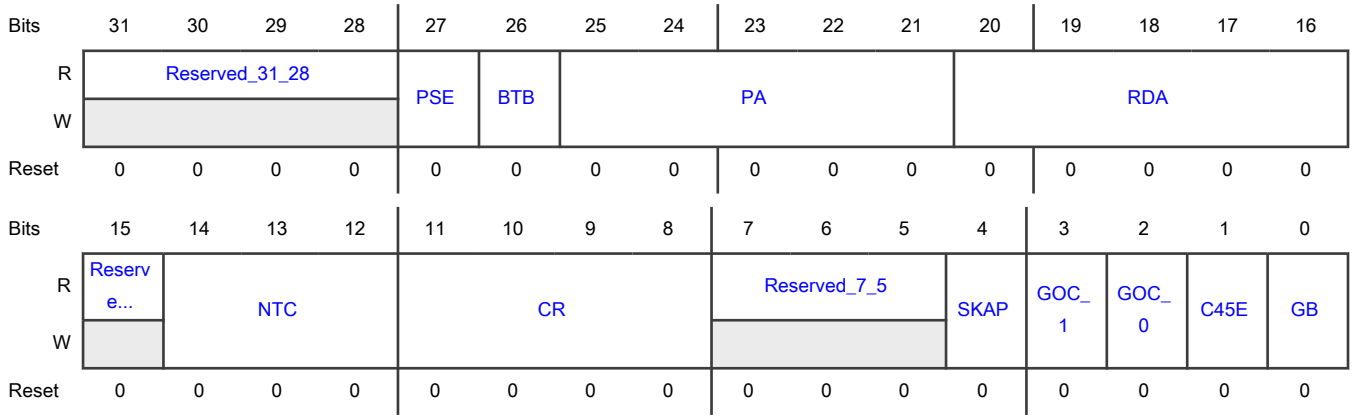
75.7.82 (MAC_MDIO_Address)

Offset

Register	Offset
MAC_MDIO_Address	200h

Function
The MDIO Address register controls the management cycles to external PHY through a management interface.

Diagram



Fields

Field	Function
31-28 Reserved_31_28	Reserved.
27 PSE	Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. 0b - Preamble Suppression disabled 1b - Preamble Suppression enabled
26 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0b - Back to Back transactions disabled 1b - Back to Back transactions enabled
25-21 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
20-16 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15 Reserved_15	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
14-12 NTC	Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is beyond the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: CSR clock/4 - 1001: CSR clock/6 - 1010: CSR clock/8 - 1011: CSR clock/10 - 1100: CSR clock/12 - 1101: CSR clock/14 - 1110: CSR clock/16 - 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.
7-5 Reserved_7_5	Reserved.
4 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. 0b - Skip Address Packet is disabled 1b - Skip Address Packet is enabled
3 GOC_1	GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: - 00: Reserved - 01: Write - 10: Post Read Increment Address for Clause 45 PHY - 11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. 0b - GMII Operation Command 1 is disabled 1b - GMII Operation Command 1 is enabled
2 GOC_0	GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0b - GMII Operation Command 0 is disabled 1b - GMII Operation Command 0 is enabled
1 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. 0b - Clause 45 PHY is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clause 45 PHY is enabled
0 GB	GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - GMII Busy is disabled 1b - GMII Busy is enabled

75.7.83 (MAC_MDIO_Data)

Offset

Register	Offset
MAC_MDIO_Data	204h

Function

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 ARPPA	ARP Protocol Address This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet. This field is available only when the Enable IPv4 ARP Offload option is selected.

75.7.85 (MAC_CSR_SW_Ctrl)

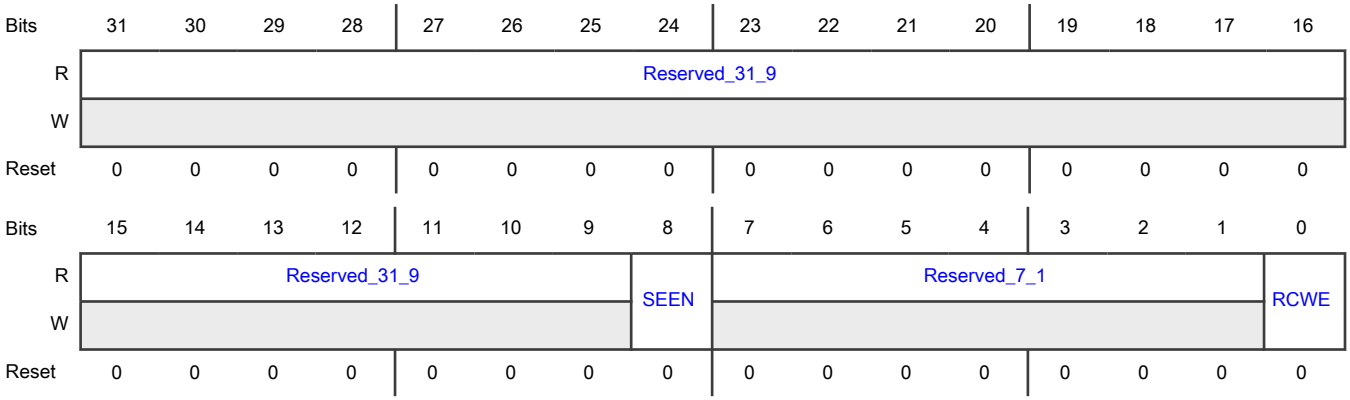
Offset

Register	Offset
MAC_CSR_SW_Ctrl	230h

Function

This register contains software programmable controls for changing the CSR access response and status bits clearing.

Diagram



Fields

Field	Function
31-9 Reserved_31_9	Reserved.
8 SEEN	Slave Error Response Enable When this bit is set, the MAC responds with Slave Error for accesses to reserved registers in CSR space. When this bit is reset, the MAC responds with Okay response to any register accessed from CSR space. 0b - Slave Error Response is disabled 1b - Slave Error Response is enabled
7-1 Reserved_7_1	Reserved.
0 RCWE	Register Clear on Write 1 Enable When this bit is set, the access mode of some register fields changes to Clear on Write 1, the application needs to set that respective bit to 1 to clear it. When this bit is reset, the access mode of these register fields remain as Clear on Read. 0b - Register Clear on Write 1 is disabled 1b - Register Clear on Write 1 is enabled

75.7.86 (MAC_FPE_CTRL_STS)

Offset

Register	Offset
MAC_FPE_CTRL_STS	234h

Function

This register controls the operation of Frame Preemption.

Diagram

Field	Function
17 RRSP	Received Respond Frame Set when a Respond mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Not received Respond Frame 1b - Received Respond Frame
16 RVER	Received Verify Frame Set when a Verify mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Not received Verify Frame 1b - Received Verify Frame
15-4 Reserved_15_4	Reserved.
3 S1_SET_0	NXP Reserved, Must be set to "0". This field is reserved for NXP Internal use, and must always be set to "0" unless instructed by NXP. Setting to "1" might cause unexpected behavior in the IP.
2 SRSP	Send Respond mPacket When set indicates hardware to send a Respond mPacket. Reset by hardware after sending the Respond mPacket. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Send Respond mPacket is disabled 1b - Send Respond mPacket is enabled
1 SVER	Send Verify mPacket When set indicates hardware to send a verify mPacket. Reset by hardware after sending the Verify mPacket. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Send Verify mPacket is disabled 1b - Send Verify mPacket is enabled
0 EFPE	Enable Tx Frame Preemption When set Frame Preemption Tx functionality is enabled. 0b - Tx Frame Preemption is disabled 1b - Tx Frame Preemption is enabled

75.7.87 (MAC_Ext_Cfg1)

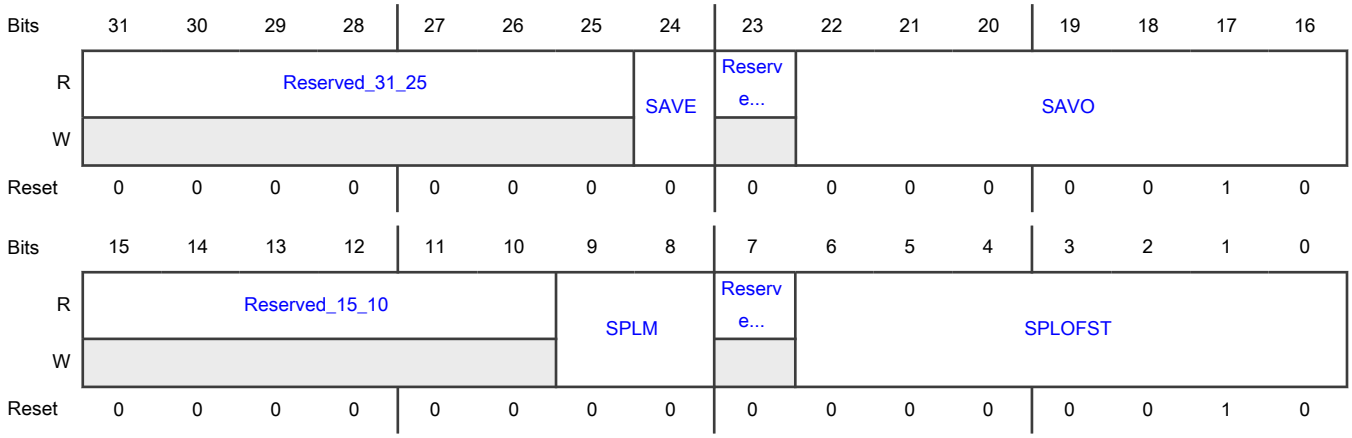
Offset

Register	Offset
MAC_Ext_Cfg1	238h

Function

This register contains Split mode control field and offset field for Split Header feature.

Diagram



Fields

Field	Function
31-25 Reserved_31_25	Reserved.
24 SAVE	Split AV Enable - When this bit is set to 1, and the received packet is an AV Type packet, the header is split at SAVO bytes from the beginning of Length/Type field of the packet, for L2 Split. - When this bit is set to 0, header is split at SPLOFST bytes from the beginning of Length/Type field of the frame, for L2 Split.
23 Reserved_23	Reserved.
22-16 SAVO	Split AV Offset When SAVE bit is set to 1, and the received packet is an AV Type packet, these bits indicate the value of the offset from the beginning of Length/Type field at which header should be split, when appropriate SPLM is selected. The reset value of this field is 2 bytes, indicating a split at L2 header. Value is in terms of bytes.
15-10 Reserved_15_10	Reserved.
9-8 SPLM	Split Mode These bits indicate the mode of splitting the incoming Rx packets. They are 00b - Split at L3/L4 header 01b - Split at L2 header with an offset. Always Split at SPLOFST bytes from the beginning of Length/Type field of the Frame 10b - Combination mode: Split similar to SPLM=00 for IP packets that are untagged or tagged and VLAN stripped 11b - Reserved
7	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
Reserved_7	
6-0 SPLOFST	Split Offset These bits indicate the value of offset from the beginning of Length/Type field at which header split should take place when the appropriate SPLM is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms of bytes.

75.7.88 (MAC_Presn_Time_ns)

Offset

Register	Offset
MAC_Presn_Time_ns	240h

Function

This register contains the 32-bit binary rollover equivalent time of the PTP System Time in ns Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 MPTN	MAC 1722 Presentation Time in ns These bits indicate the value of the 32-bit binary rollover equivalent time of the PTP System Time in ns

75.7.89 (MAC_Presn_Time_Updt)

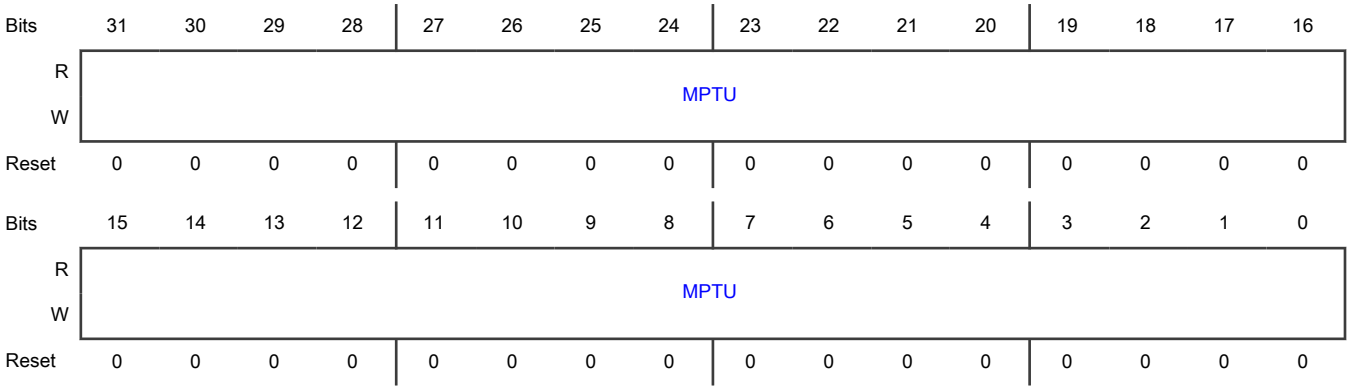
Offset

Register	Offset
MAC_Presn_Time_Updt	244h

Function

This field holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_Timestamp_ Control register). Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured

Diagram



Fields

Field	Function
31-0 MPTU	MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_Timestamp_ Control register). When ADDSUB field of MAC_System_Time_Nanoseconds_Update is set, this value is directly used for subtraction

75.7.90 (MAC_Address0_High)

Offset

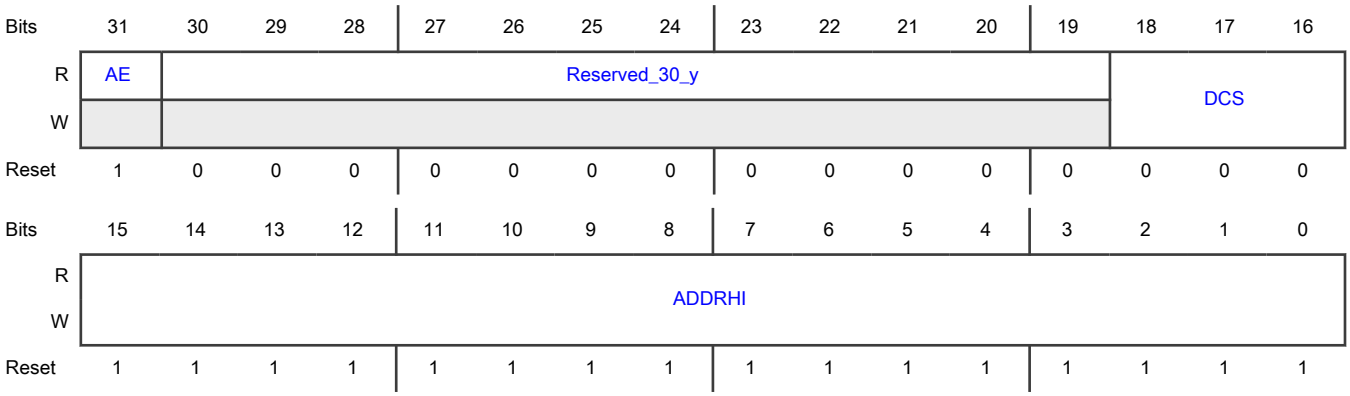
Register	Offset
MAC_Address0_High	300h

Function

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. If the MAC address registers are configured to be

double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable This bit is always set to 1. 0b - INVALID : This bit must be always set to 1 1b - This bit is always set to 1
30-19 Reserved_30_y	Reserved.
18-16 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address0 content is routed. If the PDC bit of MAC_Ext_Configuration register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address0 content is routed.
15-0 ADDRHI	MAC Address0[47:32] This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

75.7.91 (MAC_Address0_Low)

Offset

Register	Offset
MAC_Address0_Low	304h

Function

The MAC Address0 Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

Diagram

Fields

Field	Function
31-0 ADDRLO	MAC Address0[31:0] This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

75.7.92 (MAC_Address1_High)

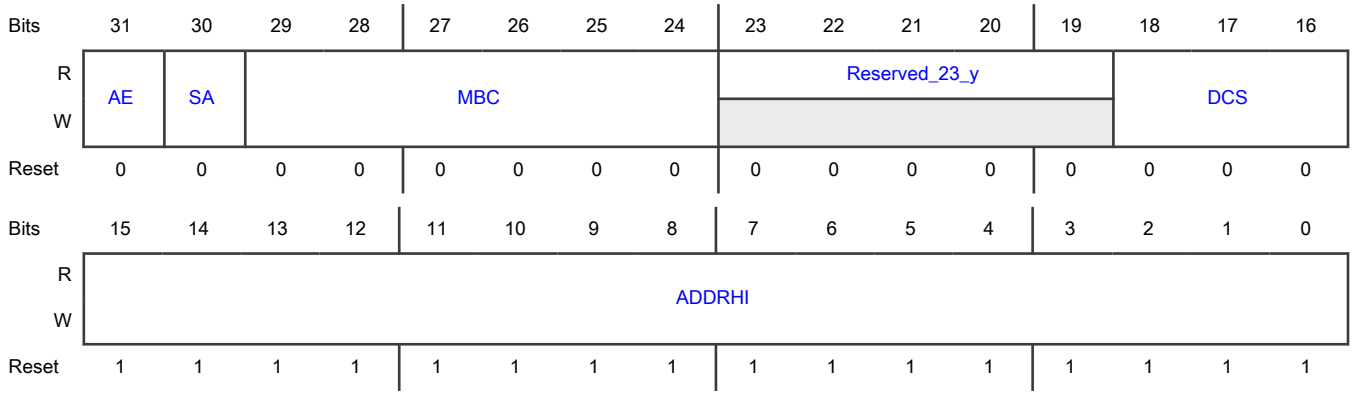
Offset

Register	Offset
MAC_Address1_High	308h

Function

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. 0b - Address is ignored 1b - Address is enabled
30 SA	Source Address When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[47:0] is used to compare with the DA fields of the received packet. 0b - Compare with Destination Address 1b - Compare with Source Address
29-24 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: - Bit 29: MAC_Address${i}_High[15:8] - Bit 28: MAC_Address${i}_High[7:0] - Bit 27: MAC_Address${i}_Low[31:24] - .. - Bit 24: MAC_Address${i}_Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-19 Reserved_23_y	Reserved.
18-16 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. If the PDC bit of MAC_Ext_Configuration register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address(#i) content is routed.
15-0 ADDRHI	MAC Address1 [47:32] This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.

75.7.93 (MAC_Address1_Low)

Offset

Register	Offset
MAC_Address1_Low	30Ch

Function
The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Diagram

Fields

Field	Function
31-0 ADDRLO	MAC Address1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

75.7.94 (MAC_Address2_High)

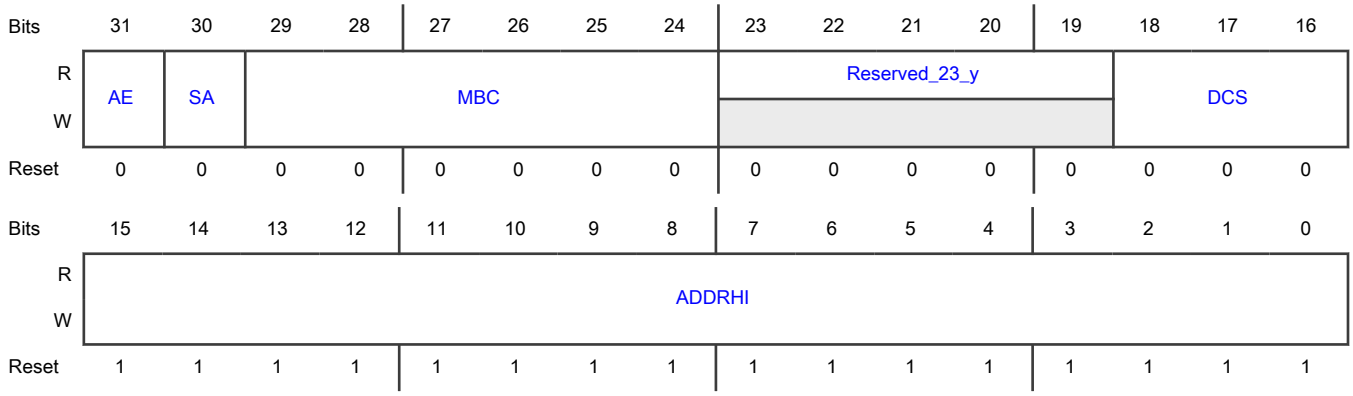
Offset

Register	Offset
MAC_Address2_High	310h

Function

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. 0b - Address is ignored 1b - Address is enabled
30 SA	Source Address When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[47:0] is used to compare with the DA fields of the received packet. 0b - Compare with Destination Address 1b - Compare with Source Address
29-24 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: - Bit 29: MAC_Address${i}_High[15:8] - Bit 28: MAC_Address${i}_High[7:0] - Bit 27: MAC_Address${i}_Low[31:24] - .. - Bit 24: MAC_Address${i}_Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-19 Reserved_23_y	Reserved.
18-16 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. If the PDC bit of MAC_Ext_Configuration register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address(#i) content is routed.
15-0 ADDRHI	MAC Address1 [47:32] This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.

75.7.95 (MAC_Address2_Low)

Offset

Register	Offset
MAC_Address2_Low	314h

Function
The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Diagram

Field	Function
31-0 ADDRLO	MAC Address1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

75.7.96 (MMC_Control)

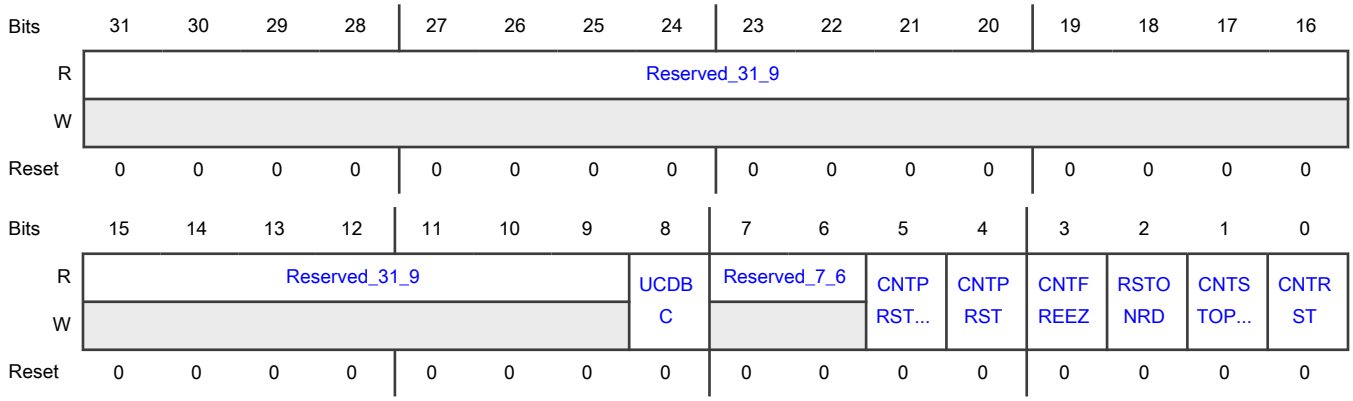
Offset

Register	Offset
MMC_Control	700h

Function

This register establishes the operating mode of MMC.

Diagram



Fields

Field	Function
31-9 Reserved_31_9	Reserved.
8 UCDBC	Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0b - Update MMC Counters for Dropped Broadcast Packets is disabled 1b - Update MMC Counters for Dropped Broadcast Packets is enabled
7-6 Reserved_7_6	Reserved.
5 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0b - Full-Half Preset is disabled 1b - Full-Half Preset is enabled
4 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0b - Counters Preset is disabled 1b - Counters Preset is enabled
3 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0b - MMC Counter Freeze is disabled 1b - MMC Counter Freeze is enabled
2 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. 0b - Reset on Read is disabled 1b - Reset on Read is enabled
1	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CNTSTOPRO	0b - Counter Stop Rollover is disabled 1b - Counter Stop Rollover is enabled
0 CNTRST	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0b - Counters are not reset 1b - All counters are reset

75.7.97 (MMC_Rx_Interrupt)

Offset

Register	Offset
MMC_Rx_Interrupt	704h

Function

This register maintains the interrupts generated from all Receive statistics counters. The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur: - Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter). - Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit. Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

75.7.98 (MMC_Tx_Interrupt)

Offset

Register	Offset
MMC_Tx_Interrupt	708h

Function

This register maintains the interrupts generated from all Transmit statistics counters. The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

75.7.99 (MMC_Rx_Interrupt_Mask)

Offset

Register	Offset
MMC_Rx_Interrupt_Mask	70Ch

Function

This register maintains the masks for interrupts generated from all Receive statistics counters. The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

4 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. 0b - MMC Receive Multicast Good Packet Counter Interrupt Mask is disabled 1b - MMC Receive Multicast Good Packet Counter Interrupt Mask is enabled
3 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. 0b - MMC Receive Broadcast Good Packet Counter Interrupt Mask is disabled 1b - MMC Receive Broadcast Good Packet Counter Interrupt Mask is enabled
2 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. 0b - MMC Receive Good Octet Counter Interrupt Mask is disabled 1b - MMC Receive Good Octet Counter Interrupt Mask is enabled
1 RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. 0b - MMC Receive Good Bad Octet Counter Interrupt Mask is disabled 1b - MMC Receive Good Bad Octet Counter Interrupt Mask is enabled
0 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. 0b - MMC Receive Good Bad Packet Counter Interrupt Mask is disabled 1b - MMC Receive Good Bad Packet Counter Interrupt Mask is enabled

75.7.100 (MMC_Tx_Interrupt_Mask)

Offset

Register	Offset
MMC_Tx_Interrupt_Mask	710h

Function

This register maintains the masks for interrupts generated from all Transmit statistics counters. The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

Fields

Field	Function
31-0 TXDEFRD	Tx Deferred Packets This field indicates the number of successfully transmitted after a deferral in the half-duplex mode.

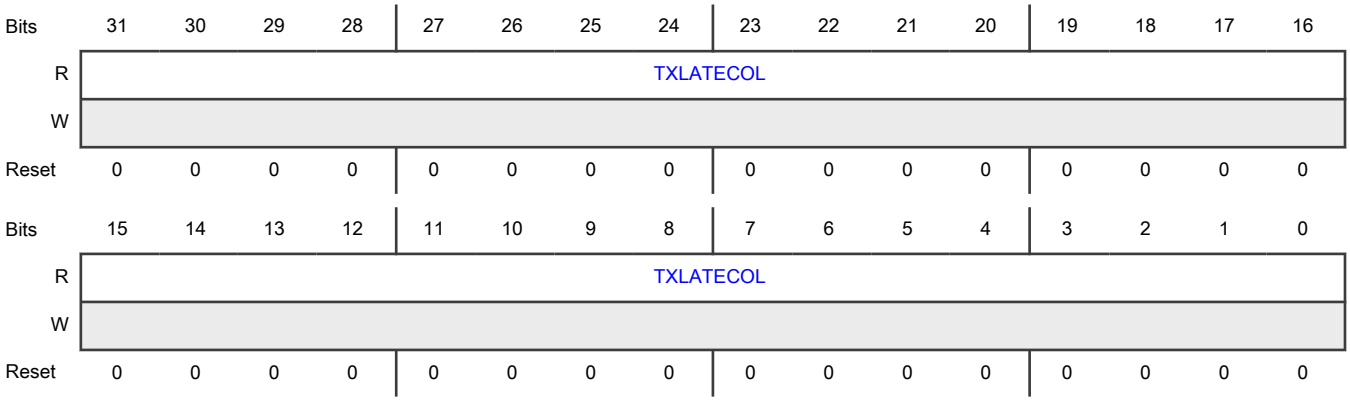
75.7.118 (Tx_Late_Collision_Packets)

Offset

Register	Offset
Tx_Late_Collision_Packets	758h

Function
This register provides the number of packets aborted by DWC_ether_qos because of late collision error.

Diagram



Fields

Field	Function
31-0 TXLATECOL	Tx Late Collision Packets This field indicates the number of packets aborted because of late collision error.

75.7.119 (Tx_Excessive_Collision_Packets)

Offset

Register	Offset
Tx_Excessive_Collision_Packets	75Ch

Function
This register provides the number of packets aborted by DWC_ether_qos because of excessive (16) collision errors.

Diagram

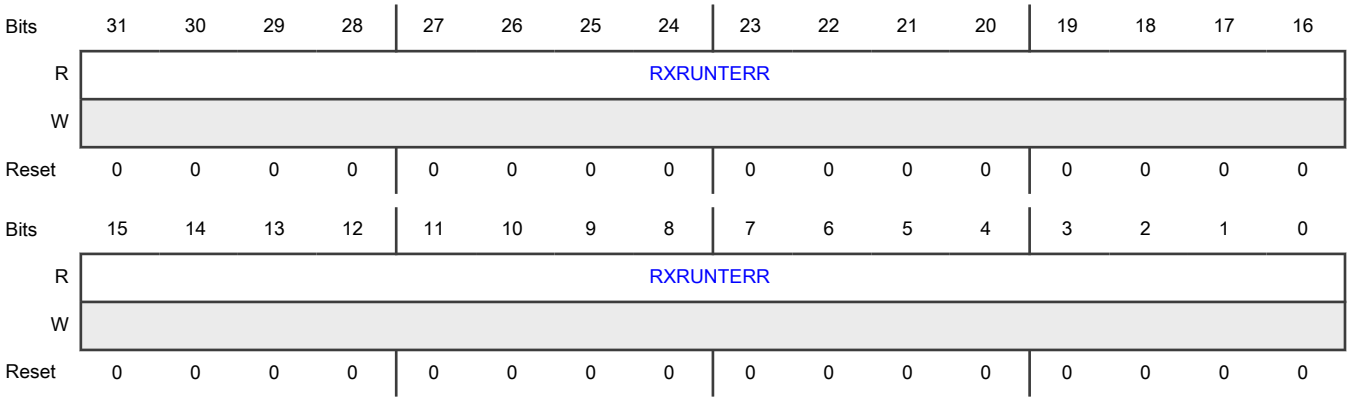
75.7.134 (Rx_Runt_Error_Packets)

Offset

Register	Offset
Rx_Runt_Error_Packets	79Ch

Function
This register provides the number of packets received by DWC_ether_qos with runt (length less than 64 bytes and CRC error) error.

Diagram



Fields

Field	Function
31-0 RXRUNTERR	Rx Runt Error Packets This field indicates the number of packets received with runt (length less than 64 bytes and CRC error) error.

75.7.135 (Rx_Jabber_Error_Packets)

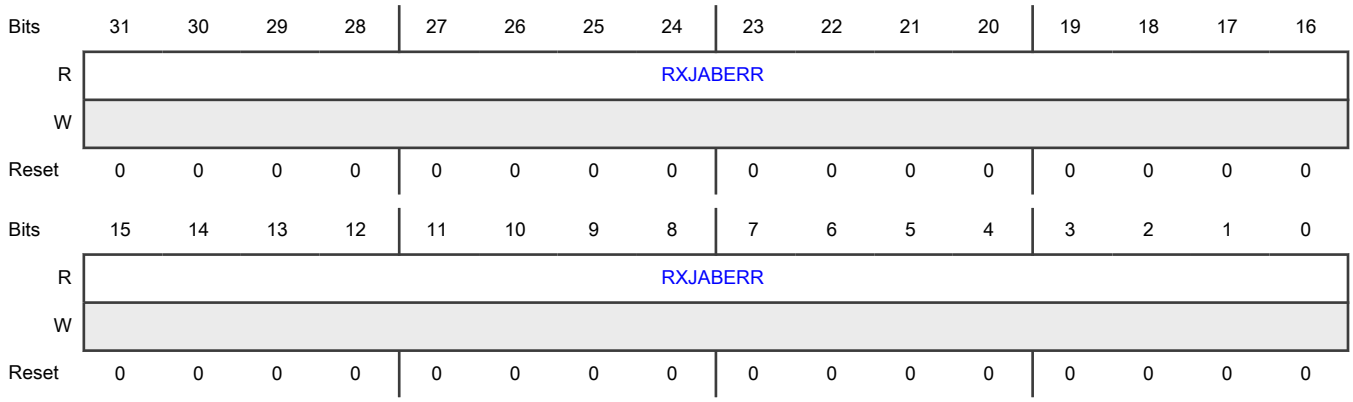
Offset

Register	Offset
Rx_Jabber_Error_Packets	7A0h

Function

This register provides the number of giant packets received by DWC_ether_qos with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.

Diagram



Fields

Field	Function
31-0 RXJABERR	Rx Jabber Error Packets This field indicates the number of giant packets received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.

75.7.136 (Rx_Undersize_Packets_Good)

Offset

Register	Offset
Rx_Undersize_Packets_Good	7A4h

Function

This register provides the number of packets received by DWC_ether_qos with length less than 64 bytes, without any errors.

75.7.153 (MMC_FPE_Tx_Interrupt)

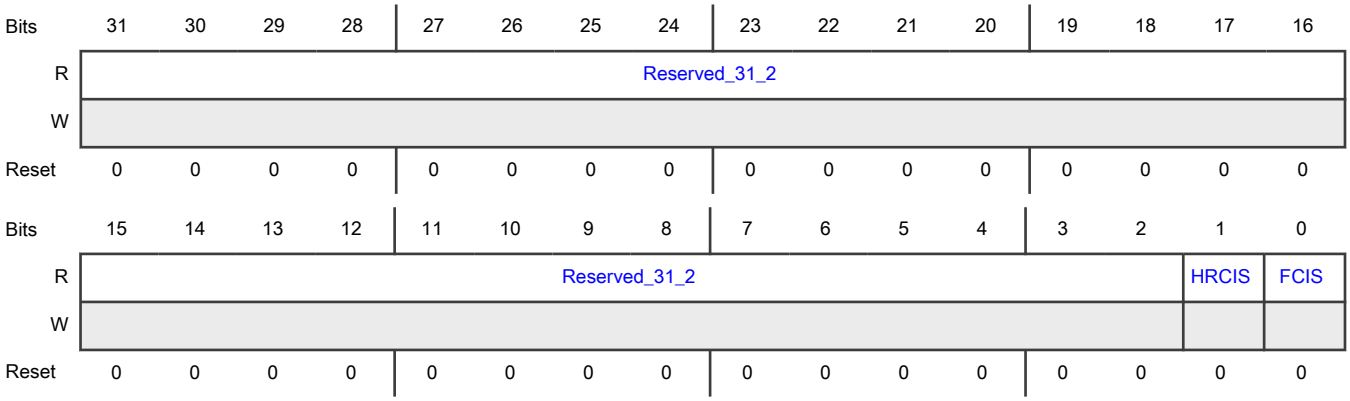
Offset

Register	Offset
MMC_FPE_Tx_Interrupt	8A0h

Function

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Diagram



Fields

Field	Function
31-2 Reserved_31_2	Reserved.
1 HRCIS	MMC Tx Hold Request Counter Interrupt Status This bit is set when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE with AV_EST Enabled configuration. 0b - MMC Tx Hold Request Counter Interrupt Status not detected 1b - MMC Tx Hold Request Counter Interrupt Status detected
0 FCIS	MMC Tx FPE Fragment Counter Interrupt status This bit is set when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE Enabled configuration. 0b - MMC Tx FPE Fragment Counter Interrupt status not detected 1b - MMC Tx FPE Fragment Counter Interrupt status detected

75.7.154 (MMC_FPE_Tx_Interrupt_Mask)

Offset

Register	Offset
MMC_FPE_Tx_Interrupt_Mask	8A4h

Function

This register maintains the masks for interrupts generated from all FPE related Transmit statistics counters. The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when FPE related receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

Diagram

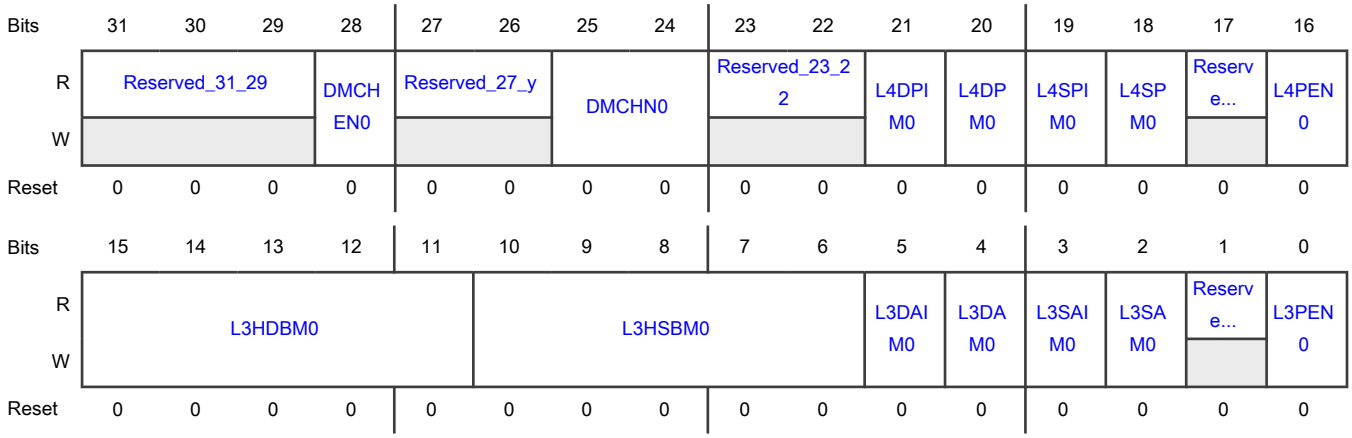
75.7.163 (MAC_L3_L4_Control0)

Offset

Register	Offset
MAC_L3_L4_Control0	900h

Function
The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28 DMCHEN0	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter. 0b - DMA Channel Select is disabled 1b - DMA Channel Select is enabled
27-26 Reserved_27_y	Reserved.
25-24 DMCHN0	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. The width of this field depends on the number of the DMA channels present in your configuration.
23-22 Reserved_23_22	Reserved.
21 L4DPIM0	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM0 bit is set high. 0b - Layer 4 Destination Port Inverse Match is disabled 1b - Layer 4 Destination Port Inverse Match is enabled
20 L4DPM0	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Layer 4 Destination Port Match is disabled 1b - Layer 4 Destination Port Match is enabled
19 L4SPIM0	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high. 0b - Layer 4 Source Port Inverse Match is disabled 1b - Layer 4 Source Port Inverse Match is enabled
18 L4SPM0	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. 0b - Layer 4 Source Port Match is disabled 1b - Layer 4 Source Port Match is enabled
17 Reserved_17	Reserved.
16 L4PEN0	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set. 0b - Layer 4 Protocol is disabled 1b - Layer 4 Protocol is enabled
15-11 L3HDBM0	Layer 3 IP DA Higher Bits Match IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: - 0: No bits are masked. - 1: LSb[0] is masked. - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
10-6 L3HSBM0	Layer 3 IP SA Higher Bits Match IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked. IPv6 Packets: This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
5 L3DAIM0	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high. 0b - Layer 3 IP DA Inverse Match is disabled 1b - Layer 3 IP DA Inverse Match is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 L3DAM0	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering. 0b - Layer 3 IP DA Match is disabled 1b - Layer 3 IP DA Match is enabled
3 L3SAIM0	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set. 0b - Layer 3 IP SA Inverse Match is disabled 1b - Layer 3 IP SA Inverse Match is enabled
2 L3SAM0	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering. 0b - Layer 3 IP SA Match is disabled 1b - Layer 3 IP SA Match is enabled
1 Reserved_1	Reserved.
0 L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0b - Layer 3 Protocol is disabled 1b - Layer 3 Protocol is enabled

75.7.164 (MAC_Layer4_Address0)

Offset

Register	Offset
MAC_Layer4_Address0	904h

Function

The MAC_Layer4_Address(#i), MAC_L3_L4_Control(#i), MAC_Layer3_Addr0_Reg(#i), MAC_Layer3_Addr1_Reg(#i), MAC_Layer3_Addr2_Reg(#i) and MAC_Layer3_Addr3_Reg(#i) registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the IP. You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the IP. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper

synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Field	Function
31-20 Reserved_31_20	Reserved.
19-16 MSEL	Mode Select This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: - 0000:Typ_RXQ_ (Type based RXQ mappping) - 0001-1111: Reserved for future use.
15-8 AOFF	Address Offset This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: - 00000000: IndReg0(Indirect register 0) - 00000001: IndReg1(Indirect register 1) - ... - 00000111: IndReg7(Indirect register 7) - 00001000-11111111: Reserved for future use.
7-6 Reserved_7_6	Reserved.
5 AUTO	Auto increment - 1: AOFF is incremented by 1. Software should ensure not to cause a wrap condition. Byte wise read/write is not supported when auto increment is enabled. - 0: AOFF is not incremented automatically. Software should program the correct Address Offset for each access.
4-2 Reserved_4_2	Reserved.
1 COM	Command type This bit indicates the register access type. - 1: Indicates a read operation. - 0: Indicates a write operation. 0b - Write operation 1b - Read operation
0 OB	Operation Busy. This bit is set along with a read or write command for initiating the indirect access to MAC_<MSEL>_<AOFF> register. This bit is reset when the read or write command to MAC_<MSEL>_<AOFF> register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into MAC_<MSEL>_<AOFF> register. During a read operation, the data should be read from MAC_Indir_Access_Data register only after this bit is reset.

75.7.212 (MAC_Indir_Access_Data)

Offset

Register	Offset
MAC_Indir_Access_Data	A74h

Function
This register holds the read/write data for Indirect Access of MAC_<MSEL_<AOFF> registers.

75.7.221 (MAC_Timestamp_Control)

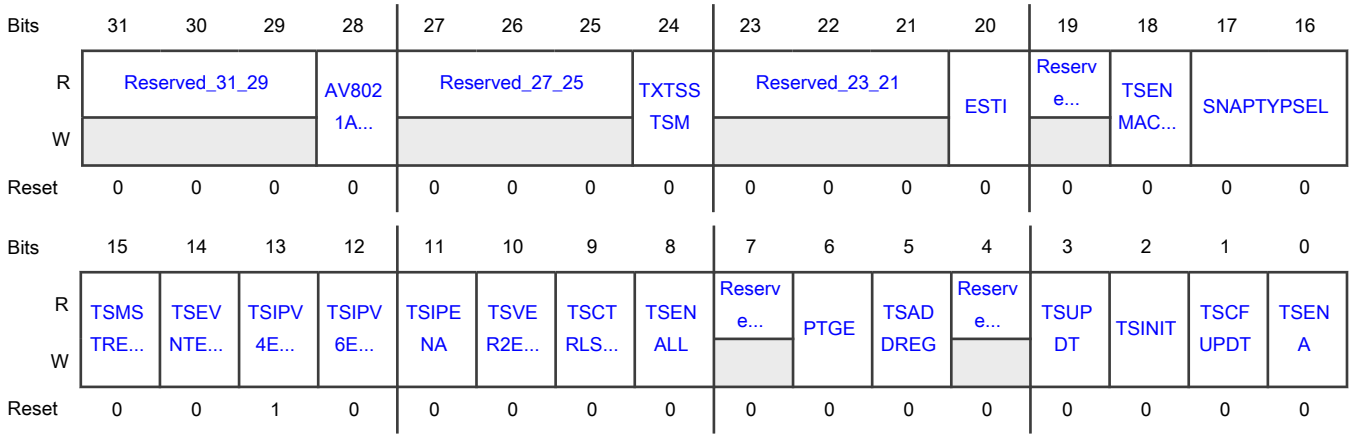
Offset

Register	Offset
MAC_Timestamp_Control	B00h

Function

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28 AV8021ASMEN	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. 0b - AV 802.1AS Mode is disabled 1b - AV 802.1AS Mode is enabled
27-25 Reserved_27_25	Reserved.
24 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. 0b - Transmit Timestamp Status Mode is disabled 1b - Transmit Timestamp Status Mode is enabled
23-21 Reserved_23_21	Reserved.
20	External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in

Table continues on the next page...

Table continued from the previous page...

Field	Function
ESTI	transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled. When this bit is reset, the MAC uses the internal reference System Time. 0b - External System Time Input is disabled 1b - External System Time Input is enabled
19 Reserved_CSC	Reserved.
18 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0b - MAC Address for PTP Packet Filtering is disabled 1b - MAC Address for PTP Packet Filtering is enabled
17-16 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
15 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. 0b - Snapshot for Messages Relevant to Master is disabled 1b - Snapshot for Messages Relevant to Master is enabled
14 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. 0b - Timestamp Snapshot for Event Messages is disabled 1b - Timestamp Snapshot for Event Messages is enabled
13 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. 0b - Processing of PTP Packets Sent over IPv4-UDP is disabled 1b - Processing of PTP Packets Sent over IPv4-UDP is enabled
12 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Processing of PTP Packets Sent over IPv6-UDP is disabled 1b - Processing of PTP Packets Sent over IPv6-UDP is enabled
11 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. 0b - Processing of PTP over Ethernet Packets is disabled 1b - Processing of PTP over Ethernet Packets is enabled
10 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. 0b - PTP Packet Processing for Version 2 Format is disabled 1b - PTP Packet Processing for Version 2 Format is enabled
9 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. 0b - Timestamp Digital or Binary Rollover Control is disabled 1b - Timestamp Digital or Binary Rollover Control is enabled
8 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. 0b - Timestamp for All Packets disabled 1b - Timestamp for All Packets enabled
7 Reserved_7	Reserved.
6 PTGE	Presentation Time Generation Enable When this bit is set the Presentation Time generation is enabled. 0b - Presentation Time Generation is disabled 1b - Presentation Time Generation is enabled
5 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Addend Register is not updated 1b - Addend Register is updated
4	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
Reserved_TSTRIG	
3 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled while configuring the IP) is not updated. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp is not updated 1b - Timestamp is updated
2 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled while configuration the IP) can only be initialized. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp is not initialized 1b - Timestamp is initialized
1 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. 0b - Coarse method is used to update system timestamp 1b - Fine method is used to update system timestamp
0 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. 0b - Timestamp is disabled 1b - Timestamp is enabled

75.7.222 (MAC_Sub_Second_Increment)

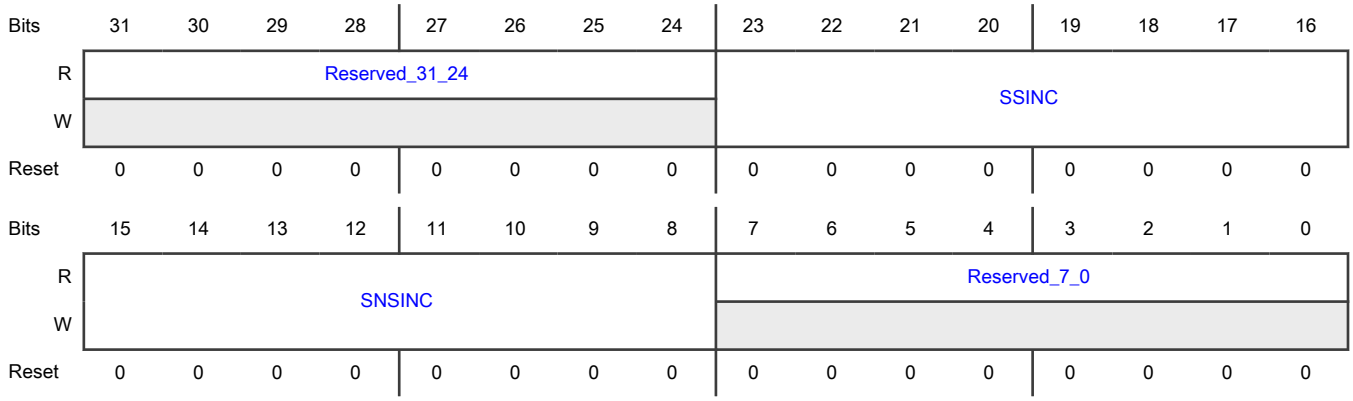
Offset

Register	Offset
MAC_Sub_Second_Increment	B04h

Function

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-16 SSINC	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15-8 SNSINC	Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the MAC_Timestamp_Control register is set. and if the required increment is 5.3ns, then SSINC should be 0x05 and SNSINC should be 0x4C.
7-0 Reserved_7_0	Reserved.

75.7.223 (MAC_System_Time_Seconds)

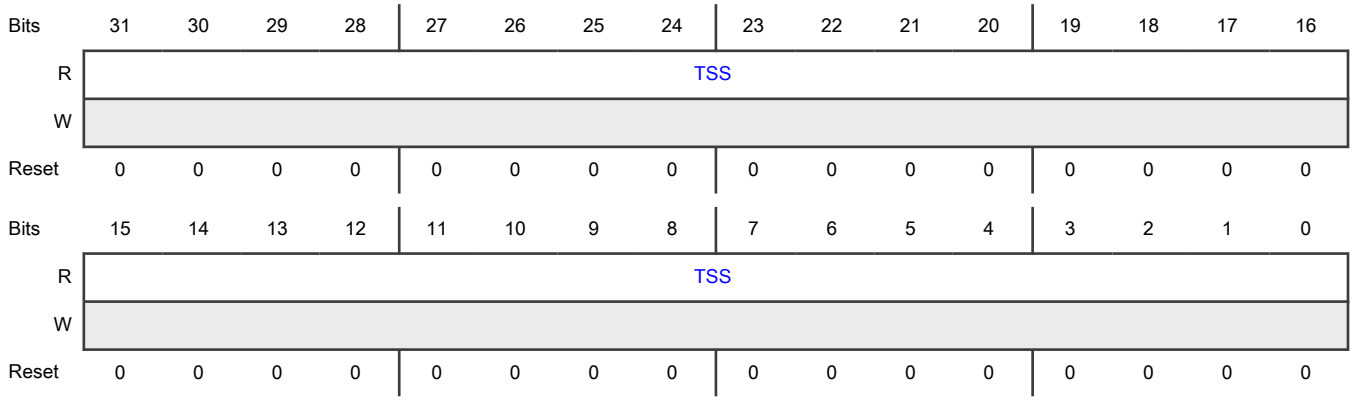
Offset

Register	Offset
MAC_System_Time_Seconds	B08h

Function

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Diagram



Fields

Field	Function
31-0 TSS	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

75.7.224 (MAC_System_Time_Nanoseconds)

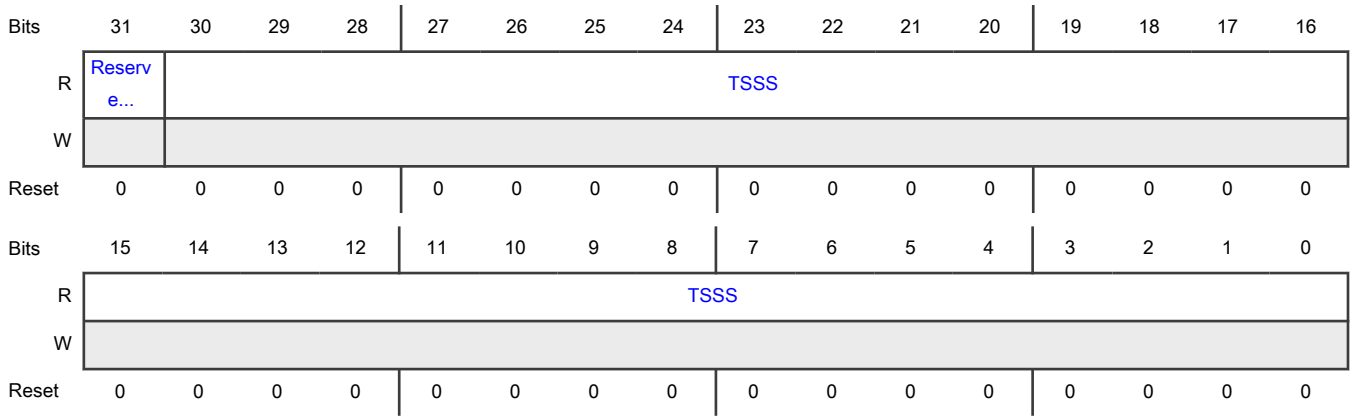
Offset

Register	Offset
MAC_System_Time_Nanoseconds	B0Ch

Function

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

Diagram



Fields

Field	Function
31 Reserved_31	Reserved.
30-0 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

75.7.225 (MAC_System_Time_Seconds_Update)

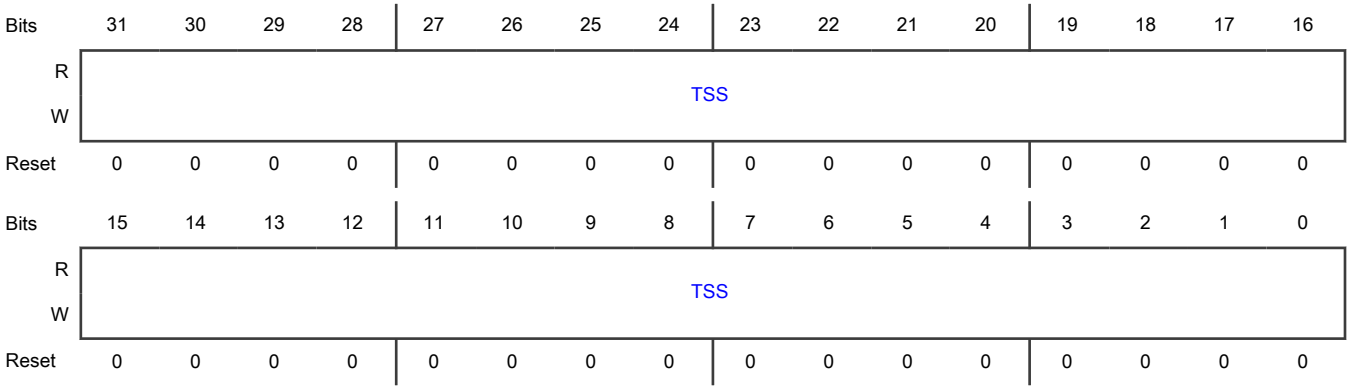
Offset

Register	Offset
MAC_System_Time_Seconds_Update	B10h

Function

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in DWC_eqos_top_map/EQOS_MAC/MAC_Timestamp_Control.

Diagram



Fields

Field	Function
31-0 TSS	Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value. For example, to subtract 2.000000001 seconds from the system time, the TSS field in the MAC_Timestamp_Seconds_Update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

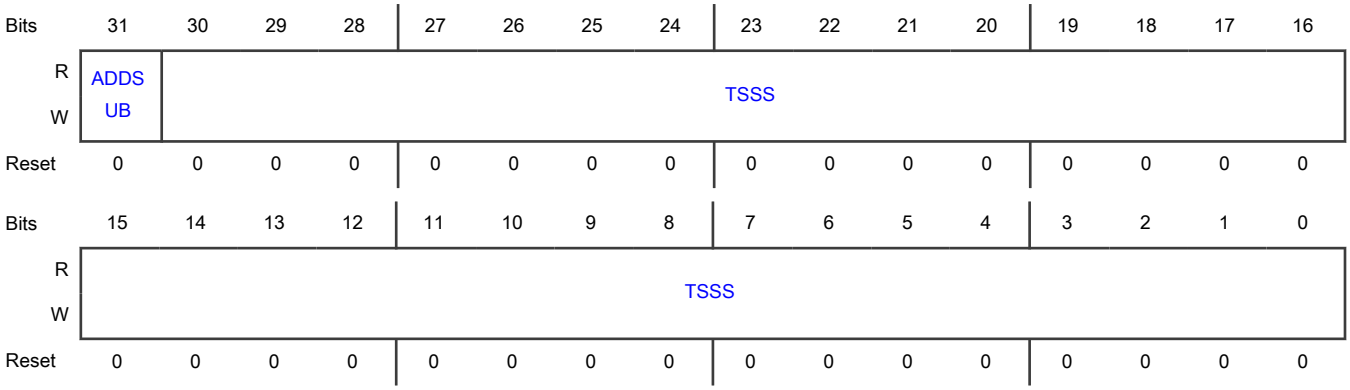
75.7.226 (MAC_System_Time_Nanoseconds_Update)

Offset

Register	Offset
MAC_System_Time_Nanoseconds_Update	B14h

Function
MAC System Time Nanoseconds Update register.

Diagram



Fields

Field	Function
31 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. 0b - Add time 1b - Subtract time
30-0 TSSS	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. - ADDSUB is 1: This field must be programmed with the complement of the sub-seconds part of the update value as described. - ADDSUB is 0: This field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. - TSCTRLSSR field in the MAC_Timestamp_Control register is 1: -- The programmed value must be 10^9 - <sub-second value>. -- Each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. - TSCTRLSSR field in the MAC_Timestamp_Control register is 0: -- The programmed value must be 2^31 - <sub-second_value>. -- Each bit represents an accuracy of 0.46 ns. For example, to subtract 2.000000001 seconds from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set.

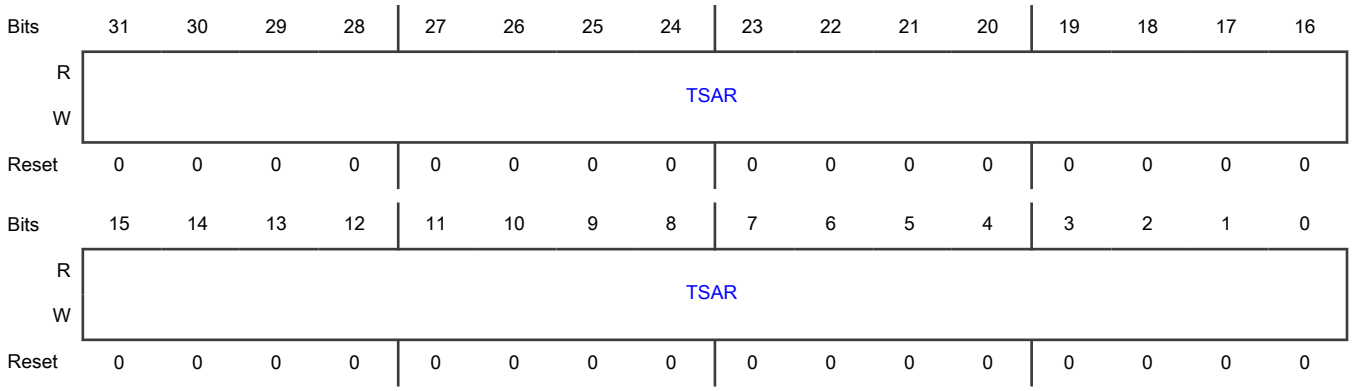
75.7.227 (MAC_Timestamp_Addend)

Offset

Register	Offset
MAC_Timestamp_Addend	B18h

Function
Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated when the accumulator overflows.

Diagram



Fields

Field	Function
31-0 TSAR	Timestamp Addend Register This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

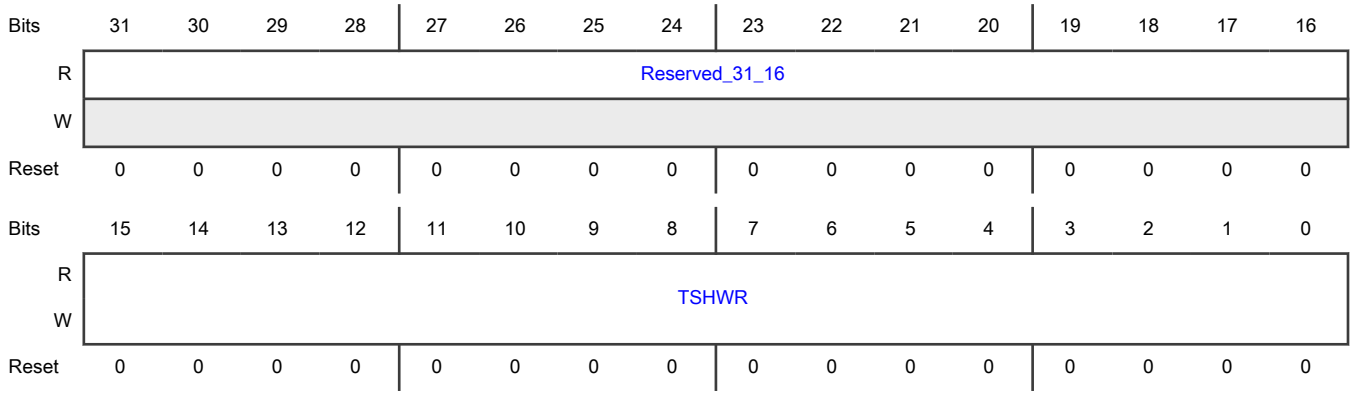
75.7.228 (MAC_System_Time_Higher_Word_Seconds)

Offset

Register	Offset
MAC_System_Time_Higher_Word_Seconds	B1Ch

Function
System Time - Higher Word Seconds register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15-0 TSHWR	Timestamp Higher Word Register This field contains the most-significant 16-bits of timestamp seconds value. This register is optional. You can add this register by selecting the Add IEEE 1588 Higher Word Register option. This register is directly written to initialize the value and it is incremented when there is an overflow from 32-bits of the System Time Seconds register. Access restriction applies. Updated based on the event. Setting 1 sets. Setting 0 clears.

75.7.229 (MAC_Timestamp_Status)

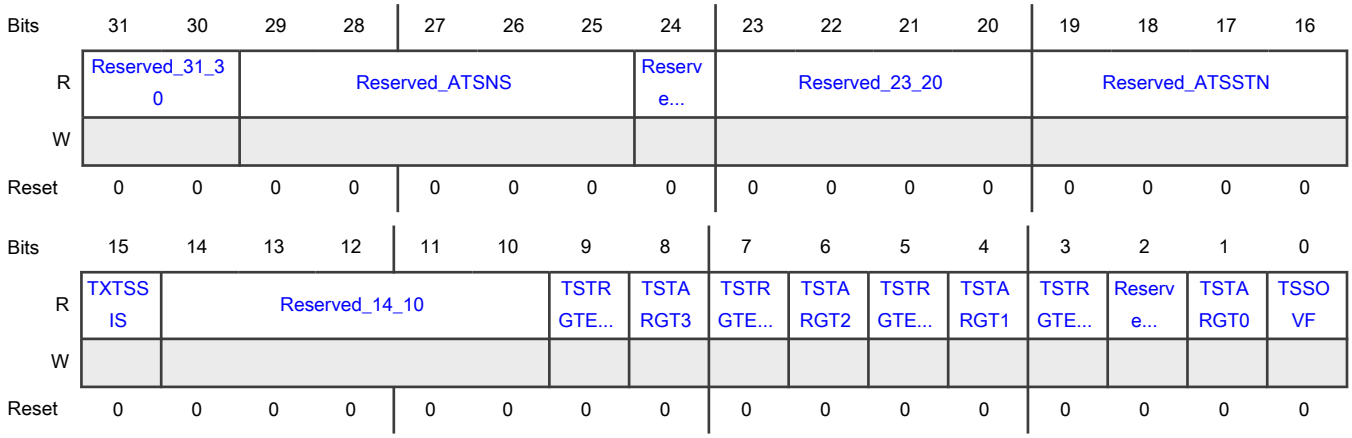
Offset

Register	Offset
MAC_Timestamp_Status	B20h

Function

Timestamp Status register. All bits except Bits[27:25] gets cleared when the application reads this register.

Diagram



Fields

Field	Function
31-30 Reserved_31_30	Reserved.
29-25 Reserved_ATSNS	Reserved.
24 Reserved_ATSTM	Reserved.
23-20 Reserved_23_20	Reserved.
19-16 Reserved_ATSTN	Reserved.
15 TXTSSIS	Tx Timestamp Status Interrupt Status In non-EQOS_CORE configurations when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the MAC_Tx_Timestamp_Status_Seconds register is read (or write to MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set). 0b - Tx Timestamp Status Interrupt status not detected 1b - Tx Timestamp Status Interrupt status detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
14-10 Reserved_14_10	Reserved.
9 TSTRGTERR3	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
8 TSTARGT3	Timestamp Target Time Reached for Target Time PPS3 When this bit is set and MCGREN3 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers. When this bit is set and MCGREN3 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[3] is asserted. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached for Target Time PPS3 status not detected 1b - Timestamp Target Time Reached for Target Time PPS3 status detected
7 TSTRGTERR2	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
6 TSTARGT2	Timestamp Target Time Reached for Target Time PPS2 When this bit is set and MCGREN2 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers. When this bit is set and MCGREN2 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[2] is asserted. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached for Target Time PPS2 status not detected 1b - Timestamp Target Time Reached for Target Time PPS2 status detected
5 TSTRGTERR1	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 TSTARGT1	Timestamp Target Time Reached for Target Time PPS1 When this bit is set and MCGREN1 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers. When this bit is set and MCGREN1 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[1] is asserted. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached for Target Time PPS1 status not detected 1b - Timestamp Target Time Reached for Target Time PPS1 status detected
3 TSTRGTERR0	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Error status not detected 1b - Timestamp Target Time Error status detected
2 Reserved_AUX TSTRIG	Reserved.
1 TSTARGT0	Timestamp Target Time Reached When this bit is set and MCGREN0 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. When this bit is set and MCGREN0 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[0] is asserted. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Target Time Reached status not detected 1b - Timestamp Target Time Reached status detected
0 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Seconds Overflow status not detected 1b - Timestamp Seconds Overflow status detected

75.7.230 (MAC_Tx_Timestamp_Status_Nanoseconds)

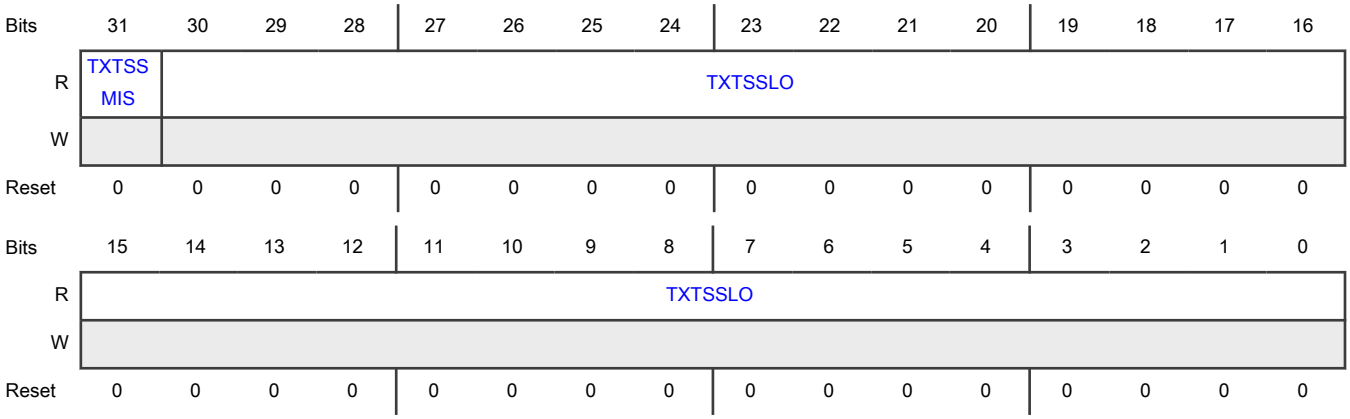
Offset

Register	Offset
MAC_Tx_Timestamp_Status_Nanoseconds	B30h

Function

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled. The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_Tx_Timestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read. If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSSIS bit [15] in MAC_Timestamp_Status register is set when the MAC transmitter captures the timestamp.

Diagram



Fields

Field	Function
31 TXTSSMIS	Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: - The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset - The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Transmit Timestamp Status Missed status not detected 1b - Transmit Timestamp Status Missed status detected
30-0 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

75.7.231 (MAC_Tx_Timestamp_Status_Seconds)

Offset

Register	Offset
MAC_Tx_Timestamp_Status_Seconds	B34h

Function
The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Diagram

R	OSTIAC															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

75.7.233 (MAC_Timestamp_Egress_Asym_Corr)

Offset

Register	Offset
MAC_Timestamp_Egress_Asym_Corr	B54h

Function
The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

Fields

Field	Function
31-0 OSTEAC	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000(2.5 * 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 216).

75.7.234 (MAC_Timestamp_Ingress_Corr_Nanosecond)

Offset

Register	Offset
MAC_Timestamp_Ingress_Corr_Nanosecond	B58h

Function

Fields

Field	Function
31 MCGREN3	MCGR Mode Enable for PPS3 Output This field enables the 3rd PPS instance to operate in PPS or MCGR mode. - 1: Operates in MCGR mode - 0: Operates in PPS mode
30-29 TRGTMODSEL3	Target Time Register Mode for PPS3 Output This field indicates the Target Time registers (MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds) mode for PPS3 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Enables MCGR Interrupt whose status bit is indicated by TSTARGT3 (MAC_Timestamp_Status[8]) 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
28 TIMESEL	Time Select When this bit is set, 64 bit PTP time is used to capture time at MCGR trigger[0] input When this bit is reset, presentation time is used to capture time at trigger input, maintaining backward compatibility
27-24 PPSCMD3	Flexible PPS3 Output Control This field controls the flexible PPS3 output (ptp_pps_o[3]) signal. This field is similar to the PPSCMD0[2:0] field. - When MCGREN3 is 1, PPSCMD3 indicated by the 4 bits [27:24] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 3. This field is similar to the PPSCMD0 Presentation Time Control bits. - When MCGREN3 is 0, only 3 bits from [26:24] are used as PPSCMD3 and the 4th bit must be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
23 MCGREN2	MCGR Mode Enable for PPS2 Output This field enables the 2nd PPS instance to operate in PPS or MCGR mode. - 1: Operates in MCGR mode - 0: Operates in PPS mode 0b - 2nd PPS instance is disabled to operate in PPS or MCGR mode 1b - 2nd PPS instance is enabled to operate in PPS or MCGR mode
22-21 TRGTMODSEL2	Target Time Register Mode for PPS2 Output This field indicates the Target Time registers (MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds) mode for PPS2 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Enables MCGR Interrupt whose status bit is indicated by TSTARGT2 (MAC_Timestamp_Status[6]) 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted

Table continues on the next page...

Field	Function
20 Reserved_20	Reserved.
19-16 PPSCMD2	Flexible PPS2 Output Control This field controls the flexible PPS2 output (ptp_pps_o[2]) signal. This field is similar to the PPSCMD0 field. - When MCGREN2 is 1, PPSCMD2 indicated by the 4 bits, [19:16] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 2. This field is similar to the PPSCMD0 Presentation Time Control bits. - When MCGREN2 is 0, only 3 bits, [18:16] are used as PPSCMD2 and the 4th bit must be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
15 MCGREN1	MCGR Mode Enable for PPS1 Output This field enables the 1st PPS instance to operate in PPS or MCGR mode. - 1: Operates in MCGR mode - 0: Operates in PPS mode 0b - 1st PPS instance is disabled to operate in PPS or MCGR mode 1b - 1st PPS instance is enabled to operate in PPS or MCGR mode
14-13 TRGTMODSEL1	Target Time Register Mode for PPS1 Output This field indicates the Target Time registers (MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds) mode for PPS1 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Enables MCGR Interrupt whose status bit is indicated by TSTARGT1 (MAC_Timestamp_Status[4]) 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
12 Reserved_12	Reserved.
11-8 PPSCMD1	Flexible PPS1 Output Control This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. This field is similar to the PPSCMD0 field. - When MCGREN1 is 1, PPSCMD1 indicated by the 4 bits [11:8] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 1. This field is similar to the PPSCMD0 Presentation Time Control bits. - When MCGREN1 is 0, only 3 bits, [10:8] are used as PPSCMD1 and the 4th bit must be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
7 MCGREN0	MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0b - 0th PPS instance is enabled to operate in PPS mode 1b - 0th PPS instance is enabled to operate in MCGR mode
6-5	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) mode for PPS0 output signal:

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRGTMODSEL0	00b - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01b - Enables MCGR Interrupt whose status bit is indicated by TSTARGT0 (MAC_Timestamp_Status[1]) 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
4 PPSEN0	Flexible PPS Output Mode Enable When this bit is - 1: Bits[3:0] function as PPSCMD. - 0: Bits[3:0] function as PPSCTRL (Fixed PPS mode). 0b - Flexible PPS Output Mode is disabled 1b - Flexible PPS Output Mode is enabled
3-0 PPSCTRL_PPSCMD	PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. - 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. - .. - 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: - When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms - When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high) - When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. or Flexible PPS Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000: No Command - 0001: START Single Pulse This command generates single pulse rising at the start point defined in MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds register and of a duration defined in the PPS0 Width Register. - 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. - 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. - 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 110: Cancel STOP Pulse train This command

Table continues on the next page...

Table continued from the previous page...

Field	Function
	cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111-1111: Reserved or Presentation Time Control When MCGREN0 is 1, these bits are treated as Presentation time control bits. The following list describes the values of PPSCMD0: - 0000: MCGR operation is not carried out. If set to this value in the mid of clock recovery or generation, all the processing inputs are flushed - 0001: Capture the Presentation time at the rising edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0010: Capture the Presentation time at the falling edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0011: Capture the Presentation time at both edges of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0100-1000: Reserved - 1001: Toggle output on compare - 1010: Pulse output low on compare for one PTP-clock cycle - 1011: Pulse output high on compare for one PTP-clock cycle - 1100-1111: Reserved

75.7.241 (MAC_PPS0_Target_Time_Seconds)

Offset

Register	Offset
MAC_PPS0_Target_Time_Seconds	B80h

Function

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

	[6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

75.7.243 (MAC_PPS0_Interval)

Offset

Register	Offset
MAC_PPS0_Interval	B88h

Function

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PPSINT0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSINT0	PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

75.7.244 (MAC_PPS0_Width)

Offset

Register	Offset
MAC_PPS0_Width	B8Ch

Function

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PPSWIDTH0

R W	PPSWIDTH0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSWIDTH0	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

75.7.245 (MAC_PPS1_Target_Time_Seconds)

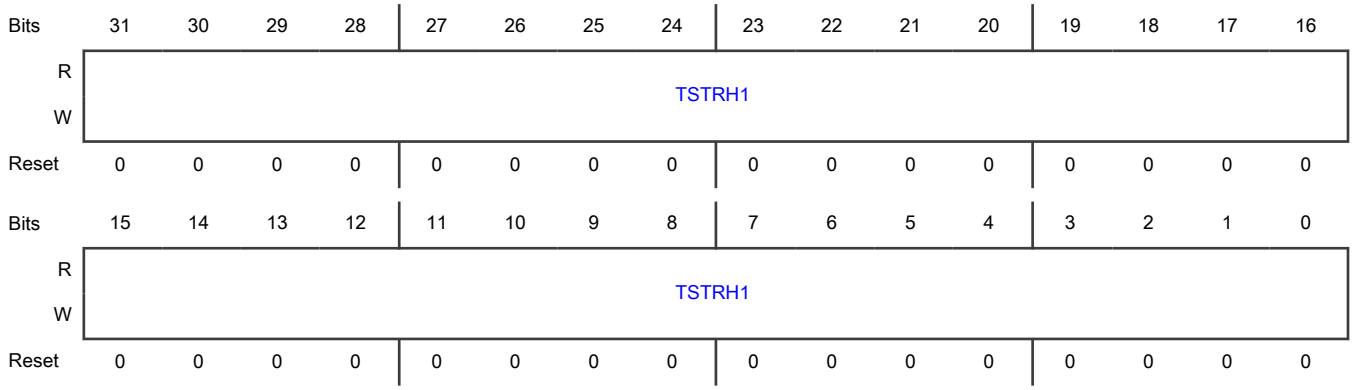
Offset

Register	Offset
MAC_PPS1_Target_Time_Seconds	B90h

Function

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Diagram



Fields

Field	Function
31-0 TSTRH1	PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_Control register. If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and PTGE field of MAC_Timestamp_Control Register is set with Presentation time control set in recovery mode, then these bits indicate the TPT being programmed by the application and in generation mode it indicates the CPT generated at the sampled trigger.

75.7.246 (MAC_PPS1_Target_Time_Nanoseconds)

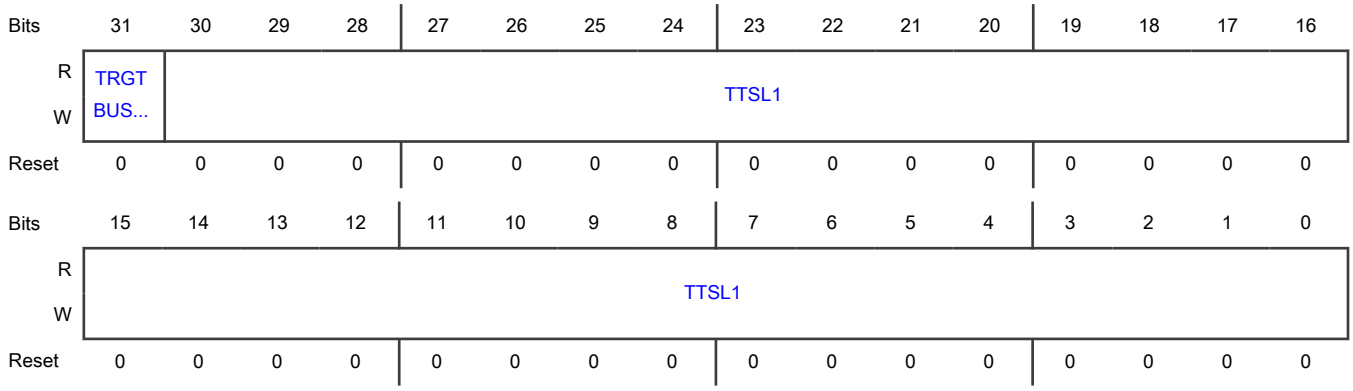
Offset

Register	Offset
MAC_PPS1_Target_Time_Nanoseconds	B94h

Function

PPS0 Target Time Nanoseconds register.

Diagram



Fields

Field	Function
31 TRGTBUSY1	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0b - PPS Target Time Register Busy status is not detected 1b - PPS Target Time Register Busy is detected
30-0 TTSL1	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

75.7.247 (MAC_PPS1_Interval)

Offset

Register	Offset
MAC_PPS1_Interval	B98h

Function

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Diagram

14-10 Reserved_14_10	Reserved.
9 STSI	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit. 0b - Transmit Status Available Interrupt Status not detected 1b - Transmit Status Available Interrupt Status detected
8 PKTI	Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit. 0b - Receive Packet Available Interrupt Status not detected 1b - Receive Packet Available Interrupt Status detected
7-5 Reserved_7_5	Reserved.
4-3 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and Byte 1 are valid 10b - Byte 0, Byte 1, and Byte 2 are valid 11b - All four bytes are valid
2-1 PKTSTATE	Encoded Packet State This field is used to get the control or status information of the selected FIFO. - Tx FIFO: -- 00: Packet Data -- 01: Control Word -- 10: SOP Data -- 11: EOP Data - Rx FIFO: -- 00: Packet Data -- 01: Normal Status -- 10: Last Status -- 11: EOP This field is applicable only for Tx FIFO and Rx FIFO during Read operation. 00b - Packet Data 01b - Control Word/Normal Status 10b - SOP Data/Last Status 11b - EOP Data/EOP
0 FIFOBUSY	FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: - All other fields of this register - All fields of the MTL_FIFO_Debug_Data register 0b - FIFO Busy not detected 1b - FIFO Busy detected

75.7.260 (MTL_FIFO_Debug_Data)

Offset

Register	Offset
MTL_FIFO_Debug_Data	C10h

Function
The FIFO Debug Data register contains the data to be written to or read from the FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	FDBGDATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 FDBGDATA	FIFO Debug Data During debug or slave access write operation, this field contains the data to be written to the Tx FIFO, Rx FIFO, or TSO FIFO. During debug or slave access read operation, this field contains the data read from the Tx FIFO, Rx FIFO, TSO FIFO, or Tx Status FIFO.

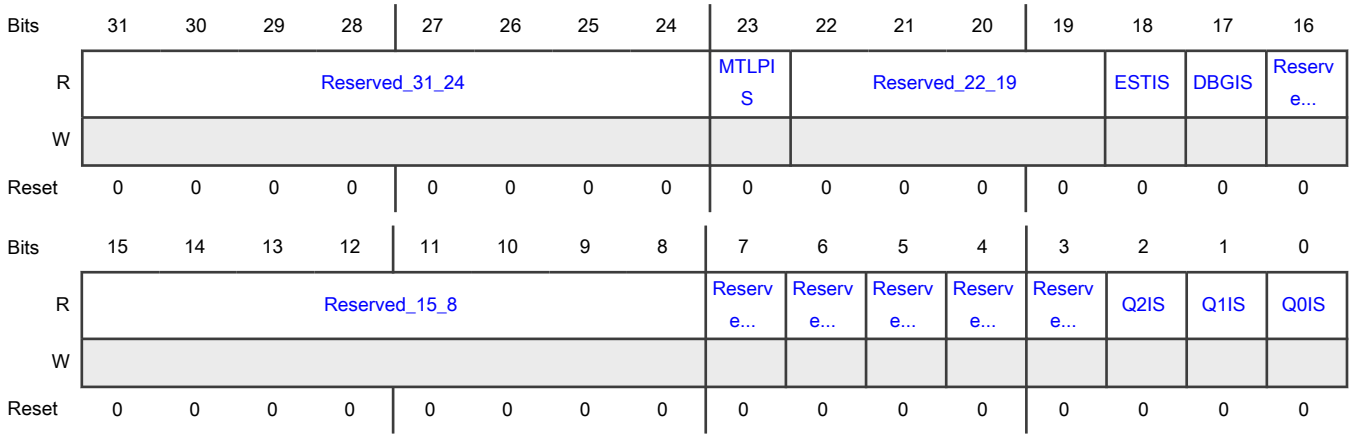
75.7.261 (MTL_Interrupt_Status)

Offset

Register	Offset
MTL_Interrupt_Status	C20h

Function
The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23 MTLPIS	MTL Rx Parser Interrupt Status This bit indicates that there is an interrupt from Rx Parser Block. To reset this bit, the application must read the MTL_ Rxp_Interrupt_Status register to get the exact cause of the interrupt and clear its source. 0b - MTL Rx Parser Interrupt status not detected 1b - MTL Rx Parser Interrupt status detected
22-19 Reserved_22_19	Reserved.
18 ESTIS	EST (TAS- 802.1Qbv) Interrupt Status This bit indicates an interrupt event during the operation of 802.1Qbv. To reset this bit, the application must clear the error/event that has caused the Interrupt. 0b - EST (TAS- 802.1Qbv) Interrupt status not detected 1b - EST (TAS- 802.1Qbv) Interrupt status detected
17 DBGIS	Debug Interrupt status This bit indicates an interrupt event during the slave access. To reset this bit, the application must read the FIFO Debug Access Status register to get the exact cause of the interrupt and clear its source. 0b - Debug Interrupt status not detected 1b - Debug Interrupt status detected
16 Reserved_MACIS	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 Reserved_15_8	Reserved.
7 Reserved_Q7IS	Reserved.
6 Reserved_Q6IS	Reserved.
5 Reserved_Q5IS	Reserved.
4 Reserved_Q4IS	Reserved.
3 Reserved_Q3IS	Reserved.
2 Q2IS	Queue 2 Interrupt status This bit indicates that there is an interrupt from Queue 2. To reset this bit, the application must read the MTL_Q2_Interrupt_Control_Status register to get the exact cause of the interrupt and clear its source. 0b - Queue 2 Interrupt status not detected 1b - Queue 2 Interrupt status detected
1 Q1IS	Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. To reset this bit, the application must read the MTL_Q1_Interrupt_Control_Status register to get the exact cause of the interrupt and clear its source. 0b - Queue 1 Interrupt status not detected 1b - Queue 1 Interrupt status detected
0 Q0IS	Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. To reset this bit, the application must read Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source. 0b - Queue 0 Interrupt status not detected 1b - Queue 0 Interrupt status detected

75.7.262 (MTL_RxQ_DMA_Map0)

Offset

Register	Offset
MTL_RxQ_DMA_Map0	C30h

Function

The Receive Queue and DMA Channel Mapping 0 register is reserved in EQOS-CORE and EQOS-MTL configurations.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25-24 Reserved_Q3MDMACH	Reserved.
23-21 Reserved_23_21	Reserved.
20 Q2DDMACH	Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 2 are routed to the DMA Channel programmed in the Q2MDMACH field (Bits[18:16]). 0b - Queue 2 disabled for DA-based DMA Channel Selection 1b - Queue 2 enabled for DA-based DMA Channel Selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-18 Reserved_19_y	Reserved.
17-16 Q2MDMACH	Queue 2 Mapped to DMA Channel This field controls the routing of the received packet in Queue 2 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: DMA Channel 5 - 110: DMA Channel 6 - 111: DMA Channel 7 This field is valid when the Q2DDMACH field is reset.
15-13 Reserved_15_13	Reserved.
12 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field (Bits[10:8]). 0b - Queue 1 disabled for DA-based DMA Channel Selection 1b - Queue 1 enabled for DA-based DMA Channel Selection
11-10 Reserved_11_y	Reserved.
9-8 Q1MDMACH	Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: DMA Channel 5 - 110: DMA Channel 6 - 111: DMA Channel 7 This field is valid when the Q1DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the other bits are reserved.
7-5 Reserved_7_5	Reserved.
4 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field. 0b - Queue 0 disabled for DA-based DMA Channel Selection 1b - Queue 0 enabled for DA-based DMA Channel Selection
3-2 Reserved_3_y	Reserved.
1-0 Q0MDMACH	Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel

Table continues on the next page...

Table continued from the previous page...

Field	Function
	3 - 100: DMA Channel 4 - 101: DMA Channel 5 - 110: DMA Channel 6 - 111: DMA Channel 7 This field is valid when the Q0DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the other bits are reserved.

75.7.263 (MTL_TBS_CTRL)

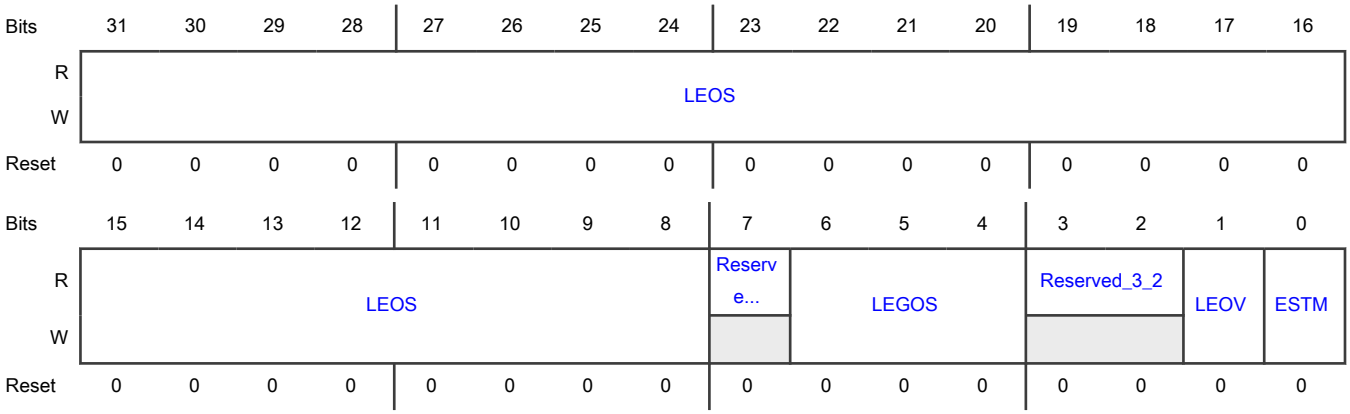
Offset

Register	Offset
MTL_TBS_CTRL	C40h

Function

This register controls the operation of Time Based Scheduling.

Diagram



Fields

Field	Function
31-8 LEOS	Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Value valid only when LEOV is set. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is set since this value is a modulo CTR value.
7 Reserved_7	Reserved.
6-4 LEGOS	Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Value valid only when LEOV is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-2 Reserved_3_2	Reserved.
1 LEOV	Launch Expiry Offset Valid When set indicates the LEOS field is valid. When not set, indicates the Launch Expiry Offset is not valid and the MTL must not check for Launch expiry time. 0b - LEOS field is invalid 1b - LEOS field is valid
0 ESTM	EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. When reset, the Launch Time value is used as an absolute value that should be compared with the System time [39:8]. 0b - EST offset Mode is disabled 1b - EST offset Mode is enabled

75.7.264 (MTL_EST_Control)

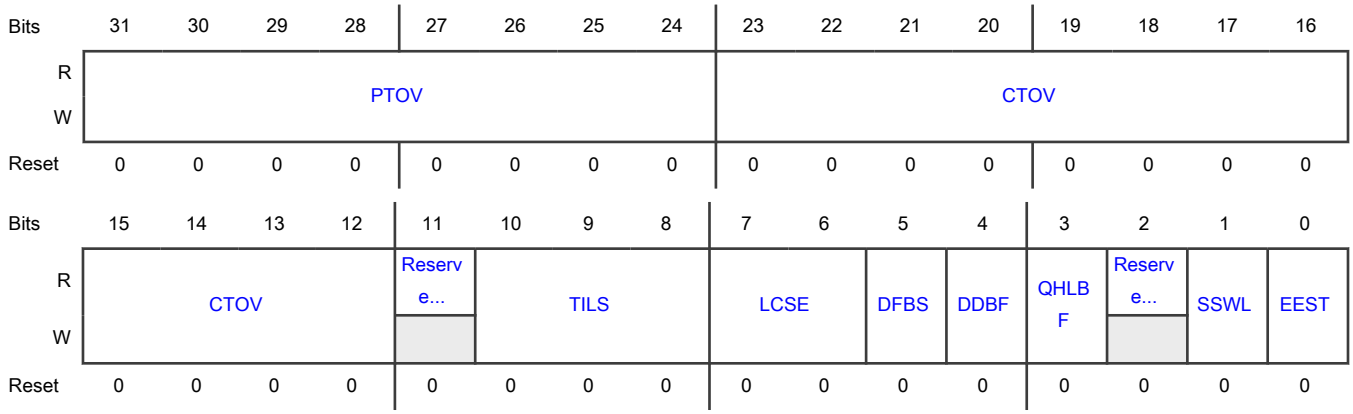
Offset

Register	Offset
MTL_EST_Control	C50h

Function

This register controls the operation of Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Diagram



Fields

Field	Function
31-24 PTOV	PTP Time Offset Value The value of PTP Clock period multiplied by 6 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.
23-12 CTOV	Current Time Offset Value Provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays and so on. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).
11 Reserved_11	Reserved.
10-8 TILS	Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - . - . - 100: Left shift TI by 7 bits (equal to x128ns) Based on the configuration one or more bits of this field should be treated as Reserved/Read-Only.
7-6 LCSE	Loop Count to report Scheduling Error Programmable number of GCL list iterations before reporting an HLBS error defined in EST_Status register. 00b - 4 iterations 01b - 8 iterations 10b - 16 iterations 11b - 32 iterations
5 DFBS	Drop Frames causing Scheduling Error When set frames reported to cause HOL Blocking due to not getting scheduled (HLBS field of EST_Status register) after 4,8,16,32 (based on LCSE field of this register) GCL iterations are dropped. 0b - Do not Drop Frames causing Scheduling Error 1b - Drop Frames causing Scheduling Error
4 DDBF	Do not Drop frames during Frame Size Error When set, frames are not be dropped during Head-of-Line blocking due to Frame Size Error (HLBF field of EST_Status register). 0b - Drop frames during Frame Size Error 1b - Do not Drop frames during Frame Size Error
3 QHLBF	Quick Assertion of HLBF Error When set, Time Window for Head-of-Line blocking due to Frame Size Error is 1 to 2 loop count of GCL list.On reset,Time Window for Head-of-Line blocking due to Frame Size Error is 2 to 3 loop counts of GCL list. 0b - Disable Quick assertion of HLBF error 1b - Quick Assertion of HLBF Error
2 Reserved_2	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 SSWL	Switch to S/W owned list When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Switch to S/W owned list is disabled 1b - Switch to S/W owned list is enabled
0 EEST	Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Should be set for the hardware to start processing the gate control lists. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit it set. When DWC_EQOS_ASP_ECC is selected during the configuration, if any uncorrectable error is detected in the EST memory the hardware resets this bit and disables the EST function. 0b - EST is disabled 1b - EST is enabled

75.7.265 (MTL_EST_Ext_Control)

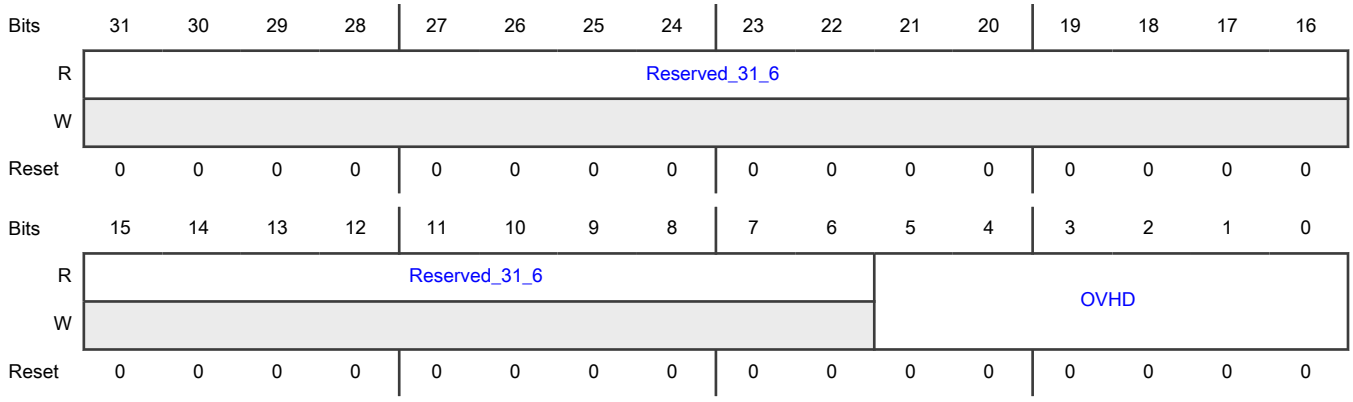
Offset

Register	Offset
MTL_EST_Ext_Control	C54h

Function

This register indicates the number of Overhead bytes for EST related scheduling.

Diagram



Fields

Field	Function
31-6 Reserved_31_6	Reserved.
5-0 OVHD	Overhead Bytes Value This field indicates the fixed overhead for every packet to account for EST Scheduler Delay, IPG or EIPG, and Preamble bytes.

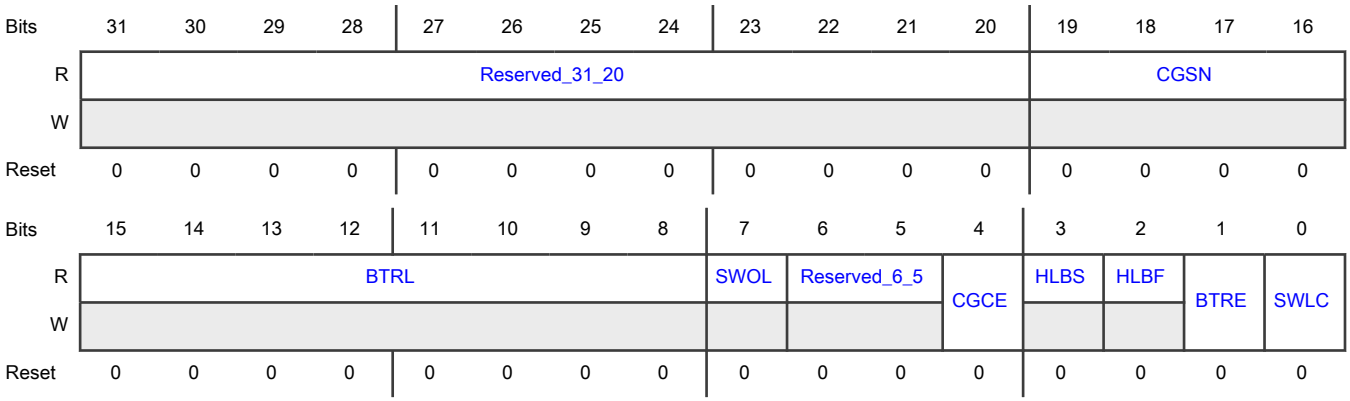
75.7.266 (MTL_EST_Status)

Offset

Register	Offset
MTL_EST_Status	C58h

Function
This register provides Status related to Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Diagram



Fields

Field	Function
31-20 Reserved_31_20	Reserved.
19-16 CGSN	Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
15-8	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "11111111" indicates the iterations exceeded the value

Table continues on the next page...

Table continued from the previous page...

Field	Function
BTRL	of 128 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
7 SWOL	S/W owned list When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access through GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0b - Gate control list number "0" is owned by software 1b - Gate control list number "1" is owned by software
6-5 Reserved_6_5	Reserved.
4 CGCE	Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional Left Shifting. This implies, Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Constant Gate Control Error not detected 1b - Constant Gate Control Error detected
3 HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros. 0b - Head-Of-Line Blocking due to Scheduling not detected 1b - Head-Of-Line Blocking due to Scheduling detected
2 HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros. 0b - Head-Of-Line Blocking due to Frame Size not detected 1b - Head-Of-Line Blocking due to Frame Size detected
1 BTRE	BTR Error When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "11111111", SWOL is not updated and software should reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "11111111", SWOL is updated and this field indicates the number of iterations

Table continues on the next page...

Table continued from the previous page...

Field	Function
	(of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - BTR Error not detected 1b - BTR Error detected
0 SWLC	Switch to S/W owned list Complete When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Cleared when the SSWL of EST_Control register transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Switch to S/W owned list Complete not detected 1b - Switch to S/W owned list Complete detected

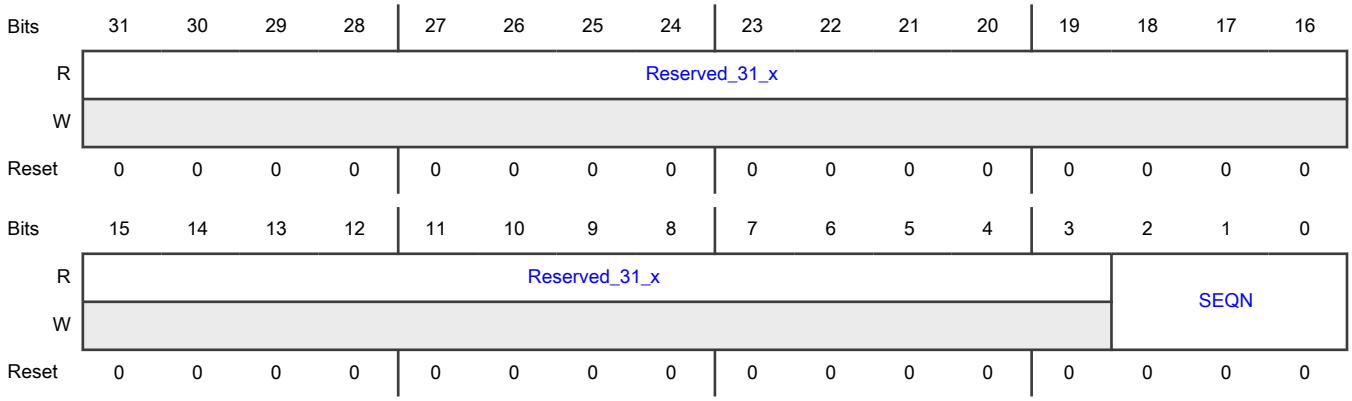
75.7.267 (MTL_EST_Sch_Error)

Offset

Register	Offset
MTL_EST_Sch_Error	C60h

Function
This register provides the One Hot encoded Queue Numbers that are having the Scheduling related error (timeout).

Diagram



Fields

Field	Function
31-3 Reserved_31_x	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-0 SEQN	Schedule Error Queue Number The One Hot Encoded Queue Numbers that have experienced error/ timeout described in HLBS field of status register. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

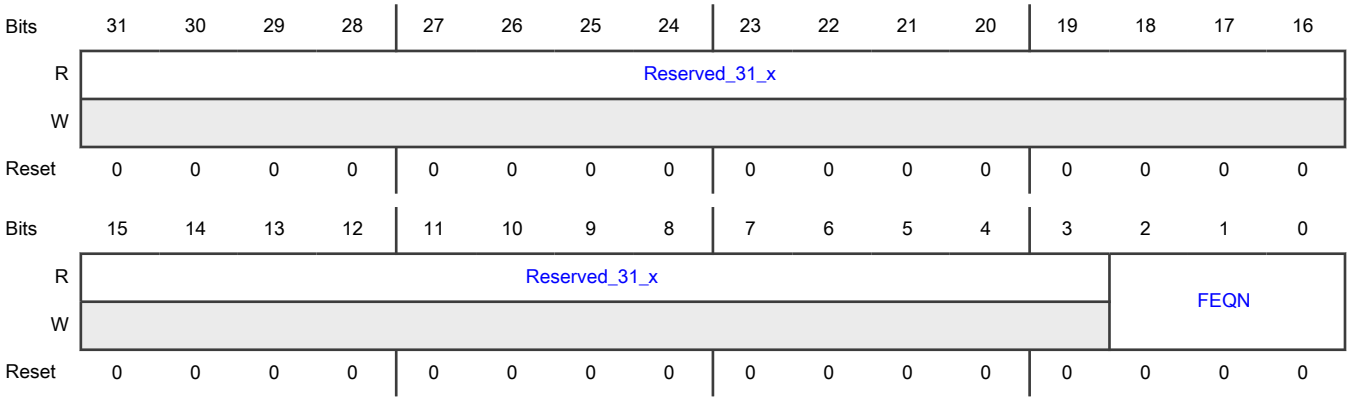
75.7.268 (MTL_EST_Frm_Size_Error)

Offset

Register	Offset
MTL_EST_Frm_Size_Error	C64h

Function
This register provides the One Hot encoded Queue Numbers that are having the Frame Size related error.

Diagram



Fields

Field	Function
31-3 Reserved_31_x	Reserved.
2-0 FEQN	Frame Size Error Queue Number The One Hot Encoded Queue Numbers that have experienced error described in HLBF field of status register. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

75.7.269 (MTL_EST_Frm_Size_Capture)

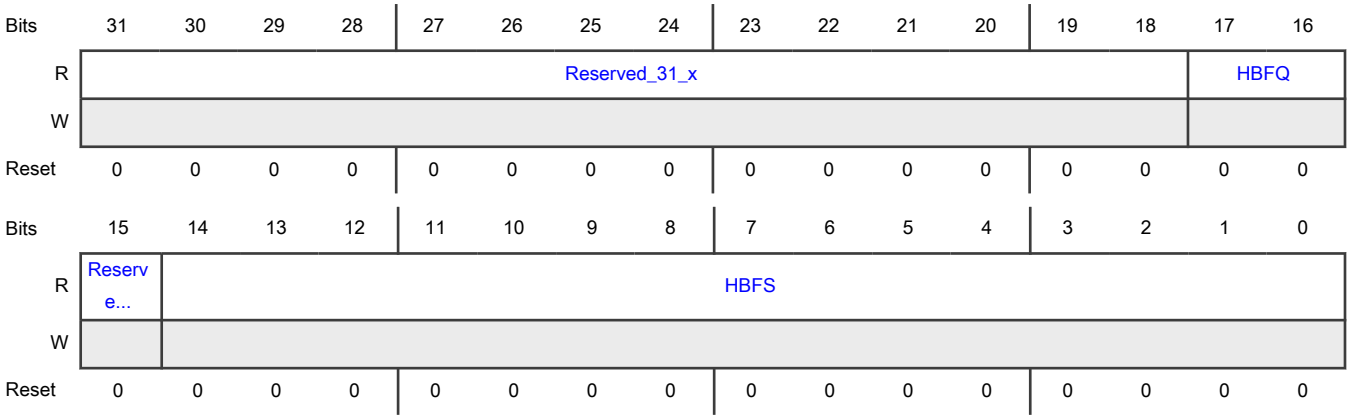
Offset

Register	Offset
MTL_EST_Frm_Size_Capture	C68h

Function

This register captures the Frame Size and Queue Number of the first occurrence of the Frame Size related error. Up on clearing it captures the data of immediate next occurrence of a similar error.

Diagram



Fields

Field	Function
31-18 Reserved_31_x	Reserved.
17-16 HBFQ	Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared the queue number of the next occurring HLBF error is captured. Width is based on the number of Tx Queues configured; remaining bits are Read-Only. Cleared when MTL_EST_Frm_Size_Error register is all zeros.
15 Reserved_15	Reserved.
14-0 HBFS	Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Contents of this register should be considered invalid, if this field is zero. Cleared when MTL_EST_Frm_Size_Error register is all zeros.

75.7.270 (MTL_EST_Intr_Enable)

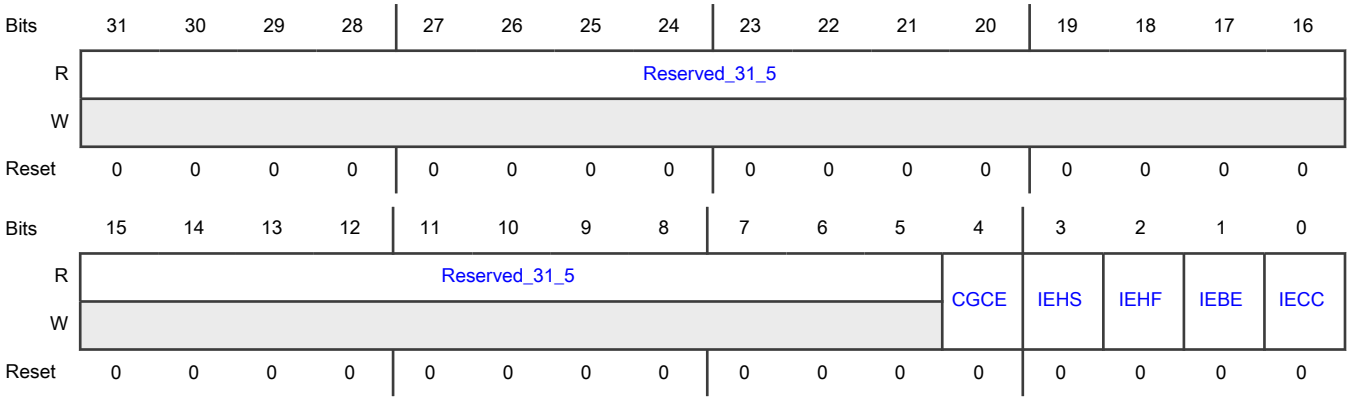
Offset

Register	Offset
MTL_EST_Intr_Enable	C70h

Function

This register implements the Interrupt Enable bits for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status register.

Diagram



Fields

Field	Function
31-5 Reserved_31_5	Reserved.
4 CGCE	Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. When reset this event does not generate an interrupt 0b - Interrupt for CGCE is disabled 1b - Interrupt for CGCE is enabled
3 IEHS	Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. When reset this event does not generate an interrupt. 0b - Interrupt for HLBS is disabled 1b - Interrupt for HLBS is enabled
2 IEHF	Interrupt Enable for HLBF When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0b - Interrupt for HLBF is disabled 1b - Interrupt for HLBF is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 IEBE	Interrupt Enable for BTR Error When set, generates interrupt when the BTR Error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0b - Interrupt for BTR Error is disabled 1b - Interrupt for BTR Error is enabled
0 IECC	Interrupt Enable for Switch List When set, generates interrupt when the configuration change is successful and the hardware has switched to the new list. When reset this event does not generate an interrupt. 0b - Interrupt for Switch List is disabled 1b - Interrupt for Switch List is enabled

75.7.271 (MTL_EST_GCL_Control)

Offset

Register	Offset
MTL_EST_GCL_Control	C80h

Function

This register provides the control information for reading/writing to the Gate Control lists.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 Reserved_31_24	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23 ESTEIEC	ECC Inject Error Control for EST Memory When ESTEIEE or ESTEIAEE bit of this register is set, following are the errors inserted based on the value encoded in this field. This field is valid only if DWC_EQOS_ASP_ECC feature is selected during the configuration, else it is reserved. 0b - Insert 1 bit error 1b - Insert 2 bit errors
22 ESTEIAEE	EST ECC Inject Address Error Enable When set along with EEST bit of MTL_EST_Control register, enables the ECC address error injection feature. When reset, disables the ECC address error injection feature. 0b - EST ECC Inject Address Error is disabled 1b - EST ECC Inject Address Error is enabled
21 ESTEIEE	EST ECC Inject Error Enable When set along with EEST bit of MTL_EST_Control register, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0b - EST ECC Inject Error is disabled 1b - EST ECC Inject Error is enabled
20-16 Reserved_20_y	Reserved.
15-8 ADDR	Gate Control List Address: (GCLA when GCRR is "0"). Provides the address (row number) of the Gate Control List at which the R/W operation has to be performed. By default the Gate Control List pointed by SWOL of MTL_EST_Status is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. The width of this field is dependent on DWC_EQOS_EST_DEP; unused bits should be treated as read only. Gate Control List Related Registers Address: (GCRA when GCRR is "1"). By default the GCL related register set pointed by SWOL of MTL_EST_Status is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Lower 3 bits are only used in this mode, higher order bits are treated as dont cares. - 000: BTR Low (31:0) - 001: BTR High (63:31) - 010: CTR Low (31:0) - 011: CTR High (39:32) - 100: TER (31:0) - 101: LLR (n:0) (where n is (log{DWC_EQOS_EST_DEP} / log2)) - Others: Reserved
7-6 Reserved_7_6	Reserved.
5 DBGB	Debug Mode Bank Select When set to "0" indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). When set to "1" indicates R/W in debug mode should be directed to Bank 1 (GCL1 and corresponding Time related registers). This value is used when DBGM is set and overrides by value of SWOL which is normally used. 0b - R/W in debug mode should be directed to Bank 0 1b - R/W in debug mode should be directed to Bank 1
4 DBGM	Debug Mode When set to "1" indicates R/W in debug mode where the memory bank (for GCL and Time related registers) is explicitly provided by DBGB value, when set to "0" SWOL bit is used to determine which bank to use.

Table continues on the next page...

Table continued from the previous page...

	0b - Debug Mode is disabled 1b - Debug Mode is enabled
3 Reserved_3	Reserved.
2 GCRR	Gate Control Related Registers When set to "1" indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When "0" indicates R/W should be directed to GCL from the address provided by GCLA. 0b - Gate Control Related Registers are disabled 1b - Gate Control Related Registers are enabled
1 R1W0	Read '1', Write '0': - 1: Read operation - 0: Write operation. 0b - Write Operation 1b - Read Operation
0 SRWO	Start Read/Write Op - 1: Indicates the start/progress of a Read/Write operation. - Reset by hardware: Indicates the R/W operation has completed or an error has occurred (when bit 20 is set) - Reads: Data can be read from MTL_EST_GCL_Data register after this bit is reset - Writes: MTL_EST_GCL_Data should be programmed with write data before setting SRWO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Start Read/Write Op disabled 1b - Start Read/Write Op enabled

75.7.272 (MTL_EST_GCL_Data)

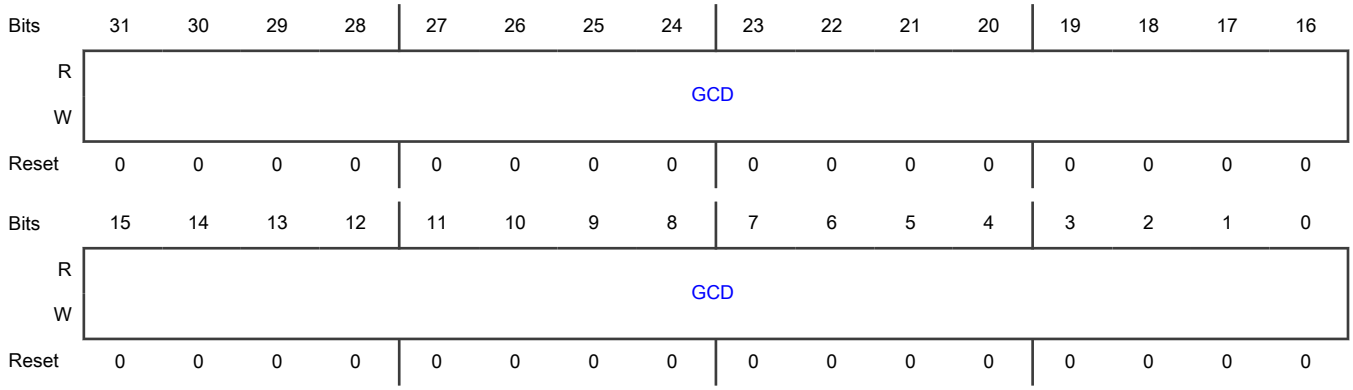
Offset

Register	Offset
MTL_EST_GCL_Data	C84h

Function

This register holds the read data or write data in case of reads and writes respectively.

Diagram



Fields

Field	Function
31-0 GCD	Gate Control Data The data corresponding to the address selected in the GCL_Control register. Used for both Read and Write operations.

75.7.273 (MTL_FPE_CTRL_STS)

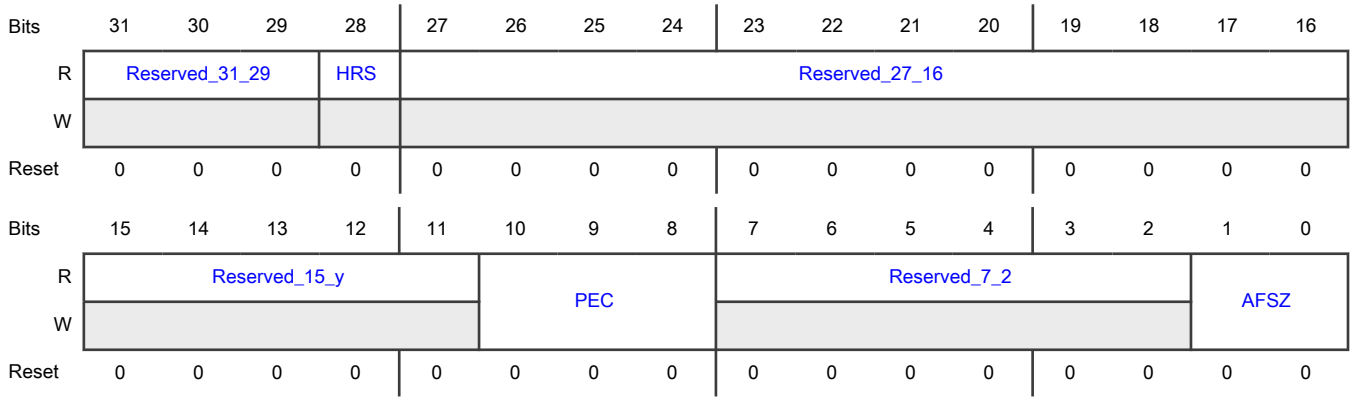
Offset

Register	Offset
MTL_FPE_CTRL_STS	C90h

Function

This register controls the operation of, and provides status for Frame Preemption (IEEE802.1Qbu/802.3br).

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28 HRS	Hold/Release Status - 1: Indicates a Set-and-Hold-MAC operation was last executed and the pMAC is in Hold State. - 0: Indicates a Set-and-Release-MAC operation was last executed and the pMAC is in Release State. 0b - Indicates a Set-and-Release-MAC operation was last executed and the pMAC is in Release State 1b - Indicates a Set-and-Hold-MAC operation was last executed and the pMAC is in Hold State
27-16 Reserved_27_16	Reserved.
15-11 Reserved_15_y	Reserved.
10-8 PEC	Preemption Classification When set indicates the corresponding Queue must be classified as preemptable, when '0' Queue is classified as express. When both EST (Qbv) and Preemption are enabled, Queue-0 is always assumed to be preemptable. When EST (Qbv) is enabled Queues categorized as preemptable here are always assumed to be in "Open" state in the Gate Control List.
7-2 Reserved_7_2	Reserved.
1-0 AFSZ	Additional Fragment Size used to indicate, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ +1) * 64 bytes

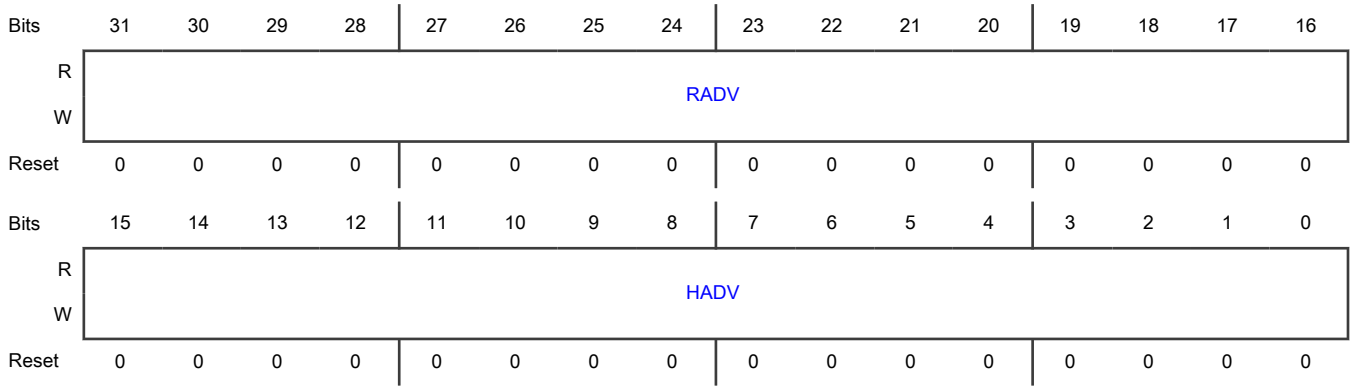
75.7.274 (MTL_FPE_Advance)

Offset

Register	Offset
MTL_FPE_Advance	C94h

Function
This register holds the Hold and Release Advance time.

Diagram



Fields

Field	Function
31-16 RADV	Release Advance The maximum time in nanoseconds that can elapse between issuing a RELEASE to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.
15-0 HADV	Hold Advance The maximum time in nanoseconds that can elapse between issuing a HOLD to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.

75.7.275 (MTL_RXP_Control_Status)

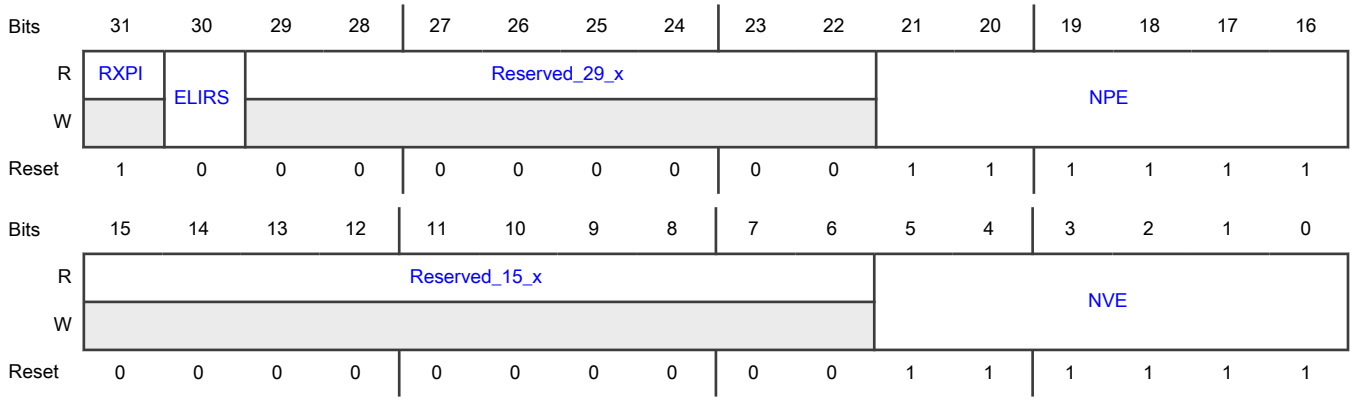
Offset

Register	Offset
MTL_RXP_Control_Status	CA0h

Function

The MTL_RXP_Control_Status register establishes the operating mode of Rx Parser and provides some status.

Diagram



Fields

Field	Function
31 RXPI	RX Parser in Idle state This status bit is set to 1 when the Rx parser is in Idle State and waiting for a new packet for processing. This bit is used as a handshake with software when parser gets disables. After disabling, when bit is set then software can update the Rx parser instruction table. 0b - RX Parser not in Idle state 1b - RX Parser in Idle state
30 ELIRS	Enable Last Instruction in RX Status When this bit is set, RDES2[31:16] indicates the index of the last instruction excecuted in Rx Parse, when set to 0 indicates MAC filter status.
29-22 Reserved_29_x	Reserved.
21-16 NPE	Number of parsable entries in the Instruction table This control indicates the number of parsable entries in the Instruction Memory. This is used in Rx parser logic to detect programming Error. In case number of parsed entries for a packet is more than this entry then NPEOVIS bit in the MTL_RXP_Interrupt_Control_Status register is set.
15-6 Reserved_15_x	Reserved.
5-0 NVE	Number of valid entry address/index in the Instruction table This control indicates the number of valid entries address/index in the Instruction Memory (i.e. when NVE field in register=31, the maximum valid entry address is NVE+1 i.e. addresses/indices=0 to 32, or 33 entries). This is used in Rx parser logic to detect any programming Error. In case while parsing Table address (memory address) found to be more than this maximum valid entry address then NVEOVIS bit in the MTL_RXP_Interrupt_Control_Status register is set. Note: The minimum value of this should be 2.

75.7.276 (MTL_RXP_Interrupt_Control_Status)

Offset

Register	Offset
MTL_RXP_Interrupt_Control_Status	CA4h

Function
The MTL_RXP_Interrupt_Control_Status registers provides enable control for the interrupts and provides interrupt status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved_15_4												PDRFIS	FOOVIS	NPEOVIS	NVEOVIS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 Reserved_31_20	Reserved.
19 PDRFIE	Packet Drop due to RF Interrupt Enable When this bit is set, the PDRFIS interrupt is enabled. When this bit is reset, the PDRFIS interrupt is disabled. 0b - Packet Drop due to RF Interrupt is disabled 1b - Packet Drop due to RF Interrupt is enabled
18 FOOVIE	Frame Offset Overflow Interrupt Enable When this bit is set, the FOOVIS interrupt is enabled. When this bit is reset, the FOOVIS interrupt is disabled. 0b - Frame Offset Overflow Interrupt is disabled 1b - Frame Offset Overflow Interrupt is enabled
17 NPEOVIE	Number of Parsable Entries Overflow Interrupt Enable When this bit is set, the NPEOVIS interrupt is enabled. When this bit is reset, the NPEOVIS interrupt is disabled. 0b - Number of Parsable Entries Overflow Interrupt is disabled 1b - Number of Parsable Entries Overflow Interrupt is enabled
16 NVEOVIE	Number of Valid Entries Overflow Interrupt Enable When this bit is set, the NVEOVIS interrupt is enabled. When this bit is reset, the NVEOVIS interrupt is disabled. 0b - Number of Valid Entries Overflow Interrupt is disabled 1b - Number of Valid Entries Overflow Interrupt is enabled
15-4 Reserved_15_4	Reserved.
3 PDRFIS	Packet Dropped due to RF Interrupt Status If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Packet Dropped due to RF Interrupt Status not detected 1b - Packet Dropped due to RF Interrupt Status detected
2 FOOVIS	Frame Offset Overflow Interrupt Status While parsing if the Instruction table entry's 'Frame Offset' found to be more than EOF offset, then then this bit is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Frame Offset Overflow Interrupt Status not detected 1b - Frame Offset Overflow Interrupt Status detected
1 NPEOVIS	Number of Parsable Entries Overflow Interrupt Status While parsing a packet if the number of parsed entries found to be more than NPE[] (Number of Parseable Entries in MTL_RXP_Control register),then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Number of Parsable Entries Overflow Interrupt Status not detected 1b - Number of Parsable Entries Overflow Interrupt Status detected
0 NVEOVIS	Number of Valid Entry Address/Index Overflow Interrupt Status While parsing if the Instruction address found to be more than NVE (Number of Valid Entry Address/index in MTL_RXP_Control register), then this bit is set to 1. For example, when NVE field in register=31, the maximum valid entry address/index is NVE+1 i.e. 32 (addresses/indices=0 to 32, or 33 entries), so NVEOVIS is set when currently processed entry indicates next address is 33 or more i.e. 34th or later entries. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Number of Valid Entries Overflow Interrupt Status not detected 1b - Number of Valid Entries Overflow Interrupt Status detected

75.7.277 (MTL_RXP_Drop_Cnt)

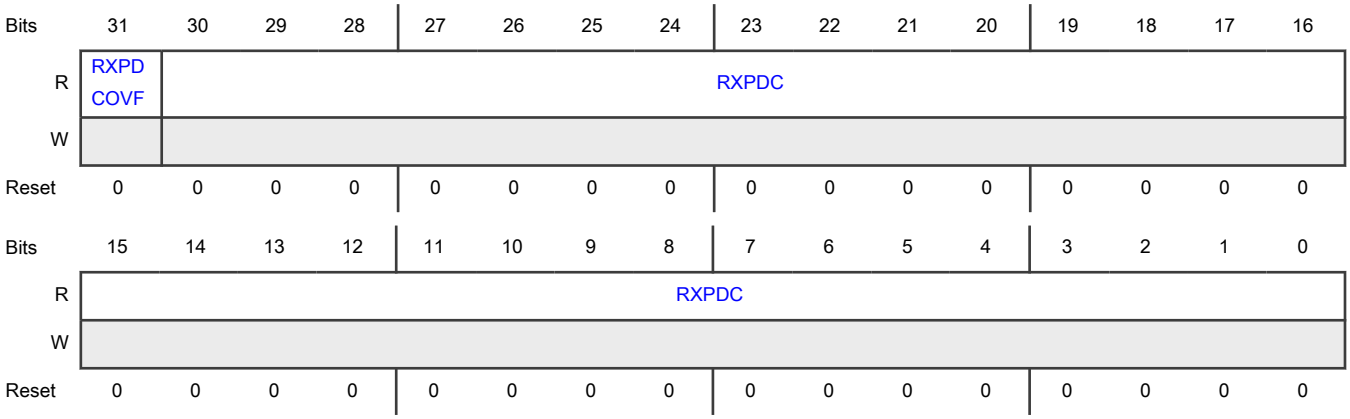
Offset

Register	Offset
MTL_RXP_Drop_Cnt	CA8h

Function

The MTL_RXP_Drop_Cnt register provides the drop count of Rx Parser initiated drops.

Diagram



Fields

Field	Function
31 RXPDCOVF	Rx Parser Drop Counter Overflow Bit When set, this bit indicates that the MTL_RXP_Drop_cnt (RXPDC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Drop count overflow not occurred 1b - Rx Parser Drop count overflow occurred
30-0 RXPDC	Rx Parser Drop count This 31-bit counter is implemented when a Rx Parser Drops a packet due to RF =1. The counter is cleared when the register is read.

75.7.278 (MTL_RXP_Error_Cnt)

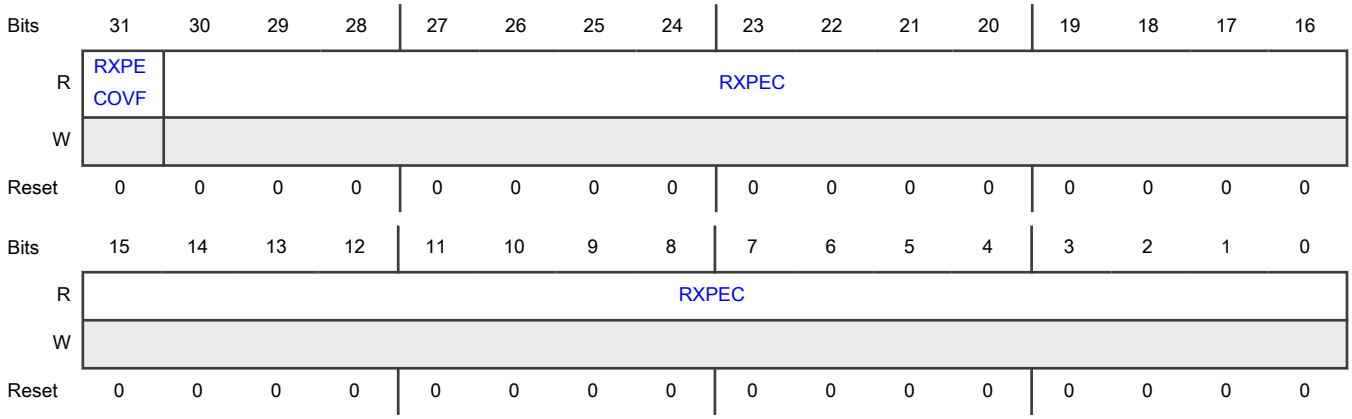
Offset

Register	Offset
MTL_RXP_Error_Cnt	CACh

Function

The MTL_RXP_Error_Cnt register provides the Rx Parser related error occurrence count.

Diagram



Fields

Field	Function
31 RXPECOVF	Rx Parser Error Counter Overflow Bit When set, this bit indicates that the MTL_RXP_Error_cnt (RXPEC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Error count overflow not occurred 1b - Rx Parser Error count overflow occurred
30-0 RXPEC	Rx Parser Error count This 31-bit counter is implemented whenr a Rx Parser encounters following Error scenarios - Entry address >= NVE[] - Number Parsed Entries >= NPE[] - Entry address > EOF data entry address The counter is cleared when the register is read.

75.7.279 (MTL_RXP_Indirect_Acc_Control_Status)

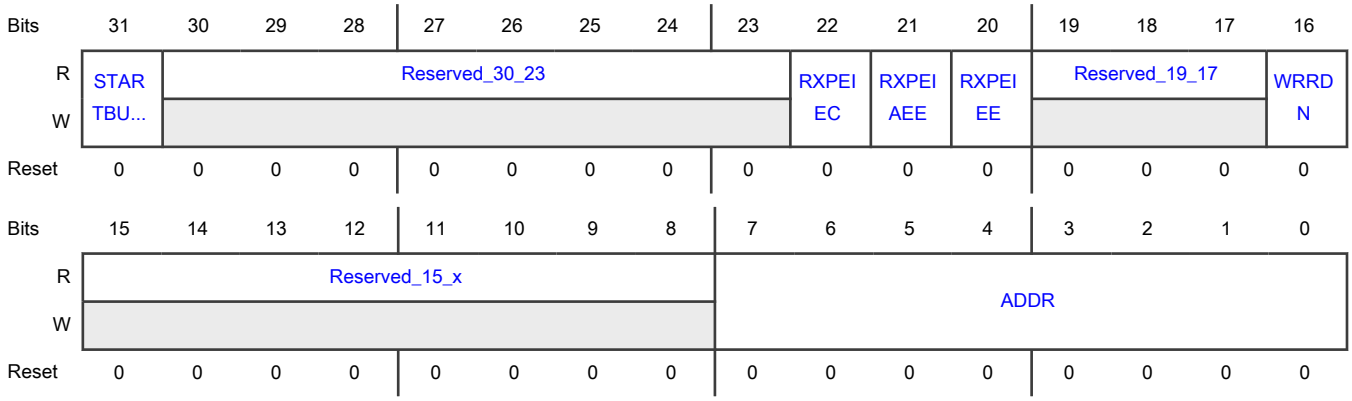
Offset

Register	Offset
MTL_RXP_Indirect_Acc_Control_Status	CB0h

Function

The MTL_RXP_Indirect_Acc_Control_Status register provides the Indirect Access control and status for Rx Parser memory.

Diagram



Fields

Field	Function
31 STARTBUSY	FRP Instruction Table Access Busy - Set to 1 by the software, indicates to start the Read/Write operation from/to the Rx Parser Memory. Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions. - Set to 1 by the IP, indicates that the IP is busy until it is cleared by the IP. Software should not issue read or write operation. 0b - hardware not busy 1b - hardware is busy (Read/Write operation from/to the Rx Parser Memory)
30-23 Reserved_30_23	Reserved.
22 RXPEIEC	ECC Inject Error Control for Rx Parser Memory When RXPEIEE or RXPEIAEE bit of this register is set, following are the errors inserted based on the value encoded in this field: - 1: Insert 1 bit error. - 0: Insert 2 bit errors. 0b - Insert 1 bit error 1b - Insert 2 bit errors
21 RXPEIAEE	ECC Inject Address Error Enable for Rx Parser Memory - 1: Enables the ECC address error injection feature. - 0: Disables the ECC address error injection feature. 0b - ECC Inject Address Error for Rx Parser Memory is disabled 1b - ECC Inject Address Error for Rx Parser Memory is enabled
20 RXPEIEE	ECC Inject Error Enable for Rx Parser Memory - 1: Enables the ECC error injection feature. - 0: Disables the ECC error injection feature. 0b - ECC Inject Error for Rx Parser Memory is disabled 1b - ECC Inject Error for Rx Parser Memory is enabled
19-17 Reserved_19_17	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 WRRDN	Read Write Control - 1: Indicates the write operation to the Rx Parser Memory. - 0: Indicates the read operation to the Rx Parser Memory. 0b - Read operation to the Rx Parser Memory 1b - Write operation to the Rx Parser Memory
15-8 Reserved_15_x	Reserved.
7-0 ADDR	FRP Instruction Table Offset Address This field indicates the ADDR of the 32-bit entry in Rx parser instruction table. Each entry has 128-bit (4x32-bit words). The X is based on the configurable DWC_EQOS_FRP_ENTRIES. If DWC_EQOS_FRP_ENTRIES is - 256: X = 9 - 128: X = 8 - 64: X = 7

75.7.280 (MTL_RXP_Indirect_Acc_Data)

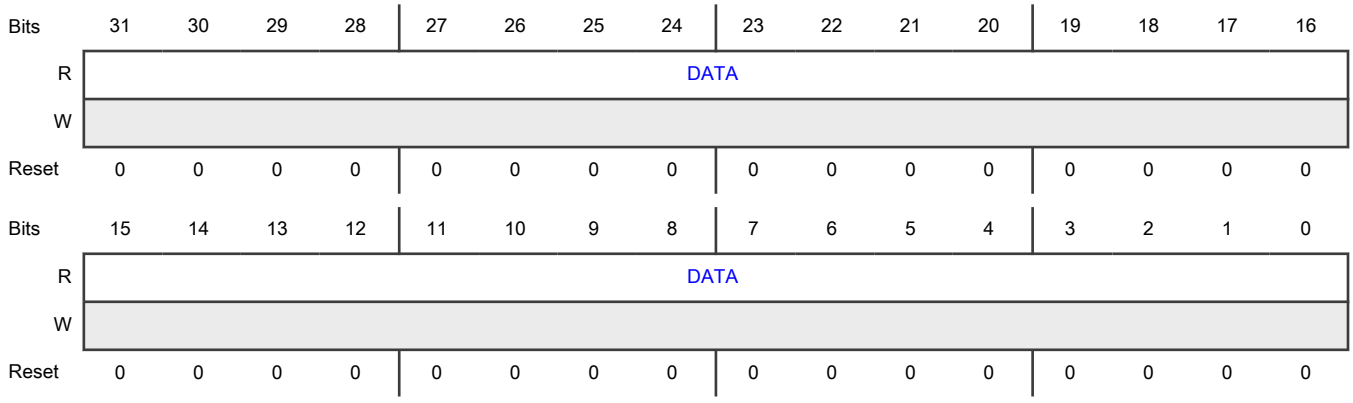
Offset

Register	Offset
MTL_RXP_Indirect_Acc_Data	CB4h

Function

The MTL_RXP_Indirect_Acc_Data registers holds the data associated to Indirect Access to Rx Parser memory.

Diagram



Fields

Field	Function
31-0 DATA	FRP Instruction Table Write/Read Data Software should write this register before issuing any write command. The hardware provides the read data from the Rx Parser Memory for read operation when STARTBUSY =0 after read command.

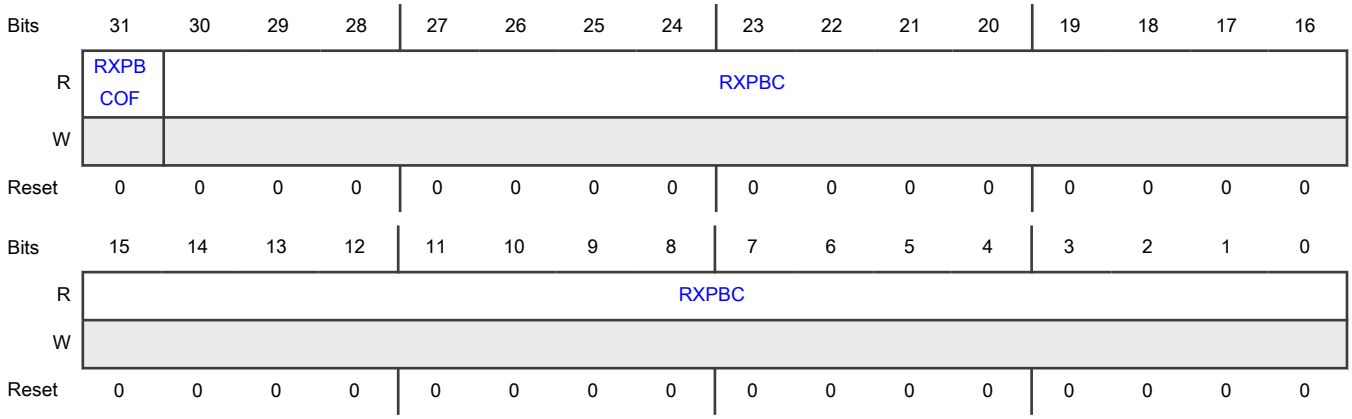
75.7.281 (MTL_RXP_Bypass_Cnt)

Offset

Register	Offset
MTL_RXP_Bypass_Cnt	CB8h

Function
The MTL_RXP_Bypass_Cnt register provides the bypass count of Rx Parser.

Diagram



Fields

Field	Function
31 RXPBCOF	Rx Parser bypass Counter Overflow Bit When set, this bit indicates that the MTL_RXP_Bypass_cnt (RXPBC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Bypass count overflow not occurred 1b - Rx Parser Bypass count overflow occurred
30-0 RXPBC	Rx Parser Bypass count This 31-bit counter is implemented when a Rx Parser bypass a packet due to AF=1 and RF =1. The counter is cleared when the register is read.

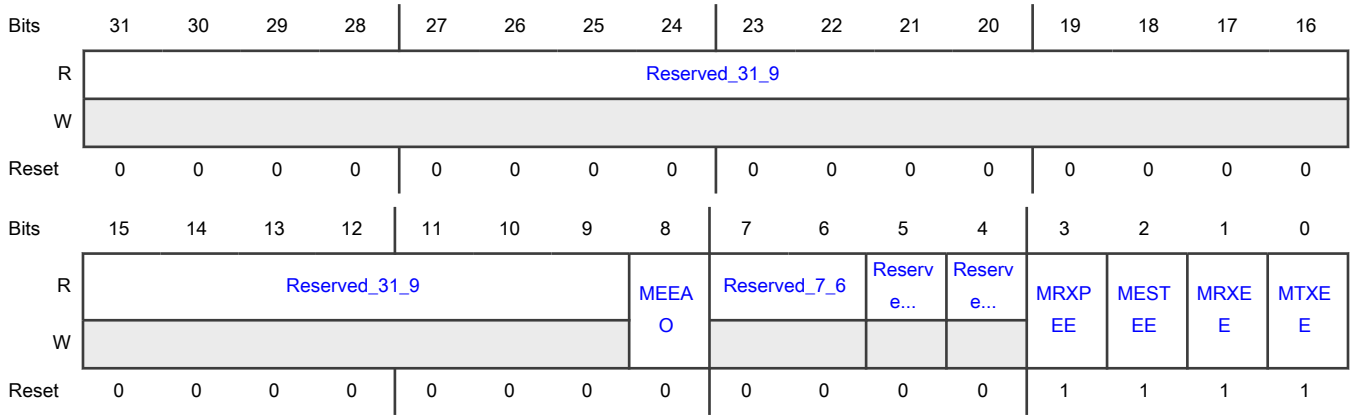
75.7.282 (MTL_ECC_Control)

Offset

Register	Offset
MTL_ECC_Control	CC0h

Function
The MTL_ECC_Control register establishes the operating mode of ECC related to MTL memories.

Diagram



Fields

Field	Function
31-9 Reserved_31_9	Reserved.
8 MEEAO	MTL ECC Error Address Status Over-ride - 1: The EUEAS/ECEAS field of MTL_ECC_Err_Addr_Status register holds the last valid address where the error is detected. - 0: The EUEAS/ECEAS field of MTL_ECC_Err_Addr_Status register holds the first address where the error is detected. 0b - MTL ECC Error Address Status Over-ride is disabled 1b - MTL ECC Error Address Status Over-ride is enabled

1 MEUIS	MTL ECC Uncorrectable error Interrupt Status This bit indicates that an uncorrectable error interrupt event in the MTL ECC safety feature. To get the exact cause of the interrupt the application should read the MTL_ECC_Interrupt_Status register. 0b - MTL ECC Uncorrectable error Interrupt Status not detected 1b - MTL ECC Uncorrectable error Interrupt Status detected
0 MECIS	MTL ECC Correctable error Interrupt Status This bit indicates that a correctable error interrupt event in the MTL ECC safety feature. To get the exact cause of the interrupt the application should read the MTL_ECC_Interrupt_Status register. 0b - MTL ECC Correctable error Interrupt Status not detected 1b - MTL ECC Correctable error Interrupt Status detected

75.7.284 (MTL_ECC_Interrupt_Enable)

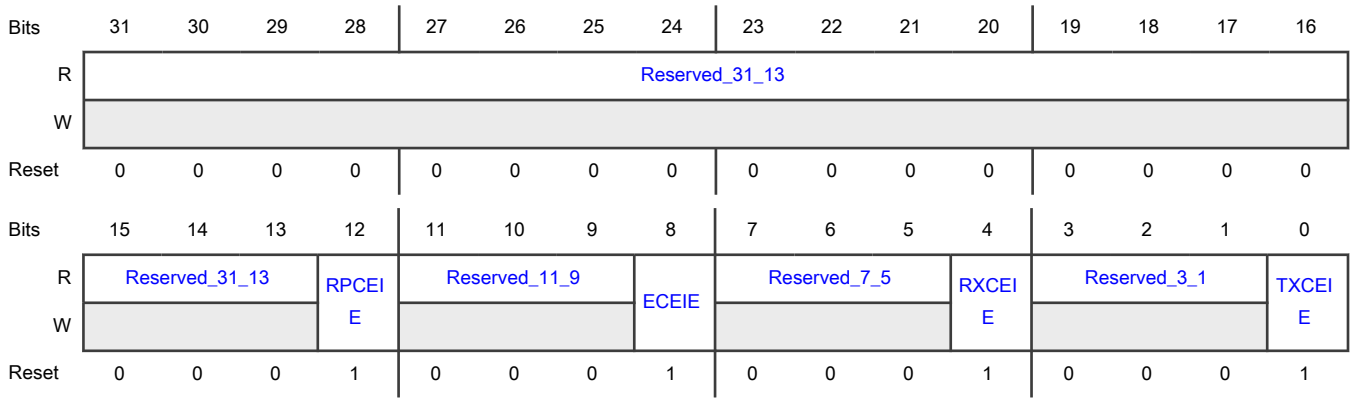
Offset

Register	Offset
MTL_ECC_Interrupt_Enable	CC8h

Function

The MTL_ECC_Interrupt_Enable register provides enable bits for the ECC interrupts.

Diagram



Fields

Field	Function
31-13 Reserved_31_13	Reserved.
12 RPCEIE	Rx Parser memory Correctable Error Interrupt Enable When set, generates an interrupt when an uncorrectable error is detected at the Rx Parser memory interface. It is indicated in RPCES status bit of MTL_ECC_Interrupt_Status register. When reset this event does not generates an interrupt. 0b - Rx Parser memory Correctable Error Interrupt is disabled 1b - Rx Parser memory Correctable Error Interrupt is enabled
11-9 Reserved_11_9	Reserved.
8 ECEIE	EST memory Correctable Error Interrupt Enable When set, generates an interrupt when a correctable error is detected at the MTL EST memory interface. It is indicated in the ECES bit of MTL_ECC_Interrupt_Status register. When reset this event does not generates an interrupt. 0b - EST memory Correctable Error Interrupt is disabled 1b - EST memory Correctable Error Interrupt is enabled
7-5 Reserved_7_5	Reserved.
4 RXCEIE	Rx memory Correctable Error Interrupt Enable When set, generates an interrupt when a correctable error is detected at the MTL Rx memory interface. It is indicated in the RXCES bit of MTL_ECC_Interrupt_Status register. When reset this event does not generates an interrupt. 0b - Rx memory Correctable Error Interrupt is disabled 1b - Rx memory Correctable Error Interrupt is enabled
3-1 Reserved_3_1	Reserved.
0 TXCEIE	Tx memory Correctable Error Interrupt Enable When set, generates an interrupt when a correctable error is detected at the MTL Tx memory interface. It is indicated in the TXCES bit of MTL_ECC_Interrupt_Status register. When reset this event does not generates an interrupt. 0b - Tx memory Correctable Error Interrupt is disabled 1b - Tx memory Correctable Error Interrupt is enabled

75.7.285 (MTL_ECC_Interrupt_Status)

Offset

Register	Offset
MTL_ECC_Interrupt_Status	CCCh

Function

The MTL_ECC_Interrupt_Status register provides MTL ECC Interrupt Status.

Diagram

0 TXCES	MTL Tx memory Correctable Error Status This bit when set indicates that a correctable error is detected at the MTL Tx memory. 0b - MTL Tx memory Correctable Error Status not detected 1b - MTL Tx memory Correctable Error Status detected

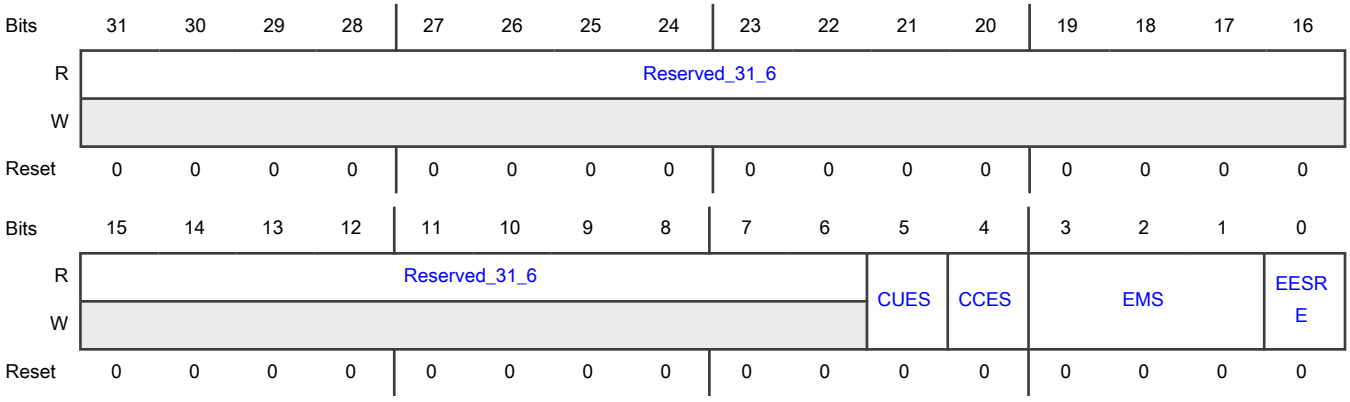
75.7.286 (MTL_ECC_Err_Sts_Rctl)

Offset

Register	Offset
MTL_ECC_Err_Sts_Rctl	CD0h

Function
The MTL_ECC_Err_Sts_Rctl register establishes the control for ECC Error status capture.

Diagram



Fields

Field	Function
31-6	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
Reserved_31_6	
5 CUES	Clear Uncorrectable Error Status When this bit is set along with EESRE bit of this register, based on the EMS field of this register, the respective memory's uncorrectable error address and uncorrectable error count values are cleared upon reading. Hardware resets this bit when all the error status values are cleared. 0b - Clear Uncorrectable Error Status not detected 1b - Clear Uncorrectable Error Status detected
4 CCES	Clear Correctable Error Status When this bit is set along with EESRE bit of this register, based on the EMS field of this register, the respective memory's correctable error address and correctable error count values are cleared upon reading. Hardware resets this bit when all the error status values are cleared. 0b - Clear Correctable Error Status not detected 1b - Clear Correctable Error Status detected
3-1 EMS	MTL ECC Memory Selection When EESRE bit of this register is set, this field indicates which memory's error status value to be read. The memory selection encoding is as described. 000b - MTL Tx memory 001b - MTL Rx memory 010b - MTL EST memory 011b - MTL Rx Parser memory 100b - DMA TSO memory 101b - DMA DCACHE memory
0 EESRE	MTL ECC Error Status Read Enable When this bit is set, based on the EMS field of this register, the respective memory's error status values are captured as described: - The correctable and uncorrectable error count values are captured into MTL_ECC_Err_Cnt_Status register - The address location's of correctable and uncorrectable errors are captured into MTL_ECC_Err_Addr_Status register. Hardware resets this bit when all the status values are captured into the MTL_ECC_Err_Cnt_Status and MTL_ECC_Err_Addr_Status registers. 0b - MTL ECC Error Status Read is disabled 1b - MTL ECC Error Status Read is enabled

75.7.287 (MTL_ECC_Err_Addr_Status)

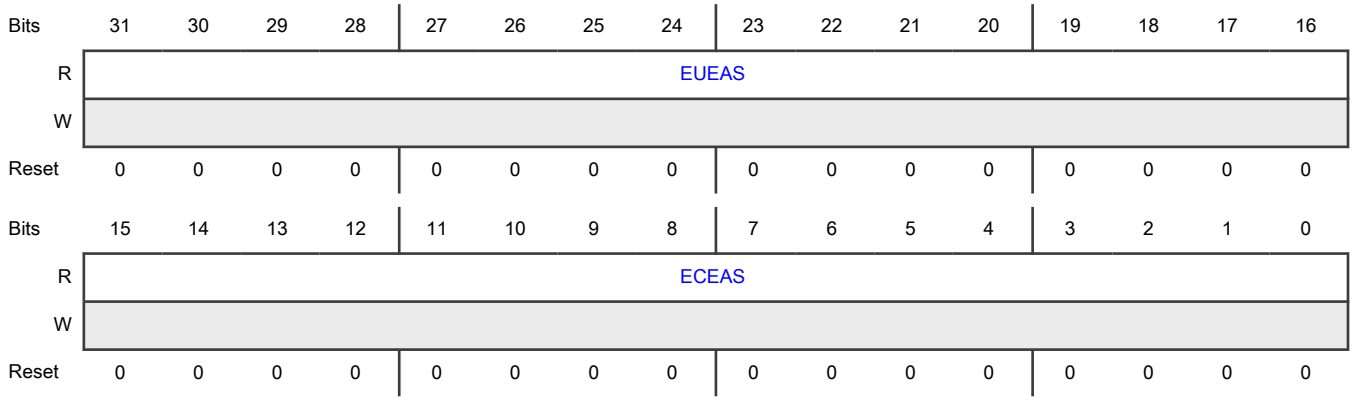
Offset

Register	Offset
MTL_ECC_Err_Addr_Status	CD4h

Function

The MTL_ECC_Err_Addr_Status register provides the memory addresses for the correctable and uncorrectable errors.

Diagram



Fields

Field	Function
31-16 EUEAS	MTL ECC Uncorrectable Error Address Status Based on the EMS field of MTL_ECC_Err_Sts_Rctl register, this field holds the respective memory's address locations for which an uncorrectable error or address mismatch is detected. - MEEAO field of MTL_ECC_Control register is 1: This field holds the last valid address of memory for which either an uncorrectable error or an address mismatch is detected. - MEEAO field of MTL_ECC_Control register is 0: This field holds the first address of the memory for which either an uncorrectable error or address mismatch is detected.
15-0 ECEAS	MTL ECC Correctable Error Address Status Based on the EMS field of MTL_ECC_Err_Sts_Rctl register, this field holds the respective memory's address locations for which a correctable error is detected. - MEEAO field of MTL_ECC_Control register is 1: This field holds the last valid address of memory for which correctable error or address mismatch is detected. - MEEAO field of MTL_ECC_Control register is 0: This field holds the first address of the memory for which correctable error is detected.

75.7.288 (MTL_ECC_Err_Cntr_Status)

Offset

Register	Offset
MTL_ECC_Err_Cntr_Status	CD8h

Function

The MTL_ECC_Err_Cntr_Status register provides ECC Error count for Correctable and uncorrectable errors.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

When set to 0, disables the parity protection for EQOS datapath. 0b - Data path Parity Protection is disabled 1b - Data path Parity Protection is enabled

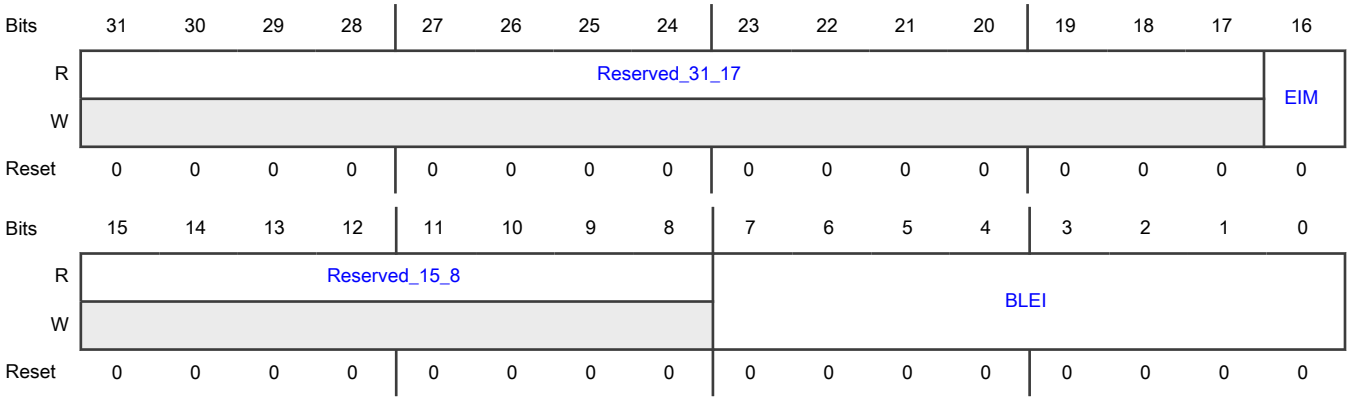
75.7.290 (MTL_DPP_ECC_EIC)

Offset

Register	Offset
MTL_DPP_ECC_EIC	CE4h

Function
The MTL_DPP_ECC_EIC establishes the operating mode of ECC/DPP error injection.

Diagram



Fields

Field	Function
31-17 Reserved_31_17	Reserved.
16 EIM	Error Injection Mode When it set to 0, indicate error injection on data; When it set to 1, indicate error injection on ECC/Parity bits(need to check the address error injection mode is disabled).
15-8 Reserved_15_8	Reserved.
7-0 BLEI	Bit Location of error injection This field indicates the bit location of DPP/ECC error injection, determination of error in Parity/ECC bits or Data (being protected) depends on the Error Injection Mode(EIM field). Depending on the interface being used for error injection not all bits of this field are valid. Example, for error injection on a 64 bit data interface this field should be programmed to a value between 63 and 0. In case of 2-bit error injection bit 0 is always included in error injection and this field should represent the second bit selection for error injection.If the second bit is programed at bit 0 when 2-bit error injection is enabled, DUT only insert 1-bit error at bit 0.

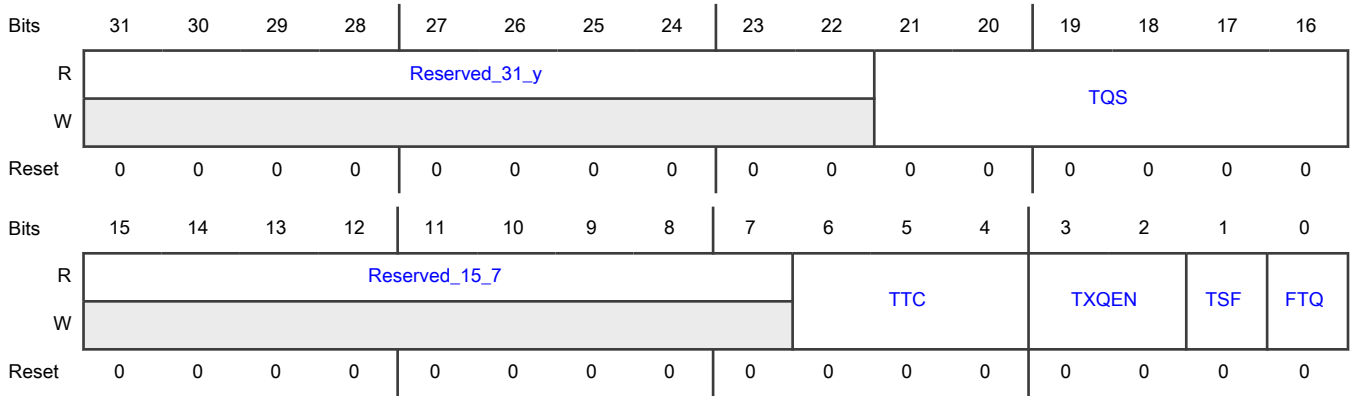
75.7.291 (MTL_TxQ0_Operation_Mode)

Offset

Register	Offset
MTL_TxQ0_Operation_Mode	D00h

Function
The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-22 Reserved_31_y	Reserved.
21-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS+1)*256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 Reserved_15_7	Reserved.
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Reserved - 2'b10: Enabled - 2'b11: Reserved This field is Read Only in Single Queue configurations and Read Write in Multiple Queue configurations. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

75.7.292 (MTL_TxQ0_Underflow)

Offset

Register	Offset
MTL_TxQ0_Underflow	D04h

Function

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Diagram

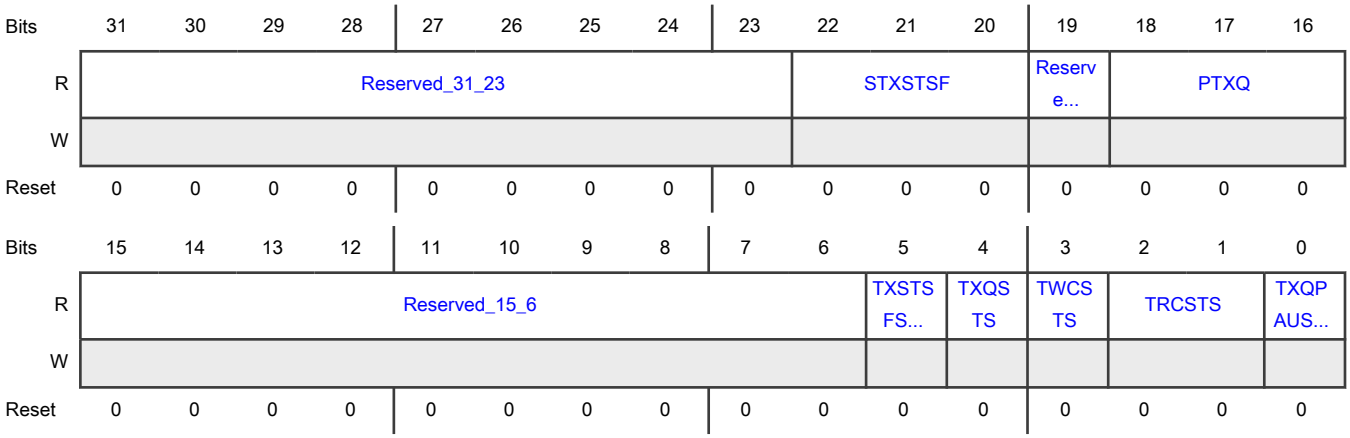
Offset

Register	Offset
MTL_TxQ0_Debug	D08h

Function

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Diagram



Fields

Field	Function
31-23 Reserved_31_23	Reserved.
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 Reserved_19	Reserved.
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 Reserved_15_6	Reserved.
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - MTL Tx Status FIFO Full status is not detected 1b - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0b - MTL Tx Queue Not Empty status is not detected 1b - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0b - MTL Tx Queue Write Controller status is not detected 1b - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending Tx Status from the MAC transmitter 11b - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802.3x Pause packet when PFC is disabled 0b - Transmit Queue in Pause status is not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Transmit Queue in Pause status is detected

75.7.294 (MTL_TxQ0_ETS_Status)

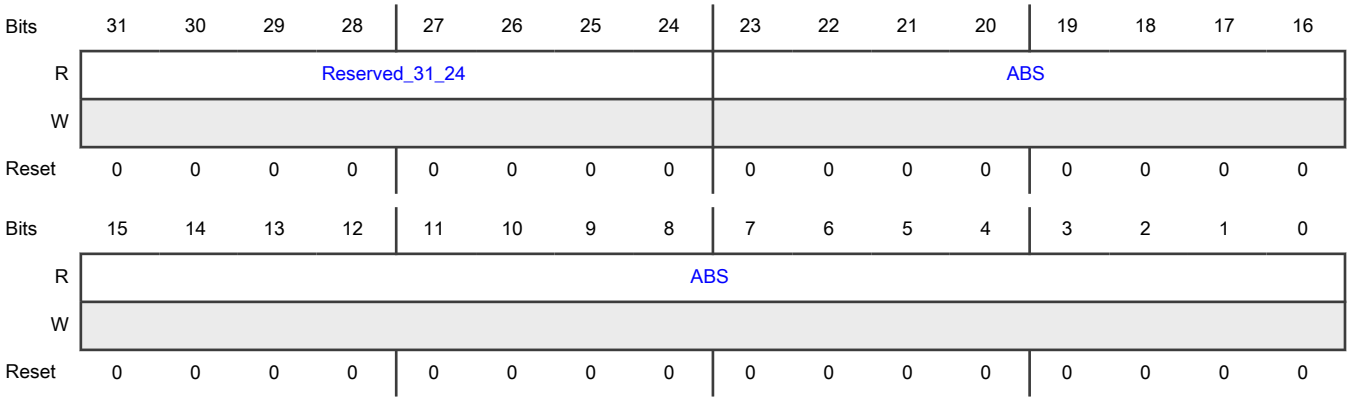
Offset

Register	Offset
MTL_TxQ0_ETS_Status	D14h

Function

The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. When the DCB operation is enabled for Queue 0, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

75.7.295 (MTL_TxQ0_Quantum_Weight)

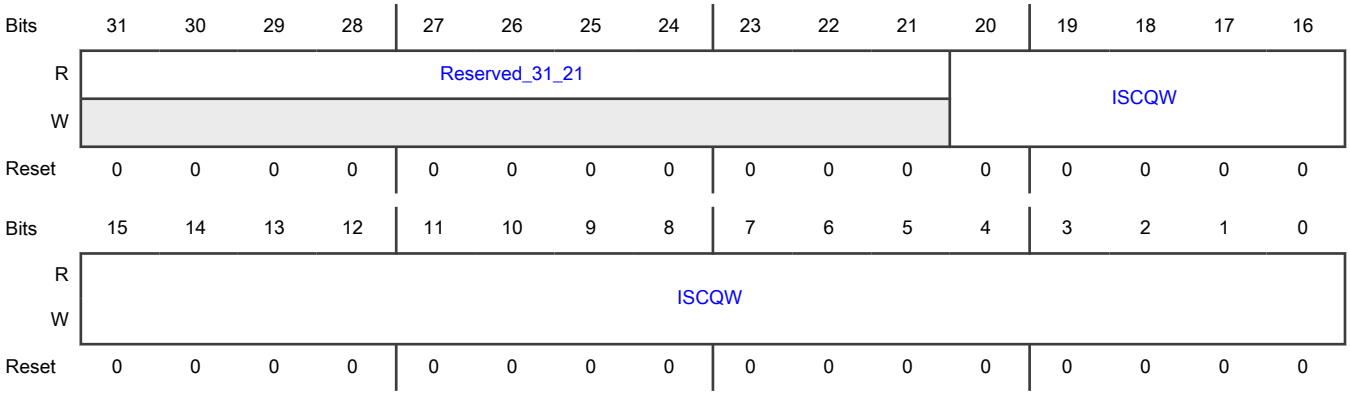
Offset

Register	Offset
MTL_TxQ0_Quantum_Weight	D18h

Function

The Queue 0 Quantum or Weights register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0.

Diagram



Fields

Field	Function
31-21 Reserved_31_21	Reserved.
20-0 ISCQW	Quantum or Weights When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights * packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

75.7.296 (MTL_Q0_Interrupt_Control_Status)

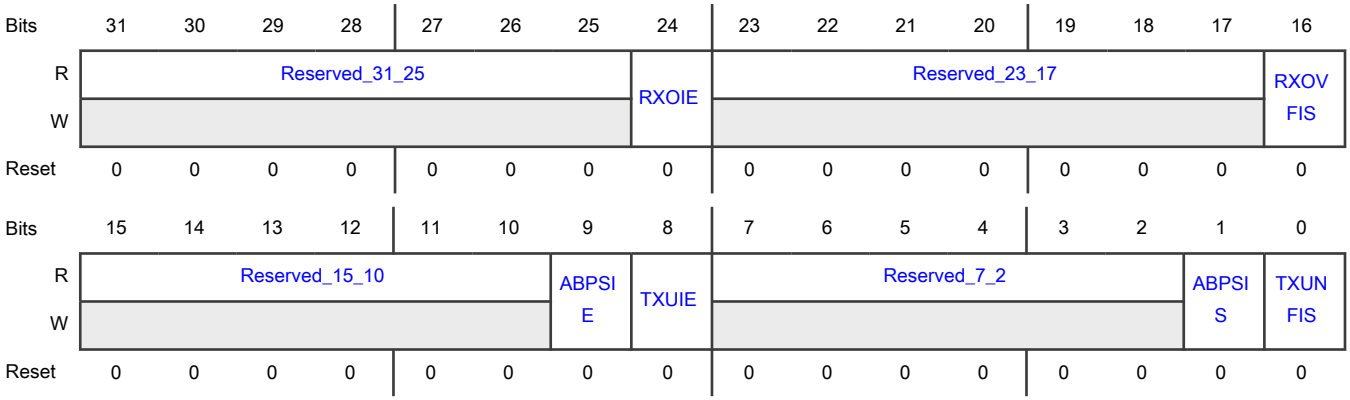
Offset

Register	Offset
MTL_Q0_Interrupt_Control_Status	D2Ch

Function

This register contains the interrupt enable and status bits for the queue 0 interrupts.

Diagram



Fields

Field	Function
31-25 Reserved_31_25	Reserved.
24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 Reserved_23_17	Reserved.
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Receive Queue Overflow Interrupt Status detected
15-10 Reserved_15_10	Reserved.
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 Reserved_7_2	Reserved.
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

75.7.297 (MTL_RxQ0_Operation_Mode)

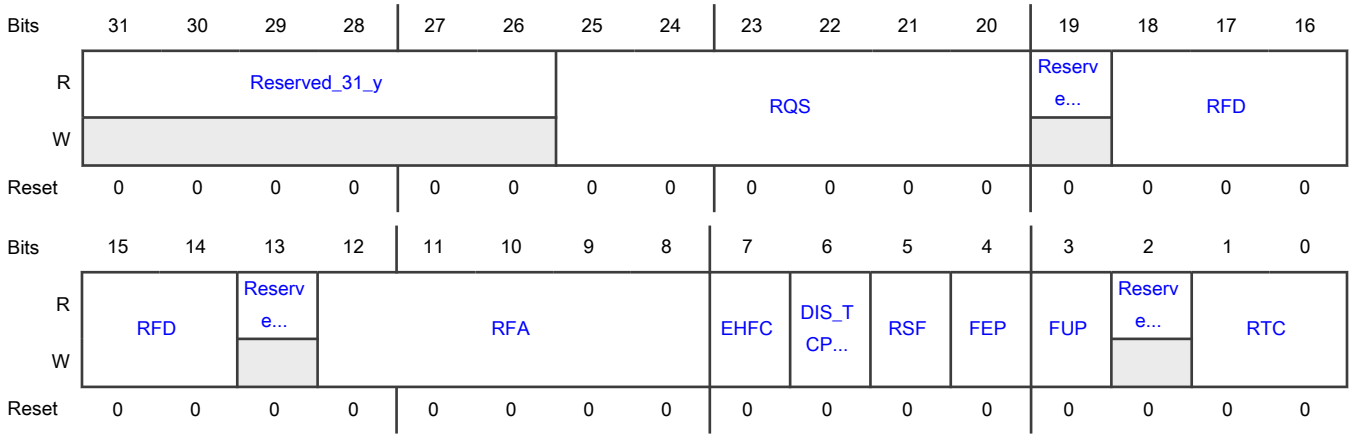
Offset

Register	Offset
MTL_RxQ0_Operation_Mode	D30h

Function

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-26 Reserved_31_y	Reserved.
25-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19 Reserved_19_y	Reserved.
18-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 30: Full minus 16 KB, that is, FULL 16 KB - 31: Full minus 16.5 KB, that is, FULL 16.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13 Reserved_13_y	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 Reserved_2	Reserved.
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are

Table continues on the next page...

Table continued from the previous page...

75.7.300 (MTL_RxQ0_Control)

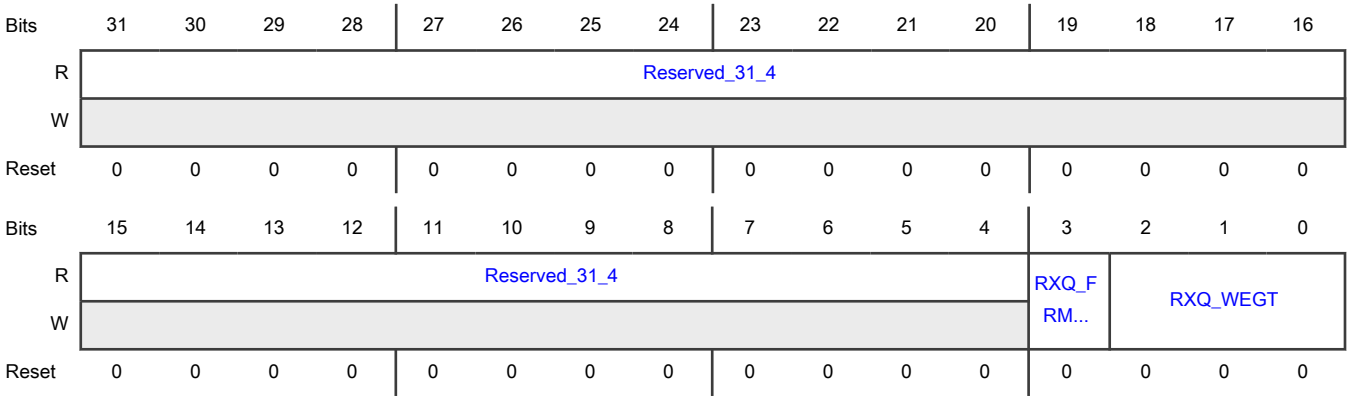
Offset

Register	Offset
MTL_RxQ0_Control	D3Ch

Function

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 Reserved_31_4	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register.

75.7.301 (MTL_TxQ1_Operation_Mode)

Offset

Table continued from the previous page...

Field	Function
21-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS+1)*256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 Reserved_15_7	Reserved.
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled

	for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

75.7.302 (MTL_TxQ1_Underflow)

Offset

Register	Offset
MTL_TxQ1_Underflow	D44h

Function

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush
