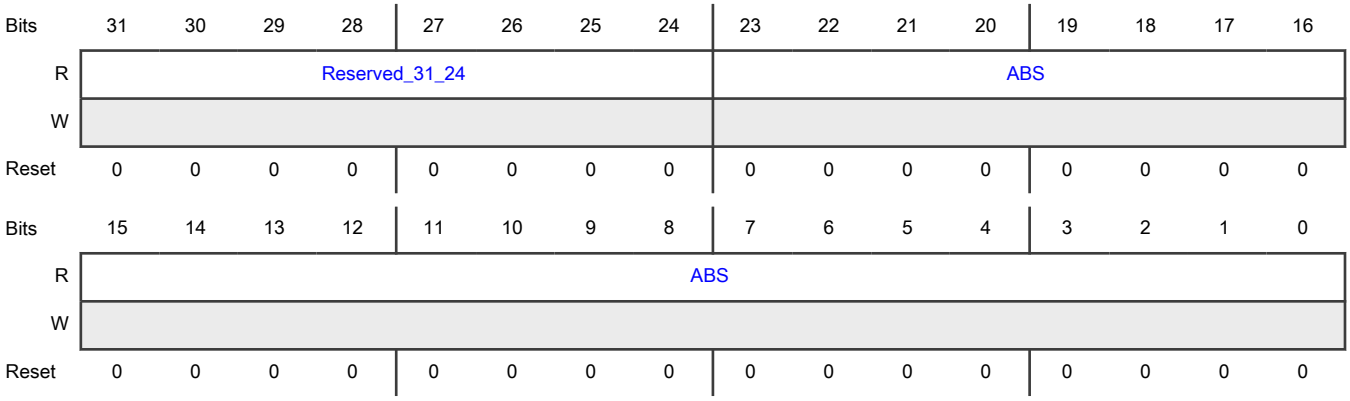
MTL_TxQ1_ETS_Status	D54h

Function

The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TxQ(#i)_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

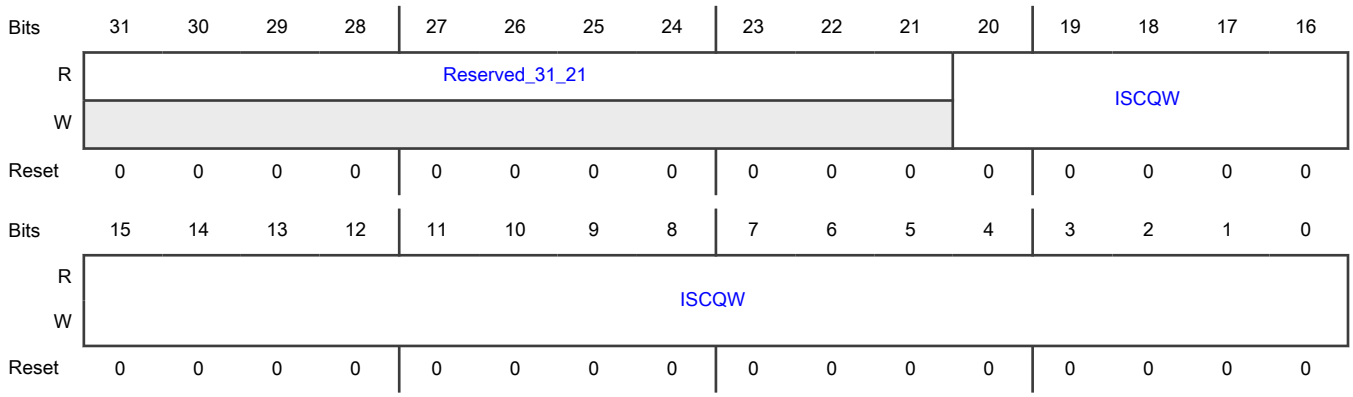
75.7.306 (MTL_TxQ1_Quantum_Weight)

Offset

Register	Offset
MTL_TxQ1_Quantum_Weight	D58h

Function
The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Diagram



Fields

Field	Function
31-21 Reserved_31_21	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

75.7.307 (MTL_TxQ1_SendSlopeCredit)

Offset

Register	Offset
MTL_TxQ1_SendSlopeCredit	D5Ch

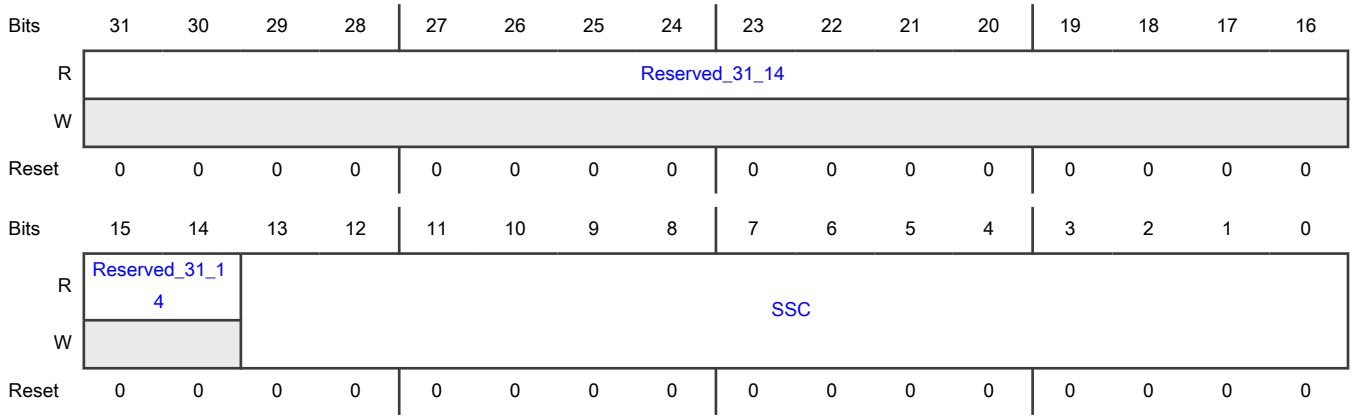
The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-14 Reserved_31_14	Reserved.
13-0 SSC	sendSlopeCredit Value When AV operation is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbps, 1000 Mbps and 2500 Mbps respectively) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. This field should be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 1 is selected for transmission.

75.7.308 (MTL_TxQ1_HiCredit)

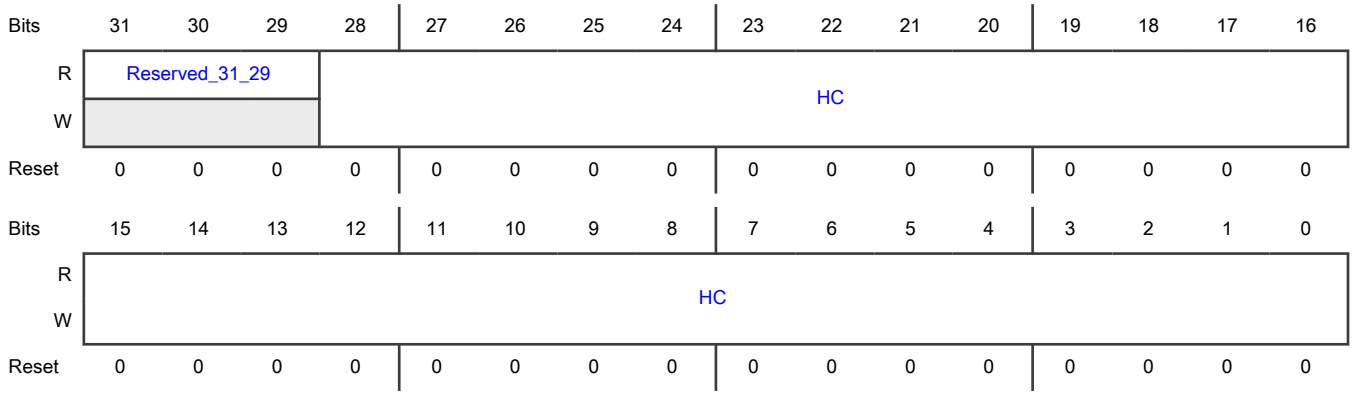
Offset

Register	Offset
MTL_TxQ1_HiCredit	D60h

Function

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28-0 HC	hiCredit Value When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

75.7.309 (MTL_TxQ1_LoCredit)

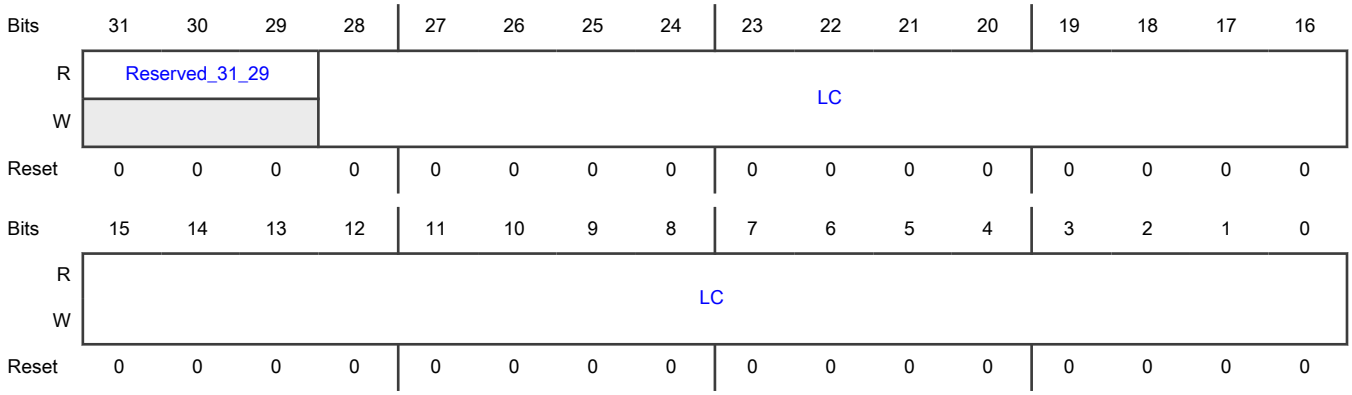
Offset

Register	Offset
MTL_TxQ1_LoCredit	D64h

Function

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28-0 LC	loCredit Value When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value to be programmed is corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.

75.7.310 (MTL_Q1_Interrupt_Control_Status)

Offset

Register	Offset
MTL_Q1_Interrupt_Control_Status	D6Ch

Field	Function
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 Reserved_7_2	Reserved.
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

75.7.311 (MTL_RxQ1_Operation_Mode)

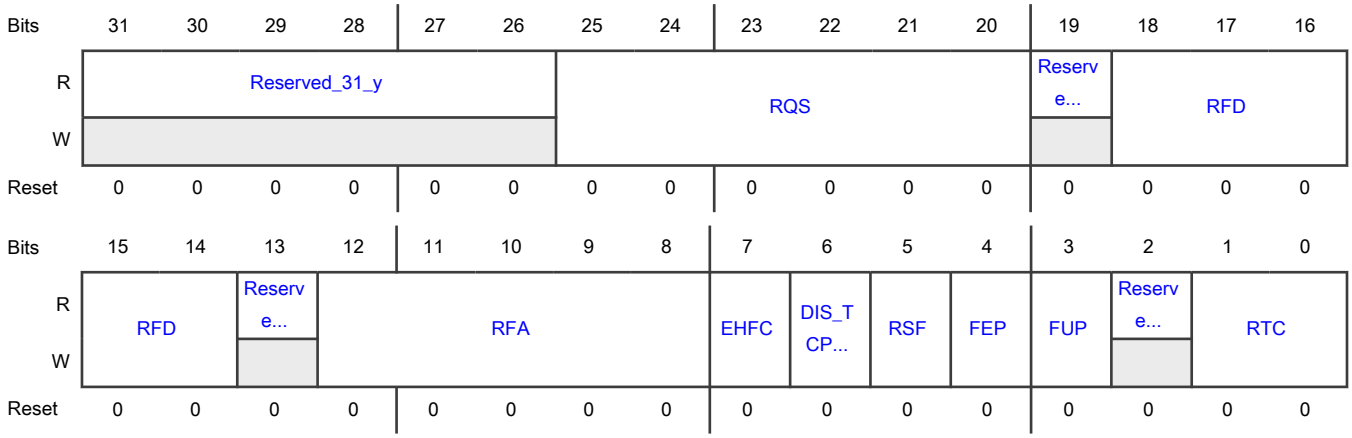
Offset

Register	Offset
MTL_RxQ1_Operation_Mode	D70h

Function

The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-26 Reserved_31_y	Reserved.
25-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19 Reserved_19_y	Reserved.
18-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 30: Full minus 16 KB, that is, FULL 16 KB - 31: Full minus 16.5 KB, that is, FULL 16.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13 Reserved_13_y	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 Reserved_2	Reserved.
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are

Table continues on the next page...

Table continued from the previous page...

Field	Function
	automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

75.7.314 (MTL_RxQ1_Control)

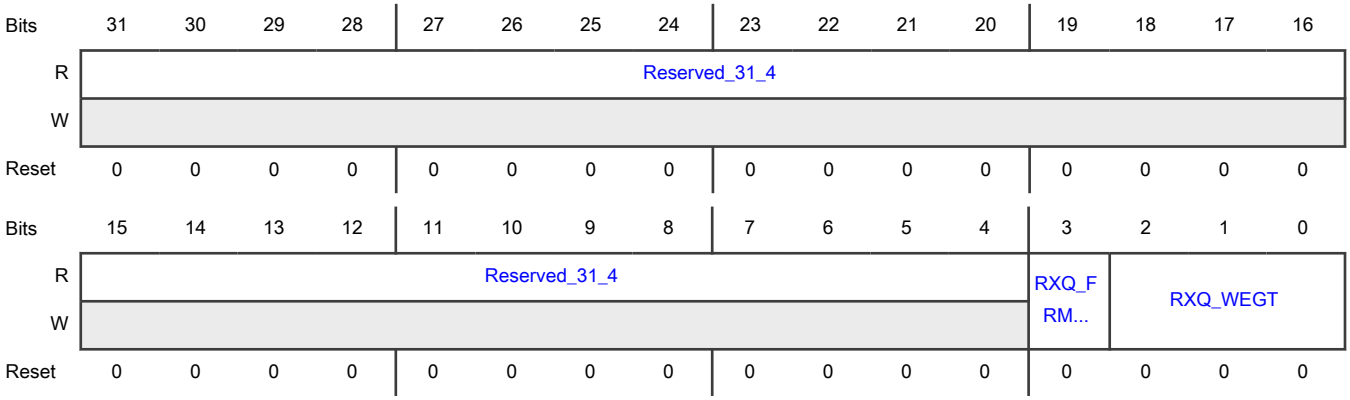
Offset

Register	Offset
MTL_RxQ1_Control	D7Ch

Function

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 Reserved_31_4	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register.

75.7.315 (MTL_TxQ2_Operation_Mode)

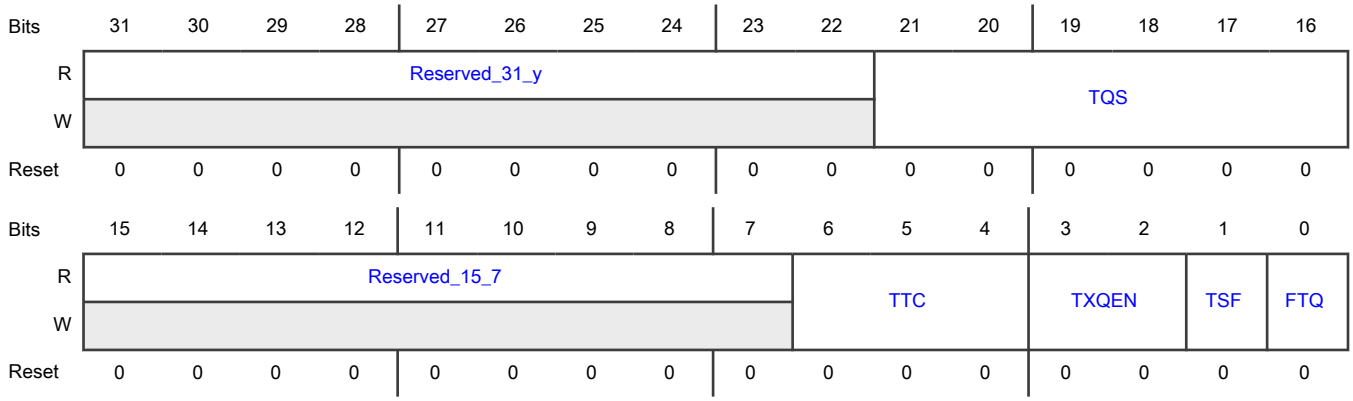
Offset

Register	Offset
MTL_TxQ2_Operation_Mode	D80h

Function

The Queue 2 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-22 Reserved_31_y	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS+1)*256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 Reserved_15_7	Reserved.
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

75.7.316 (MTL_TxQ2_Underflow)

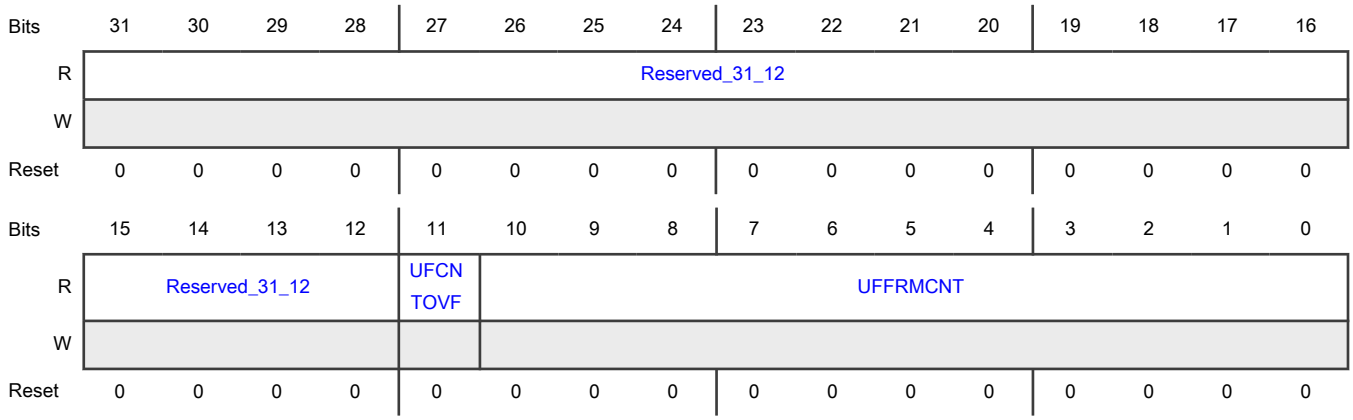
Offset

Register	Offset
MTL_TxQ2_Underflow	D84h

Function

The Queue 2 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Diagram



Fields

Field	Function
31-12 Reserved_31_12	Reserved.
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow

Table continues on the next page...

Table continued from the previous page...

Field	Function
	packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow not detected for Underflow Packet Counter 1b - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

75.7.317 (MTL_TxQ2_Debug)

Offset

Register	Offset
MTL_TxQ2_Debug	D88h

Function

The Queue 2 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Fields

Field	Function
31-23 Reserved_31_23	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 Reserved_19	Reserved.
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 Reserved_15_6	Reserved.
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - MTL Tx Status FIFO Full status is not detected 1b - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0b - MTL Tx Queue Not Empty status is not detected 1b - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0b - MTL Tx Queue Write Controller status is not detected 1b - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending Tx Status from the MAC transmitter 11b - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802.3x Pause packet when PFC is disabled 0b - Transmit Queue in Pause status is not detected 1b - Transmit Queue in Pause status is detected

75.7.318 (MTL_TxQ2_ETS_Control)

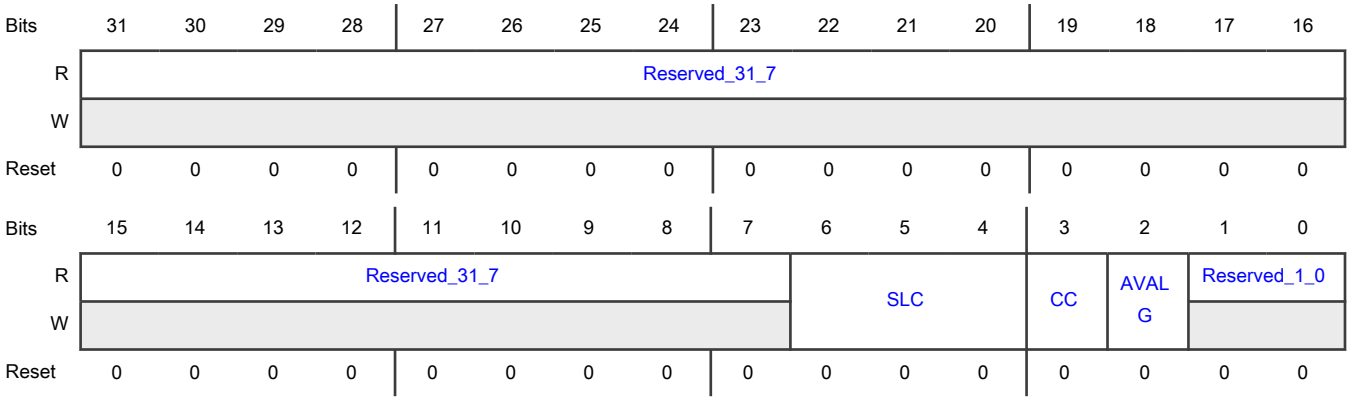
Offset

Register	Offset
MTL_TxQ2_ETS_Control	D90h

Function

The Queue ETS Control register controls the enhanced transmission selection operation.

Diagram



Fields

Field	Function
31-7 Reserved_31_7	Reserved.
6-4 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of duration programmed in DMA_CH(#i)_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TxQ(#i)_ETS_Status register, need to be computed for Queue. The encoding is as follows: 000b - 1 slot 001b - 2 slots 010b - 4 slots 011b - 8 slots 100b - 16 slots 101b - Reserved
3 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper

Table continues on the next page...

Table continued from the previous page...

Field	Function
	algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated. 0b - Credit Control is disabled 1b - Credit Control is enabled
2 AVALG	AV Algorithm When Queue 1 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected. 0b - CBS Algorithm is disabled 1b - CBS Algorithm is enabled
1-0 Reserved_1_0	Reserved.

75.7.319 (MTL_TxQ2_ETS_Status)

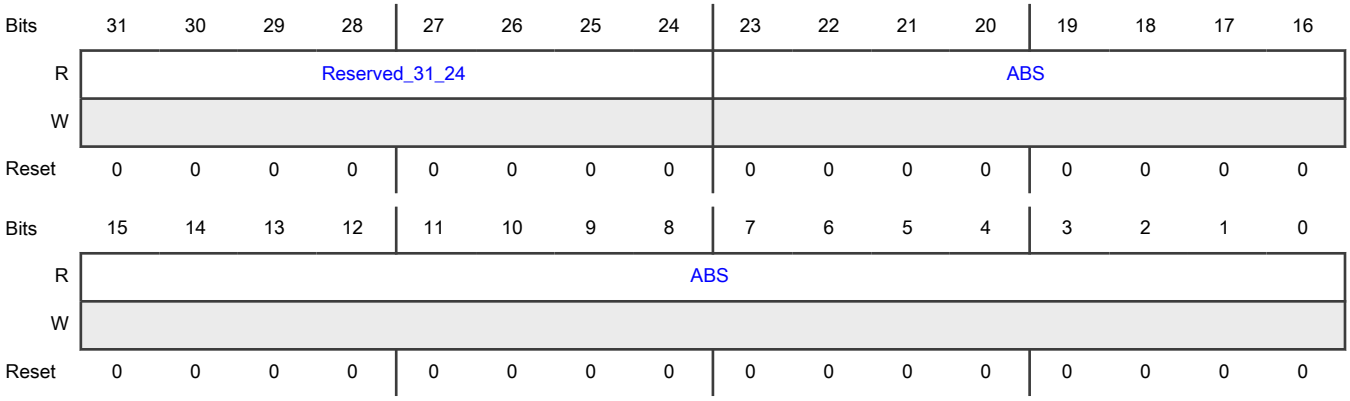
Offset

Register	Offset
MTL_TxQ2_ETS_Status	D94h

Function

The Queue 2 ETS Status register provides the average traffic transmitted in Queue 2.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TxQ(#i)_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

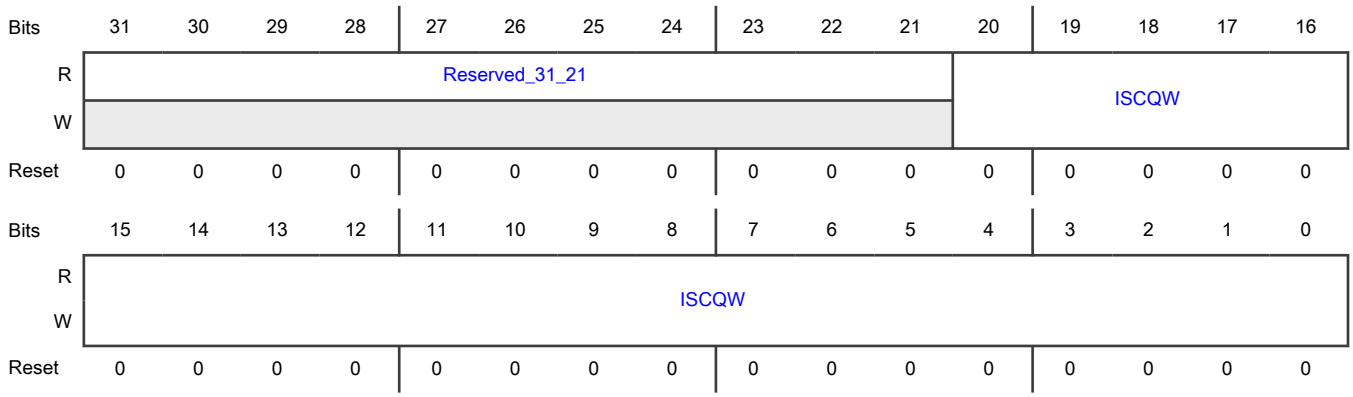
75.7.320 (MTL_TxQ2_Quantum_Weight)

Offset

Register	Offset
MTL_TxQ2_Quantum_Weight	D98h

Function
The Queue 2 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 2.

Diagram



Fields

Field	Function
31-21 Reserved_31_21	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

75.7.321 (MTL_TxQ2_SendSlopeCredit)

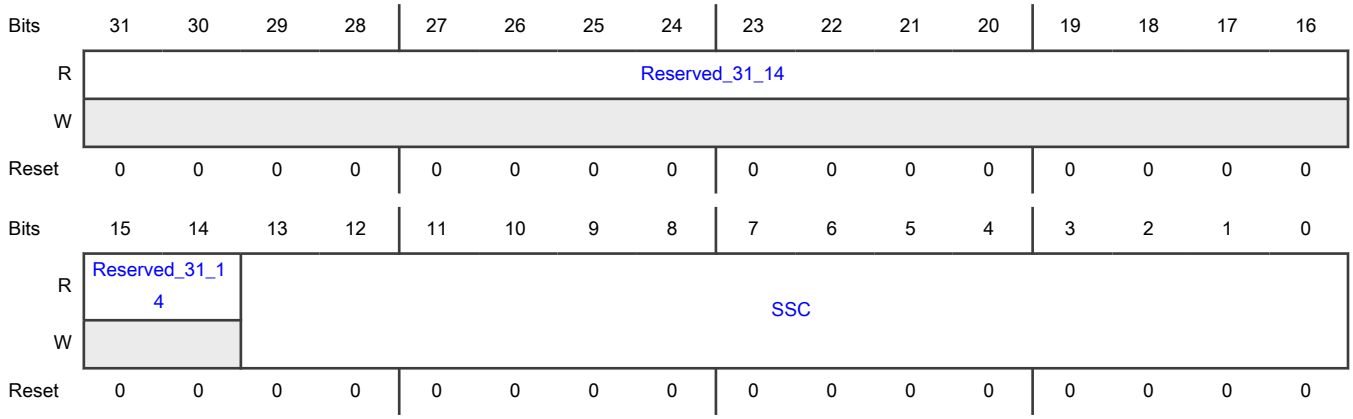
Offset

Register	Offset
MTL_TxQ2_SendSlopeCredit	D9Ch

Function

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-14 Reserved_31_14	Reserved.
13-0 SSC	sendSlopeCredit Value When AV operation is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbps, 1000 Mbps and 2500 Mbps respectively) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. This field should be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 1 is selected for transmission.

75.7.322 (MTL_TxQ2_HiCredit)

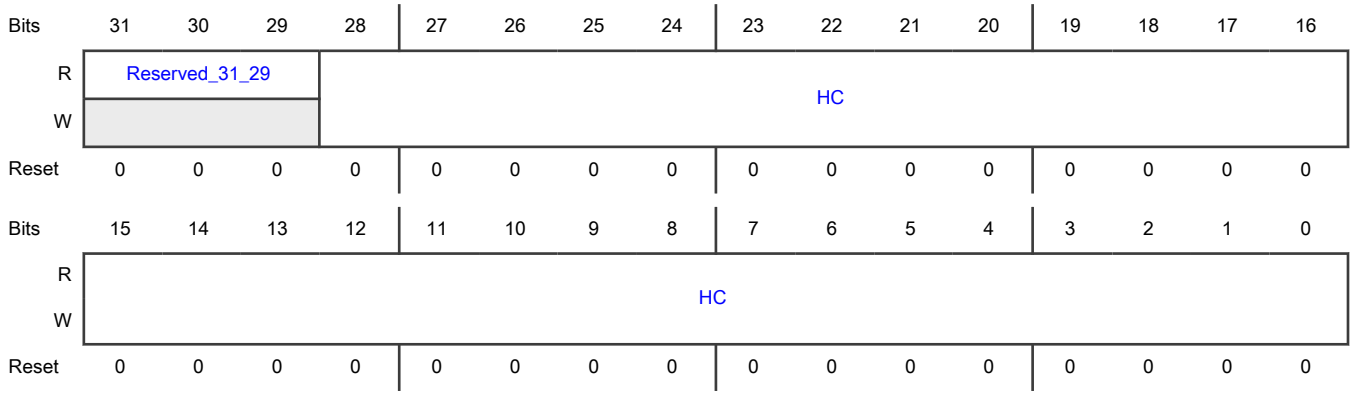
Offset

Register	Offset
MTL_TxQ2_HiCredit	DA0h

Function

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28-0 HC	hiCredit Value When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

75.7.323 (MTL_TxQ2_LoCredit)

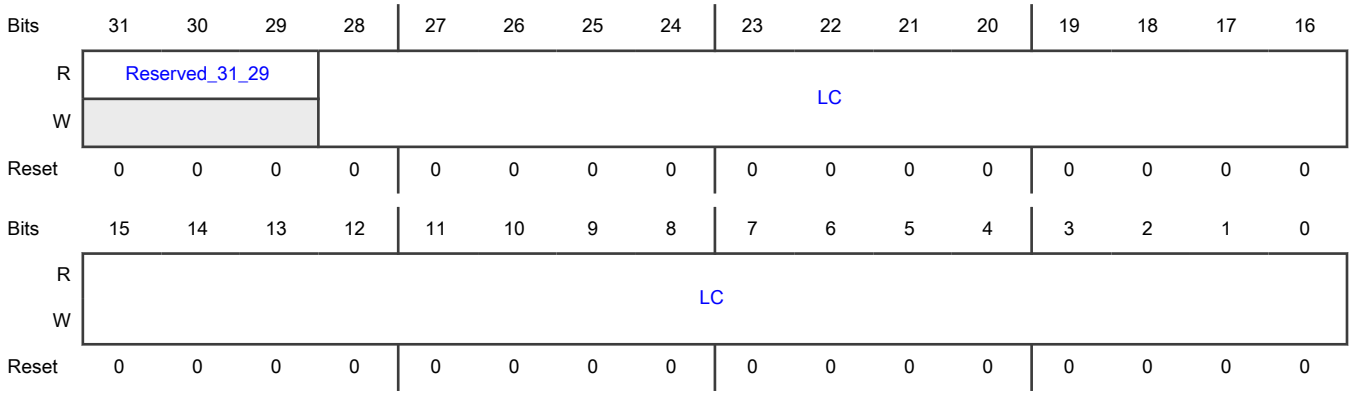
Offset

Register	Offset
MTL_TxQ2_LoCredit	DA4h

Function

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-29 Reserved_31_29	Reserved.
28-0 LC	loCredit Value When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value to be programmed is corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.

75.7.324 (MTL_Q2_Interrupt_Control_Status)

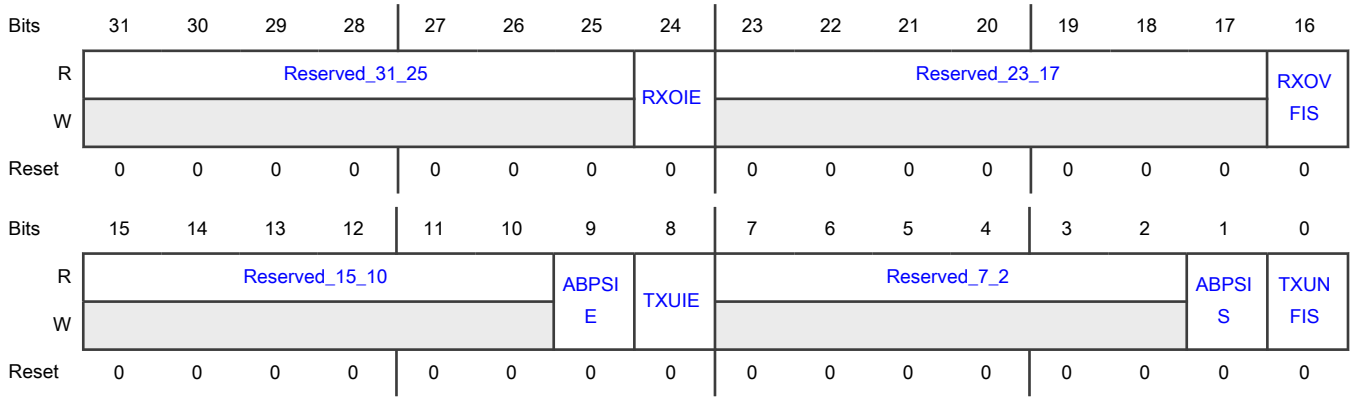
Offset

Register	Offset
MTL_Q2_Interrupt_Control_Status	DACh

Function

This register contains the interrupt enable and status bits for the queue 2 interrupts.

Diagram



Fields

Field	Function
31-25 Reserved_31_25	Reserved.
24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 Reserved_23_17	Reserved.
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected 1b - Receive Queue Overflow Interrupt Status detected
15-10 Reserved_15_10	Reserved.
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 Reserved_7_2	Reserved.
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

75.7.325 (MTL_RxQ2_Operation_Mode)

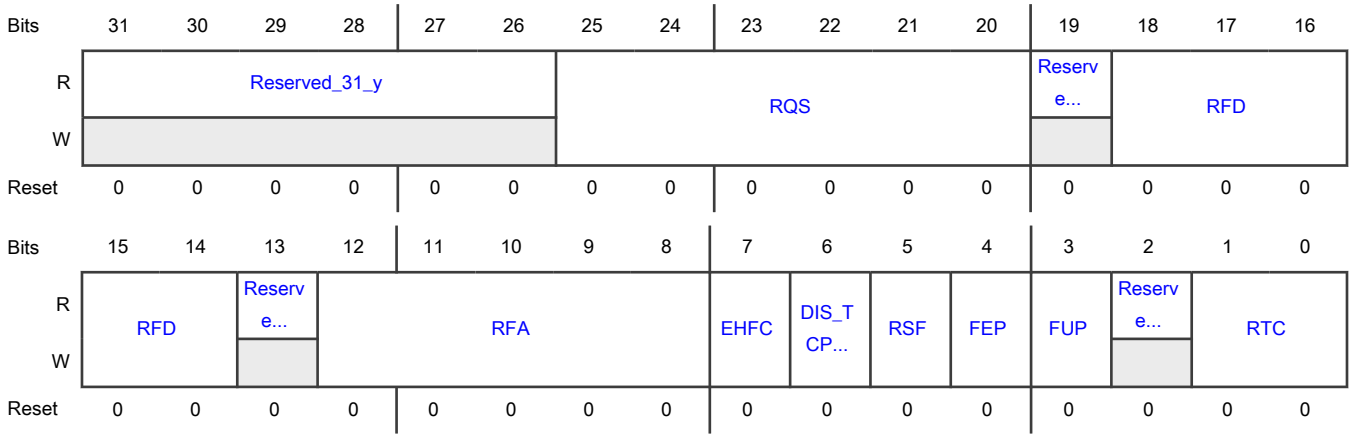
Offset

Register	Offset
MTL_RxQ2_Operation_Mode	DB0h

Function

The Queue 2 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-26 Reserved_31_y	Reserved.
25-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19 Reserved_19_y	Reserved.
18-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 30: Full minus 16 KB, that is, FULL 16 KB - 31: Full minus 16.5 KB, that is, FULL 16.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13 Reserved_13_y	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0b - Hardware Flow Control is disabled 1b - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 Reserved_2	Reserved.
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are

Table continues on the next page...

Table continued from the previous page...

Field	Function
	automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Missed Packet Counter overflow not detected 1b - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 Reserved_15_12	Reserved.
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow Counter overflow not detected 1b - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

75.7.327 (MTL_RxQ2_Debug)

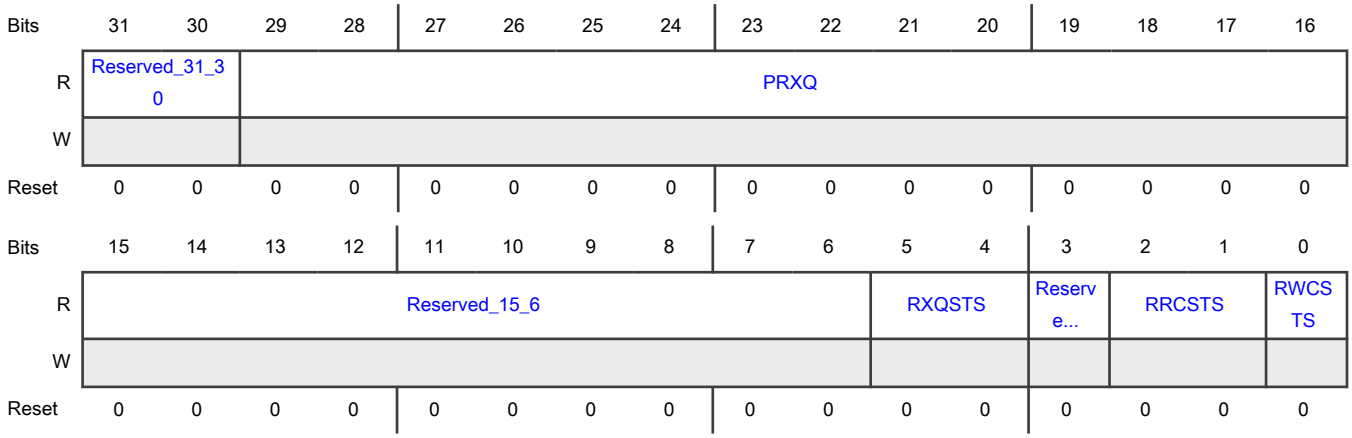
Offset

Register	Offset
MTL_RxQ2_Debug	DB8h

Function

The Queue 2 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Diagram



Fields

Field	Function
31-30 Reserved_31_30	Reserved.
29-16 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 Reserved_15_6	Reserved.
5-4 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 Reserved_3	Reserved.
2-1 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - MTL Rx Queue Write Controller Active Status not detected 1b - MTL Rx Queue Write Controller Active Status detected

75.7.328 (MTL_RxQ2_Control)

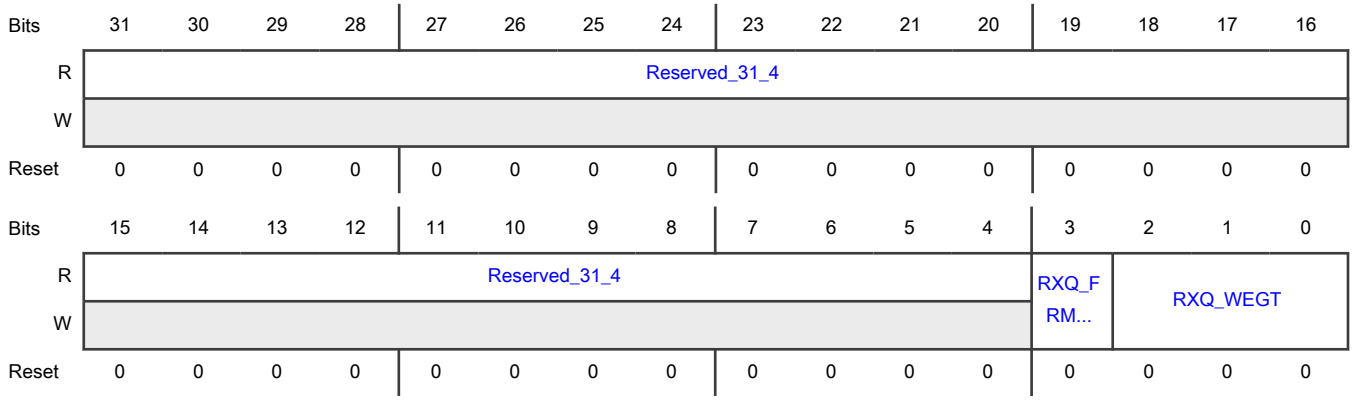
Offset

Register	Offset
MTL_RxQ2_Control	DBCh

Function

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 Reserved_31_4	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register.

75.7.329 (DMA_Mode)

Offset

Register	Offset
DMA_Mode	1000h

Function

The Bus Mode register establishes the bus operating modes for the DMA.

21-20 Reserved_TNDF	Reserved.
19 Reserved_DCHE	Reserved.
18 Reserved_18	Reserved.
17-16 INTM	Interrupt Mode This field defines the interrupt mode of DWC_ether_qos. The behavior of the following outputs change depending on the following settings: - sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) - sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) - sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status. - 00: sbd_perch_* are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. sbd_intr_o is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. - 01: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 10: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 11: Reserved For more details, see Table "DWC_ether_qos Transfer Complete Interrupt Behavior". 00b - See above description 01b - See above description 10b - See above description 11b - Reserved
15 Reserved_15	Reserved.
14-12 PR	Priority Ratio These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - The priority ratio is 1:1 001b - The priority ratio is 2:1 010b - The priority ratio is 3:1 011b - The priority ratio is 4:1 100b - The priority ratio is 5:1 101b - The priority ratio is 6:1 110b - The priority ratio is 7:1 111b - The priority ratio is 8:1
11 TXPR	Transmit Priority When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus or Descriptor reads from DCACHE memory when DWC_EQOS_DCEXT is enabled 0b - Transmit Priority is disabled 1b - Transmit Priority is enabled
10 Reserved_SCSW	Reserved.
9 ARBC	ARBC is NXP Reserved, This field must be set to "0". - This field is reserved for NXP Internal use, and must always be set to "0" unless instructed by NXP. - Setting this field to "1" might cause unexpected behavior in the IP. 0b - NXP reserved field disabled 1b - NXP reserved field enabled up on NXP request
8 Reserved_DSPW	Reserved.
7-5 Reserved_7_5	Reserved.
4-2 TAA	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 000b - Fixed priority (Channel 0 has the lowest priority and the last channel has the highest priority) 001b - Weighted Strict Priority (WSP) 010b - Weighted Round-Robin (WRR) 011b - Reserved (for 3'b011 to 3'b111)
1	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: - 0: Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the

Table continues on the next page...

Table continued from the previous page...

Field	Function
DA	paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit. - 1: Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path. 0b - Weighted Round-Robin with Rx:Tx or Tx:Rx 1b - Fixed Priority
0 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all DWC_ether_qos clock domains. Before reprogramming any DWC_ether_qos register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Software Reset is disabled 1b - Software Reset is enabled

75.7.330 (DMA_SysBus_Mode)

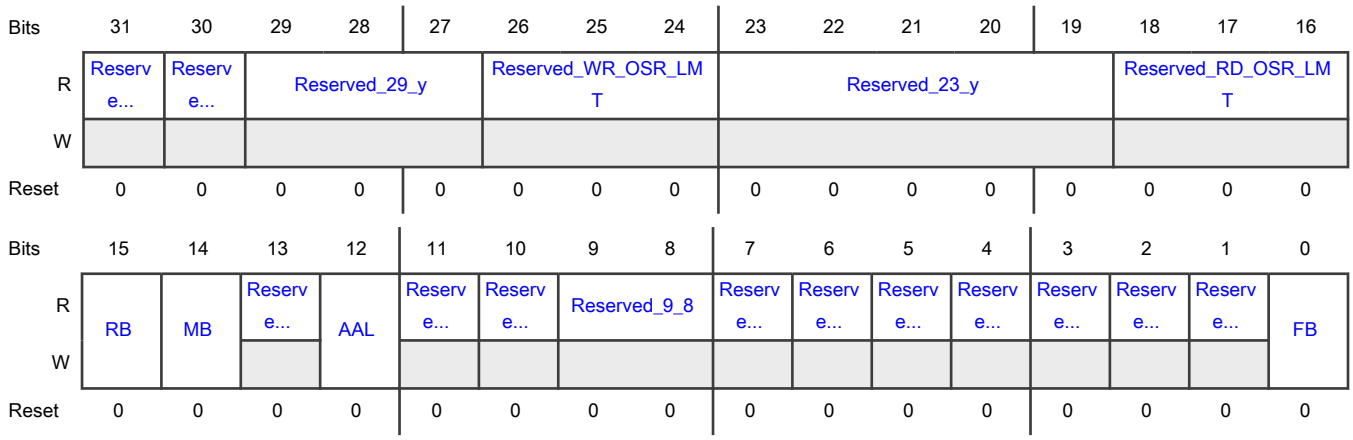
Offset

Register	Offset
DMA_SysBus_Mode	1004h

Function

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

Diagram



Fields

75.7.337 (DMA_Safety_Interrupt_Status)

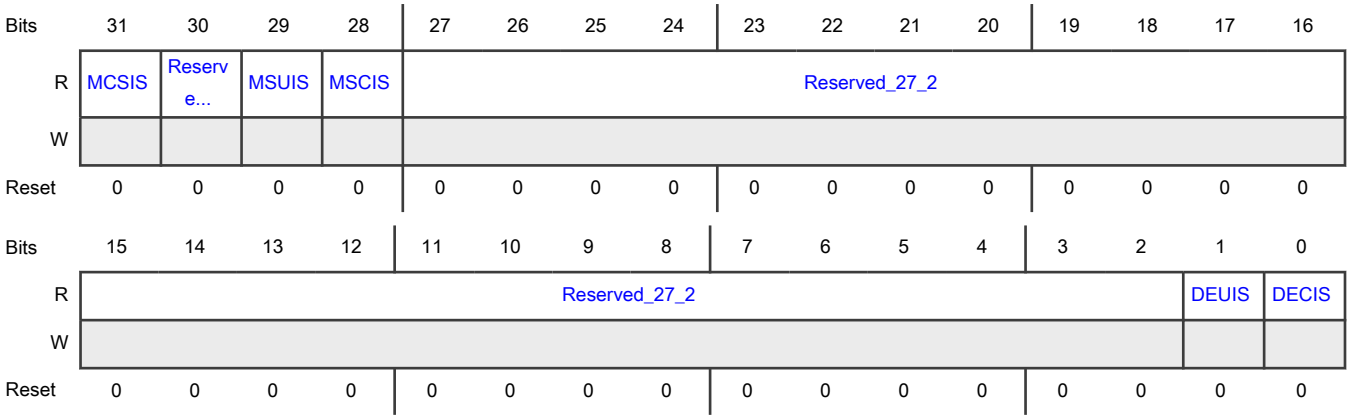
Offset

Register	Offset
DMA_Safety_Interrupt_Status	1080h

Function

This register indicates summary (whether error occured in DMA/MTL/MAC and correctable/uncorrectable) of the Automotive Safety related error interrupts.

Diagram



Fields

Field	Function
31 MCSIS	MAC Safety Uncorrectable Interrupt Status Indicates a uncorrectable Safety related Interrupt is set in the MAC module. MAC_DPP_FSM_Interrupt_Status register should be read when this bit is set, to get the cause of the Safety Interrupt in MAC. 0b - MAC Safety Uncorrectable Interrupt Status not detected 1b - MAC Safety Uncorrectable Interrupt Status detected
30 Reserved_30	Reserved.
29 MSUIS	MTL Safety Uncorrectable error Interrupt Status This bit indicates an uncorrectable error interrupt event in MTL. To get exact cause of the interrupt the software should read the MTL_Safety_Interrupt_Status register. 0b - MTL Safety Uncorrectable error Interrupt Status not detected 1b - MTL Safety Uncorrectable error Interrupt Status detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 MSCIS	MTL Safety Correctable error Interrupt Status This bit indicates a correctable error interrupt event in MTL. To get exact cause of the interrupt the software should read the MTL_Safety_Interrupt_Status register. 0b - MTL Safety Correctable error Interrupt Status not detected 1b - MTL Safety Correctable error Interrupt Status detected
27-2 Reserved_27_2	Reserved.
1 DEUIS	DMA ECC Uncorrectable error Interrupt Status This bit indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt the application should read the DMA_ECC_Interrupt_Status register. 0b - DMA ECC Uncorrectable error Interrupt Status not detected 1b - DMA ECC Uncorrectable error Interrupt Status detected
0 DECIS	DMA ECC Correctable error Interrupt Status This bit indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt the application should read the DMA_ECC_Interrupt_Status register. 0b - DMA ECC Correctable error Interrupt Status not detected 1b - DMA ECC Correctable error Interrupt Status detected

75.7.338 (DMA_CH0_Control)

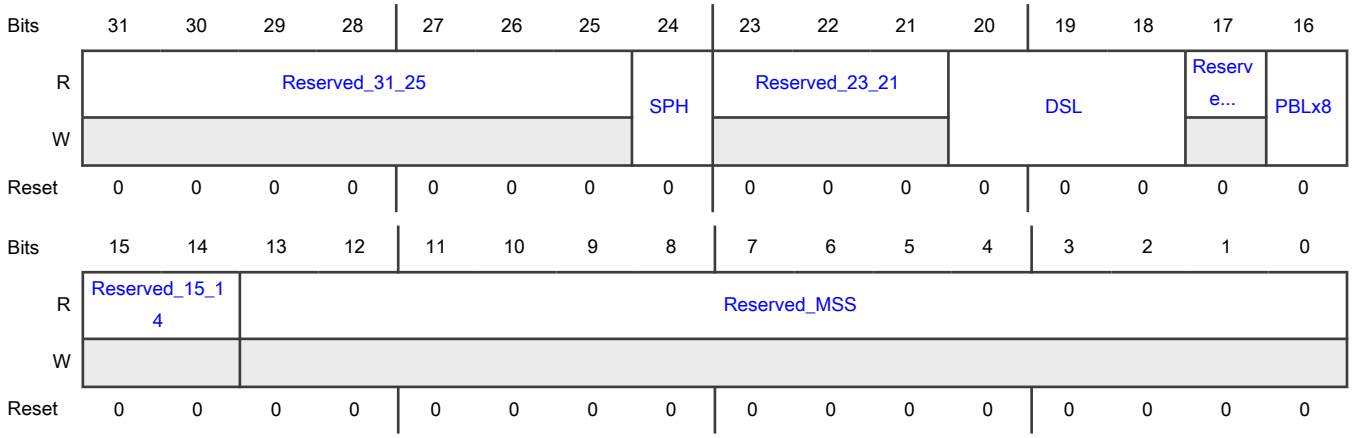
Offset

Register	Offset
DMA_CH0_Control	1100h

Function

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram



Fields

Field	Function
31-25 Reserved_31_25	Reserved.
24 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. 0b - Split Headers feature is disabled 1b - Split Headers feature is enabled
23-21 Reserved_23_21	Reserved.
20-18 DSL	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 Reserved_17	Reserved.
16 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-14 Reserved_15_14	Reserved.
13-0 Reserved_MSS	Reserved.

75.7.339 (DMA_CH0_Tx_Control)

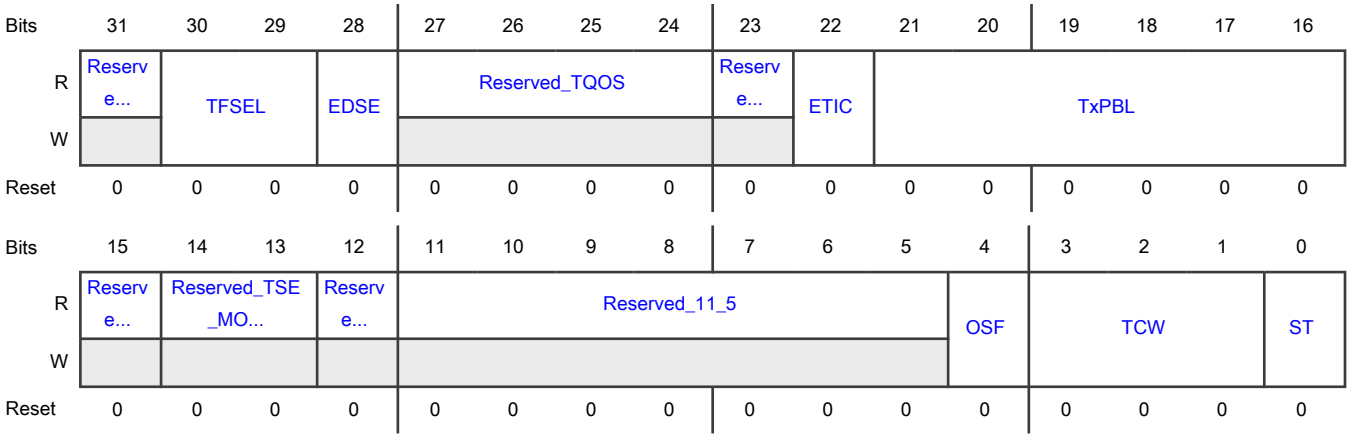
Offset

Register	Offset
DMA_CH0_Tx_Control	1104h

Function

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Diagram



Fields

Field	Function
31 Reserved_31	Reserved.
30-29 TFSEL	TBS Fetch Select Select bits for one of the four DMA_TBS_CTRL register fields (FTOS,FGSN,FTOV) for the channel Values: - 2'b00: DMA_TBS_CTRL0 - 2'b01: DMA_TBS_CTRL1 - 2'b10: DMA_TBS_CTRL2 - 2'b11: DMA_TBS_CTRL3 (Reserved if DWC_EQOS_NUM_DMA_TX_CH=3)

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes. 0b - Enhanced Descriptor is disabled 1b - Enhanced Descriptor is enabled
27-24 Reserved_TQOS	Reserved.
23 Reserved_23	Reserved.
22 ETIC	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 Reserved_IPBL	Reserved.
14-13 Reserved_TSE_MODE	Reserved.
12 Reserved_TSE	Reserved.
11-5 Reserved_11_5	Reserved.
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

75.7.340 (DMA_CH0_Rx_Control)

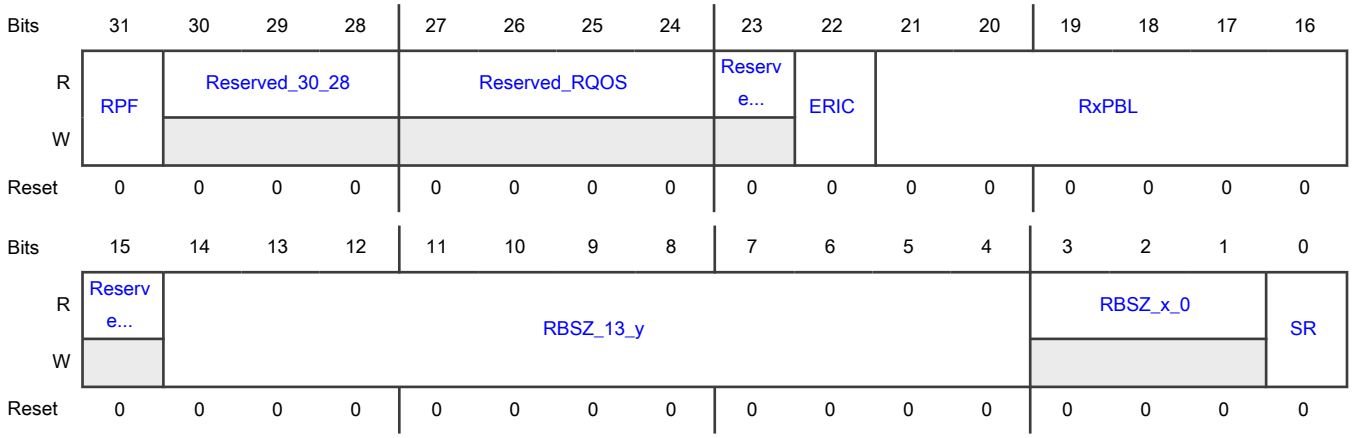
Offset

Register	Offset
DMA_CH0_Rx_Control	1108h

Function

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush. - 1: DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing is done on the Read side of the Rx Queue. - 0: DWC_ether_qos does not flush the packet in the Rx Queue destined to this RxDMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding RxQueue. Note: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in any DMA_CH(#i)_Rx_Control register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 Reserved_30_28	Reserved.
27-24 Reserved_RQOS	Reserved.
23 Reserved_23	Reserved.
22 ERIC	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after the completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA. 0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 Reserved_15	Reserved.
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. - The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

75.7.341 (DMA_CH0_TxDesc_List_Address)

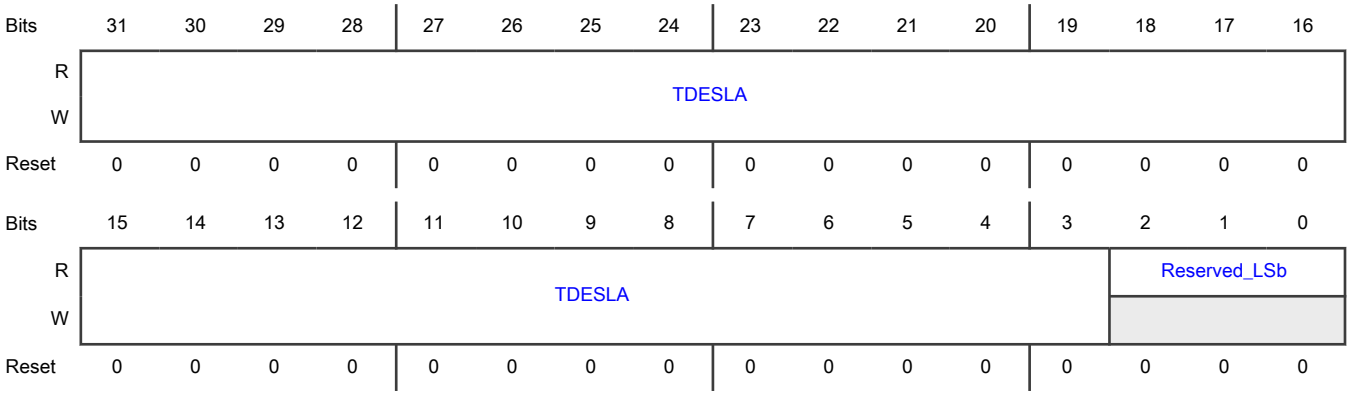
Offset

Register	Offset
DMA_CH0_TxDesc_List_Address	1114h

Function

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Diagram



Fields

Field	Function
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.342 (DMA_CH0_RxDesc_List_Address)

Offset

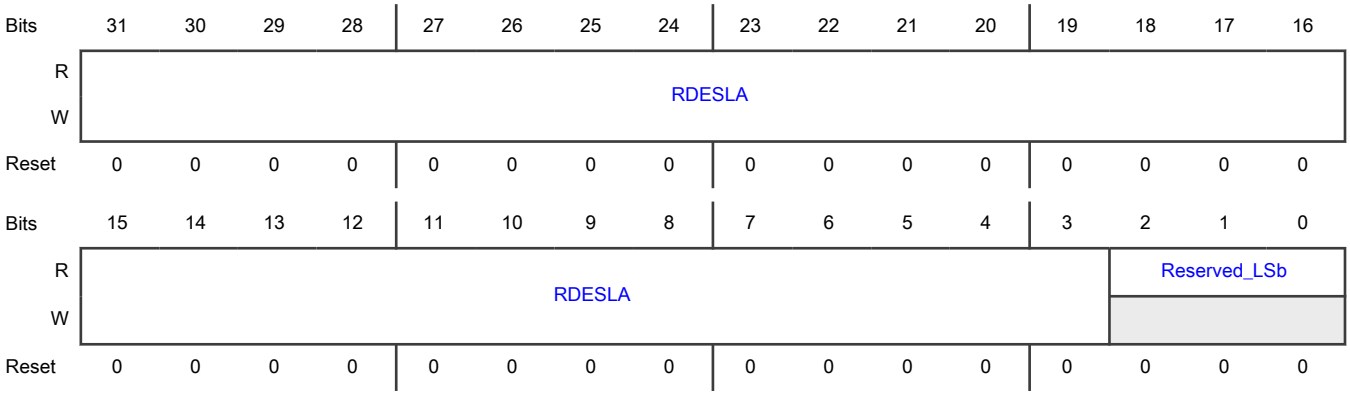
Register	Offset
DMA_CH0_RxDesc_List_Address	111Ch

Function

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only

when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-3 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.343 (DMA_CH0_TxDesc_Tail_Pointer)

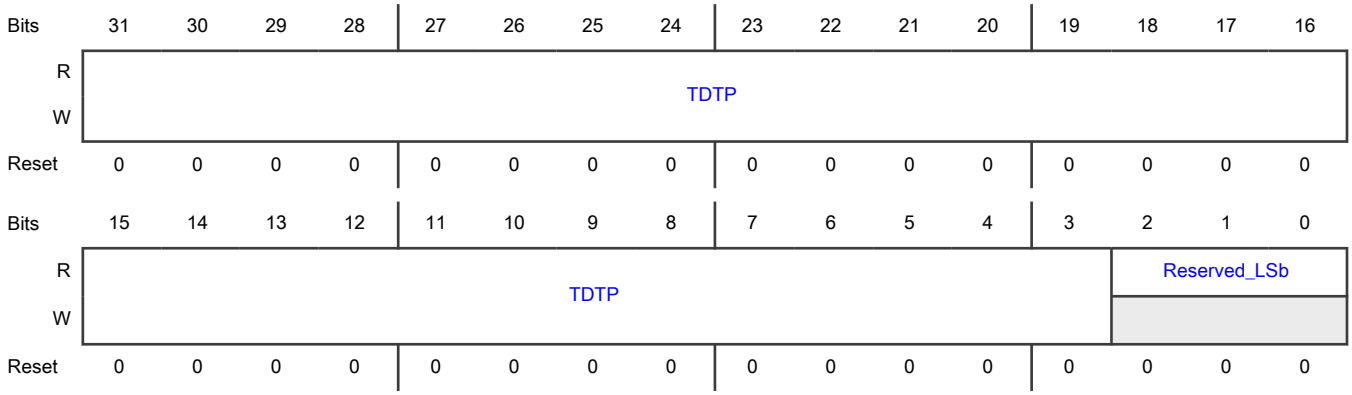
Offset

Register	Offset
DMA_CH0_TxDesc_Tail_Pointer	1120h

Function

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-3 TDTP	Transmit Descriptor Tail Pointer This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.344 (DMA_CH0_RxDesc_Tail_Pointer)

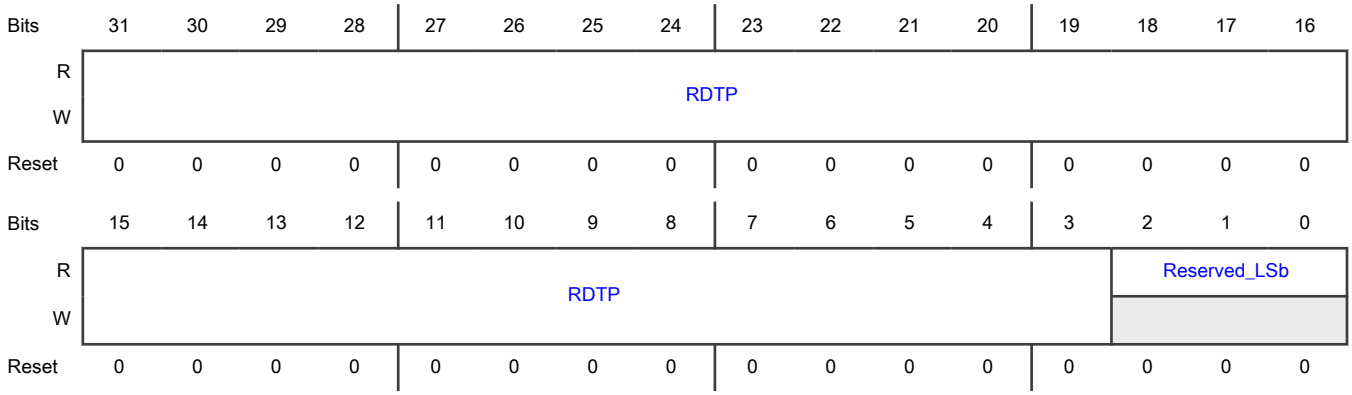
Offset

Register	Offset
DMA_CH0_RxDesc_Tail_Pointer	1128h

Function

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-3 RDTP	Receive Descriptor Tail Pointer This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.345 (DMA_CH0_TxDesc_Ring_Length)

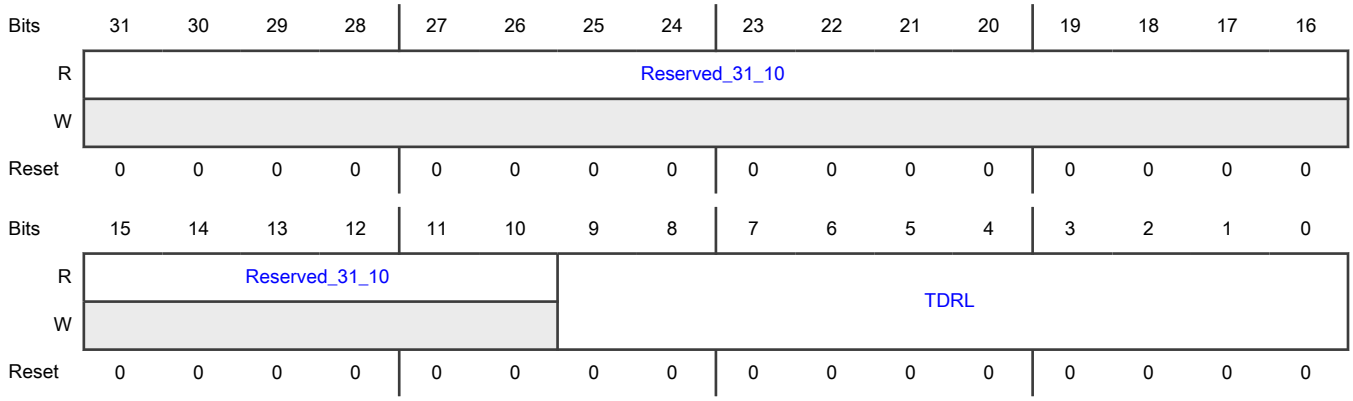
Offset

Register	Offset
DMA_CH0_TxDesc_Ring_Length	112Ch

Function

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Diagram



Fields

Field	Function
31-10 Reserved_31_10	Reserved.
9-0 TDRL	Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. NXP recommends a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

75.7.346 (DMA_CH0_Rx_Control2)

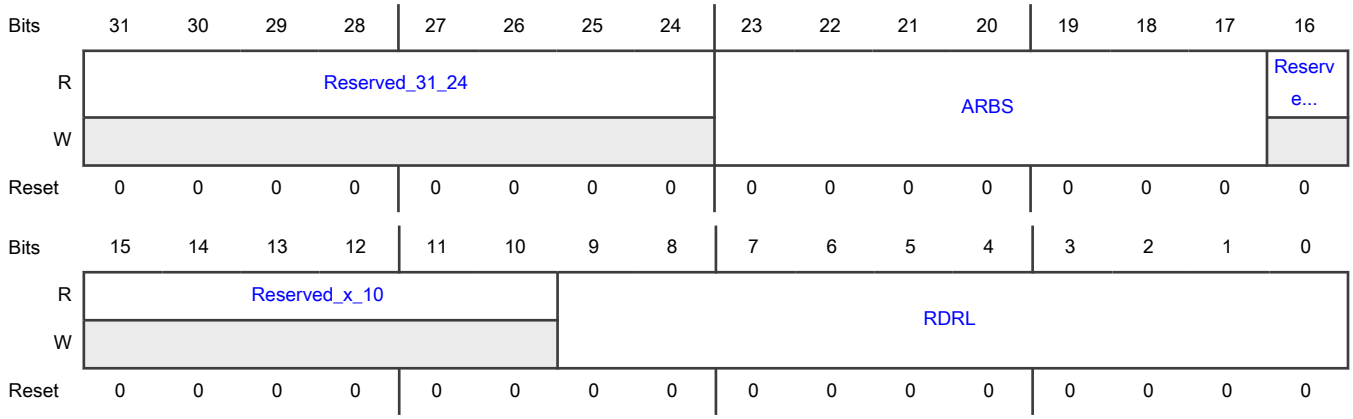
Offset

Register	Offset
DMA_CH0_Rx_Control2	1130h

Function

The Channeli Receive Control register controls the Rx features such as Rx Descriptor Ring Length and Alternate Rx Buffer Size.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-17 ARBS	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CH(#i)_Rx_Control. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively)
16-10 Reserved_x_10	Reserved.
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

75.7.347 (DMA_CH0_Interrupt_Enable)

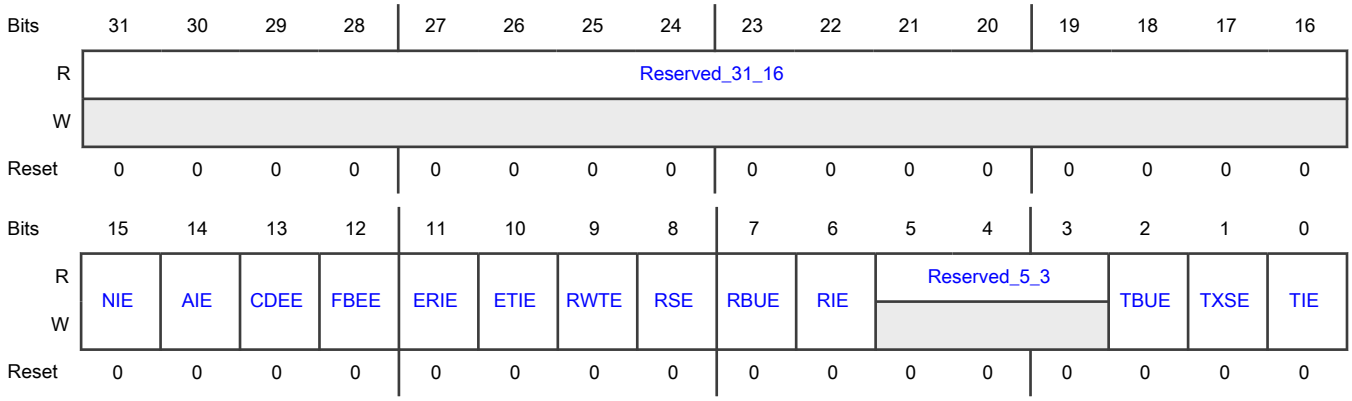
Offset

Register	Offset
DMA_CH0_Interrupt_Enable	1134h

Function

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled. 0b - Normal Interrupt Summary is disabled 1b - Normal Interrupt Summary is enabled
14 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: - Bit 1: Transmit Process Stopped - Bit 7: Rx Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 9: Receive Watchdog Timeout - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled. 0b - Abnormal Interrupt Summary is disabled 1b - Abnormal Interrupt Summary is enabled
13 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled. 0b - Context Descriptor Error is disabled 1b - Context Descriptor Error is enabled
12 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled. 0b - Fatal Bus Error is disabled 1b - Fatal Bus Error is enabled
11	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Table continues on the next page...

Table continued from the previous page...

75.7.348 (DMA_CH0_Rx_Interrupt_Watchdog_Timer)

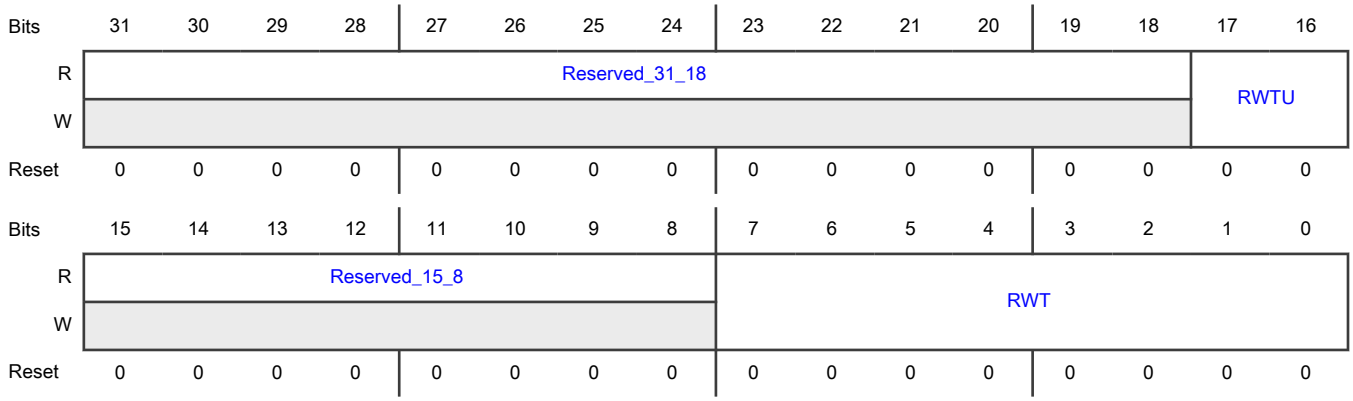
Offset

Register	Offset
DMA_CH0_Rx_Interrupt_Watchdog_Timer	1138h

Function

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 Reserved_31_18	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 Reserved_15_8	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

75.7.349 (DMA_CH0_Slot_Function_Control_Status)

Offset

Register	Offset
DMA_CH0_Slot_Function_Control_Status	113Ch

Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved_31_20												RSN			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 Reserved_31_20	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 Reserved_3_2	Reserved.
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

75.7.350 (DMA_CH0_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH0_Current_App_TxDesc	1144h

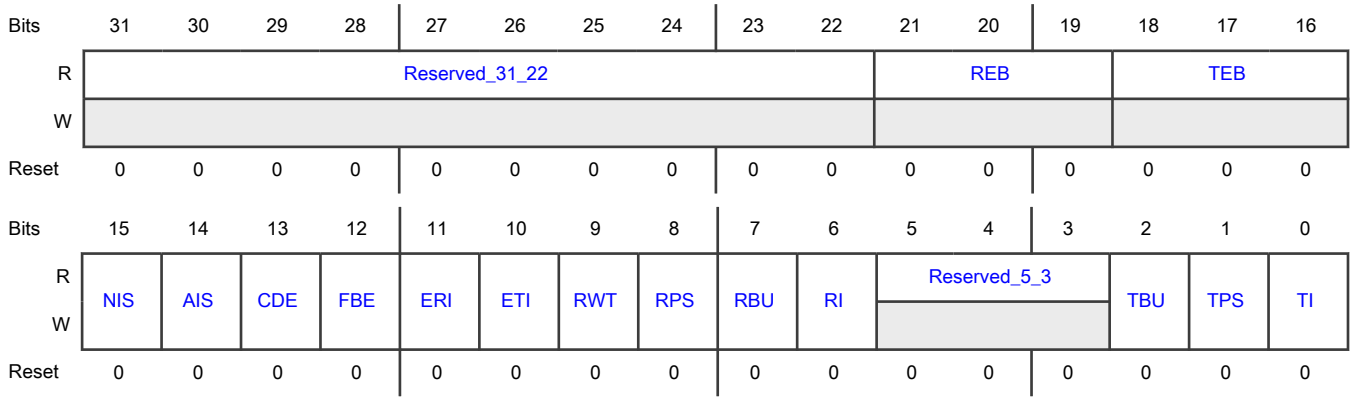
75.7.354 (DMA_CH0_Status)

Offset

Register	Offset
DMA_CH0_Status	1160h

Function
The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Diagram



Fields

Field	Function
31-22 Reserved_31_22	Reserved.
21-19 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 21 -- 1'b1: Error during data transfer by Rx DMA -- 1'b0: No Error during data transfer by Rx DMA - Bit 20 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configurations supporting ERIC, - ERIC = 0: This bit is set only after the Rx DMA has completely filled up a receive buffer with packet data. - ERIC = 1: This bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configurations supporting ERIC: - ETIC = 0: This bit is set only after the Tx DMA has transferred a complete packet to MTL. - ETIC = 1: This bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC = 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing

Table continues on the next page...

Table continued from the previous page...

Field	Function
RBU	Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 Reserved_5_3	Reserved.
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: - Change the ownership of the descriptor by setting Bit 31 of TDES3. - Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

75.7.355 (DMA_CH0_Miss_Frame_Cnt)

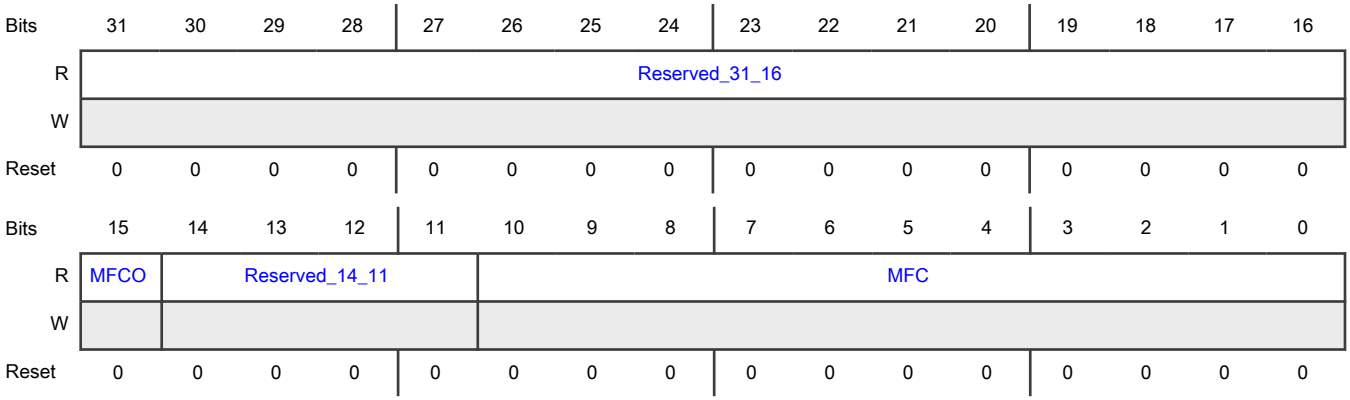
Offset

Register	Offset
DMA_CH0_Miss_Frame_Cnt	1164h

Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 Reserved_14_11	Reserved.
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

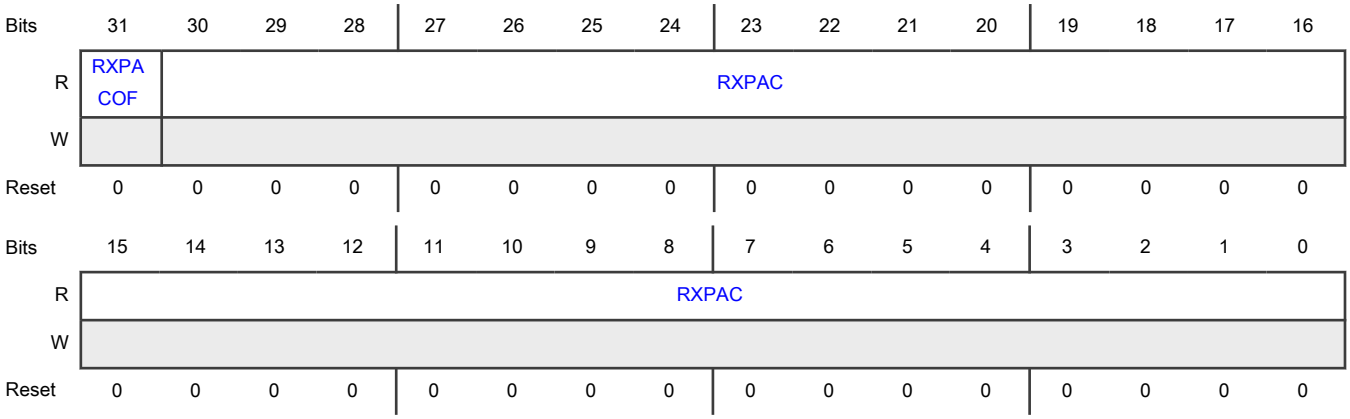
75.7.356 (DMA_CH0_RXP_Accept_Cnt)

Offset

Register	Offset
DMA_CH0_RXP_Accept_Cnt	1168h

Function
The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Diagram



Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Accept Counter overflow not occurred 1b - Rx Parser Accept Counter overflow occurred
30-0 RXPAC	Rx Parser Accept Counter This 31-bit counter is implemented when a Rx Parser Accept a packet due to AF =1. The counter is cleared when the register is read.

75.7.357 (DMA_CH0_RX_ERI_Cnt)

Offset

Register	Offset
DMA_CH0_RX_ERI_Cnt	116Ch

Function
The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Diagram

31-12 Reserved_31_12	Reserved.
11-0 ECNT	ERI Counter When ERIC bit of DMA_CH(#i)_RX_Control register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter is reset at the start of new packet.

75.7.358 (DMA_CH1_Control)

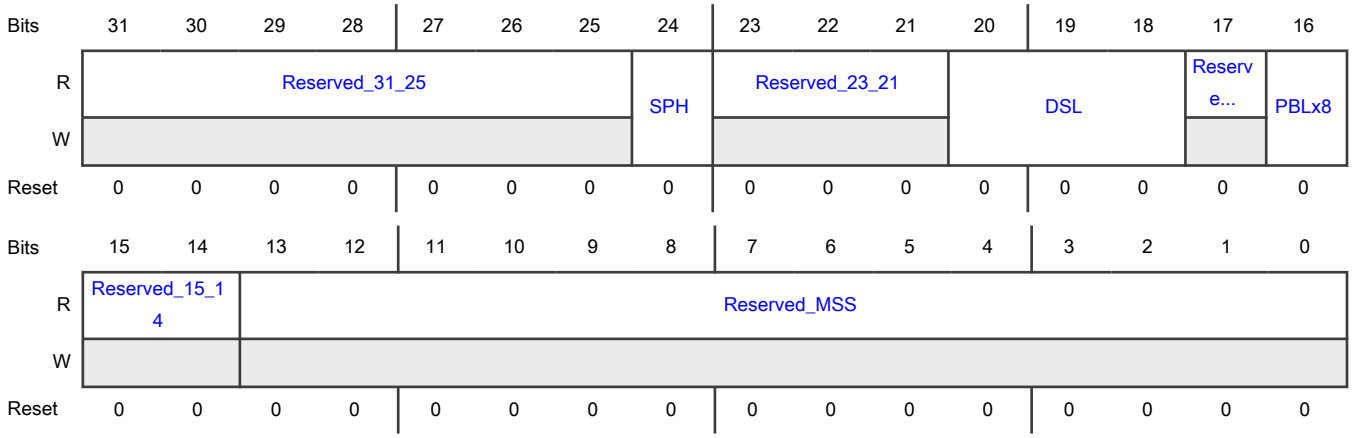
Offset

Register	Offset
DMA_CH1_Control	1180h

Function

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram



Fields

Field	Function
31-25 Reserved_31_25	Reserved.
24 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. 0b - Split Headers feature is disabled 1b - Split Headers feature is enabled
23-21 Reserved_23_21	Reserved.
20-18 DSL	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 Reserved_17	Reserved.
16 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled

Table continues on the next page...

Table continued from the previous page...

15-14 Reserved_15_14	Reserved.
13-0 Reserved_MSS	Reserved.

75.7.359 (DMA_CH1_Tx_Control)

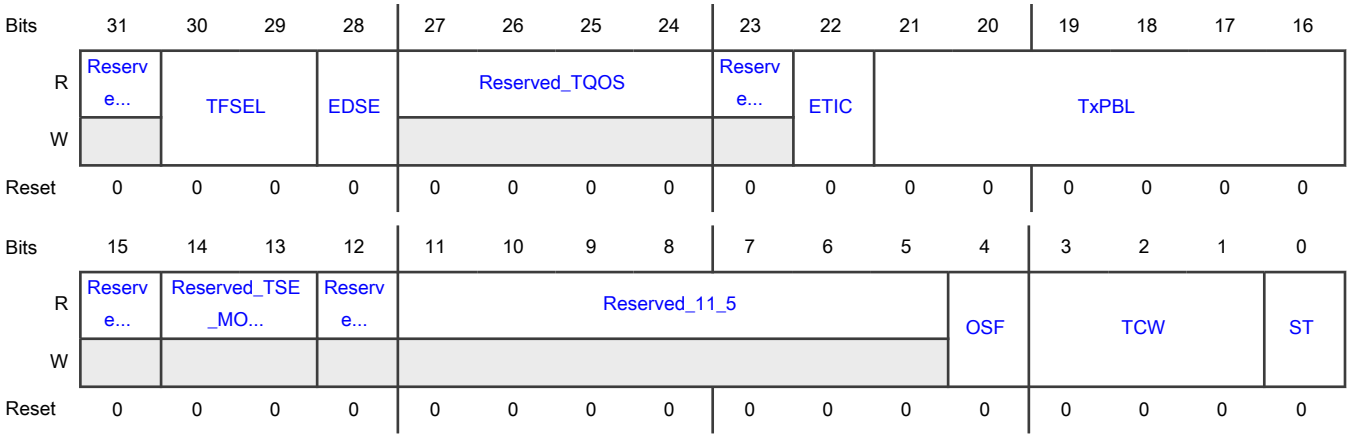
Offset

Register	Offset
DMA_CH1_Tx_Control	1184h

Function

The DMA Channeli Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Diagram



Fields

Field	Function
31 Reserved_31	Reserved.
30-29 TFSEL	TBS Fetch Select Select bits for one of the four DMA_TBS_CTRL register fields (FTOS,FGSN,FTOV) for the channel Values: - 2'b00: DMA_TBS_CTRL0 - 2'b01: DMA_TBS_CTRL1 - 2'b10: DMA_TBS_CTRL2 - 2'b11: DMA_TBS_CTRL3 (Reserved if DWC_EQOS_NUM_DMA_TX_CH=3)

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes. 0b - Enhanced Descriptor is disabled 1b - Enhanced Descriptor is enabled
27-24 Reserved_TQOS	Reserved.
23 Reserved_23	Reserved.
22 ETIC	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 Reserved_IPBL	Reserved.
14-13 Reserved_TSE_MODE	Reserved.
12 Reserved_TSE	Reserved.
11-5 Reserved_11_5	Reserved.
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

75.7.360 (DMA_CH1_Rx_Control)

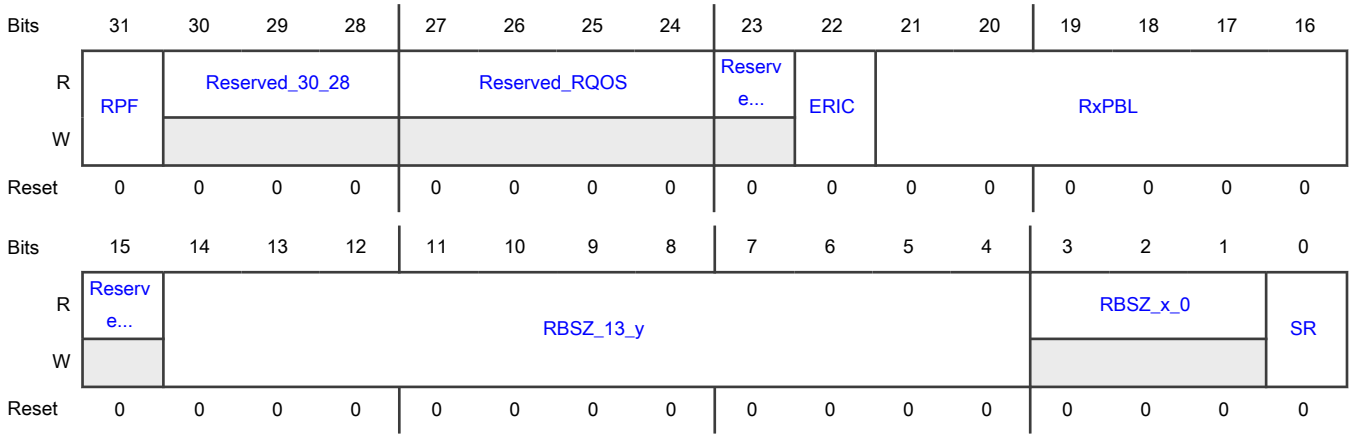
Offset

Register	Offset
DMA_CH1_Rx_Control	1188h

Function

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush. - 1: DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing is done on the Read side of the Rx Queue. - 0: DWC_ether_qos does not flush the packet in the Rx Queue destined to this RxDMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding RxQueue. Note: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in any DMA_CH(#i)_Rx_Control register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 Reserved_30_28	Reserved.
27-24 Reserved_RQOS	Reserved.
23 Reserved_23	Reserved.
22 ERIC	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after the completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA. 0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 Reserved_15	Reserved.
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. - The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

75.7.361 (DMA_CH1_TxDesc_List_Address)

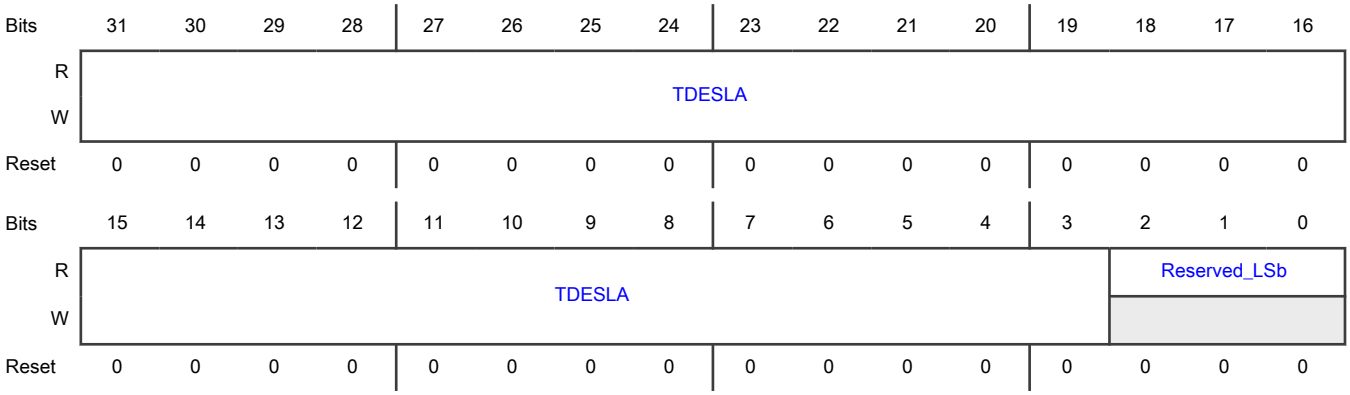
Offset

Register	Offset
DMA_CH1_TxDesc_List_Address	1194h

Function

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Diagram



Fields

Field	Function
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.362 (DMA_CH1_RxDesc_List_Address)

Offset

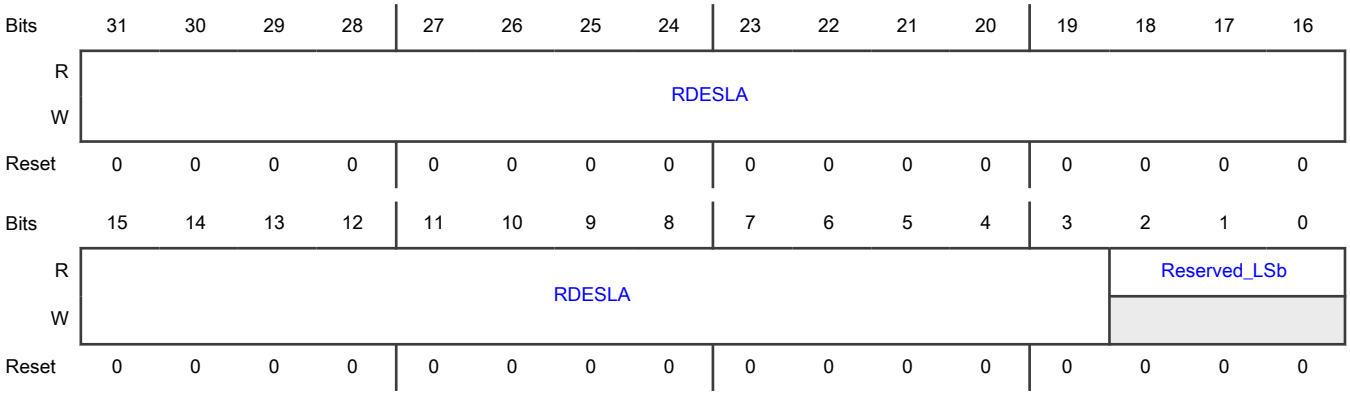
Register	Offset
DMA_CH1_RxDesc_List_Address	119Ch

Function

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only

when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-3 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.363 (DMA_CH1_TxDesc_Tail_Pointer)

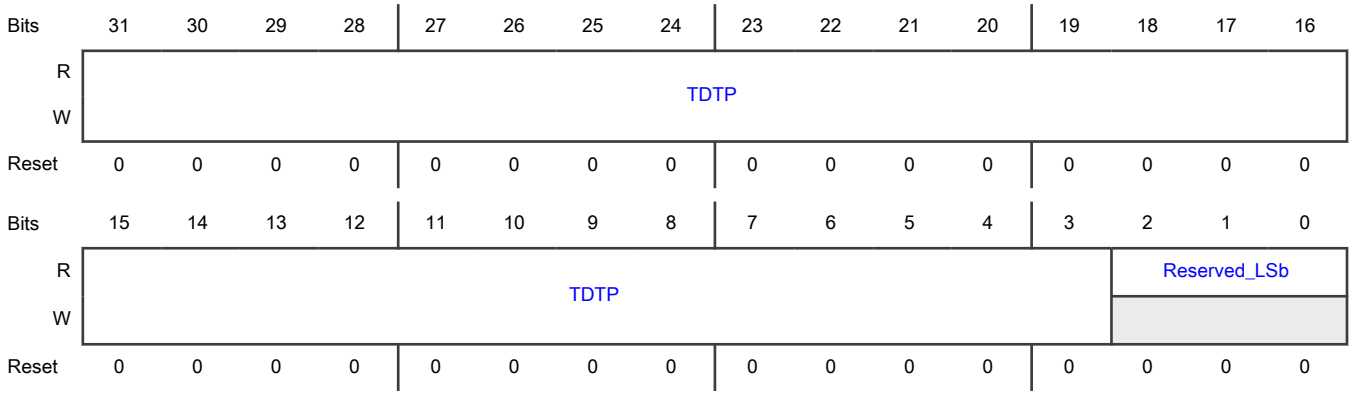
Offset

Register	Offset
DMA_CH1_TxDesc_Tail_Pointer	11A0h

Function

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-3 TDTP	Transmit Descriptor Tail Pointer This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.364 (DMA_CH1_RxDesc_Tail_Pointer)

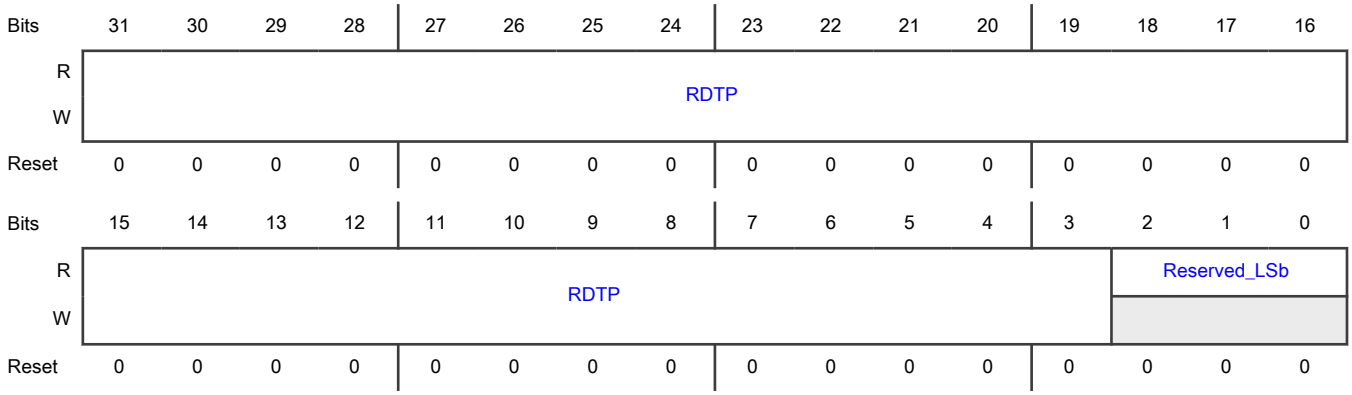
Offset

Register	Offset
DMA_CH1_RxDesc_Tail_Pointer	11A8h

Function

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-3 RDTP	Receive Descriptor Tail Pointer This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.365 (DMA_CH1_TxDesc_Ring_Length)

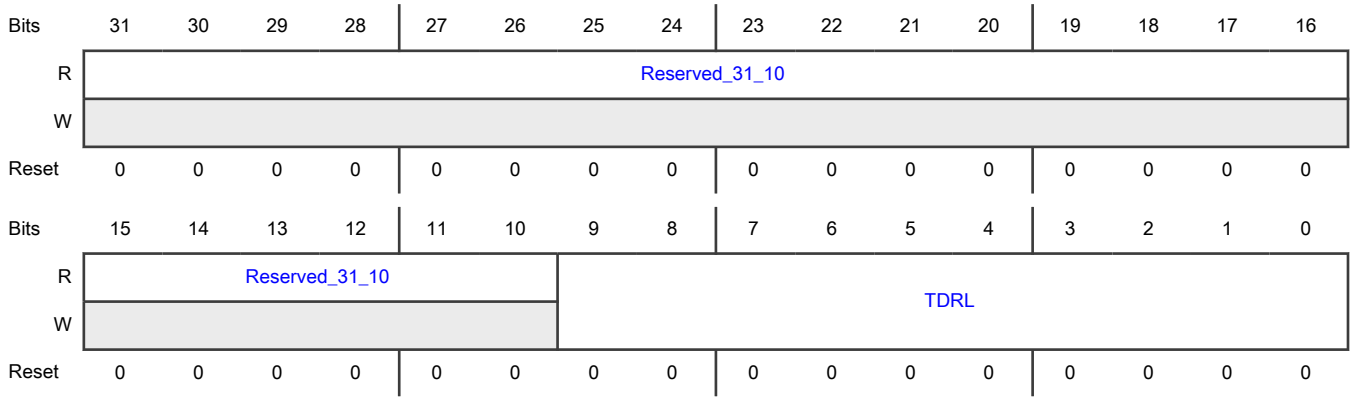
Offset

Register	Offset
DMA_CH1_TxDesc_Ring_Length	11ACh

Function

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Diagram



Fields

Field	Function
31-10 Reserved_31_10	Reserved.
9-0 TDRL	Transmit Descriptor Ring Length. This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. NXP recommends a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

75.7.366 (DMA_CH1_Rx_Control2)

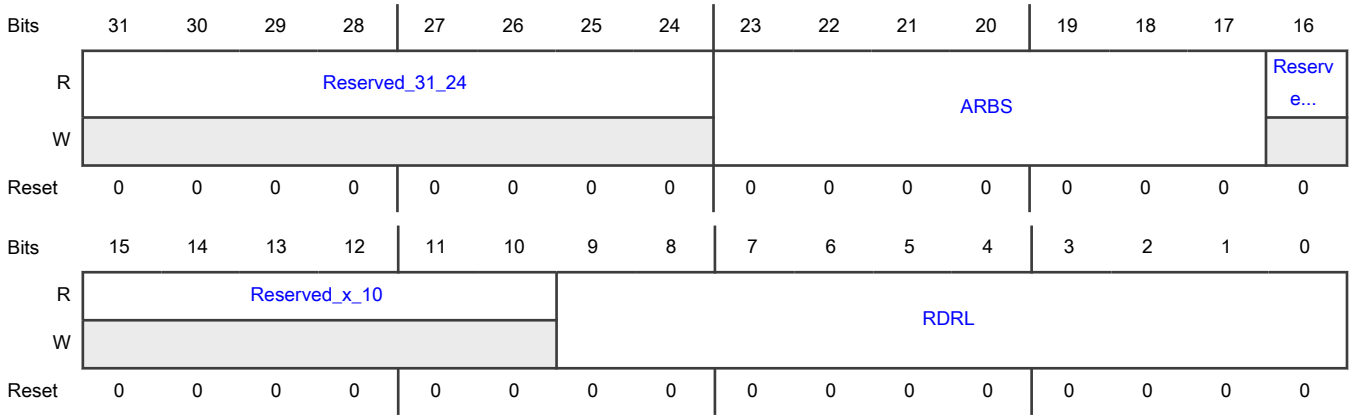
Offset

Register	Offset
DMA_CH1_Rx_Control2	11B0h

Function

The Channeli Receive Control register controls the Rx features such as Rx Descriptor Ring Length and Alternate Rx Buffer Size.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-17 ARBS	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CH(#i)_Rx_Control. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively)
16-10 Reserved_x_10	Reserved.
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

75.7.367 (DMA_CH1_Interrupt_Enable)

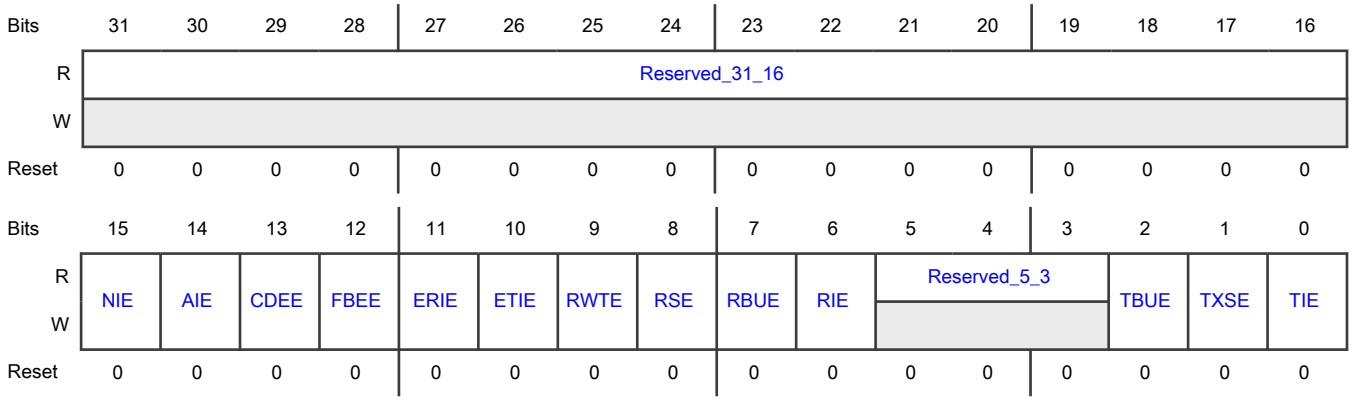
Offset

Register	Offset
DMA_CH1_Interrupt_Enable	11B4h

Function

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled. 0b - Normal Interrupt Summary is disabled 1b - Normal Interrupt Summary is enabled
14 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: - Bit 1: Transmit Process Stopped - Bit 7: Rx Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 9: Receive Watchdog Timeout - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled. 0b - Abnormal Interrupt Summary is disabled 1b - Abnormal Interrupt Summary is enabled

0 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. 0b - Transmit Interrupt is disabled 1b - Transmit Interrupt is enabled

75.7.368 (DMA_CH1_Rx_Interrupt_Watchdog_Timer)

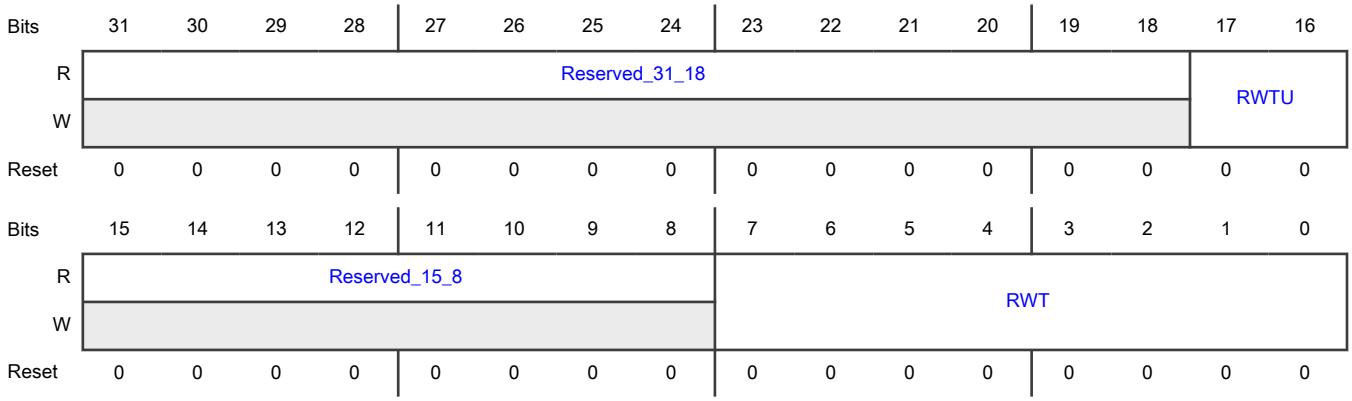
Offset

Register	Offset
DMA_CH1_Rx_Interrupt_Watchdog_Timer	11B8h

Function

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 Reserved_31_18	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 Reserved_15_8	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

75.7.369 (DMA_CH1_Slot_Function_Control_Status)

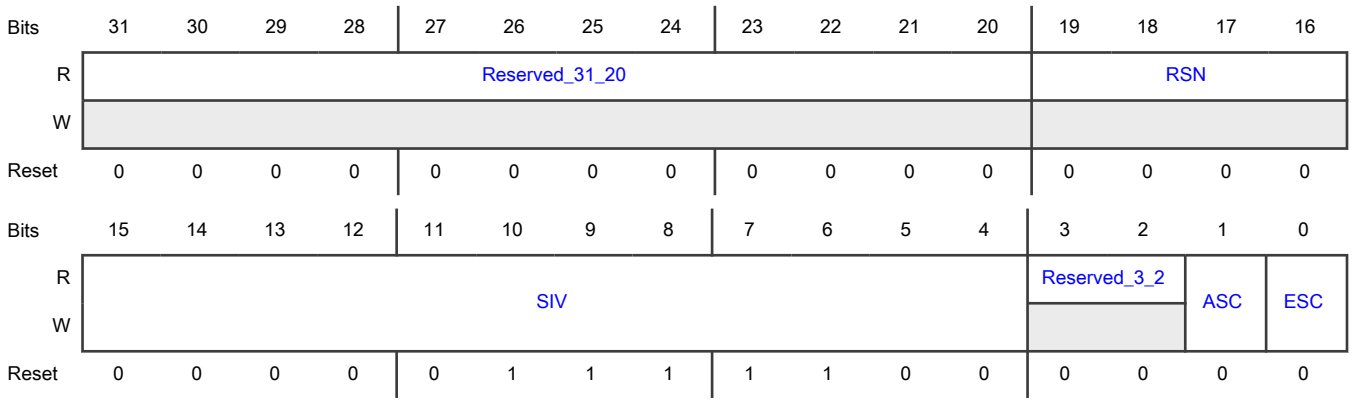
Offset

Register	Offset
DMA_CH1_Slot_Function_Control_Status	11BCh

Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Diagram



Fields

Field	Function
31-20 Reserved_31_20	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 Reserved_3_2	Reserved.
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

75.7.370 (DMA_CH1_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH1_Current_App_TxDesc	11C4h

Function

The Channeli Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

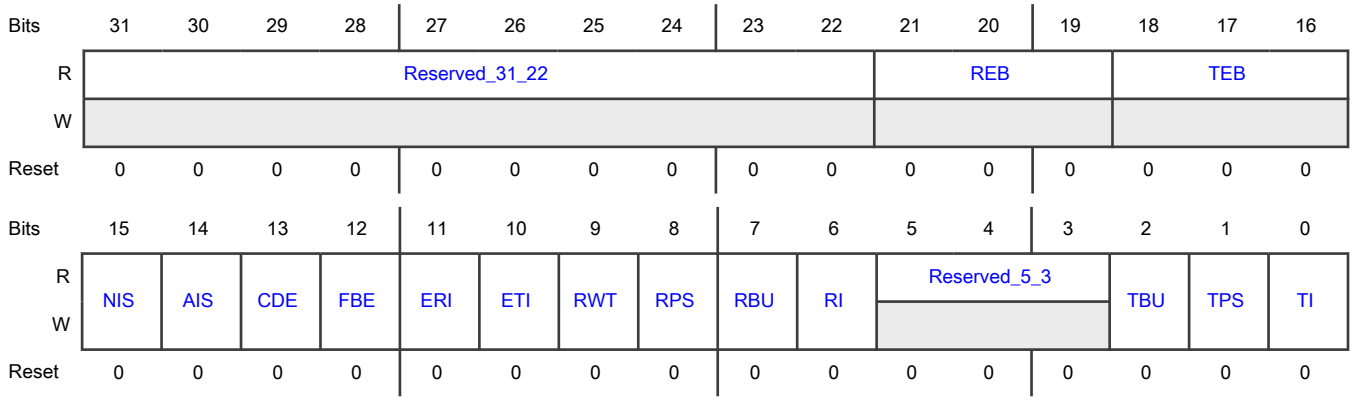
75.7.374 (DMA_CH1_Status)

Offset

Register	Offset
DMA_CH1_Status	11E0h

Function
The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Diagram



Fields

Field	Function
31-22 Reserved_31_22	Reserved.
21-19 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 21 -- 1'b1: Error during data transfer by Rx DMA -- 1'b0: No Error during data transfer by Rx DMA - Bit 20 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configurations supporting ERIC, - ERIC = 0: This bit is set only after the Rx DMA has completely filled up a receive buffer with packet data. - ERIC = 1: This bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configurations supporting ERIC: - ETIC = 0: This bit is set only after the Tx DMA has transferred a complete packet to MTL. - ETIC = 1: This bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC = 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing

Table continues on the next page...

Table continued from the previous page...

Field	Function
RBU	Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 Reserved_5_3	Reserved.
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: - Change the ownership of the descriptor by setting Bit 31 of TDES3. - Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

75.7.375 (DMA_CH1_Miss_Frame_Cnt)

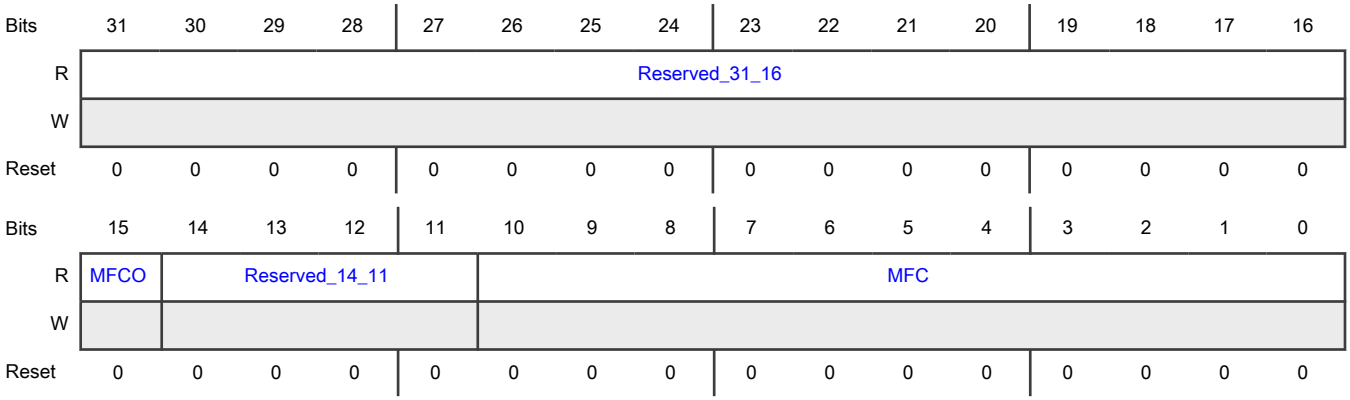
Offset

Register	Offset
DMA_CH1_Miss_Frame_Cnt	11E4h

Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 Reserved_14_11	Reserved.
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

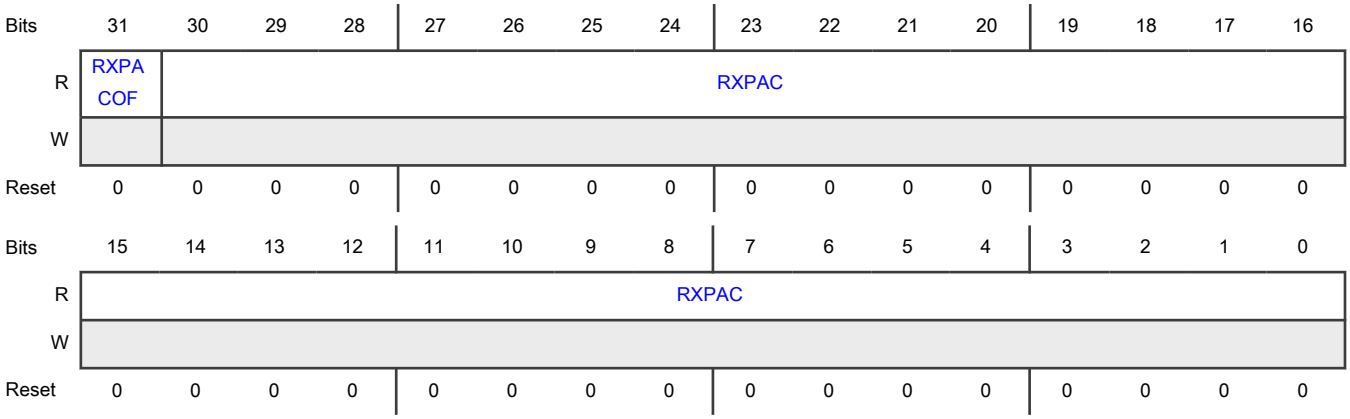
75.7.376 (DMA_CH1_RXP_Accept_Cnt)

Offset

Register	Offset
DMA_CH1_RXP_Accept_Cnt	11E8h

Function
The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Diagram



Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Accept Counter overflow not occurred 1b - Rx Parser Accept Counter overflow occurred
30-0 RXPAC	Rx Parser Accept Counter This 31-bit counter is implemented when a Rx Parser Accept a packet due to AF =1. The counter is cleared when the register is read.

75.7.377 (DMA_CH1_RX_ERI_Cnt)

Offset

Register	Offset
DMA_CH1_RX_ERI_Cnt	11ECh

Function
The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

Diagram

Fields

Field	Function
31-12 Reserved_31_12	Reserved.
11-0 ECNT	ERI Counter When ERIC bit of DMA_CH(#i)_RX_Control register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter is reset at the start of new packet.

75.7.378 (DMA_CH2_Control)

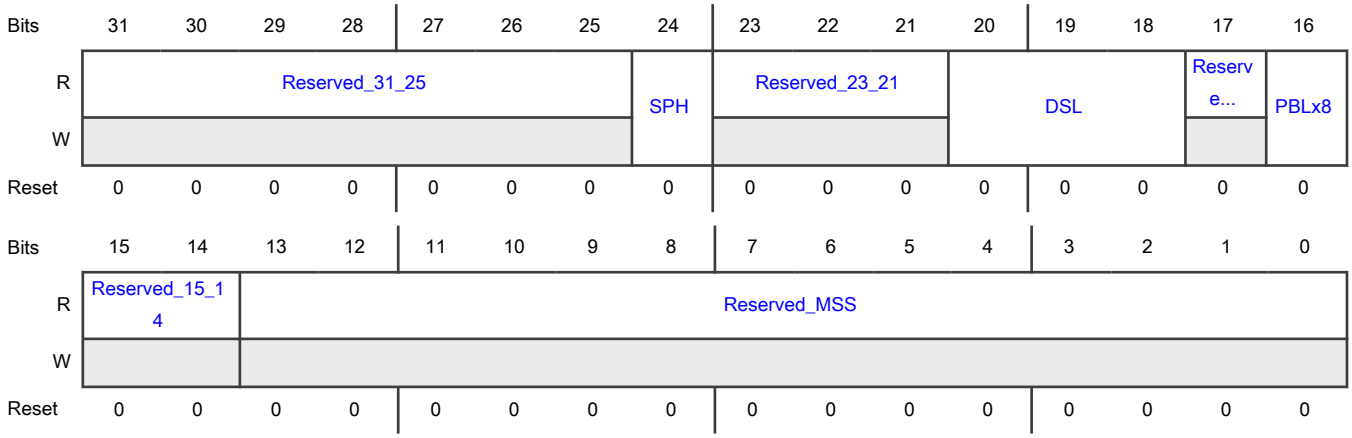
Offset

Register	Offset
DMA_CH2_Control	1200h

Function

The DMA Channeli Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram



Fields

Field	Function
31-25 Reserved_31_25	Reserved.
24 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. 0b - Split Headers feature is disabled 1b - Split Headers feature is enabled
23-21 Reserved_23_21	Reserved.
20-18 DSL	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 Reserved_17	Reserved.
16 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled

30-29 TFSEL	TBS Fetch Select Select bits for one of the four DMA_TBS_CTRL register fields (FTOS,FGSN,FTOV) for the channel Values: - 2'b00: DMA_TBS_CTRL0 - 2'b01: DMA_TBS_CTRL1 - 2'b10: DMA_TBS_CTRL2 - 2'b11: DMA_TBS_CTRL3 (Reserved if DWC_EQOS_NUM_DMA_TX_CH=3)

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel uses Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes. 0b - Enhanced Descriptor is disabled 1b - Enhanced Descriptor is enabled
27-24 Reserved_TQOS	Reserved.
23 Reserved_23	Reserved.
22 ETIC	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 Reserved_IPBL	Reserved.
14-13 Reserved_TSE_MODE	Reserved.
12 Reserved_TSE	Reserved.
11-5 Reserved_11_5	Reserved.
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

75.7.380 (DMA_CH2_Rx_Control)

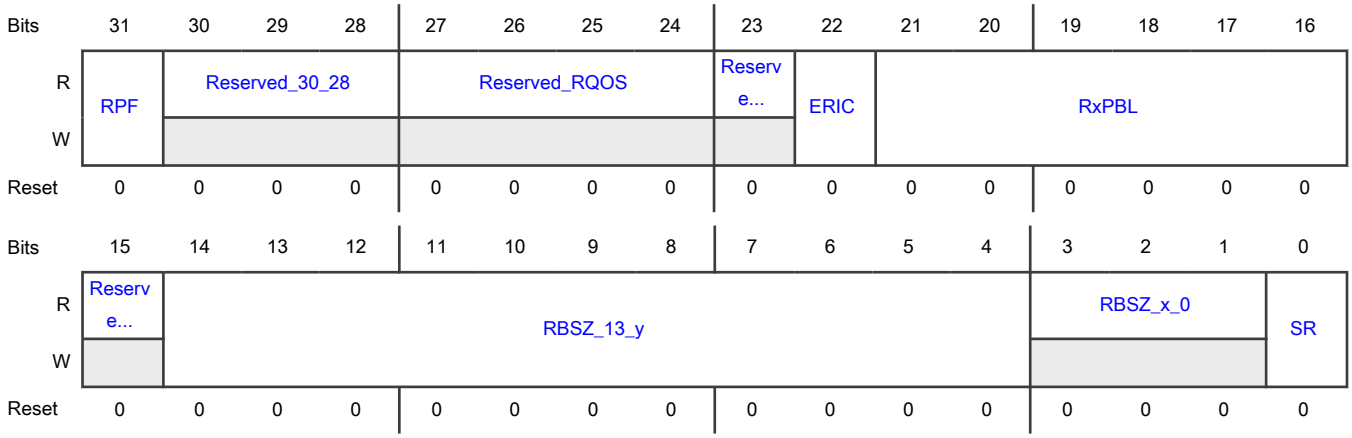
Offset

Register	Offset
DMA_CH2_Rx_Control	1208h

Function

The DMA Channeli Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush. - 1: DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing is done on the Read side of the Rx Queue. - 0: DWC_ether_qos does not flush the packet in the Rx Queue destined to this RxDMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding RxQueue. Note: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in any DMA_CH(#i)_Rx_Control register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 Reserved_30_28	Reserved.
27-24 Reserved_RQOS	Reserved.
23 Reserved_23	Reserved.
22 ERIC	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after the completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA. 0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 Reserved_15	Reserved.
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. - The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

75.7.381 (DMA_CH2_TxDesc_List_Address)

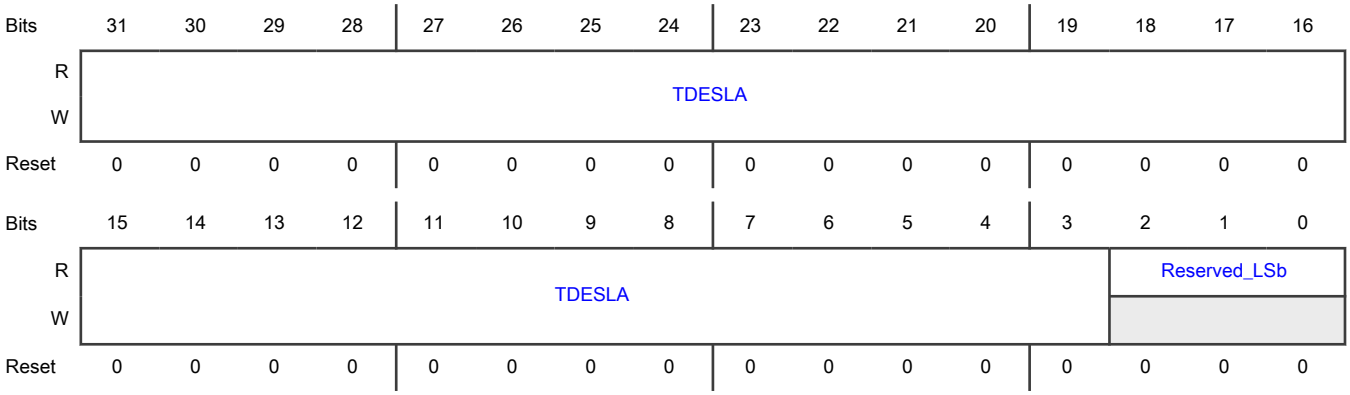
Offset

Register	Offset
DMA_CH2_TxDesc_List_Address	1214h

Function

The Channeli Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Diagram



Fields

Field	Function
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.382 (DMA_CH2_RxDesc_List_Address)

Offset

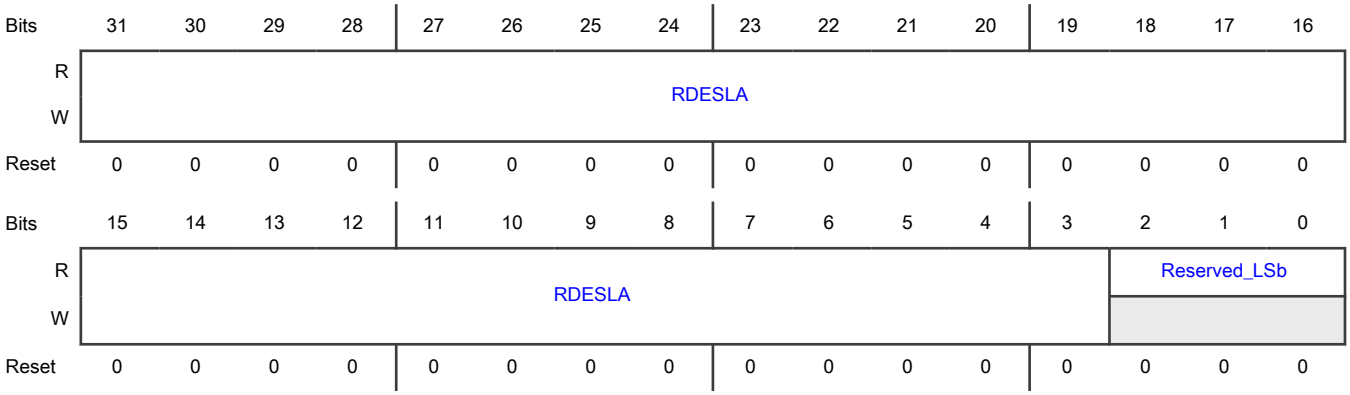
Register	Offset
DMA_CH2_RxDesc_List_Address	121Ch

Function

The Channeli Rx Descriptor List Address register points the DMA to the start of Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only

when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-3 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration

75.7.383 (DMA_CH2_TxDesc_Tail_Pointer)

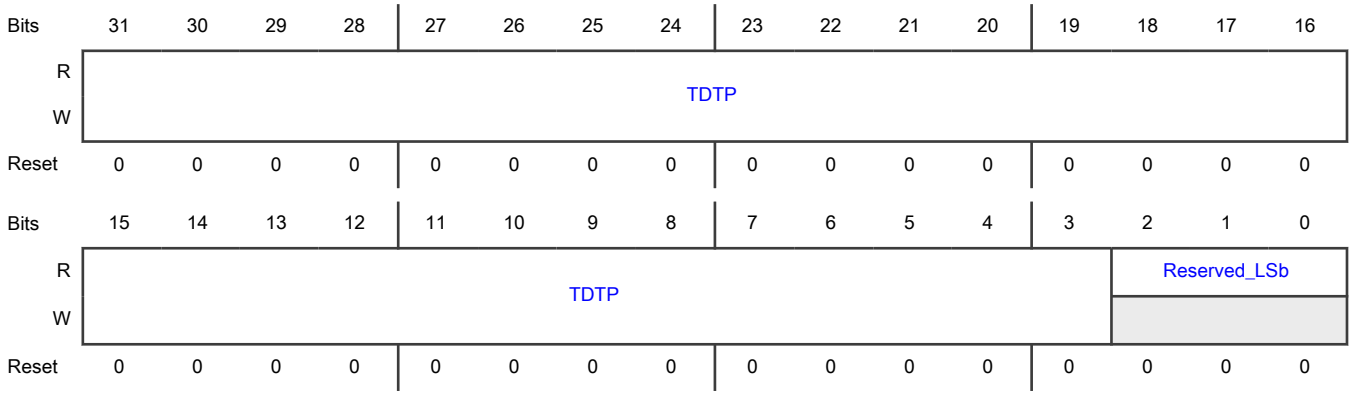
Offset

Register	Offset
DMA_CH2_TxDesc_Tail_Pointer	1220h

Function

The Channeli Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-3 TDTP	Transmit Descriptor Tail Pointer This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.384 (DMA_CH2_RxDesc_Tail_Pointer)

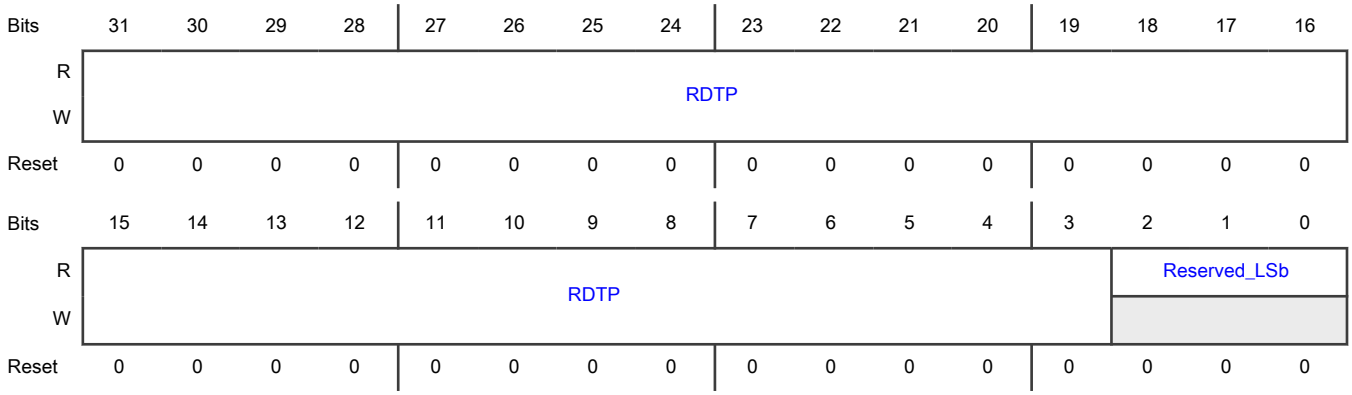
Offset

Register	Offset
DMA_CH2_RxDesc_Tail_Pointer	1228h

Function

The Channeli Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-3 RDTP	Receive Descriptor Tail Pointer This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers. The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 Reserved_LSb	Reserved.

75.7.385 (DMA_CH2_TxDesc_Ring_Length)

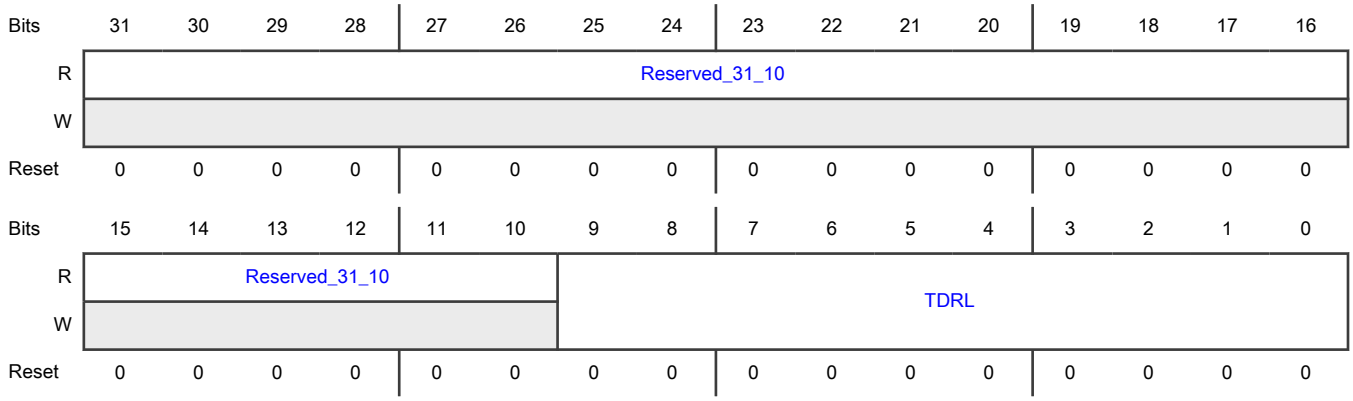
Offset

Register	Offset
DMA_CH2_TxDesc_Ring_Length	122Ch

Function

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Diagram



Fields

Field	Function
31-10 Reserved_31_10	Reserved.
9-0 TDRL	Transmit Descriptor Ring Length. This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. NXP recommends a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

75.7.386 (DMA_CH2_Rx_Control2)

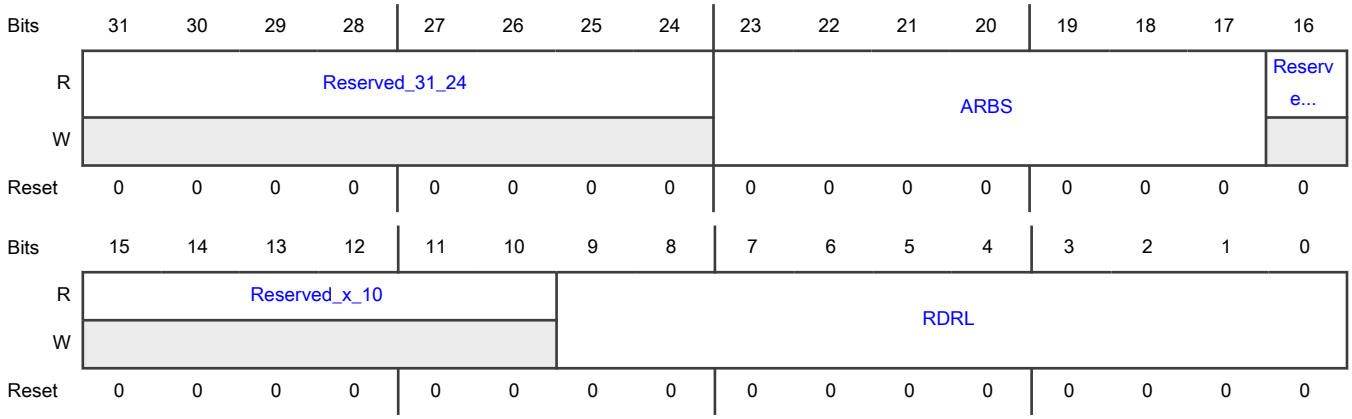
Offset

Register	Offset
DMA_CH2_Rx_Control2	1230h

Function

The Channeli Receive Control register controls the Rx features such as Rx Descriptor Ring Length and Alternate Rx Buffer Size.

Diagram



Fields

Field	Function
31-24 Reserved_31_24	Reserved.
23-17 ARBS	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CH(#i)_Rx_Control. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively)
16-10 Reserved_x_10	Reserved.
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

75.7.387 (DMA_CH2_Interrupt_Enable)

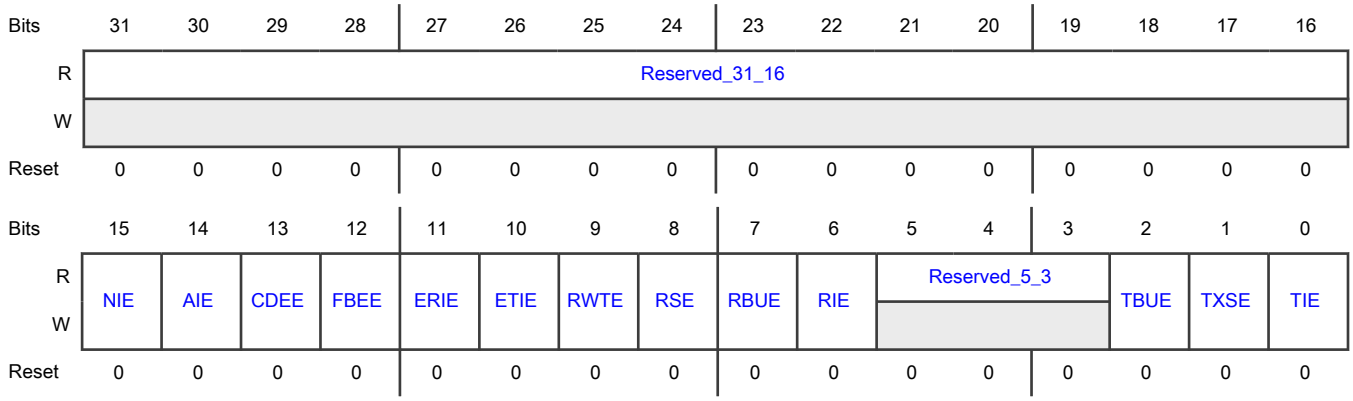
Offset

Register	Offset
DMA_CH2_Interrupt_Enable	1234h

Function

The Channeli Interrupt Enable register enables the interrupts reported by the Status register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled. 0b - Normal Interrupt Summary is disabled 1b - Normal Interrupt Summary is enabled
14 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: - Bit 1: Transmit Process Stopped - Bit 7: Rx Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 9: Receive Watchdog Timeout - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled. 0b - Abnormal Interrupt Summary is disabled 1b - Abnormal Interrupt Summary is enabled
13 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled. 0b - Context Descriptor Error is disabled 1b - Context Descriptor Error is enabled
12 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled. 0b - Fatal Bus Error is disabled 1b - Fatal Bus Error is enabled
11	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERIE	0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled
10 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
9 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled. 0b - Receive Watchdog Timeout is disabled 1b - Receive Watchdog Timeout is enabled
8 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled. 0b - Receive Stopped is disabled 1b - Receive Stopped is enabled
7 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled. 0b - Receive Buffer Unavailable is disabled 1b - Receive Buffer Unavailable is enabled
6 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled. 0b - Receive Interrupt is disabled 1b - Receive Interrupt is enabled
5-3 Reserved_5_3	Reserved.
2 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled. 0b - Transmit Buffer Unavailable is disabled 1b - Transmit Buffer Unavailable is enabled
1 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled. 0b - Transmit Stopped is disabled 1b - Transmit Stopped is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. 0b - Transmit Interrupt is disabled 1b - Transmit Interrupt is enabled

75.7.388 (DMA_CH2_Rx_Interrupt_Watchdog_Timer)

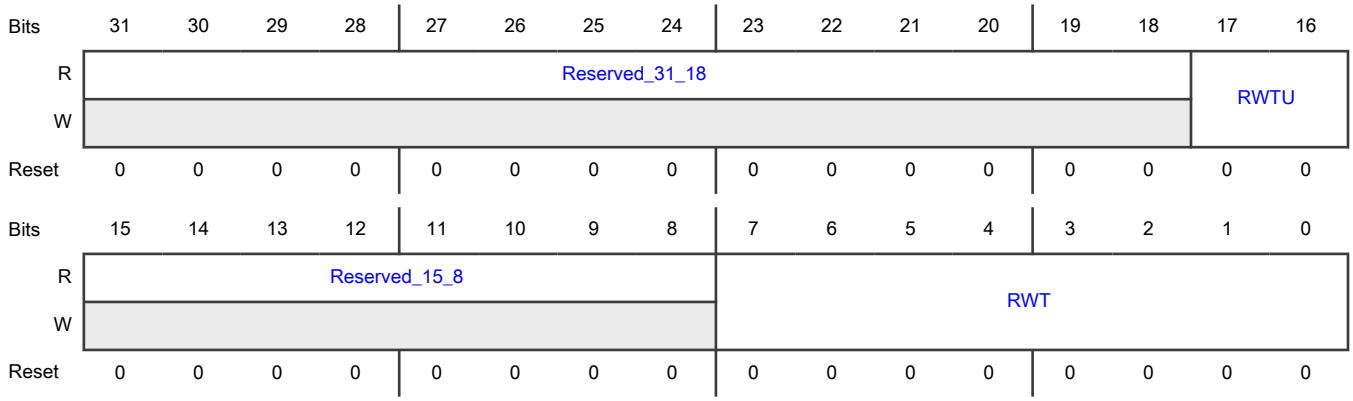
Offset

Register	Offset
DMA_CH2_Rx_Interrupt_Watchdog_Timer	1238h

Function

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 Reserved_31_18	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 Reserved_15_8	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

75.7.389 (DMA_CH2_Slot_Function_Control_Status)

Offset

Register	Offset
DMA_CH2_Slot_Function_Control_Status	123Ch

Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SIV												Reserved_3_2		ASC	ESC
W																
Reset	0	0	0	0	0	1	1	1	1	1	0	0	0	0	0	0

Fields

Field	Function
31-20 Reserved_31_20	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 Reserved_3_2	Reserved.
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

75.7.390 (DMA_CH2_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH2_Current_App_TxDesc	1244h

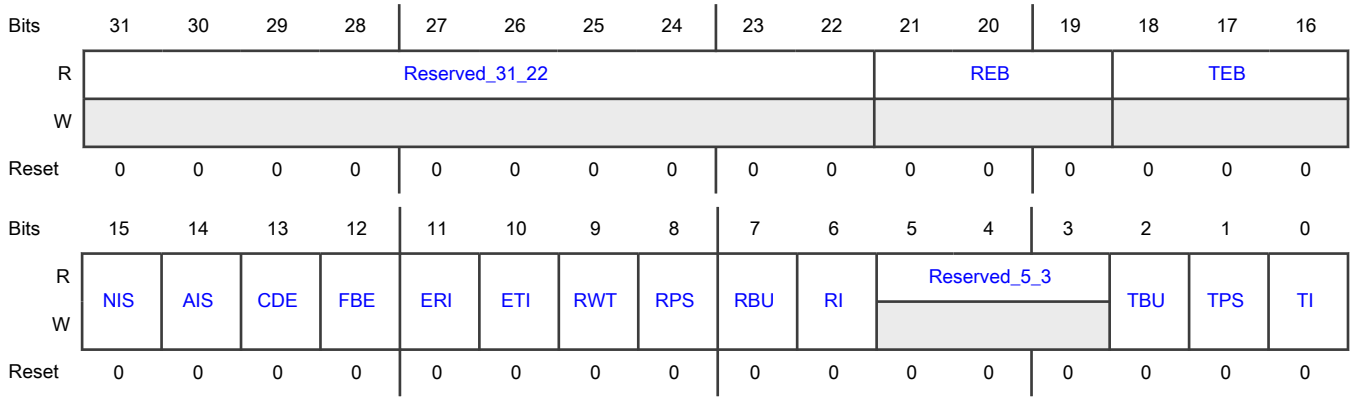
75.7.394 (DMA_CH2_Status)

Offset

Register	Offset
DMA_CH2_Status	1260h

Function
The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA. Note: The number of DMA_CH(#i)_Status register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Diagram



Fields

Field	Function
31-22 Reserved_31_22	Reserved.
21-19 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 21 -- 1'b1: Error during data transfer by Rx DMA -- 1'b0: No Error during data transfer by Rx DMA - Bit 20 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configurations supporting ERIC, - ERIC = 0: This bit is set only after the Rx DMA has completely filled up a receive buffer with packet data. - ERIC = 1: This bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configurations supporting ERIC: - ETIC = 0: This bit is set only after the Tx DMA has transferred a complete packet to MTL. - ETIC = 1: This bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC = 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing

Table continues on the next page...

Table continued from the previous page...

Field	Function
RBU	Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 Reserved_5_3	Reserved.
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: - Change the ownership of the descriptor by setting Bit 31 of TDES3. - Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

75.7.395 (DMA_CH2_Miss_Frame_Cnt)

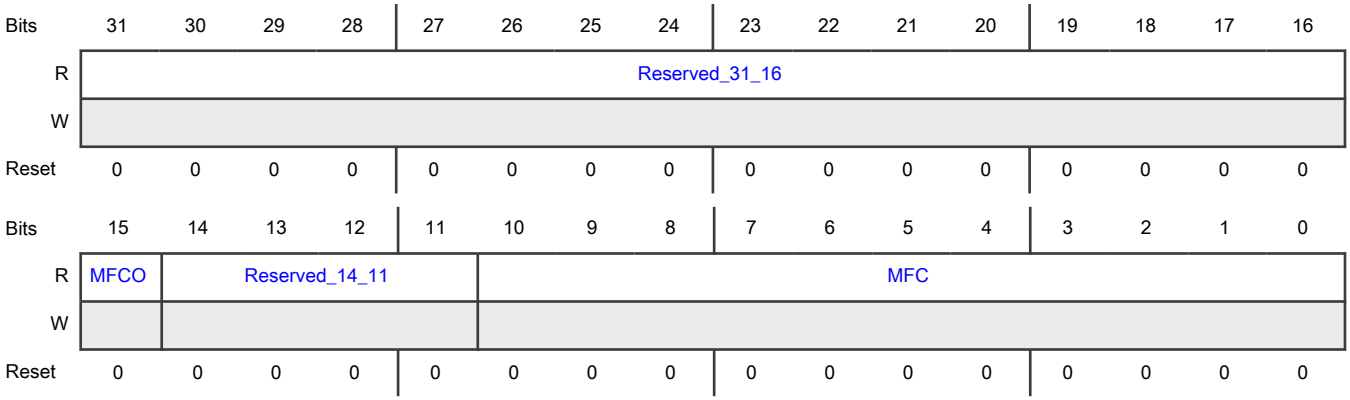
Offset

Register	Offset
DMA_CH2_Miss_Frame_Cnt	1264h

Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Diagram



Fields

Field	Function
31-16 Reserved_31_16	Reserved.
15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 Reserved_14_11	Reserved.
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

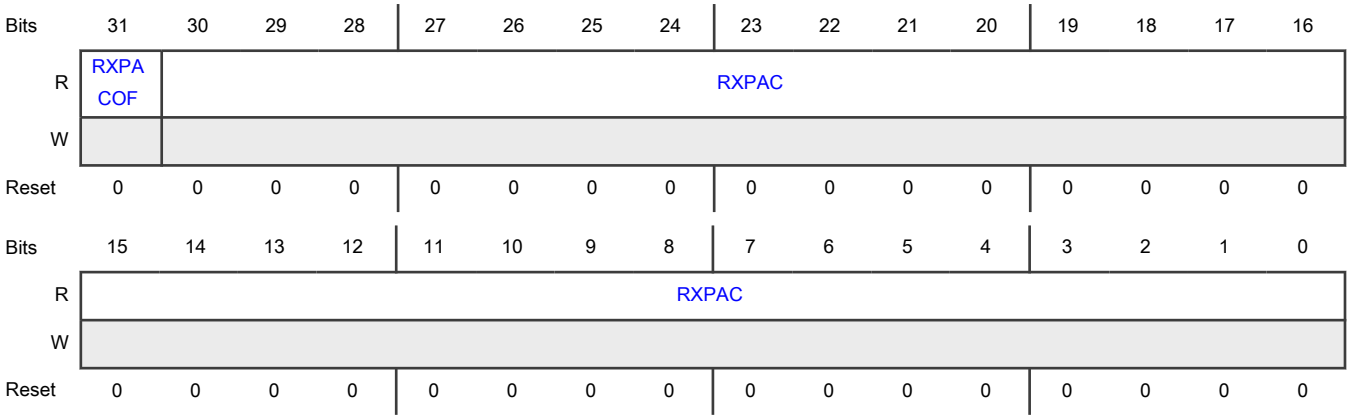
75.7.396 (DMA_CH2_RXP_Accept_Cnt)

Offset

Register	Offset
DMA_CH2_RXP_Accept_Cnt	1268h

Function
The DMA_CH(#i)_RXP_Accept_Cnt registers provides the count of the number of frames accepted by Rx Parser.

Diagram



Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Rx Parser Accept Counter overflow not occurred 1b - Rx Parser Accept Counter overflow occurred
30-0 RXPAC	Rx Parser Accept Counter This 31-bit counter is implemented when a Rx Parser Accept a packet due to AF =1. The counter is cleared when the register is read.

75.7.397 (DMA_CH2_RX_ERI_Cnt)

Offset

Register	Offset
DMA_CH2_RX_ERI_Cnt	126Ch

Function
The DMA_CH(#i)_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted.

75.8 Using PHY interfaces

This section is Synopsys Proprietary. Used with permission.

This module support the following modes:

- RGMII 100/1000 Mbps inerface
- RMII 10/100 Mbps interface
- MII 10/100 Mbps interface

Phy_intf_sel input signal decides which mode is selected. Samples the Phy_intf_sel signal at reset. See Signal descriptions for more information. MAC_Configuration[PS] and MAC_Configuration[FES] selects the mode's speed.

The module supports the IEEE802.3-2015 specification for MII, RMII specification version 1.2 from RMII consortium, and RGMII specification version 2.6 from HP/Marvell.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports the access of the phy registers through SMA. It is a two wire Station management interface (MIM):

1. MDC
2. MDIO

According to IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which system clock derives using a divider. MAC_MDIO_Address[CR] programs to generate different MDC clock frequency.

SMA supports MDIO clause 45 and clause 22 frame structure per the IEEE802.3 specification. Writing 1 to MAC_MDIO_Address[C45E] enables the clause 45 frame structure.

The MII interface reduces the accuracy of the 1588 timestamp if it is overclocked to run at 200 Mbps. This happens because the MAC logic uses the MII interface speed,to adjust or compensate for the timestamps taken at MII, as compared to the time generated in the PTP clock domain as specified in MAC_Configuration[FES].

75.9 VLAN and double VLAN insertion, deletion, replacement and tagging

This section and all its sub-sections are Synopsys proprietary. These are used with permission.

The following sections describe the VLAN and double VLAN features.

75.9.1 Double VLAN processing

In the double VLAN tagging processing, the module supports the processing of two VLAN tags. The two VLAN tags are:

1. Inner VLAN tag (C-VLAN)
2. Outer VLAN tag (S-VLAN)

If there is only one tag in a packet then it is considered as an outer tag.

The module uses MAC_VLAN_Incl and MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers to support the following functions in a double VLAN processing feature.

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path.
- Packet filtering and stripping on the basis of any one of the two VLAN tags in the receive path. Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

75.9.1.1 Transmit path

Table 561. Double VLAN processing features in transmit path

Feature	Description
Support for C-VLAN and S-VLAN tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. MAC_VLAN_Incl[CSVL] and MAC_Inner_VLAN_Incl[CSVL] specifies the VLAN type. The module supports the processing of any sequence of outer and inner VLAN tags. NOTE The module does not support the C-VLAN and S-VLAN sequence. MAC does not examine whether the packet, which the application provides has a valid sequence of the VLAN tag types or the insertion or replacement operation results in an invalid sequence of VLAN tag type. Therefore, the application must provide a correct sequence of VLAN tag types and program the MAC in such a way that it results in correct sequence of VLAN tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when C-VLAN replaces the outer tag. • The outer tag should not be C-VLAN when S-VLAN replaces the inner tag.
VLAN tag deletion	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag deletion for an outer or inner tag. When you enable the VLAN deletion, MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If you enable the inner tag deletion and if there is only one tag in the packet, then the MAC does not delete the tag.

Table continues on the next page...

Table 561. Double VLAN processing features in transmit path (continued)

VLAN tag insertion or replacement	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag insertion or replacement for an outer or inner tag. When you enable the VLAN tag insertion or replacement, the MAC_VLAN_Incl[VLTI] or MAC_Inner_VLAN_Incl[VLTI] determines whether the VLAN tag must be fetched from the register or from the control word.

75.9.1.2 Receive path

Table 562. Double VLAN processing in receive path

Feature	Description
Outer or inner VLAN tag-based filtering	Mac can filter packets through the ERIVLT bit on the basis of the outer or inner VLAN tag.
C-VLAN or S-VLAN tag-based filtering	Mac can filter packets through the ERSVLM bit on the basis of the C-VLAN or S-VLAN type.
Outer and inner VLAN tag stripping	Mac can strip the outer and inner VLAN tags from received frame on the basis of the EVLS and EIVLS bits.
16-bit outer and inner VLAN tag and type in Rx status	Mac can provide the 16-bit outer and inner VLAN tag and type in the Rx status on the basis of the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN tag type	Mac can disable or skip checking of an outer VLAN tag type to match C-VLAN or S-VLAN on the basis of the DOVLTC bit.

75.9.1.3 Source address and VLAN insertion, replacement, or deletion

This module supports the SA, and VLAN insertion, replacement and deletion feature. The SA and VLAN fields are Tx packet-related control information that interfaces provide as part of the control word. IP supports the feature to insert or replace the source address on the basis of the information in the MAC address registers, and it also supports the feature to insert, replace, or delete the VLAN fields (VLAN type and VLAN tag) on the basis of the setting of the MAC_VLAN_Incl[VLTI]. SA insertion or replacement feature is enabled for all the transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature is enabled for all the Tx packets or selective packets.

75.9.1.4 Programming source address insertion or replacement

You can use the SA insertion or replacement feature to instruct MAC to perform the following actions for Tx packets:

- Insert the content of the MAC address registers in the SA field
- Replace the content of the SA field with the content of the MAC address registers

When SA insertion is enabled, the application must ensure that the packets sent to MAC do not have the SA field. The MAC does not check whether the SA field is present in the transmit packet and it inserts the content of MAC address registers in the SA field. Similarly, when the SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

MAC replaces the six bytes following the DA field in the transmit packet with the content of the MAC address registers.

- Configure MAC_Configuration[SARC] to enable the SA insertion or replacement for all Tx packets.
- Enable the SA insertion for selective packet by configuring the SA insertion control field (bits [25:23] of TDES3) in the first transmit descriptor of the packet. When you write 1 to bit 25 of TDES3, the SA insertion control field indicates insertion or

replacement by MAC Address1 registers. When bit 25 of TDES3 resets, it indicates insertion or replacement by MAC Address 0 registers.

If you do not enable the MAC Address1 registers, then the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA insertion control field.

75.9.1.5 Programming VLAN insertion, replacement, or deletion

You can use the VLAN insertion, replacement, or deletion feature to instruct MAC to perform the following actions for the Tx packets:

- Delete the VLAN type and VLAN tag fields.
- Insert or replace the VLAN type and VLAN tag fields.

Insertion or replacement is done on the basis of the setting of the MAC_VLAN_Incl[VLTI] as described in theTable 563:

Table 563. VLAN insertion or replacement based on VLTI bit

Condition	Description
VLTI bit=1	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field depending on the content of the VT field of transmit context descriptor of the packet
VLTI bit resets	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field with the MAC_VLAN_Incl[VLT]

When the VLAN replacement or deletion is enabled, MAC checks whether the VLAN type field (0x8100 or 0x88a8) is present after the DA and SA fields in the transmit packet. The replace or delete operation does not occur if the VLAN type field is not detected in two bytes following the DA and SA fields. However, when the VLAN insertion is enabled, MAC does not check the presence of VLAN type field in the transmit packet and just inserts the VLAN type and VLAN tag fields.

Configuring MAC_VLAN_Incl[VLC] and MAC_VLAN_Incl[VLP] enables the VLAN insertion, replacement, or deletion feature for all Tx packets.

Configuring the VTIR field of TDES2 normal descriptor enables the VLAN insertion, replacement, or deletion for selective packets.

In addition, the VLP (VLAN Priority control) field must reset in MAC_VLAN_Incl (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for MAC to take the control inputs from the host, depending on the configuration.

75.10 Packet Filtering

This section and all its sub-sections are Synopsys proprietary. Used with permission.

MAC receiver contains various packet filtering scheme. Figure 2 shows the filtering sequence in their precedence order of received packet.

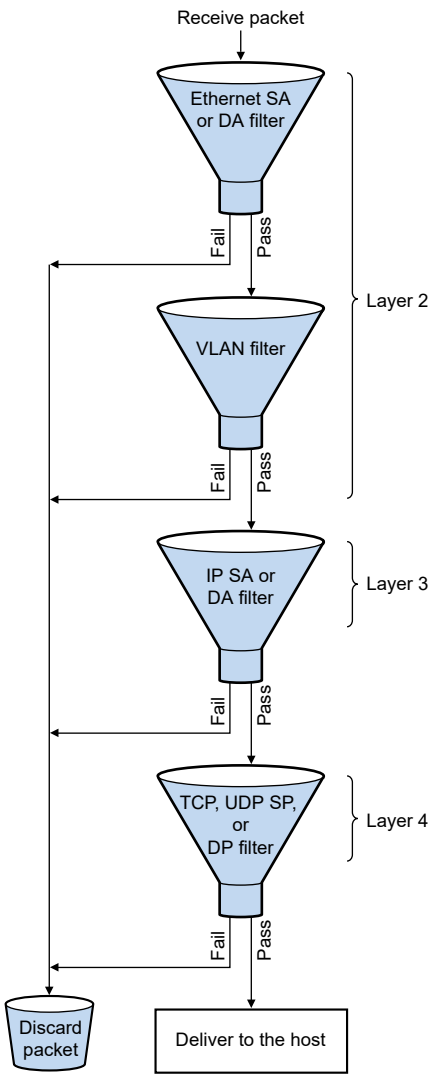

Figure 430. Packet filtering sequence

If you do not enable any of the layer filters, then that filter is bypassed and the subsequent filter is applied. Discard the packet that fails any of the filters. However, you can forward the discarded packet to the host on the basis of the register control.

75.10.1 Source address or destination address filtering

The address filtering module of MAC checks the SA and DA fields of each incoming packet. Programming of different types of address filtering is described in the sections that follows.

75.10.1.1 Unicast destination address filtering

MAC supports up to three MAC addresses for unicast perfect filtering. If perfect filtering is selected (MAC_Packet_Filter[HUC] resets), MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. MAC selects the MacAddr1 to MacAddr2 addresses with an individual enable field. Each byte of MacAddr1 to MacAddr2 can be masked when you compare them with corresponding received DA byte by writing 1 to the corresponding Mask byte control field in the register. This enables group address filtering for the DA.

In hash filtering mode (when you write 1 to HUC bit), MAC performs imperfect filtering by using a 64-bit hash table for unicast addresses . For hash filtering, MAC uses the upper 6 bits CRC of the received destination address to index the content of the hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of hash table register. If the value of

the corresponding bit (indicated by the 6-bit CRC) is 1, the unicast packet is considered to have passed the hash filter, otherwise, the packet is considered to have failed the hash filter.

75.10.1.2 Multicast destination address filtering

Enable MAC_Packet_Filter[PM] to pass all the multicast packets or disable to do multicast addresses filtering on the basis of MAC_Packet_Filter[HMC]. Compare the multicast address with the configured MAC destination address registers (1–2), also supports the group address filtering.

In Hash filtering mode, MAC performs imperfect filtering using a 64-bit hash table. MAC uses the upper 6-bits CRC of received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the hash table register. The multicast packet is considered to have passed the hash filter if the value of the corresponding bit is equal to 1. Otherwise, the packet is considered to have failed the hash filter.

75.10.1.3 Hash or perfect address filtering

Configure MAC_Packet_Filter[HPF] to enable or disable the destination address filtering either by hash filter or perfect filter. Also configure MAC_Packet_Filter[HUC] and MAC_Packet_Filter[HMC] to select the hash filtering or perfect filtering for unicast or multicast packet.

75.10.1.4 Broadcast address filtering

MAC does not filter any broadcast packets by default. You must write 1 to MAC_Packet_Filter[DBF] to reject the broadcast packets.

75.10.1.5 Unicast source address filtering

MAC by default compares the source address field with the value configured in the source address registers. Configure bit 30 of MAC address register [1-2] to use it for source address instead of destination address comparison. MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. MAC drop the packets that fail the SA filter if you write 1 to MAC_Packet_Filter[SAF] field. Otherwise, the result of the SA filter is given as a status bit in the receive status word. When you write 1 to the SAF field, the SA filter and DA filter results ends to decide whether you can forward the packets. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

75.10.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by writing 1 to the DAIF and SAIF fields of MAC_Packet_Filter register. The DAIF field is applicable for both the unicast and multicast DA packets. The unicast or multicast destination address filter result is inverted in this mode. Similarly, writing 1 to the SAIF field reverses the result of unicast SA filter.

Table 564 and Table 565 summarize the DA and SA filtering on the basis of the type of packets received.

Table 564. Destination address filtering

Packet type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA filter operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	All packets pass
	0	X	0	0	X	X	X	Pass on perfect or group filter match

Table continues on the next page...

Table 564. Destination address filtering (continued)

	0	X	0	1	X	X	X	Fail on perfect or group filter match
	0	0	1	0	X	X	X	Pass on hash filter match
	0	0	1	1	X	X	X	Fail on hash filter match
	0	1	1	0	X	X	X	Pass on hash or perfect or group filter match
	0	1	1	1	X	X	X	Fail on hash or perfect or group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on hash filter match and drop pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on hash or perfect or group filter match and drop pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on hash filter match and drop pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on hash or perfect/group filter match and drop pause packets if PCF = 0x

Table 565. Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on perfect or group filter match but do not drop packets that fail
	0	1	0	Fail status on perfect or group filter match but do not drop packet
	0	0	1	Pass status on perfect or group filter match and drop packets that fail
	0	1	1	Fail status on perfect or group filter match and drop packets that fail

NOTE

When you write 1 to the MAC_Packet_Filter[RA] field, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

75.10.2 VLAN filtering

VLAN tag filter can be done either by perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forward the VLAN tagged packet with match status when it drop all the packets which do not match.

MAC uses 16-bit VLAN hash table for group address filtering on the basis of the VLAN tag. If MAC enables the hash filtering then the most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the MAC_VLAN_Hash_Table. A value of 1 in the VLAN hash table register, corresponding to the index indicates that the VLAN tag of the packet has matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

MAC supports the inverse matching for VLAN packets. In the Inverse matching mode, the packet must be dropped when the VLAN tag of a packet matches the perfect or hash filter. If MAC enables the VLAN perfect and VLAN hash match, then a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, MAC forwards a packet only when both the perfect and hash filters indicate mismatch.

Table 566 specifies the different possibilities for VLAN matching and the final VLAN match status. When you write 1 to MAC_Packet_Filter[RA] all packets are received and it indicates the VLAN match status in the VF field of RDES2 normal descriptor (write-back format). When the RA field is not set and when you write 1 to MAC_Packet_Filter[VTFE] the packet drops if the final VLAN match status fails

When VLAN VID programs to 0 in the VL field of MAC_VLAN_Tag register, consider that all the VLAN-tagged packets are perfectly matched but the status of the VLAN hash match depends on the VTHM and VTIM fields in MAC_VLAN_Tag register.

Table 566. VLAN match status

VID	VLAN perfect filter match result	VTHM bit	VLAN hash filter match result	VTIM bit	Final VLAN match status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID1= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In Table 566, X represents any value.

75.10.3 VLAN filter fail packets queue

When you enable VLAN filtering, route the VLAN filter fail packets to a programmable queue (VFFQ) when the value of MAC_Packet_Filter[RA] = 1 or MAC_Packet_Filter[VTFE] = 0 and write 1 to MAC_RxQ_Ctrl4[VFFQE] for the queue.

Route the packets that passes the VLAN filtering to Rx queues on the basis of the VLAN tag priority field by configuring the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. Discard the packets that fail the VLAN filter if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, forward the VLAN filter fail packets to the application. In such case, when you write 1 to the VLAN filter fail queue enable (VFFQE) field, the VLAN filter fail packets forward to the Rx queue number programmed in the VFFQ field. If the value of VFFQE=0, the VLAN priority mapping determines the Rx queue number per the PSRQ fields.

Table 567 shows the Rx queue routing table for unicast tagged packets, with DA or SA filter enabled.

Table 567. Rx queue routing table for unicast tagged packets

RA	VFTE	SA or DA filter result	VLAN filter result	VFFQE	Queue routing
X	X	Pass	Pass	X	PSRQ
0	0	Pass	Fail	0	PSRQ
0	0	Pass	Fail	1	VFFQ
0	X	Fail	X	X	Dropped
0	1	Pass	Fail	X	Dropped
1	X	Fail	X	0	UFFQ*/PSRQ
1	X	Fail	X	1	UFFQ*/VFFQ
1	X	Pass	Fail	0	PSRQ
1	X	Pass	Fail	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ.

75.10.4 Extended receive VLAN filtering and routing

When the extended Rx VLAN filtering and routing is enabled then both the perfect filtering and hash filtering can be enabled. The overall VLAN filter result is based on the perfect filter result and hash filter result (if enabled). Filter result is passed to application as part of the status bit. Extended routing will take place only if VLAN filter has passed. Routing is only based on perfect filter result. Each perfect filter has a DMA channel enable and DMA channel number filed which must be programmed for routing.

See the extended VLAN based DMA selection in Dynamic (per packet) mapping for more information about routing.

75.10.4.1 Comparison mode

Application has these comparison option for each VLAN tag filter:

- Programs MAC to compare the inner or outer VLAN tag either with 12 bits or 16 bits programmed VID.
- Selects whether the VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

75.10.4.2 Filtering

Perfect filtering is done on the basis of the MAC_VLAN_Tag_Filter registers. MAC compares the relevant VLAN tag ID and gives a result for each VLAN tag filter.

The results for each VLAN tag filter are:

- Pass- If any one of the VLAN tag filters gives a match.
- Fail- If the frame mismatches all the filters.

This behavior is applicable only when the inverse filtering is not enabled in MAC_VLAN_Tag_Ctrl.

If inverse filtering is enabled and the frame mis-matches all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered to have failed. The frame is bypassed to the application if none of the enabled filters can perform a comparison or if none of the filters are enabled.

The overall filter result and the programming on MAC_Packet_Filter[VTFE] and MAC_Packet_Filter[RA] determines if the frame will drop or it is forwarded to the application. If the value of RA = 1 or VTFE = 0, then the frame is always forwarded whether the filter result is a pass or fail, . If the value of RA = 0 and VTFE = 1, only then, if the VLAN tag filter result is a pass the MAC forwards the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the status bits.

75.10.4.3 Filter status

The extended receive VLAN filtering and routing feature provides two status fields to show the comparison result of the VLAN tags.

By default, MAC indicates the VLAN filter status through one bit in the status VF field in RDES2. When you enable the extended RX VLAN filtering and routing, two status fields will show the comparison result of the VLAN tags. The outer VLAN tag filter pass and inner VLAN tag filter pass bits are defined in the following positions. The status indicated through these fields depends on the programming as described below.

In RDES2:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In ARI status: MAC filter status:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In MRI status:

- Bit 47 – Outer VLAN tag filter status
- Bit 46 – Inner VLAN tag filter status

Outer VLAN tag filter status (OTS)

- In perfect filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's outer VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's outer VLAN tag has either failed the relevant outer VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for outer VLAN tag comparison.
- If inverse filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it is resets, then it has failed at least one filter or bypassed all the filters programmed for outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN tag filter status (ITS)

- In perfect Filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's inner VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's inner VLAN tag has either failed the relevant inner VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for inner VLAN tag comparison.
- If Inverse Filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it resets, then it has failed at least one filter or bypassed all the filters programmed for inner VLAN tag comparison.

- This bit is valid for only double VLAN tagged frames, when double VLAN processing is enabled.

The application must observe the status fields and the program to determine if the frame has passed or failed the VLAN filter.

Table 568 and Table 569 describes the possible filter combinations and the corresponding filter results and they also explain the scenarios when the double VLAN processing and the hash VLAN filter are enabled in the design.

Legend for the table OTS and ITS Bit Values with at least 1 perfect filter enabled

- VTIM: VLAN tag inverse match enable – bit 17 in VLAN_Tag_Ctrl register.
- HFO: Hash filter enabled for outer VLAN tag comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- HFI: Hash filter enabled for inner VLAN tag comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- PFO – Perfect filter comparison enabled for outer VLAN tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for outer VLAN tag comparison (write 0 to bit 20).
- PFI – Perfect filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for inner VLAN tag comparison (write 1 to bit 20).
- OTS – Outer VLAN tag filter status
- ITS – Inner VLAN tag filter status

Table 568 shows the possible values of status bits (OTS and ITS) when at least one perfect filter is enabled.

Table 568. OTS and ITS bit values with at least 1 perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0

Table continues on the next page...

Table 568. OTS and ITS bit values with at least 1 perfect filter enabled (continued)

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 569 shows the possible values of status bits (OTS and ITS) when no perfect filters are enabled except the VLAN hash filter is enabled.

Table 569. OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of OTS and ITS bit values with only VLAN hash filter enabled indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes atleast one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: The last row of table "OTS and ITS bit values with only VLAN hash filter enabled" indicates that the inverse filtering is enabled, hash filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

75.10.4.4 Stripping

Each VLAN tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or outer VLAN tag stripping is based on the pass or fail results of the individual tag. If all the relevant filters bypasses a tag, stripping is not applicable for the tag.

- If strip on pass is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has passed the relevant filters. The outer VLAN tag filter result field will be 1.
- If strip on fail is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has failed relevant filters. The outer VLAN tag filter result field will reset.
- If the outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the status bit is 0.

- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of thefilters. The VLAN Tag's value is not always deterministic from the filter status bits.

If an application strips the VLAN tag on the basis of the filter result, it might lose the VID. You can use it, if stripping is enabled for any of the tags, place the tag in the status. For this the software or application will enable the respective VLAN tag in status bit - 24 or 31 in the MAC VLAN tag control register.

See section Programming guidelines for extended VLAN filtering and routing on receive for more information.

75.10.5 Layer 3 and layer 4 filtering

IP supports the layer 3 based packet filtering which is an IP source or destination address filtering in the IPv4 or IPv6 packets, and layer 4 based packet filtering which is a source or destination port number filtering in TCP or UDP. When you enable layer 3 and layer 4 packet filtering then packets are filtered in the following manner.

- Matched packets: MAC forward the packets that match all enabled fields to the application along with the status. It gives the matched field status only if MAC_Configuration[IPC] = 1 and if one of the following conditions is true:
  - All enabled layer 3 and layer 4 fields match
  - At least one enabled field matches and other fields are bypassed or disabled

When you enable multiple layer 3 and layer 4 filters, any filter match is considered as a match. If more than one filter matches, MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter.

- Unmatched packets: MAC drop the packets that do not match any enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP packets: By default, all the non-TCP or UDP IP packets bypasses the layer 3 and layer 4 filters. You can optionally program MAC to drop all the non-TCP or UDP packets over IP packets.
- IP has a control register MAC_L3_L4_Control to control the layer L3 and L4 packet filtering along with address registers to program the layer L3 and L4 fields to be matched.

75.10.6 Flexible receive parser

When you enable this function, all incoming packets are parsed per the programmable instruction stored in memory. It perform these functions:

- Packet filter (Accept or reject)
- DMA channel selection

Flexible receive parser block operates over the first 128 bytes data of receive packet on the basis of 64 bytes of instruction on each packet. Figure 431 shows the functional block diagram of flexible receive parser.

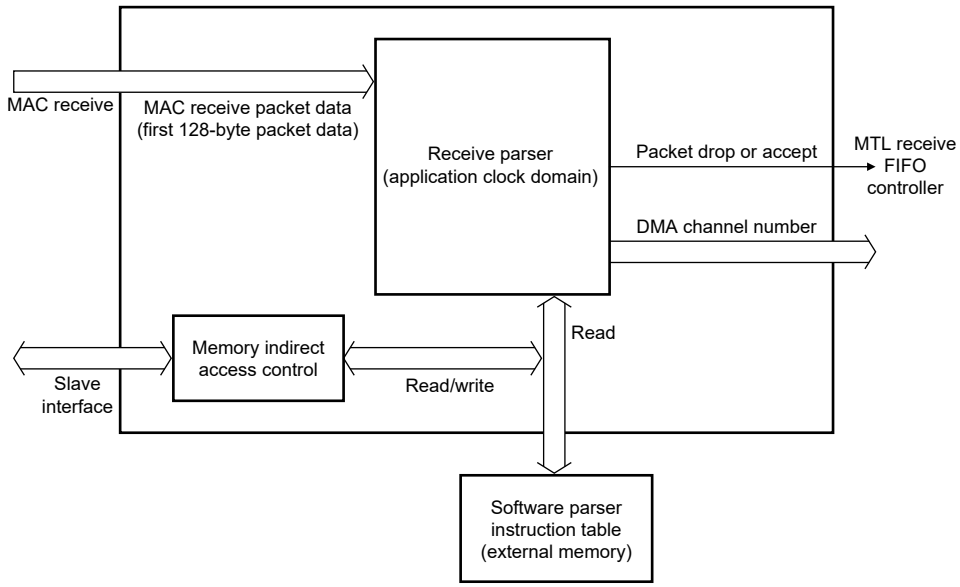

Figure 431. Functional block diagram of flexible recieve parser

75.10.6.1 Instruction table format of the flexible receive parser

You must build the 96-bit wide instruction before enabling the receive parser feature and program each instruction as an entry in the instruction memory.

Table 570 shows the format of each entry in the instruction table .

Table 570. Rx parser instruction entry format

Field	Field Name	Description
31:0	MATCH_DATA	This is a 4-byte data. You can use it to compare with incoming packet data which starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are 1 (MATCH_EN bits of [63:32]). See the notes (below this table) on the byte order relative to Ethernet arrival data and endianness which the QoS IP supports on the slave interface. The programming of this instruction table must adhere to the same.
62:32	MATCH_EN	When the MATCH_EN = 1, you can use the corresponding packet data bit for comparing. Otherwise, corresponding data bit is don’t care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NC	Next instruction control
71:68	Reserved	-

Table continues on the next page...

Table 570. Rx parser instruction entry format (continued)

Field	Field Name	Description
79:72	Frame offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0) Conpare the frame offset in the packet data for Match.This is in terms of 4 bytes. The value of actual frame offset in bytes are 0 01 42 8… ..63 252 The max value programmed in this instruction table is 128 B. The 'Actual frame offset' must not cross this limit.
87:80	OK index	If (NIC==0) the memory index you can use next when ENTRY_MATCH==1 and neither AF or RF = 1. If (NIC==1) the memory index you can use next when ENTRY_MATCH==0
95:88	DMA Ch No	Indicates the DMA channel number (1-bit for each). You can use this when ENTRY_MATCH ==1 and AF = 1 (Accept frame). The following bits give the encoding: bit[0]- DMA channel number o, bit[1]- DMA channel number , 1bit[2]- DMA channel number 2… bit[7]- DMA channel number 7. **NOTE** You can encode the DMA channel number using bit wise as QoS IP support multicasting or broadcast across DMA channels. See section 3.3.12 for more information and proper usage.
128:96	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 96-bits).

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the current entry parser result. Flexible receive parser flow chart shows the detailed flow.

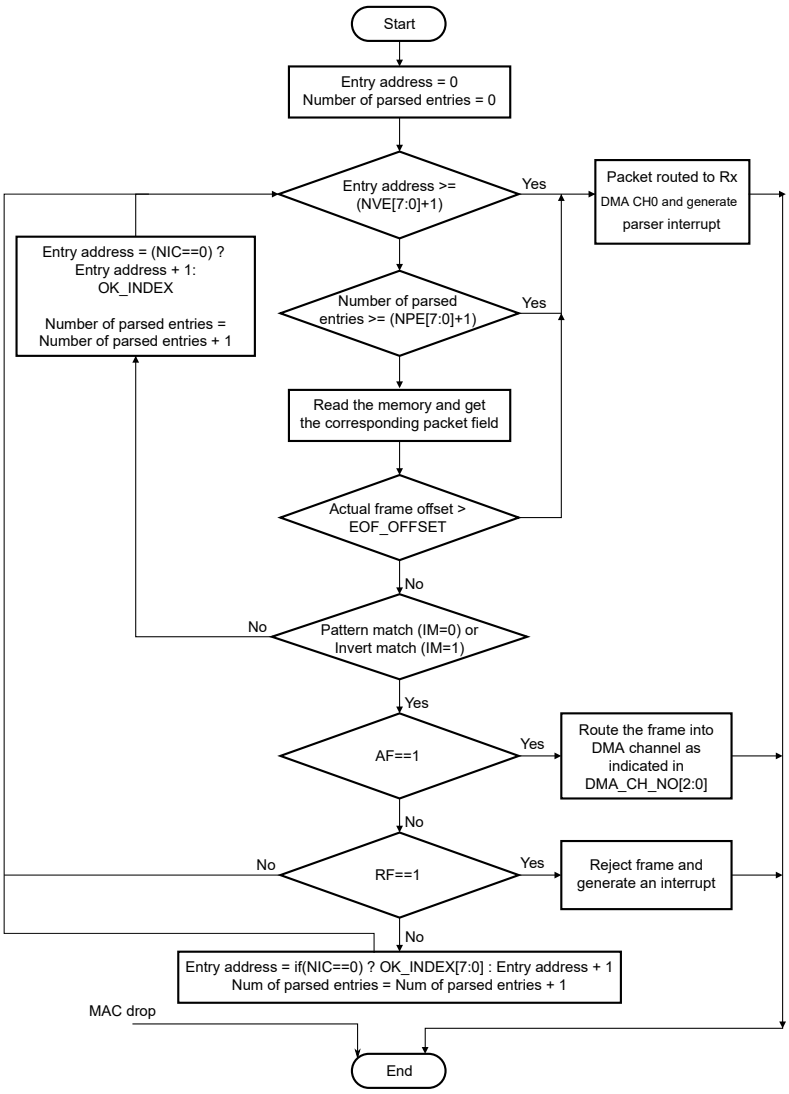

Figure 432. Flexible recieve parser flow chart

The EOF_OFFSET shown in the figure is the least among the following:

- Actual packet size
- 128 Byte when frame pre-emption feature is not enabled or configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible
- 64 Byte when frame pre-emption feature is enabled and packet is express packet

75.10.6.2 Number of valid entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. You can change this value by writing into MTL_RXP_Control_Status[NVE].

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NVEOVIS], if the entry address is greater than MTL_RXP_Control_Status[NVE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

75.10.6.3 Number of parsable entries (NPE)

NPE indicates the number of entries that you can parse on an incoming packet. The default value is 64. Write into MTL_RXP_Control_Status[NPE] to change this value.

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NPEOVIS], if the number of parsed of parsed entries is more than MTL_RXP_Control_Status[NPE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

NVE[] indicates the number of valid entries in the receive parser memory which you have built and NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

75.10.6.4 Frame offset

It indicates the frame offset, in terms of 4 bytes which you use when comparing against the current table entry.

In an entry, an error is flagged in MTL_RXP_Interrupt_Control_Status[FOOVIS] in any of the following cases:

When frame offset is more than:

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an express packet

IP generates an interrupt status (<xref href="DWC_ether_qos.dita#MTL_Interrupt_Status/MTL_Interrupt_Status.MTLPIS" >MTL_Interrupt_Status[MTLPIS]</xref>).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the receive parser declares a frame offset error if you enable comparison (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

75.10.6.5 Frame reject

You can drop the frame in cases, where an entry matches (considering the inverse match, IM bit in the instruction table) and frame accept bit is not 1, and frame reject bit (RF) = 1.

When a frame drops because RF = 1, IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

75.10.6.6 Out of order processing

The Rx parser flow can be out of order. The decision tree is not based on the order in which packet arrives. This implies that the next entry and next frame offset (OK_INDEX[] and FRAME_OFFSET[]) can be less than the current entry address and current frame offset.

75.10.6.7 DMA channel selection

When you enables the receive parser (MTL_Operation_Mode[FRPE] = 1) it overrides the MAC DMA selection criteria.

When you disables the receive parser (MTL_Operation_Mode[FRPE] = 0) the MAC/MTL determines the DMA channel number.

75.10.6.8 Receive queue selection

The existing MAC functionality determines the receive queue, irrespective of whether the receive parser is enabled or disabled. This is because the receive parser is mainly designed to select the DMA channel and the MAC decides the receive queuing to enable the proper functioning of the pause or PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on receive parser.

75.10.6.9 MAC packet filtering/drop/error handling

Packet filtering is done on the basis of the received packet fields. You must disable the packet filtering features inside the MAC when the receive parser is enabled. Follow these steps to disable the packet filtering features inside the MAC :

1. Write 1 to the Promiscuous mode (MAC_Packet_Filter[PR]).
2. Write 1 to all other fields in MAC_Packet_Filter to its default values.

When MAC decides to drop the packet due to the receive MAC dependent error such as:

- GMII error
- Receive watchdog error
- CRC error
- Giant frame error

the packet drops irrespective of the receive parser decision.

75.10.6.10 Pad strip or CRC strip handling

Software controls the pad strip and CRC strip and it is applicable to all the received packets. Also,software must build the receive parser instructions accordingly, when you enable these features.

NOTE

Enable pad and CRC stripping in real use case.

75.10.6.11 VLAN strip handling

MAC supports stripping the outer VLAN as well as inner VLAN. When you program MAC to strip the VLAN, the receive parser considers those VLAN tags to be part of the incoming packet.

75.10.6.12 Multicast and broadcast support

IP supports multicast and broadcast packet and the packet route to the highest queue number.

When you enables the receive parser, the DMA channel numbers (DMA CH NO, Bits [95:88]) in the instruction table, decide the packet routing.

When you disables the receive parser, DCS (DMA Channel Select) field of the MAC_AddressX_High register determines the packet routing. See the Broadcast/multicast packet duplication.

NOTE

You can select multiple DMA channels for the packet routing because the DCS/DMA CH NO field is per the DMA channel control.

75.10.6.13 Pre-emption support

IP supports the frame pre-emption feature when the flexible receive parser feature is enabled. It has the following limitations:

- Number of bytes would be 64, so that the receive parser can operate on an express traffic
- Number of bytes would be 128, so that receive parser can operate on a pre-emptible traffic.

75.10.6.14 Software access to the flexible receive parser memory

Software can read and write into the receive parser memory. It uses the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_Data

For more details, see GMAC register descriptions.

75.10.6.15 Statistical counters

IP supports these statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see GMAC register descriptions.

75.10.6.16 Changing the instruction table by software

Software can update the instruction table in the memory in the following ways:

- Disables the MAC receiver and receive parser by writing 0 to MAC_Configuration[RE] and MTL_Operation_Mode[FRPE]. It waits for receive parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Programs in the entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory), where you can program it to reject or accept all the packets.

75.10.6.17 Receive cut-through functionality

In the Cut-Through mode, the receive controller transfer the received packets to DMA just after it receives the cut-through threshold amount of packet data (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the receive controller delays the packet transfer to DMA accordingly, and the cut-through functionality is re-defined as follows:

The receive controller transfers packet to DMA after at least RTC number of bytes have been received and receive parser results are available.

75.10.6.18 Receive packet drop indication

In most cases, the packet drops internally in the receive queue. However, back-to-back packets can arrive for the same queue and the first packet's receive parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the application interface and indicates the status accordingly. See RDES2, bit 16(RXPD) in Receive normal descriptor (write-back format) for more information.

75.10.6.19 Runt packet handling

The receive parser can performs the operation with 64B minimum size packet. If the runt packet is received (MAC must indicate it), the receive parser assumes that it is dropped in the MAC, this is because, the back-to-back runt packets (< 64B) cannot be handled in the receive parser.

75.10.6.20 Uncorrectable ECC error handling

The packet does not drops when the parser detects an uncorrectable ECC error while parsing the parser memory. The packet is sent to the application with an error indication. The RXPI (RX parser incomplete) sets in the packet status along with error summary (ES) bit.

See the Receive normal descriptor (write-back format) for more information.

75.11 IEEE 1588 timestamp support

This section and all its sub-sections are Synopsys proprietary. Used with permission.

IP supports the IEEE 1588 precision time protocol (PTP). It is also able to do precise time stamping and captures incoming and outgoing frame because of the PTP protocol implementation in the IP. It supports all the clock types defined in IEEE 1588-2008. The typical frequency of PTP timestamp clock is 125 MHz.

IP supports these features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

75.11.1 Delay request-response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 433 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

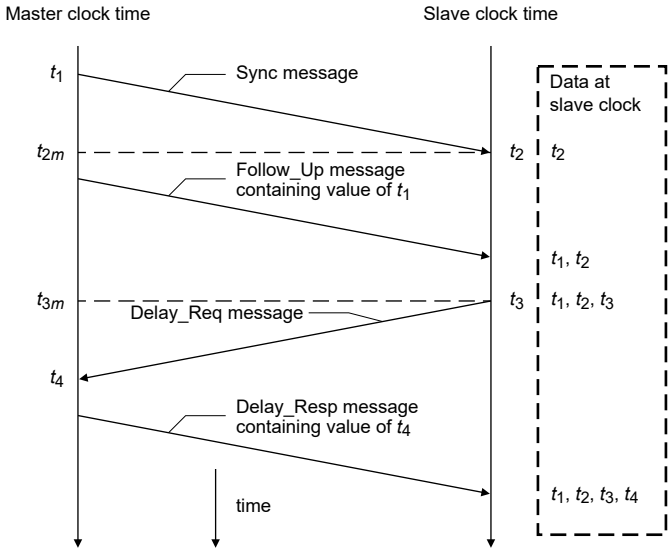

Figure 433. Networked time synchronization

As shown in the figure, PTP uses this process:

1. The master broadcast the PTP sync messages to all its nodes. The sync message contains the reference time information of the master. This message leaves the system of the master at t1. You must capture this time for Ethernet ports at GMII or MII.
2. The slave receives the sync message and it also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and note the exact time, t3, at which this packet leaves the GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave use the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware captures the exact time when specific PTP packets enter into or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

75.11.2 Peer-to-peer PTP transparent clock (P2P TC) message support

The IEEE 1588-2008 supports the peer-to-peer PTP (Pdelay) message in addition to the sync, delay request, follow-up, and delay response messages. Figure 434 shows the method to calculate the propagation delay in clocks supporting the peer-to-peer path correction.

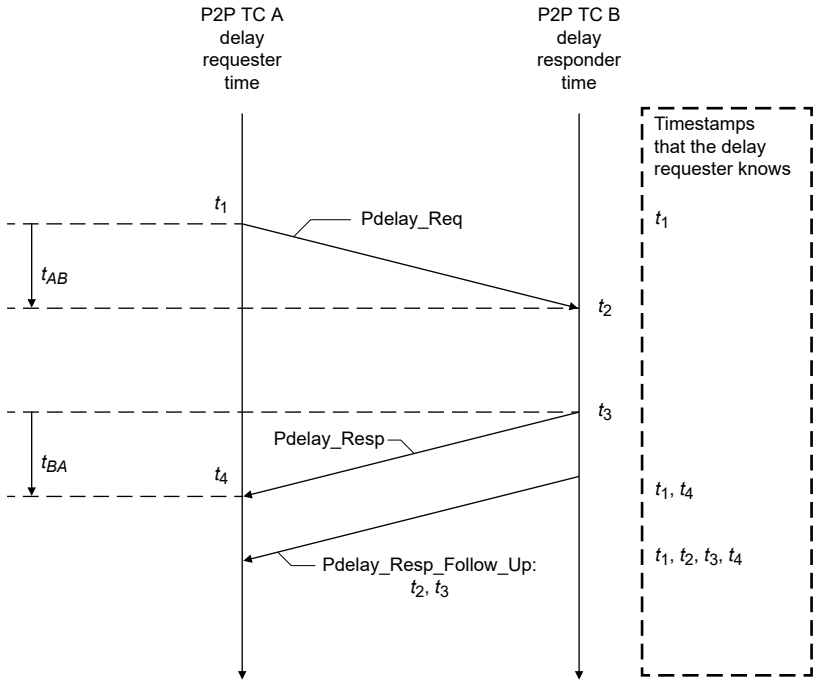

Figure 434. Propagation delay calculation in clocks supporting peer-to-peer path correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives a Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message, to minimize the errors because of any frequency offset between the two ports. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) after receiving the Pdelay_Resp message.
5. Port 1 uses all the four timestamps t1, t2, t3, and t4 to compute the mean link delay.

75.11.3 Timestamp correction

According to the IEEE 1588 specification, you must capture a timestamp when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the start frame delimiter octet) crosses the boundary between the node and the network. As MAC takes the timestamp at an internal point far from the actual boundary of the node and network, you must correct or update the captured timestamp for the ingress or egress path latency (including the delay in the PHY layers). Further

correction is done for the inaccuracies or errors introduced because the clock (MII Tx, Rx clock) is different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that generates the time. The resultant CDC (Clock domain crossing) circuits add an error depending on the clock period of the MII and PTP clocks.

75.11.3.1 Ingress correction

The timestamp captured at the internal snapshot point In the receive side is delayed (later in time) as compared to the time at which the packet's SFD bit is received at the port's boundary. Therefore, the ingress latency and the errors in CDC sampling reduces the captured timestamp. You must determine or calculate the correction value and write into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum ingress latency. You can read these registers and determines the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the ingress latency from its datasheet or timing characteristics.

2. Internal latency from the core's input to the internal capture point.

   You can read the internal ingress latency from MAC_Timestamp_Ingress_Latency. This is a read-only register and provides the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC, to determine the current internal latency.

3. CDC synchronization

   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_pt-p_ref_i).

You must add the values that these three components determine and must write into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written into the register must be negative (two's complement as explained below), because it is subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When MAC_Timestamp_Control[TSCTRLSSR] is 1, it indicates that the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be 1 (for negative value) and bits[30:0] must write with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When MAC_Timestamp_Control[TSCTRLSSR] becomes 0, it indicates that the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must write with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

75.11.3.2 Egress correction

The timestamp captured at the internal snapshot point in the transmit side is earlier (advanced in time) as compared to the time at which the packet's SFD bit is output at the port's boundary. Therefore, the egress latency and the errors in CDC sampling must compensate the captured timestamp. You must determine or calculate this correction value and write into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between the core output and the port and the network boundary

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum egress latency. You can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), you must dertermine the egress latency from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the core output of the c

   You can read this internal egress latency from MAC_Timestamp_Egress_Latency. This is a read-only register and gives the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

75.11.3.3 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains that is from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between the two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between the two captured timestamp is less than this delay, MAC does not take a timestamp snapshot for the second packet.

75.11.3.4 PTP processing and control

Table 571 shows the common message header for the PTP messages. This format is defined in the IEEE 1588-2008.

Table 571. Message format defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2 message type field is used for detecting different message types.

There are some fields in the Ethernet payload that detects the PTP packet type and controls the snapshot to be taken. These fields are specified in Table 572 for PTP packets over Ethernet.

Following table provides the information about the fields that match to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and version 2. The octet positions are offset by 4 for the tagged packets. This is based on the IEEE 1588-2008, Annex D, and the message format.

Table 572. Ethernet PTP packet fields required for control And status

Field matched	Octet position	Matched value	Description
MAC destination multicast address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC packet type	12, 13	0x88F7	PTP Ethernet packet
PTP control field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP message type field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), which is programmed in MAC address 0 to 31, is used if MAC_Timestamp_Control[TSENMACADDR] = 1.
2. IEEE 1588-2008, Annex F
3. MAC does not consider the PTP version 1 messages with peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

75.11.4 Transmit path functions

MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. You can control the packets, for which the timestamps are captured on a per-packet basis and mark each transmit packet to indicate whether to capture a timestamp for it. MAC does not process the transmitted packets to identify the PTP packets. You can use the control bits in the transmit descriptor to specify the packets. MAC returns the timestamp to the software inside the corresponding transmit descriptor and therefore connects the timestamp automatically to the specific PTP packet. You must write the 64-bit timestamp information to TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

75.11.5 Receive path functions

You can program MAC to capture the timestamp of all packets received on the MII interface or to process the packets to identify the valid PTP messages.

You can use these options of MAC_Timestamp_Control to control the snapshot of the time sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 573. Timestamp snapshot dependency on register bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

DMA returns the timestamp to the software inside the corresponding receive descriptor. The extended status, contains the timestamp message status and the IPC status. You must write the extended status in the normal descriptor RDES1 and the snapshot of the timestamp in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

See the System time correction for programming guidelines for IEEE 1588 timestamping (System time correction).

75.11.6 IEEE 1588 system time source

IP supports both the external and internal time source for reference timestamping.

- External time source uses the 64-bit external time reference and clock as an input in IP. The clock input synchronizes the external timing reference into the MAC clock domain. Upper 32-bit indicates the time in seconds and the lower 32-bit indicates the time in nanoseconds.
- Internal time source uses the only clock input to generate timing reference internally for snapshot and capture timestamps. Internal time reference has two fields.
  - UInteger48 seconds field: The seconds field is the integer portion of the timestamp in seconds units. It is 48-bit wide.

    For example, 2.000000001 seconds are represented as seconds field = 0x0000_0000_0002.

— UInteger32 nanoseconds field The nanoseconds field is the fractional portion of the timestamp in nanoseconds units.

For example, 2.000000001 seconds are represented as nanoseconds field = 0x0000_0001. The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after 0x7FFF_FFFF value . Accuracy is ~0.466 ns per bit.

There is a system time register module, it is used when you use an internal time reference. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets which is transmitted or received at the MII interface.

Initialize or correct the system time counter using the coarse correction method. In this method, write the initial value or the offset value to the timestamp update register. For initialization, write the system time counter with the value in the timestamp update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, correct the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) over a period of time instead of in one clock, as in coarse correction. This maintains linear time and does not introduce drastic changes (or a large jitter) in the reference time between the PTP sync message intervals.

See Initialization guidelines for system time generation for programming guidelines for IEEE 1588 timestamping (For internal timestamp source configuration).

75.11.7 IEEE 1588 higher word register

You can invoke the higher word register if system time source is internal. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field are read from the CSR register.

75.11.8 Flexible pulse-per-second output

IP supports the flexibility of programming the start or stop time, generates pulse width and interval on pulse-per-second output. It also support four such output signals. By default, IP is in fixed pulse-per-second output mode with interval of 1 second.

Initially you must program the start time in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired or enabled pps output. If you re-programs start or stop time then you must do it after the synchronization of earlier programmed value. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, MAC sets an error status bit which indicates the programming error. If enabled, MAC also sets the target time reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

Program the PPS width and interval in terms of granularity of system time, that is, the number of units of sub-second increment value.

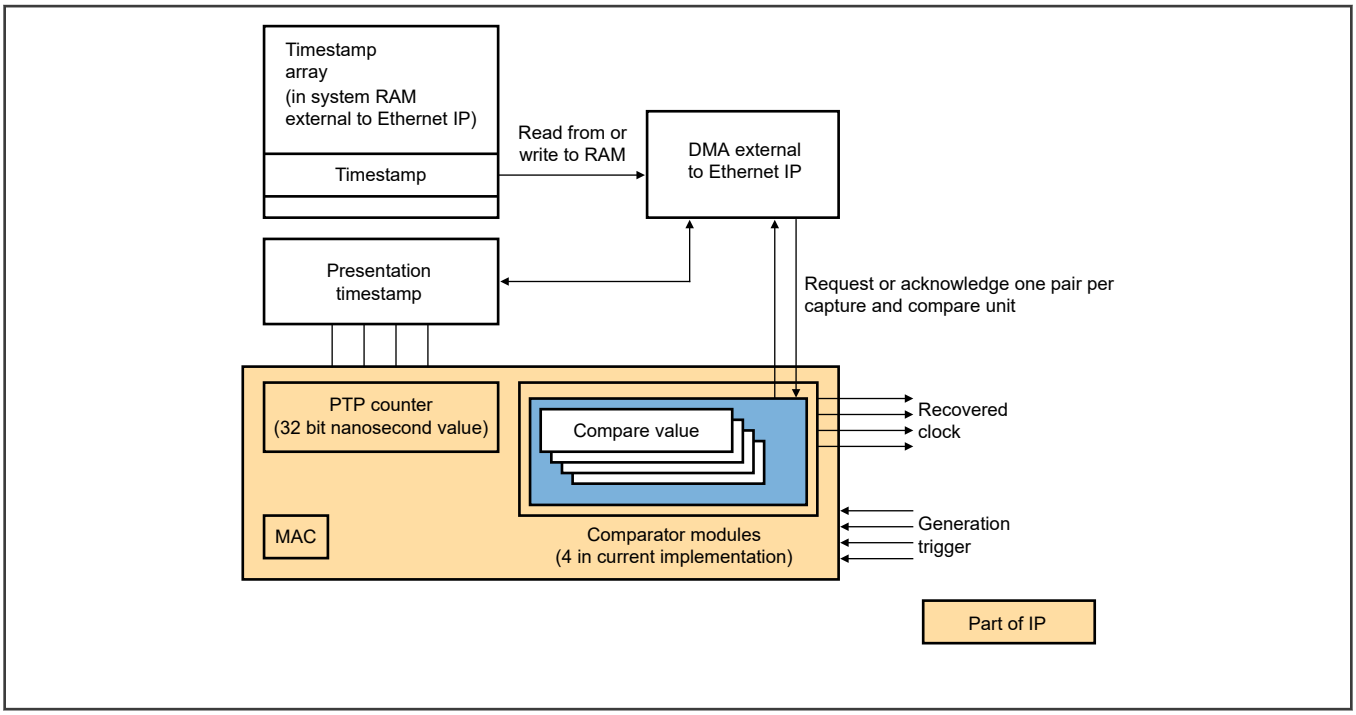
See Programming guidelines for flexible pulse-per-second output for more information.

75.11.9 Media clock generation and recovery

Media clock recovery and generation requires a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of a dedicated hardware which multiplies to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and program these values into CSR registers so that IP can read them for media clock recovery.

Figure 435 shows that the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that completes at the full 32-bit value to match with 1722 presentation time format and an handshake mechanism with an external application (such as DMA) to program the presentation time into CSR register.

Figure 435. Media clock generation and recovery block diagram



75.11.9.1 Presentation time counter

Presentation time counter provides an another perspective of the PTP system time (1588 timer). For a given PTP system time (PTP[63:32] represents time in seconds Comparator modules and PTP[31:0] represents time in nanoseconds), there exists a corresponding presentation time (32-bit value in nanosecond). The presentation time computed is referred to as current presentation time (CPT).

CPT derives from 64-bit PTP system time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64-bit nanosecond value.

Current presentation time[31:0] = PTPNS[31:0]

Media clock recovery is possible when the system time is internally generated in IP and compute the CPT in the same way as the internal PTP system time generation. The increment cycle of CPT and system time are same because the values of both the timers are in nanoseconds and they are synchronous. The timer updates at the same instance, but the updated value could be different. You must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input generates media clock timestamps that are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

75.11.9.2 Comparator modules

Figure 435 shows that the module supports four comparator modules to handle multiple media clocks that it may require. When MAC_Timestamp_Control[PTGE] is 1, it indicates that the comparator modules handshake with the application to program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register.

Write 1 to presentation time control fields of the particular instance for recovery mode.

The timestamps received from the application are referred as target presentation time (TPT).

When MCGREN#i field of MAC_PPS_Control is 1, it indicates that the IP operates in MCGR mode. The comparator module sends upto two requests to the application for TPT write, when MAC_Timestamp_Control[PTGE] and the presentation time control bits of the particular instance are 1 for MCGR mode. Subsequent requests are generated each time a presentation time match occurs. CPT transitions from a value less than TPT, to a value greater than or equal to CPT. The first request asserts when a specific comparator instance sets to MCGR mode with a non-zero presentation time control and an additional request is made when the comparator receives the first data. This allows the application to write the next TPT value when IP processes the previous TPT value for a match.

TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle or pulse is generated in the next cycle when a match is detected. Also,the mcgr_dma_req_o#i request for that comparator asserts (to obtain next TPT) until the corresponding application acknowledgment is set, when a match is detected.

The presentation control fields (PPSCMD#i field of MAC_PPS_Control) determine the shape of the generated waveform. You can program these fields to either toggle or generate a high/low pulse for one PTP clock cycle, when matched.

Media clock recovery: A match occurs, when the free-running CPT value matches the received TPT value. An output signal, EMAC_TMR signal as shown in the IO mux sheet asserts (toggle, low pulse, or high pulse) on the basis of the programmed presentation control value.

Media clock generation: On the basis of the presentation control value programmed in MAC_PPS_Control, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. The captured timestamp is read when a request is raised to the application. No new timestamps are captured, until the read operation is complete acknowledgment is received from the application.

75.11.9.3 Media clock generation and recovery flow

Figure 436 shows the media clock generation and recovery flow. Write 1 to MAC_Timestamp_Control[PTGE] for CPT generation and write 1 to MAC_PPS_Control MCGREN#i field to enable the corresponding instance in the MCGR mode, for both media clock generation and recovery.

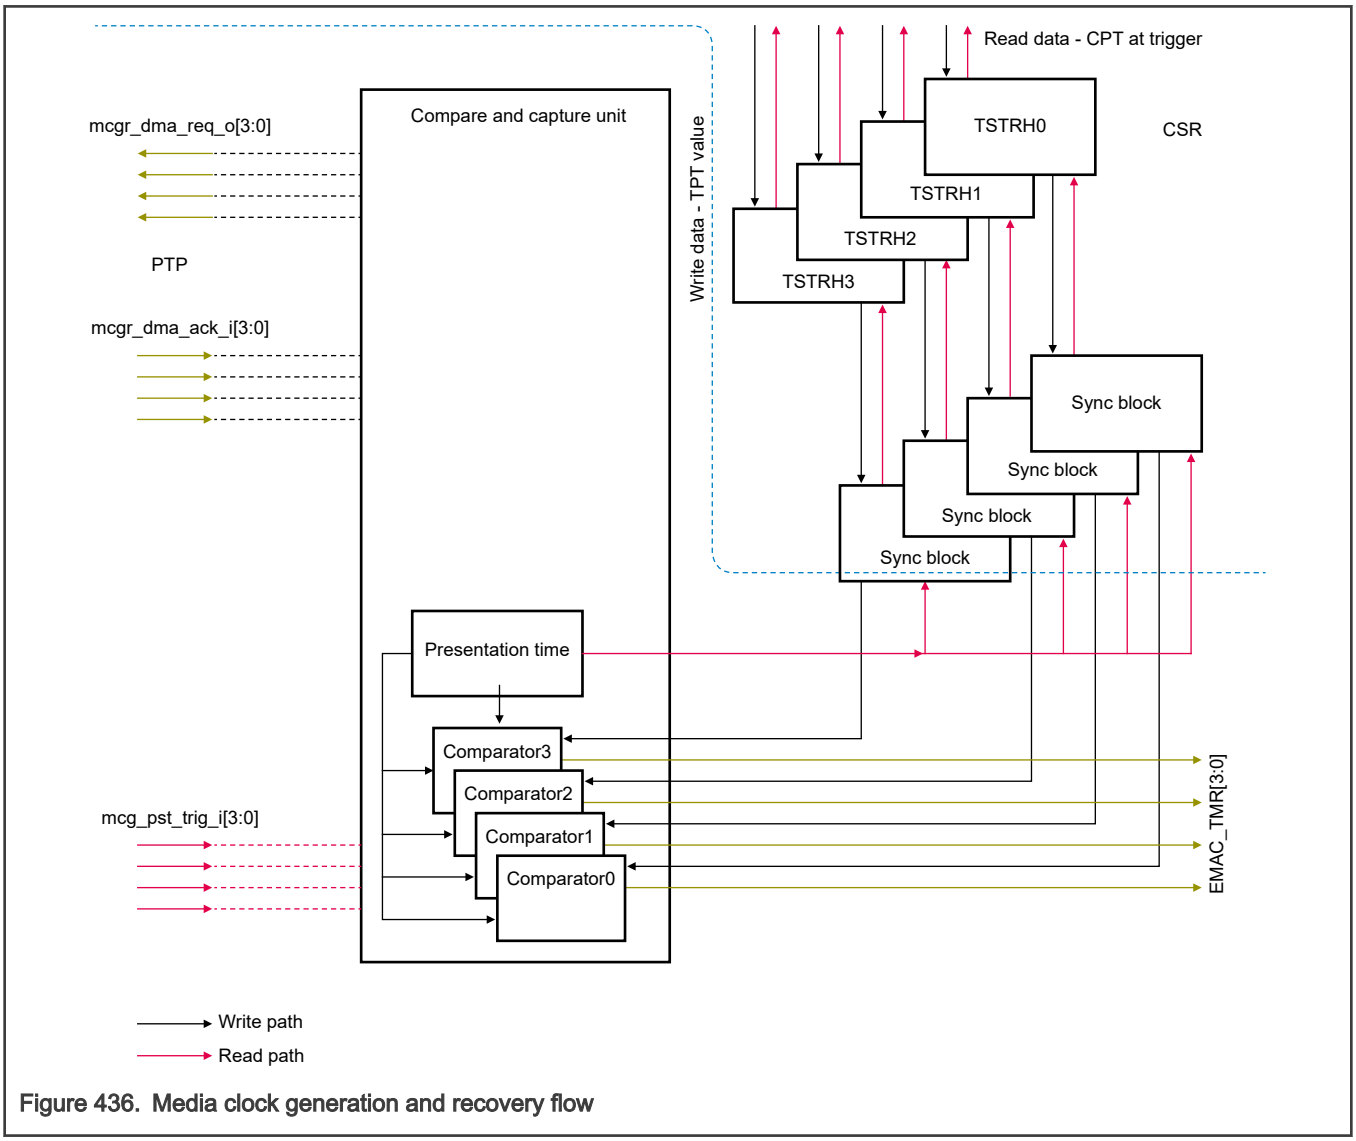


Figure 436. Media clock generation and recovery flow

NOTE

1. The consecutive triggers to sample the presentation time must assert after a few PTP clock cycles so as to allow synchronization delays. (There is no such issue when the input trigger maximum frequency is 8 KHz and the PTP clock runs at least at 1MHz)
2. In the Media Clock Recovery mode, the DMA acknowledgment is both posted as well as non-posted.

See Programming guidelines for media clock generation and recovery for more information.

75.11.10 One step timestamp

IP supports the one step timestamp feature. Writing 1 to bit 20 (OSTC) in the control word, enables the one step timestamp feature for a packet.

See the Programming guidelines for IEEE 1588 timestamping for more information.

75.11.11 IEEE 1588 sub nanoseconds timestamp

IP supports the ingress and egress correction accuracy in sub nanoseconds. It is programmed in MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS], respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. You must program the least significant 8 bits of the value in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Egress_Corr_Nanosecond[TSEC] must be 0x3 and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS] must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Ingress_Corr_Nanosecond[TSIC] must be 0xBB9A_C9FC and MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] must be 0x66 (fractional part of (10^9 - 3.6) * 256).

75.12 Multiple channels and queues support

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP support three queues and channel on Tx and Rx paths. Figure 437 shows the architecture of IP with three queues and channel.

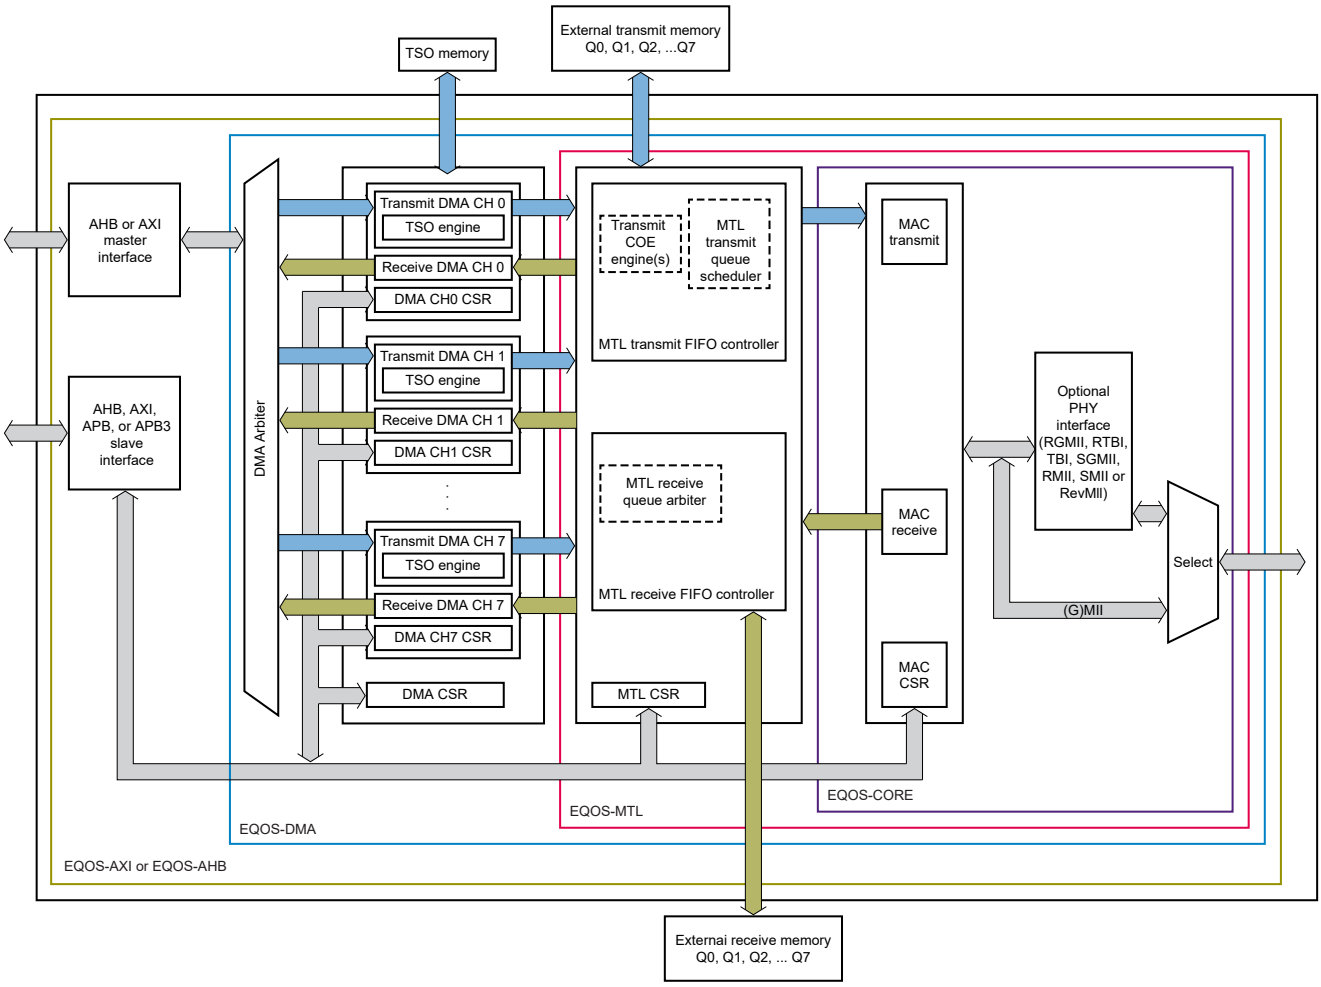

Figure 437. Module with multiple channels and queues block diagram

The above block diagram, support only three queues.

IP DMA arbiter support two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels to access descriptors and data buffers. DMA_Mode[DA] specifies the arbitration scheme (fixed or weighted round-robin) between the channel Tx and Rx DMA.

DMA_Mode[TXPR] sets the priority between the corresponding Tx DMA and Rx DMA. Writing 1 to DMA_Mode[PR] specifies the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Table 574 provides an information about the priority scheme between Tx DMA and Rx DMA.

Table 574. Priority scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1

Table continues on the next page...

Table 574. Priority scheme for Tx DMA and Rx DMA (continued)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

75.12.1 Multiple queues and channels support in the transmit path

IP support three transmit queues and three channels.

Fixed priority scheme is the default priority scheme for the DMA channels and channel with highest priority always wins the arbitration when it requests for the bus. Channel 0 is always of lowest priority and channel 1 is always of highest priority.

In weighted strict priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. Reallocate the unused burst transfers of one or more channels on the basis of the priority. The channel with highest priority receives the unused burst transfer time before it is allocated to a channel with the next highest priority. You can process the next lower priority, when a channel uses the allocated burst transfers. After processing the allocated bandwidth of all the channels that have packets to transmit, allocate any unused burst transfer time to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

In weighted round robin (WRR) priority scheme, program the weight through TCW field of DMA_CH#_Tx_Control register. IN WRR scheme, service all channels in round-robin order according to the weights settings. Table 575 shows that the TCW field of DMA_CH#_Tx_Control register provides the weight for each transmit channel.

Table 575. Weight for DMA channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

See Programming guidelines for multi-channel multi-queuing for more information.

75.12.2 Multiple queues and channels support in the receive path

IP support three receive channels and three queues.

In the receive direction, the MTL Rx controller selects the Rx DMA for which it transfers or reads the data from the receive FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it will transfer. The scheduler checks whether sufficient data (of requested burst length) is available to transfer to these DMAs and then selects the receive DMA that is serviced using the programmed priorities.

See Programming guidelines for multi-channel multi-queuing for more information.

75.12.3 Rx queue to DMA mapping

You can program MTL_RxQ_DMA_Map0 (for queues 0, 1, and 2) to route the packets in the MTL receive queues to any one of the multiple DMA channels.

The following types of receive queue to DMA mapping is possible through programming.

75.12.3.1 Static mapping

In this mode, you can connect all the packets of the receive queue to a specific DMA channel. For example, all the packets from the receive queue 0 program MTL_RxQ_DMA_Map0[Q0MDMACH] (bit[3:0]) and MTL_RxQ_DMA_Map0[Q0DDMACH] (bit[7] = 0) to route to a DMA channel.

Similarly, packets from other receive queues program register fields corresponding to each queue to route to any DMA channel.

75.12.3.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet read from a Rx queue is not constant but it is decided independently for each packet. For example, if you write 1 to MTL_RxQ_DMA_Map0[Q1DDMACH], it indicates that the static mapping disables for receive queue 1 and ignores the value in MTL_RxQ_DMA_Map0[Q1MDMACH]. The MAC receiver decides the destination DMA channel for each packet, depending on the following in decreasing order of priority:

1. **L3-L4 filter based DMA selection**: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number, if DMCHEN field of the same register is 1. If none of the L3-L4 registers give a comparison match, then the module proceeds to the next step below.
2. **Extended VLAN based DMA selection**: Extended routing is applicable only if the VLAN filter has passed. Routing is done only on the basis of the perfect filter result. Each perfect filter has a DMA channel enable and a DMA channel number field which you can program. Routing is applicable for a filter, only if the DMA channel enable field is 1. The frame routes to the smallest matching filter's DMA channel, if it is enabled. If the filter's DMA channel number is not enabled, the frame route to channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1, then the MAC checks if DMA channel number of filter 1 is enabled through programming. If yes, the frame route to the programmed value; otherwise it route to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame routes on the basis of the DA based addressing or to channel 0.

   If hash filter is also enabled, it is determines the filter result only. Routing will still depends on the enabled perfect filters. Routing based on the VLAN filter will not occur if none of the perfect filters are enabled or if all of them are bypassed. The frame will route via DA based addressing or to channel 0. If all the perfect filters fails and the hash filter has passed, then the VLAN filter result is a pass but routing will be based on DA based addressing or to channel 0. Similar behavior is seen when you enables inverse filtering as well.
3. **Ethernet DA-based DMA selection**: The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations make a successful match or decision, then the packet routes to the DMA channel 0 by default.

75.12.3.2.1 Broadcast/multicast packet duplication

This feature provides a mechanism to send the received broadcast or multicast packets to multiple DMA channels.

MAC_Address0_High[DCS] and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC address present in that register) must route.

DMA channel routing mechanisms such as extended VLAN, or L3-L4 based routing does not support the packet duplication.

The packet duplication feature is supported only on the highest MTL queue configured. Therefore, you must program MAC_RxQ_Ctrl1[MCBCQ] to the highest RxQ present in the configuration for the packet duplication for broadcast or multicast packets.

75.12.4 Selection of tag priorities assigned to receive queues

Program the PSRQ field in the corresponding MAC_RxQ_Ctrl2 to assign the VLAN tag priorities to receive queues. The bit corresponding to the VLAN tag priority can be set in the PSRQ field for assigning that priority to the receive queue. For example, if you want to assign VLAN tag priority of 3 to receive queue 0, write 1 to bit [3] in PSRQ field of MAC_RxQ_Ctrl2. The VLAN tag priority assigned to particular receive queue must be unique, that is, you cannot assign more than one receive queue to the same VLAN tag priority. However, more than one VLAN tag priorities can be assigned to same receive queue.

The settings in the PSRQ field is used for VLAN tagged receive packet routing to receive queues as well as for PFC based transit flow control. The received VLAN tagged receive packet route to receive queue that has the VLAN tag priority match. In PFC based transit flow control, PSRQ field corresponding to a particular receive queue enables VLAN tag priorities in the PFC packet transmitted when corresponding receive queue reach the threshold level.

75.12.5 Receive side routing from MAC to queues

IP supports receive side routing from MAC to queues. MAC route the receive packets to the receive queues on the basis of the these packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter

- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN tag priority field in VLAN tagged AV data packets
- AV control packets
- VLAN tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN tag priority field in VLAN tagged packets
- Untagged packets

You can route the outer C-VLAN tagged AV data receive packets on the basis of the priorities assigned to receive queues through PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature enables (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with an inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of Rx packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the AV control receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[AVCPQ] and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature is enabled (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of receive packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the VLAN tagged receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue for DCB/generic. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged IEEE 1588 PTP over Ethernet receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[PTPQ] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. Also, you can route the VLAN tagged IEEE 1588 PTP over Ethernet receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 or the receive queue number specified in the MAC_RxQ_Ctrl1[PTPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 register enables the corresponding Rx queue. Programming MAC_RxQ_Ctrl1[TPQC] determines this. This type of receive packet routing is available when IEEE 1588 timestamp feature supports and the multiple receive queues are selected in the configuration. The VLAN tagged IEEE 1588 PTP over Ethernet receive packets are detected only when you disables 802.1AS mode (MAC_Timestamp_Control[AV8021ASMEN] = 0), otherwise this type of receive packets are routed as generic VLAN tagged Rx packets.

You can route the multicast or broadcast destination address receive packets that passes the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[MCBCQ]the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MAC_RxQ_Ctrl1[MCBCQEN] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of Rx packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[UPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The unicast destination address receive packets that fail the destination address filter can be routed based on the receive queue number specified in MAC_RxQ_Ctrl4[UFFQ] when enabled through MAC_RxQ_Ctrl4[UFFQE]UFFQE, MAC_Packet_Filter[RA] = 1 and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the multicast destination address receive packets that fails the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl4[MFFQ] when MAC_RxQ_Ctrl4[MFFQE] enables it. MAC_Packet_Filter[RA] = 1 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The receive packet will route through the receive queue 0, if it is not classified in any of the defined packet type for routing.

75.12.6 Receive side arbitration between DMA and MTL

IP controller supports receive side arbitration between DMA and MTL.

After the current packet processing completes, the DMA channel controller fetches the next descriptor and after the descriptor fetching completes, the DMA channel controller evaluates the amount of data to transfer to the Rx buffer on the basis of the programmed PBL and receive buffer length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL receive queue arbitration scheme selects receive queue on the basis of the arbitration scheme (MTL_Operation_Mode[RAA]) and the weights programmed in queue <n> receive control register. The arbitration is done among queues for which DMA is ready to service. After the receive queue is selected, PBL amount of data is read out from that queue and route to the receive DMA channel on the basis of the receive channel selection criteria.

The arbitration occur after every PBL data transfer completes and descriptors are ready for processing from at least one DMA channel.

75.12.7 Transit side arbitration between DMA and MTL

IP supports transit side arbitration between DMA and MTL. Transit DMA channels and transit queues are always mapped directly because the number of transit DMA channels are always equal to the number of transit queues in MTL. For instance, each transit DMA pushes data into its respective transit queue assigned to it.

The data inside each transit queue is stored in packets. Therefore, if two DMAs are allowed to transfer data into the same queue, when a transit DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding transit queue.

75.12.8 Audio video bridging

IP supports the audio video bridging in 100 Mbps mode only, which allows the transmission of time sensitive traffic over network. IP implements these protocol for supporting the AVB feature:

- IEEE 802.1Qbv-2015 (Enhancements to scheduling traffic)
- IEEE 802.3br (Interspersing traffic)
- IEEE 802.1Qbu (Frame preemption)

The queue 0 transmit path supports the strict priority algorithm, and it is used for best-effort traffic when transmit paths of additional queues use the credit-based shaper algorithm to support traffic management. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if these conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive per the algorithm
- AV traffic is received on all queues. IP can also receive untagged PTP packets in addition to AV traffic on any queue.

75.12.9 Data Centre Bridging

The Data Center Bridging feature supports three types of algorithms:

- Weighted Round Robin: In Weighted Round Robin (WRR) algorithm, each queue is assigned a weight based on the percentage of configured bandwidth. All queues are serviced in the round-robin order according to the weight settings. This algorithm is less complex and requires less hardware as compared to other algorithms. Large packets get more bandwidth in this algorithm.
- Deficit Weighted Round Robin: In Deficit Weighted Round Robin (DWRR) algorithm, each queue is assigned a weight based on the percentage of configured bandwidth. A deficit counter holds the credit for transmission. The quantum value, proportional to the bandwidth, is added to the deficit counter every time a queue is scanned. The packet in the queue is selected for transmission only if the credit in the deficit counter is less than or equal to the size of the packet available at the head of the queue. A selected queue is serviced until the outstanding credit is lesser than the packet size at the head of the queue during a particular queue scan cycle. After this, the next lower priority queue is serviced. When the packets in a queue

are over, the credit becomes zero for that queue scan cycle. This algorithm is less complex, and it provides more fairness in scheduling as compared to other algorithms.

- Weighted Fair Queuing: In Weighted Fair Queuing (WFQ) algorithm, each queue is assigned a weight based on the percentage of configured bandwidth. The algorithm computes the finish time of packets at the head of the queues based on the packet size and weights for the queue. The packets with earliest finish time is scheduled for transmission first. The algorithm is more complex and less scalable as compared to other algorithms.

75.12.10 Queue modes

Transit and receive queues both handles the AV traffic.

Queueing is based on WRR (Weighted round robin) or WSP (Weighted strict priority) algorithm for generic traffic. It is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

The receive queue is configured for generic or AV based routing, which depends on the RXQ#EN field of corresponding queue. Queueing is done on the basis of the VLAN tag priority. The VLAN tag priority must match the PSRQ field of MAC_RxQ_Ctrl2. The receive packets can route to a particular DMA channel on the basis of the DCS field of perfectly-matched MAC address register.

By default, the untagged packets in a generic traffic route to the receive queue specified in MAC_RxQ_Ctrl1[UPQ]. Queue 0 is the default value of MAC_RxQ_Ctrl1[UPQ]. You can override the default value with any other value, for the MAC_RxQ_Ctrl1[UPQ].

The AV control packets (tagged or untagged) route on the basis of MAC_RxQ_Ctrl1[AVCPQ]. The PTP over Ethernet packets route on the basis of MAC_RxQ_Ctrl1[PTPQ].

75.12.11 Queue priorities

You can program the priority of an receive queue in the corresponding field of MAC_RxQ_Ctrl2. Also, you must program the AV queue (high priority) as an higher priority than the best-effort queue (low priority).

75.12.12 Enhancements to scheduled traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each queues on every egress port which makes the implementation aware of traffic arrival schedule. This information blocks the lower priority traffic from transmission in this time window or slot. This ensures that the sender forward the scheduled traffic to receiver through all the network nodes with a deterministic delay.

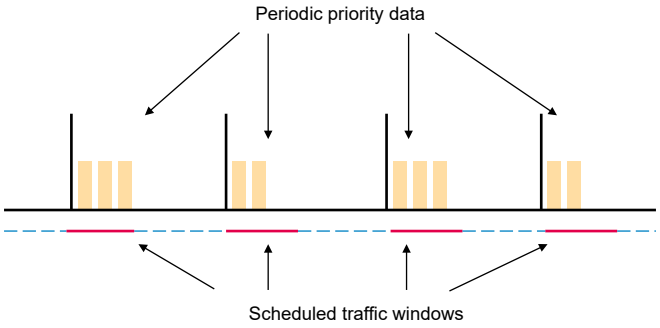

Figure 438. Time aware shaper implementation for traffic scheduling

An important requirement to achieve a low latency is to ensure that there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations when a transmission starts.

As shown in Figure 439 , if an interfering frame begins transmission just before the reserved time period starts, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

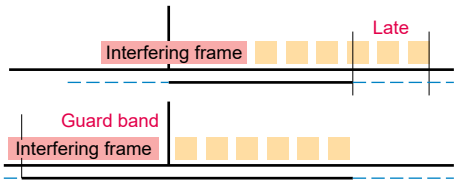

Figure 439. Implementing a guard band to avoid delays due to interfering frames

A larger guard band equates to a less efficient use of network bandwidth. However, this issue is addressed with the implementation of IEEE802.1Qbu (frame preemption). Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band must be as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

75.12.12.1 Frequently used terms in EST

These are some of the frequently used terms in the EST support and their definitions.

- Gate control list: The list in the hardware memory that hold the gate controls and the associated time intervals.
- Gate controls: For a given schedule (row in gate control list) there is a gate open (O) and gate close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the gate controls. Example: CCOCOOCO means TC7=C, TC6=C, TC5=O and so on.
- Time interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the gate control list that indicates the time for which the associated gate controls are valid.
- Base time register: Each gate control list is associated with a 64-bit base time register that holds the start time (in PTP format) for the list.

75.12.12.2 Updates to the transmit scheduling to support EST

To support EST, these updates are required to transmit scheduling:

- Implementation of gate control list (GCL)
- Enforcing gate controls in the scheduler
- Utilizing gate open (O) duty cycle in the computation of idleSlope (CBS)

75.12.12.2.1 Implementation of gate control list (GCL)

Figure 440 shows how the gate control list governs the gate close(C) and open(O) events on the basis of the schedule provided for each event. GCL has two parts:

- Time interval: Defines the time in nanoseconds for which the gate controls are valid and must apply before reading the next gate controls from the list. The configurable width of 16, 20 or 24-bit represents a maximum of 64us, 1ms, or 16ms schedule interval respectively. It supports left shift of the time interval upto 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate control: Defines the open (O) represented by logic 1 or close (C) represented by logic 0 state for the gate of each TC.

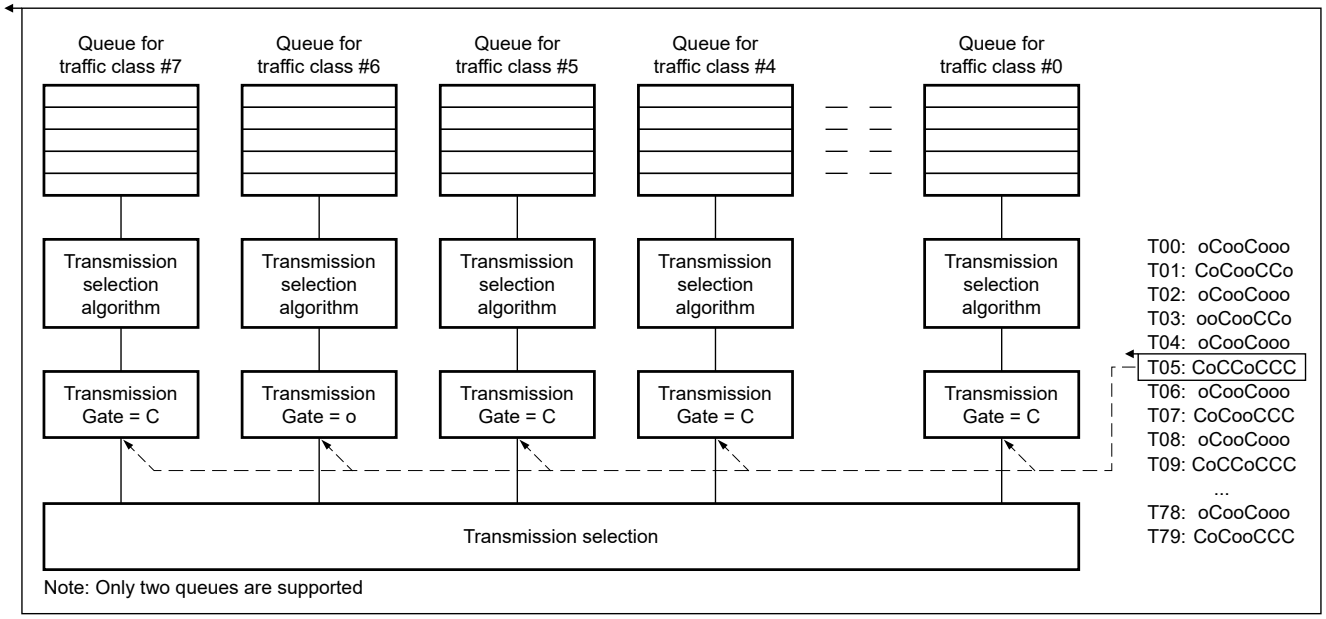

Figure 440. Block diagram from IEEE 802.1 Qbv specification - GCL governing gate close and open events

The implementation of GCL consists of these two gate control lists:

- HWOL - Hardware owned list which is a list for hardware access.
- SWOL - Software owned list which is a list for software access.

The access to these lists is mutually exclusive. Hardware sets the ownership to the list in MTL_EST_Status[SWOL]. Table 576 provides the implementation details of GCL.

Table 576. External memory used for holding the two gate-control lists

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
I	I	
I	I	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	

Table continues on the next page...

Table 576. External memory used for holding the two gate-control lists (continued)

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T2	
OOOOCCCC	T3	
I	I	
I	I	
OCOCCCCC		
OOCCCCCC	T last	

75.12.12.2.2 Registers related to gate control list

The following are the set of four registers (one for each GCL) related to GCL. These registers are implemented through Indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data registers.

1. 64-bit Base time register (BTR)

2. 40-bit Cycle time register (CTR)

3. m-bit Time extension register (TER)

4. n-bit [Gate control] List length register (LLR) (n depends of the configured GCL depth)

75.12.12.2.2.1 Base time register (BTR)

This is a 64-bit register that specifies the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nanoseconds). After the execution of a given list starts, the implementation can update the value in BTR to indicate the next list execution start time.

75.12.12.2.2.2 Cycle time register (CTR)

This is a 40-bit register that specifies the time at which the execution of the GCL must repeat. This register consists of an 8-bit value in seconds, and a 32-bit value in nanoseconds (similar to the PTP time format with truncated seconds register). For a given GCL, the start time is "Base Time" + N * "Cycle Time" where N is an integer value that represents the iteration number starting with 0 for first iteration. If the GCL execution takes longer than the cycle time, then the list is truncated at the cycle time and the subsequent loop begins at cycle time.

75.12.12.2.2.3 Time extension register (TER)

This is a m-bit (where m = Configured time interval width + 7) register that specifies the amount of time (in nano seconds) the current GCL can extend before switching to the new GCL. This helps to avoid the execution of the small fragments of the current list before switching to a new list.

75.12.12.2.2.4 List length register (LLR)

This is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that specifies the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

75.12.12.2.3 Transmission gating implementation

A bridge or an end station can enhance to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if you can select the queued frames for transmission.

For a TC, the transmission gate can be in one of these two states:

1. Open: Select queued frames for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. Closed: Does not select queued frames for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that you can avoid the transmission overruns and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by MTL_EST_Control[CTOV]). This ensures that the schedule provided is always accurately implemented at the line.

You must ensure that the GCL slot interval is always greater than the expected packet size and overhead (scheduler delay, inter frame gap (IFG), and preamble, all combined).

75.12.12.3 Idle slope computation updates

When EST is enabled, credit accumulates only when the gate is open therefore, the effective data rate of the idleSlope must increase to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed on the basis of the gate open time and oper cycle time values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient field width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

75.12.12.3.1 Operational details of GCL

Write 1 to MTL_EST_Control[SSWL], so that the hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the base time register (BTR) and is held until the programmed "time interval" value.

One additional gate control event is always read ahead from the list, to avoid the transmission overruns. This enables the GCL to determine the next gate close events (if any) for the open TCs.

The scheduling is done on the basis of the gate open state and time interval of only the current and subsequent schedule. An internal accumulator adds the time intervals when gate controls are applied. BTR + Accumulator specifies the time at which the next set of gate controls are applied.

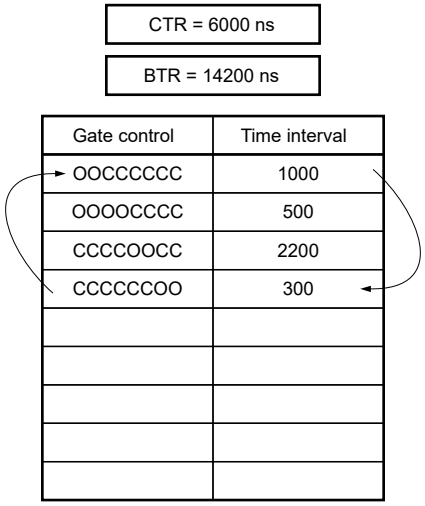

Figure 441. GCL and associated registers - basetime and cycletime

GCL is read progressively from the first row adhering to the schedule. The read operations continue until the list length (from LLR register) is reached and the execution of the list restarts at BTR + CTR time. At this point the value in CTR increments BTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are in open state, during the execution of the list.

In cases where the execution time of the list is greater than the cycletime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 577. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

Table 577 describes an example in which the execution starts at 14200 and the first set of gate controls "OOCCCCCC" are applied immediately. The time interval is 1000 ns, so the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . The above table shows that there are no gate controls available after the execution of the last gate control and before the next iteration of the loop. The gates are deemed in open state during that time period as depicted at 18200 current time.

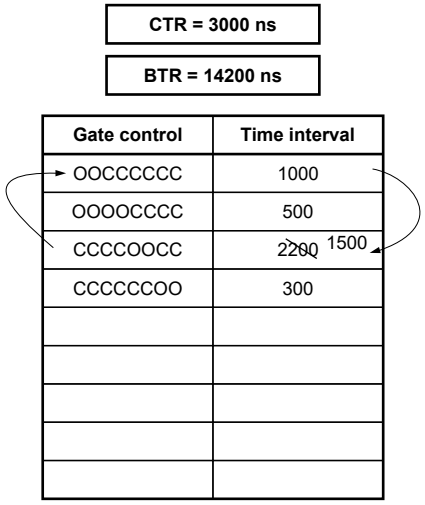

Figure 442. GCL and associated registers - BaseTime and CycleTime list execution time > CycleTime

Table 578 indicates that the list execution takes longer than the allocated CycleTime, so the list is truncated and the list starts from the BTR+CTR.

Table 578. GCL and associated registers - BTR and CTR, execution time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

When you apply the third set of gate controls, BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

75.12.12.3.2 Installing a new GCL

The switch to the new GCL can happen in one of the following ways when a new software programmed GCL is available and executed at the new BTR value:

- New base time aligned with current schedule
- New base time unaligned with current schedule

75.12.12.3.2.1 New base time aligned with current schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and

executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New base time > = Current time)

ConfigChangeTime = New BaseTime

Else If (New base time < Current time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is true.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requires the software to reprogram the new base time.

Figure 443 illustrates the installation of the new GCL along with the timelines.

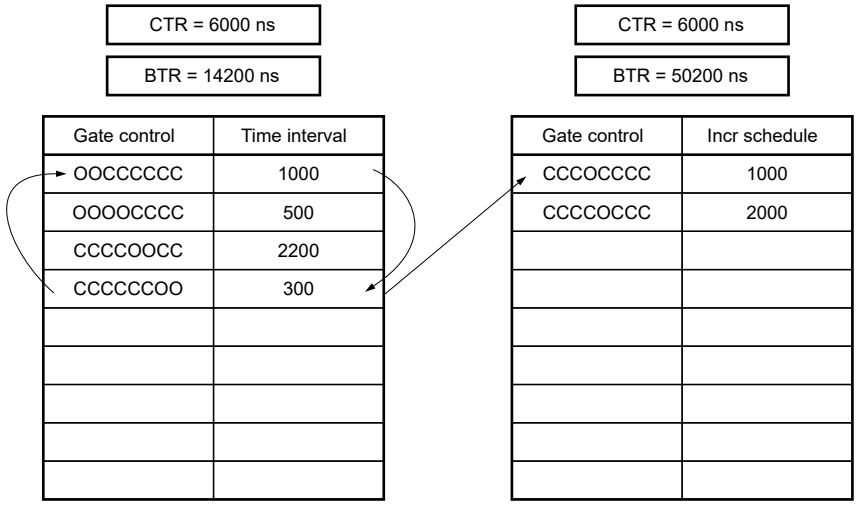

Figure 443. Switching to a new configuration that is aligned with the existing configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 579. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200

Table continues on the next page...

Table 579. GCL and associated registers - BTR and CTR (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

75.12.12.3.2.2 New base time unaligned with current schedule

If the new cycletime differs from the current cycletime or new basetime in the future and is not an integer multiple of current cycletime, then the old and new cycles do not line up. When new basetime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

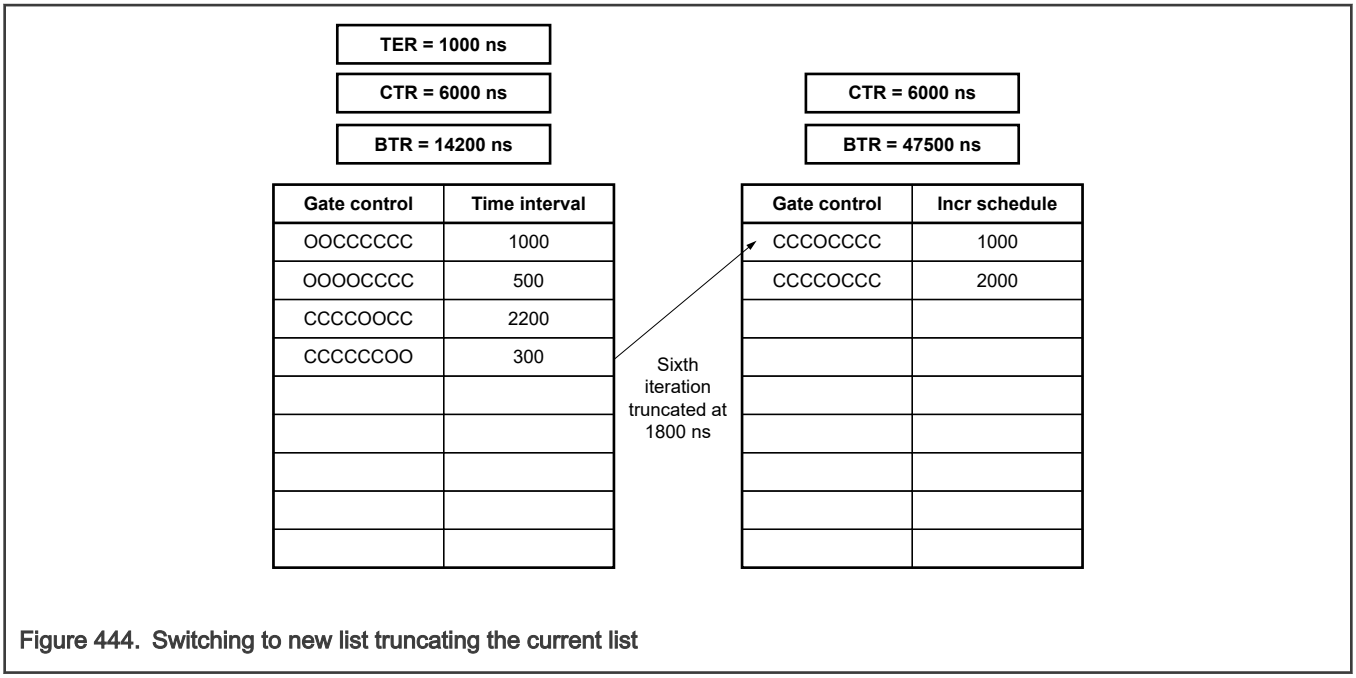

Figure 444. Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 580. Extending to new list by truncating the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200

Table continues on the next page...

Table 580. Extending to new list by truncating the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

Figure 445. Switching to new list by extending the current list

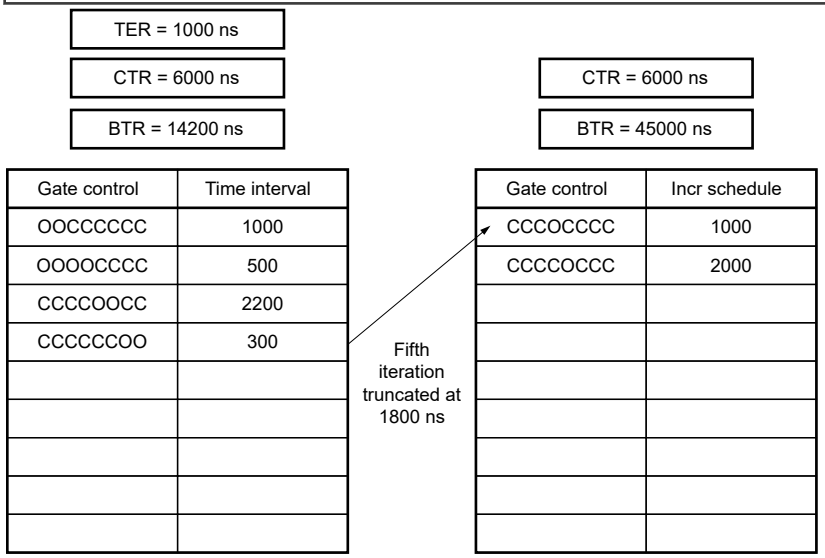

Table 581. Switching to new list by extending the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

75.12.12.4 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming guidelines for EST

75.12.13 Frame preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemtable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

If you are unable to schedule fragmented packets after a certain number of attempts because of some reason, there is a possibility that the remaining fragmented packets are dropped. For this, software can program MTL_EST_Control[LCSE] to increase number of iterations or MTL_EST_Control[DFBS] to disable dropping of packet.

75.12.13.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate control (up to 8 bits)	Time interval (ns) 16, 20 or 24 bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
|	|
|	|
OCOCOCOO	T126
OOOOCCCC	T127

Figure 446. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate control (up to 7 bits)	Release or hold indication	Time interval (ns) 16, 20 or 24 bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

Figure 447. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

75.12.13.2 Impact of Preemption on CBS

In Credit Base Shaper(CBS), the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

75.12.13.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 582. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 583. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC
- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

Table 584. Current and Previous SMD Values

Previous Preemptable packet SMD	Current Preemptable packet SMD
SMD-S0	SMD-S1
SMD-S1	SMD-S2
SMD-S2	SMD-S3
SMD-S3	SMD-S0

75.12.13.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

All the PTP packets should be transmitted as express packets

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 586. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

75.12.13.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

75.12.13.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

75.12.13.5 Receive Preemption

75.12.13.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 587. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

75.12.13.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

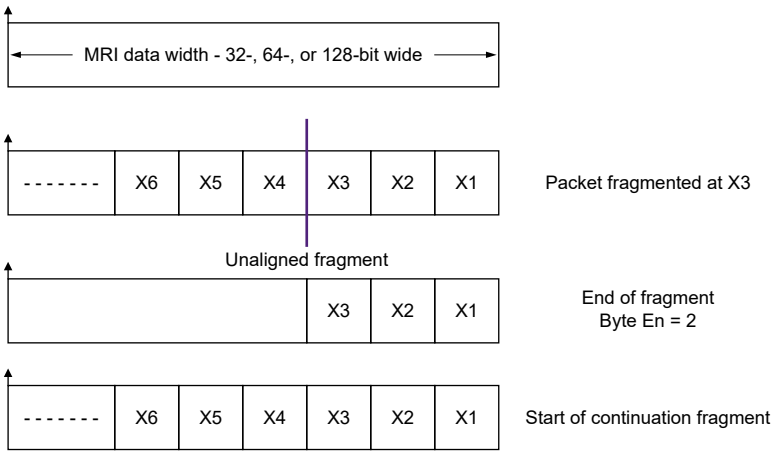

Figure 448. Data Alignment Feature of MAC

75.12.13.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 588. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

75.12.13.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

75.12.13.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Software must ensure that frame preemption verify and response packet are not triggered at the same time. Trigger either of the packets and then wait for its completion before triggering another packet.

75.12.13.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 589. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

75.12.13.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

75.12.14 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

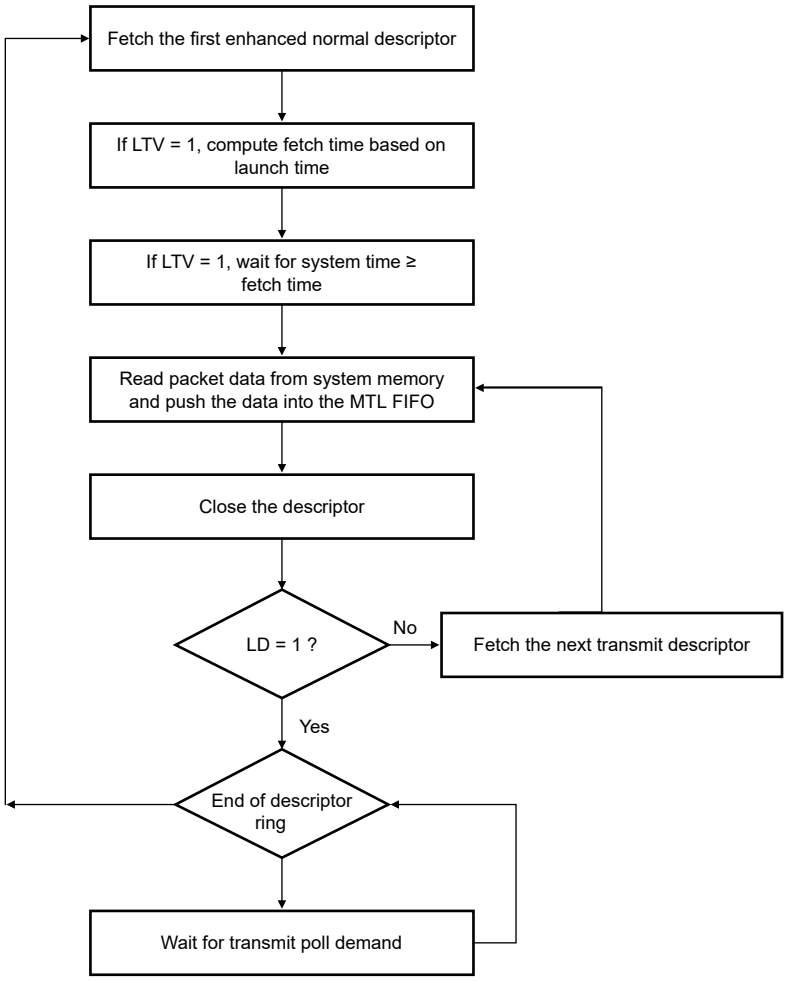

Figure 449. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

75.12.14.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time resets after the transmission of one frame. These are the two formats of the launch time.

Normal or absolute format:

In this format, the launch time is interpreted in the normal or absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24-bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based system or PTP time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of system time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24-bits of the launch time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of launch time is 256 seconds,

- Launch time is greater than current system time when its value is between system time[39:8] and System time[39:8] + 128 sec.
- Launch time is less than current system time when its value is between System Time[39:8] + 128sec and System Time[39:8] + 256 sec, because this is a modulo 256 computation.

EST or offset format

In this format, the launch time is a offset value relative to the time which the BTR of the GCL list provided in the GCL slot number (GSN) indicates. The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the launch time value are specified in the enhanced transmit descriptor in the DMA configurations, or as control word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL slot number. The value of the launch time offset must be smaller than the value of the cycle time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of launch time offset must be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch time = Launch GSN BTR[63:0] + (Launch time offset[31:0] << 8), which is compared with the system time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL slot number (GSN) A modulo 16 count of the GCL loop count is implemented and it is known as GSN. The count is incremented for every new GCL loop. Installation of new GCL list does not impact the count. Read MTL_EST_Status[CGSN] to obtain the current GCL slot number.

The maximum value of GSN is 15. Therefore the GSN values between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8 represent current or future slots and all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8.

75.12.14.2 Launch expiry time

Normal or Absolute Mode

In this mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch expiry time = (Launch time[39:8] + LEOS[32:8]) * 256 ns

The packet with a specific launch time is considered as eligible for transmission when the launch time is less than the system time and (if MTL_TBS_CTRL[LEOV] = 1) the system time is less than the launch expiry time.

When the system time is greater than the launch expiry time, the frame is categorized as expired and it drops from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the fetch, launch, and launch expiry time must never set to a value larger than the Current system time + 128 sec; such a value is interpreted as time that has already elapsed.
- In Full Duplex mode, the frames dropped from the MTL FIFO have error summary (Bit 15) and excessive deferral (bit 3) of TxStatus set.

EST/Offset Mode

In EST mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEGOS] and MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999 ns or CTR-1 ns.

The Launch expiry GSN is computed as follows:

Launch expiry GSN = (Launch GSN + LEGOS + CCMA) where, CCMA is the CTR carry due to modulo addition. This value is 1 if ((Launch time offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch expiry offset = (Launch time offset+ LEOS) - CTR

When CCMA = 0,

Launch expiry offset = (Launch time offset + LEOS).

Launch expiry time = Launch expiry GSN BTR [63:0] + Launch expiry time offset.

When MTL_TBS_CTRL[LEOV] is not 1, the launch expiry time is not checked.

When MTL_TBS_CTRL[LEOV] = 1, and

- the system time is greater than the launch expiry time, the frame drops from MTL FIFO. Then the frame is considered as expired.
- the launch time is smaller than the system time and the launch expiry time is greater than the system time, then the frame is considered eligible for launch.

NOTE

- Max value of MTL_TBS_CTRL[LEGOS] is 7. This indicates that when MTL_TBS_CTRL[LEOV] = 1, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for launch.
- The slot number of the first GCL list that executes each time after EST is enabled, is zero.

75.12.14.3 Fetch time

This accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If DMA_TBS_CTRL[FTOV] is 1, it indicates the fetch time for each packet. If DMA_TBS_CTRL[FTOV] is not 1, it indicates that the fetch time offset is not valid and DMA fetches packets without any time constraints.

Normal/Absolute mode

In this mode fetch time is derived or calculated by reducing the time specified in DMA_TBS_CTRL[FTOS] from the given launch time.

In Normal mode, the fetch launch time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The fetch time is 32-bits and is compared against the system time[39:8] to determine whether it is eligible for fetching the frame:

- The fetch time is defined as greater than system time if the fetch time is in the range of system time[39:8]" and system time[39:8] + 128 sec. The frame is considered as not-eligible for fetch.
- The fetch time is defined as smaller than the system time if the fetch time is in the range of system time[39:8] + 128 sec and system time[39:8] + 256 sec. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset mode

In this mode, the fetch GSN offset (DMA_TBS_CTRL[FGOS]) provides the slot number offset to deduct from the launch GSN. In this case the FTOS value must be smaller than 999,999,999 ns or CTR-1 ns.

If (Launch time offset >= FTOS):

Fetch time offset = ((Launch time offset - FTOS) * 256ns)

CBFS(CTR borrow for fetch subtraction) = 0

If (Launch time offset < FTOS) Fetch time offset = CTR + ((Launch time offset - FTOS) * 256ns)

CBFS (CTR borrow for fetch subtraction) = 1

The fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch time = Fetch GSN BTR[63:0] + Fetch time offset

The frame is eligible for DMA fetch when the fetch time is smaller than the system time.

DMA operations sequence

This is the sequence of operation when FTOV = 1:

1. Fetch the first enhanced normal descriptor (FD = 1).
2. Compute the fetch time on the basis of the launch time and wait for the system time to be greater than fetch time, if LTV = 1 and fetch is enabled.
3. Read the frame (data) from the host memory and transfer to MTL FIFO.
4. Close the normal descriptor.
5. Fetch the next normal descriptor (if the previous descriptor was not the last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD = 1).

After the last descriptor of a frame, program the next enhanced normal descriptor with a new launch time and with LTV = 1. Otherwise, process the subsequent frames without any time restrictions.

See Programming the launch time in time-based scheduling for more information.

75.13 TCP/IP Offloading Features

This section and all other sections, along with respective sub-sections are Synopsys Proprietary. Used with permission.

75.13.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

75.13.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0 in Table 19-12 on page 1330). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corre-sponding Header Length field in an extension header) is completely received.

75.13.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in Table 19-3 on page 1324). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. Following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 590. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not applicable • Not applicable	• No • No

Table continues on the next page...

Table 590. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

75.13.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 591. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No

Table continues on the next page...

Table 591. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv4 Tunnels:	• Not Applicable • Not Applicable	• No • No

Table continues on the next page...

Table 591. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
• IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel		
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

75.13.3 Header payload split

MAC is capable of identifying the boundary between header and payload of the received packet and store them into separate buffers. The MAC supports multiple methods and packet types for header-payload splitting. This is controlled by the setting the SPLM field in MAC_Ext1_cfg register.

75.13.4 IPv4 ARP offload engine

MAC supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows the processing of the IPv4 ARP request packet in the receive path and generating corresponding ARP response packet in the transmit path. MAC generates the ARP reply packets for appropriate ARP request packets. The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

NOTE

When the received ARP request is less than 64 bytes packet length, MAC does not send a ARP response. It is treated as normal packet and forwarded to the application based on the MAC filter settings.

75.14 MAC Management Counters

This section is Synopsys Proprietary. Used with permission.

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in GMAC register descriptions.

75.15 Flow Control

This section and its sub-sections are Synopsys Proprietary. Used with permission.

75.15.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

75.15.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 592. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

75.15.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

75.15.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 593. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.

Table continues on the next page...

Table 593. Tx MAC Flow Control (continued)

EHFC	TFE	DM	Description
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

75.15.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

75.15.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 594. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

75.15.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

75.16 Loopback Mode

This section is Synopsys Proprietary. Used with permission.

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

75.17 Automotive Safety Features

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP supports the automotive safety feature.

75.17.1 Error Correction Code (ECC) Protection for Memories

The Error Correction Code (ECC) block can correct single-bit error and detect double-bit error.

At the write interface, ECC checkbits are generated by computing ECC on the contents of the data bus and respective address is appended with the data that is written to the memory.

At the read interface, ECC checkbits are recomputed on the content of the read data and the respective address is compared with the received checkbits in the memory.

Following figure shows the block diagram of ECC protection for memories

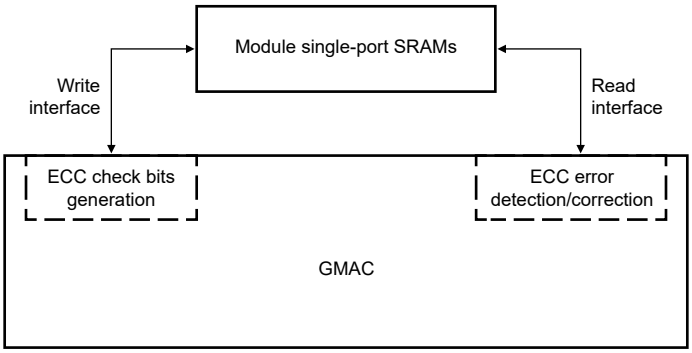

Figure 450. Block Diagram of ECC Protection for Memories

75.17.1.1 Handling the Address Mismatch

The ECC is calculated over the sum of memory data and memory location address. However only data is written in the memory along with the ECC(address is excluded).

On the read interface, the ECC is checked over the sum of memory DATA, memory ECC, and Internally generated address. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

75.17.1.2 Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_EC-C_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first errored memory address is reported or the latest errored memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected. The module sets the respective interrupt enable bits (in the DMA/MTL_ECC_Interrupt_enable register).
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Inter-rupt_Status registers.

NOTE

- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

75.17.1.3 ECC Error Injection Capabilities

IP supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection
- Two bits to indicate the type of error to be injected ❑ 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for

- MTL Tx/Rx and DMA TSO memory are specified in the MTL_DBG_CTL register, for and for R.
- MTL EST memory are specified in the MTL_EST_GCL_Control register
- Rx parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register

NOTE

While using debug mode for ECC error injection:

- There should be no traffic in the module
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write main-tains the same value for the error injection control word.
- See Programming guidelines for ECC protection for memories

75.17.2 Finite State Machine(FSM) Parity and Timeout Protection

The FSM protection feature supports FSM parity and time out protection.

75.17.2.1 FSM State Parity Protection

Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control Register.

75.17.2.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of CSR cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1us, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on the programmable bits NTMRMD, LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

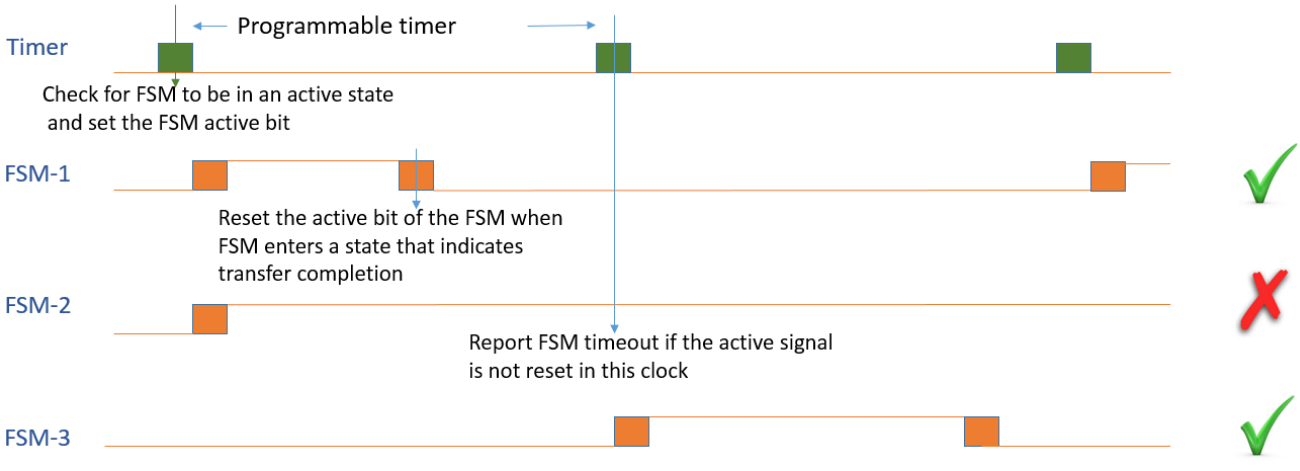

Figure 451. FSM Timeout Timing Diagram

In the above figure, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains. IP does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting IP).

75.17.2.3 Enabling FSM Parity and Timeout Protection

FSM timeout feature is enabled by setting the TMOUTEN field of MAC_FSM_Control register.

NOTE

See Programming guidelines for FSM parity and timeout

75.17.3 Application/CSR Interface Timeout Protection

This feature provides timeout protection to the application/CSR Interface. All the interfaces which has the handshake mechanism monitored for potential hangs due to the external agent (Master/Slave/Interconnect/Application client) not responding to the requests/transfers initiated by the QoS. After the request is initiated the response arrival interval is monitored. If the response does not arrive within a programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered, using similar trigger generation as explained in the Section FSM protection.

The timeout is triggered when IP initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register. The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when application timeout status is set.

The hardware does not attempt to recover from Application/CSR Interface hangs and relies on software to take appropriate corrective action.

NOTE

- Protection is not needed for APB3 Slave interfaces because potential hangs can be only when IP does not respond to the requests. In such cases the IP internal protection logic (FSM timeout) detects such defects.
- Based on the time at which the transfer is initiated relative to the timer ticks, the timeout period could be any value between the programmed timeout and 2x times the programmed timeout.
- When an uncorrectable safety interrupt is issued and the read of the Interrupt status register returns all zeros, it implies that the CSR read is not functional. As soft reset of IP is not possible without the CSR access, and therefore, a hard reset of IP is recommended.
- See Programming guidelines for FSM parity and timeout .

75.18 Descriptors

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

75.18.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

75.18.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

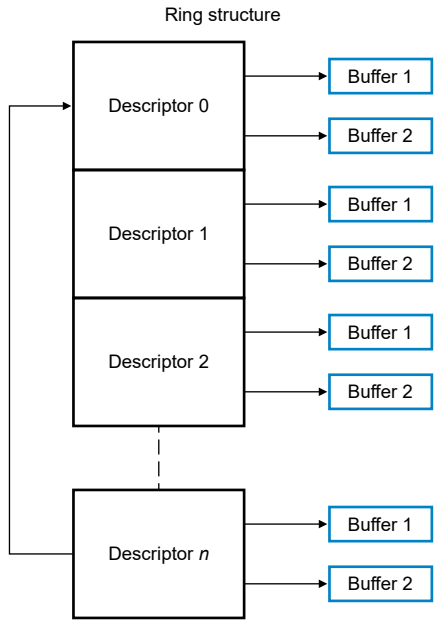

Figure 452. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

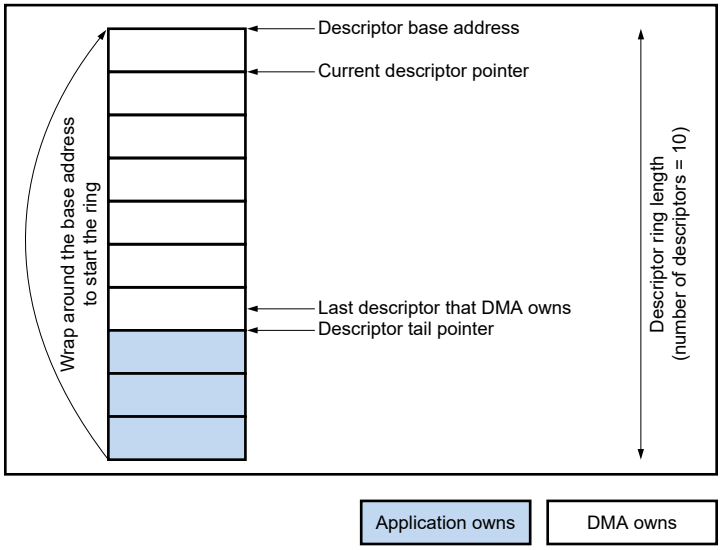

Figure 453. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

75.18.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

NOTE

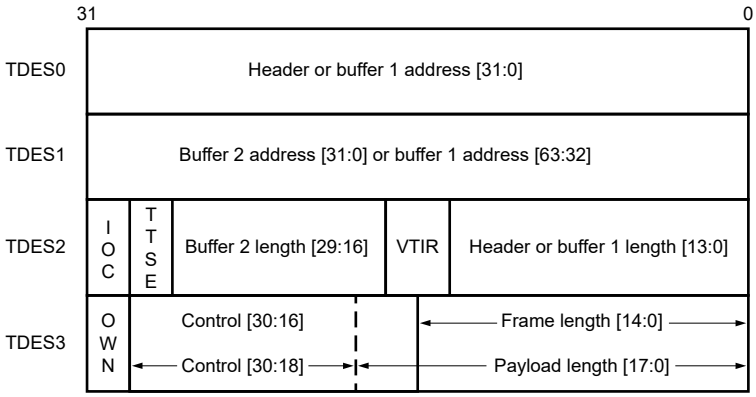
TSO Split header is not supported.

Software must not write same tail pointer addresses when DMA is in Suspended state before setting new descriptor(s) for further processing.

75.18.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 454. Transmit Descriptor Read Format



75.18.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 595. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

75.18.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 596. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

75.18.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 597. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 598. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/ TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

75.18.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 599. TDES2 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 600. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet.

Table continues on the next page...

Table 600. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support.

Table continues on the next page...

Table 600. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

75.18.3.1.5 Transmit normal descriptor (write-back format)

The transmit descriptor write-back format includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. Write 1 to the LD bit (TDES3[28]) in the descriptor where DMA writes back the status and timestamp information for the corresponding transmit packet.

Figure 455 shows the transmit descriptor write-back format.

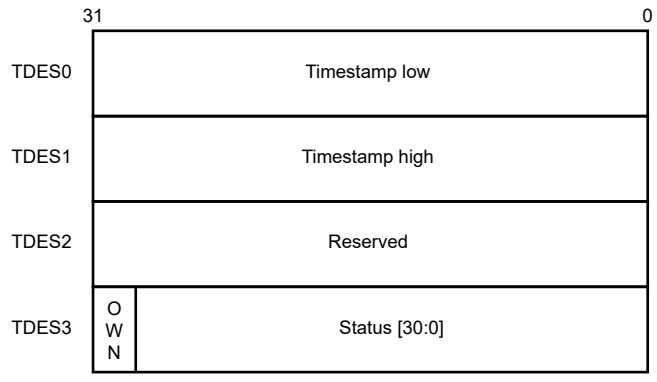


Figure 455. Transmit descriptor write-back format

TDES0 normal descriptor (write-back format)

Table 601 shows that this format is only applicable to the last descriptor of a packet.

Table 601. TDES0 normal descriptor (write-back format)TDES0 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding transmit packet. DMA writes the timestamp only if TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and the Timestamp status (TTSS) bit.

TDES1 normal descriptor (write-back format)

Table 602 shows that this format is only applicable to the last descriptor of a packet.

Table 602. TDES1 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High DMA updates this field with the most significant 32 bits of the timestamp captured for a corresponding transmit packet. DMA writes the timestamp only if the TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and Timestamp status (TTSS) bit.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 603. TDES2 normal descriptor (write-back format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 604. TDES3 normal descriptor (write-back format)

31	30	29	28	27:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 605. TDES3 normal descriptor (write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. DMA write 0 to this field when it completes the packet transmission. After the write-back is complete, this field is set to 'b0.
30	CTXT	Context Type

Table continues on the next page...

Table 605. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
		This field must be set to 'b0 for normal descriptor.
29	FD	First Descriptor This field indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This field is set to 'b1 for last descriptor of a packet. DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when the descriptor is closed. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT is 1 along with LD or FD bits as 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA write 1 to TI bit in the DMA_CH#_Status register **NOTE** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might consider as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This field indicates that a timestamp has been captured for the corresponding transmit packet. When this field is 1, it indicates that TDES0 and TDES1 have timestamp values that were captured for the transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is 1. This field is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. **NOTE** An uncorrectable error in the transmit FIFO memory is reported with (Bit 13) FF = 1. This is because the module flushes all such packets.

Table continues on the next page...

Table 605. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
15	ES	Error Summary This field indicates the logical OR of the following bits: • TDES3[0]: IP header error • TDES3[14]: Jabber timeout • TDES3[13]: Packet flush • TDES3[12]: Payload checksum error • TDES3[11]: Loss of carrier • TDES3[10]: No carrier • TDES3[9]: Late collision • TDES3[8]: Excessive collision • TDES3[3]: Excessive deferral • TDES3[2]: Underflow error This field is 1 when EUE (bit 16) = 1.
14	JT	Jabber Timeout This field indicates that the MAC transmitter experiences a jabber time-out. This field is 1 only when MAC_Configuration[JD] is not 1.
13	FF	Packet Flushed This field indicates that DMA or MTL flushes the packet because the CPU gives a software flush command.
12	PCE	Payload Checksum Error This field indicates that the checksum offload engine had a failure and does not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can either because of insufficient bytes, as the payload length field of the IP header indicates or the MTL starting to forward the packet to the MAC transmitter in Store-and-forward mode without calculating the checksum. This second error condition only occurs when the transmit FIFO depth is less than the length of the Ethernet packet that is transmitted to avoid deadlock. The MTL starts forwarding the packet when the FIFO is full, even in the Store-and-forward mode. This error can also occur when you detects a bus error during packet transfer. When the full checksum offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This field indicates that a loss of carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This field is valid only for the packets transmitted without collision and when MAC operates in the Half-duplex mode.
10	NC	No Carrier This field indicates that the carrier sense signal from the PHY was not asserted during transmission.

Table continues on the next page...

Table 605. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This field indicates that the transmission was aborted after 16 successive collisions when you transmits the current packet. If MAC_Configuration[DR] = 1, this field is 1 after first collision and abort the packet transmission.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before transmitting the packet. The count is not valid when the EC bit = 1.
3	ED	Excessive Deferral This field indicates that the transmission ends because of an excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode or Jumbo packet enabled mode) if MAC_Configuration[DC] = 1. When TBS is enabled in Full duplex mode and this field is 1, it indicates that the frame drops after the expiry time is reached.
2	UF	Underflow Error This field indicates that MAC aborts the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • DMA encounters an empty transmit buffer when it transmits the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the Suspended state and sets the underflow bit corresponding to a queue in MTL_Interrupt_Status.
1	DB	Deferred Bit This field indicates that MAC defers before transmitting because of presence of carrier. This field is valid only in the Half-Duplex mode.
0	IHE	IP Header Error When IP Header Error is 1, this field indicates that the checksum offload engine detects an IP header error. This field is valid only when transit checksum offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload. In Full-Duplex mode, when EST/Qbv is enabled and this field is 1, it indicates the frame drop status due to the frame size error or schedule error.

75.18.3.2 Transmit context descriptor

The transmit context descriptor can provide any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor provide the timestamps for one-step timestamp correction and VLAN tag ID for VLAN insertion feature. Write back is done on a context descriptor only to write 0 to OWN bit.

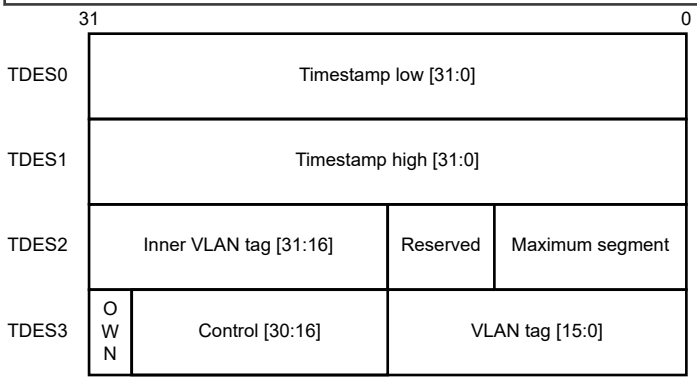
NOTE

DMA internally store the VLAN tag IDs and MSS values which the application provides in a context descriptor with their corresponding valid bits set. DMA always passes the last valid VLAN tag to the MTL, when the outer or inner VLAN tag is provided with the valid bit set. The application cannot invalidate the valid VLAN tag which DMA stores. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The inner VLAN tag control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which DMA must use the inner VLAN tag control input.

Figure 456 shows the transmit context descriptor format.

Figure 456. Transmit context descriptor format



75.18.3.2.1 TDES0 context descriptor

Table 606 describes the TDES0 context descriptor format.

Table 606. TDES0 context descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

75.18.3.2.2 TDES1 context descriptor

Table 607 describes the TDES1 context descriptor format.

Table 607. TDES1 context descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

75.18.3.2.3 TDES2 context descriptor

Table 608 shows the TDES2 context descriptor format.

Table 608. TDES2 context descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is 1 and the TCMSSV and OSTC bits of TDES3 context descriptor becomes 0, it indicates that the TDES2[31:16] contains the inner VLAN tag to insert in the subsequent transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO split header is not supported. The value of this bit is always zero.

75.18.3.2.4 TDES3 context descriptor

Table 609. TDES3 context descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Table 610 shows the TDES3 context descriptor format.

Table 610. TDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field immediately after the read.
30	CTXT	Context Type This field must set to 1'b1 for context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this field is 1, it indicates that DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this field and the OSTC field are 1, it indicates that the timestamp correction input provided in TDES0 and TDES1 is valid. When the OSTC field becomes 0 and this field and the TSE bit of TDES3 are 1 in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved

Table continues on the next page...

Table 610. TDES3 context descriptor (continued)

Bit	Name	Description
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when it closes the context descriptor. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All ones. • CD, LD, and FD bits = 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits are 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA writes 1 to TI bit in the DMA_CH#_Status register **NOTE** On the basis of CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might considered as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this field is 1, it requests MAC to perform inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. You must use this option only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. You must use this option only with the VLAN frames.. These fields are valid when you select the enable SA and VLAN insertion on transit and enable double VLAN processing options.
17	IVLTV	Inner VLAN Tag Valid When this field is 1, it indicates that IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this field is 1, it indicates that VT field of TDES3 is valid.
15:0	VT	VLAN Tag

Table continues on the next page...

Table 610. TDES3 context descriptor (continued)

Bit	Name	Description
		Contains the VLAN tag to insert or replace in the packet. This field is used as VLAN tag only when MAC_VLAN_Incl[VLTI] becomes 0.

75.18.4 Receive descriptor

DMA in the module reads a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that accommodates at least two complete packets which MAC receives. Otherwise, the performance of DMA is impacted because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following receive descriptors are present:

- Normal descriptors
- Context descriptors

You can prepare all the receive descriptors and give to DMA as normal descriptors with the content as shown in receive normal descriptor (read format). DMA reads this descriptor and the receive DMA closes the descriptor with the corresponding packet status after transferring a received packet (or part of) to the buffers indicated by the descriptor. The receive normal descriptor (write-back format) describes the format of this status.

For some packets, only the normal descriptor bits cannot write the complete status. For such packets, the receive DMA writes the extended status to the next descriptor (without processing or using the buffers or pointers embedded in that descriptor). Receive context descriptor describes the descriptor write back format and content.

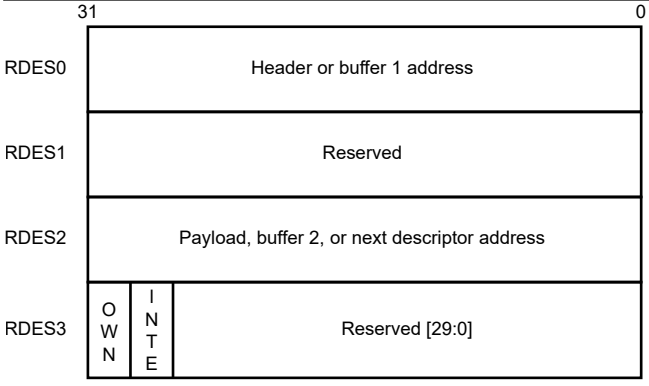
75.18.4.1 Receive normal descriptor (read format)

The read format for a receive normal descriptor is made up of the following:

- A header or buffer 1 address
- Reserved field
- Payload or buffer 2 or next descriptor address
- A 30-bit reserved field
- OWN bit
- An interrupt field

Figure 457 shows the read format for a receive normal descriptor.

Figure 457. Receive normal descriptor read format



NOTE

In the receive descriptor (read format), if the buffer address field is all zeros, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

75.18.4.1.1 RDES0 normal descriptor (read format)

Table 611 shows the RDES0 normal descriptor read format.

Table 611. RDES0 normal descriptor (read format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH field of control register of a channel becomes 0, these field indicates the physical address of buffer 1. When the SPH field is 1, these field indicates the physical address of header buffer where the receive DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, DMA performs a write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero, when the start of packet is transfered. However, the packet data shifts per the actual offset which the buffer address pointer provides. If the address pointer points to a buffer where the middle or last part of the packet is stored, DMA ignores the offset address and writes to the full location which the data-width indicates .

75.18.4.1.2 RDES1 normal descriptor (read format)

Table 612 shows the RDES1 normal descriptor read format.

Table 612. RDES1 normal descriptor (read format)

Bit	Name	Description
31:0	Reserved or BUF1AP	Contains the most-significant 32 bits of the buffer 1 address pointer in 64-bit Addressing mode. Otherwise, this field is reserved.

75.18.4.1.3 RDES2 normal descriptor (read format)

Table 613 shows the RDES2 normal descriptor read format.

Table 613. RDES2 normal descriptor (read format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer Indicates the physical address of buffer 2. When the SPH bit of the DMA_CH#_Control register = 1, it indicates that the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register becomes 0, it indicates that there is no limitations on the RDES2 value. However, the RxDMA uses the LS fields of the pointer address only when it transfers the start bytes of a packet. If the BUF2AP provides the address of a buffer in which the middle or last part of a packet is stored, DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

75.18.4.1.4 RDES3 normal descriptor (read format)

#unique_3961/unique_3961_Connect_42_id_1746ef2a-ecdf-425a-a0eb-74c5a5b90e21 describes the RDES3 normal descriptor read format.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

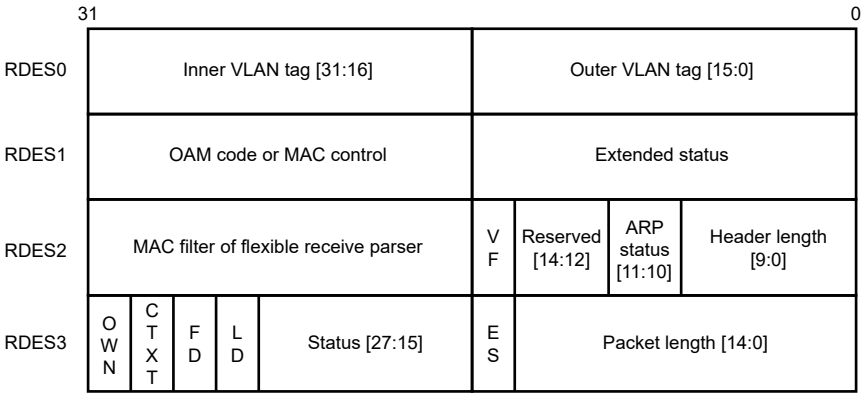
Table 614. RDES3 normal descriptor (read format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA write 0 this field when either of the following conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	IOC	Interrupt Enabled on Completion When this field is 1, it indicates that an interrupt is issued to the application when DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this field is 1, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must write 1 to this field so that DMA can use the address, to which the buffer 2 address in RDES2 points to write received packet data.
24	BUF1V	Buffer 1 Address Valid When this field is 1, it indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must write 1 to this field, if DMA uses the address to which the buffer 1 address in RDES1 points to write the received packet data.
23:0	Rsvd	Reserved

75.18.4.1.5 Receive normal descriptor (write-back format)

Figure 458 shows the write-back format for a receive normal descriptor.

Figure 458. Receive normal descriptor (write-back format)



NOTE

When you enables the flexible receive parser, RDES2[31:16] indicates the parser status, and not the MAC filter status. The MAC filter status is not available when flexible receive parser is enabled.

75.18.4.1.5.1 RDES0 normal descriptor (write-back format)

Table 615 shows the write-back format for the RDES0 normal descriptor.

Table 615. RDES0 normal descriptor (write-back format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag Contains the inner VLAN tag of the received packet if the RS0V bit of RDES3 = 1. This field is valid only when you enables the double VLAN tag processing and VLAN tag stripping.
15:0	OVT	Outer VLAN Tag Contains the outer VLAN tag of the received packet if the RS0V bit of RDES3 = 1.

75.18.4.1.5.2 RDES1 normal descriptor (write-back format)

The status fields in the write-back format are valid only for the last descriptor (RDES3[28] = 1). #unique_3963/unique_3963_Connect_42_table_18e086e2-bda5-4002-b444-4d7ac47c01e8 provide the details of the write-back format for RDES1 normal descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 616. RDES1 normal descriptor (write-back format)

Bit	Name	Description
31:16	OPC	Indicates any one of the following: • OAM sub-type code: If bits [18:16] of RDES3 as described in RDES3 normal descriptor (read format) are 111b, this field contains the OAM sub-type and code fields.

Table continues on the next page...

Table 616. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• MAC control packet opcode: Bits 15:8 of RDES3 as described in RDES3 normal descriptor (read format) contain the subtype and bits 7:0 contain the code.
15	TD	Timestamp Dropped Indicates that the timestamp was captured for this packet but it dropped in the MTL Rx FIFO because of overflow. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
14	TSA	Timestamp Available Indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1) when timestamp is present. This is valid only when the last descriptor field (RDES3 [28]) = 1 You can write the context descriptor in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version Indicates that the received PTP message has the IEEE 1588 version 2 format. When this field becomes 0, it indicates the IEEE 1588 version 1 format. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
12	PFT	PTP Packet Type Indicates that the PTP message is sent directly over Ethernet. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
11:8	PMT	PTP Message Type Encodes to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with reserved message type These fields are available only when you select the timestamp feature.

Table continues on the next page...

Table 616. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
7	IPCE	IP Payload Error When this field is 1, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) which MAC calculates does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this field is 1.
6	IPCB	IP Checksum Bypassed Indicates that the checksum offload engine is bypassed. This field is available when you select the enable receive TCP/IP checksum check feature.
5	IPV6	IPv6 header Present Indicates that an IPV6 header is detected. When you select the enable split header feature option and the SPH bit of control register of a channel is 1, the IPV6 header is available in the header buffer area to which RDES0 points.
4	IPV4	IPV4 Header Present Indicates that an IPV4 header is detected. When the SPH bit of RDES3 is 1, the IPV4 header is available in the header buffer area to which RDES0 points.
3	IPHE	IP Header Error When this field is 1, it indicates either of the following: • The 16-bit IPv4 header checksum which MAC calculates does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet type value. • Ethernet packet does not have the expected number of IP header bytes. This field is valid when either bit 5 or bit 4 is 1. This field is available when you select the enable receive TCP/IP checksum check feature.
2:0	PT	Payload Type Indicates the type of payload encapsulated in the IP datagram that the receive checksum offload engine (COE) process. • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV tagged data packet • 3'b111: AV tagged control packet

Table continues on the next page...

Table 616. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• 3'b101: AV untagged control packet • 3'b100: IGMP, if IPV4 header present field = 1, else DCB (LLDP) control packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these fields to 3'b000.

75.18.4.1.5.3 RDES2 normal descriptor (Write-back format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 617. RDES2 normal descriptor (Write-back format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched Indicates the number of the layer 3 and layer 4 filter that matches the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when bit 28 or bit 27 = 1. When more than one filter matches, these fields provide the number of lowest filter. **NOTE** This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of these conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match • All enabled layer 3 and layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].

Table continues on the next page...

Table 617. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		NOTE This status is not available when the flexible receive parser is enabled.
27	L3FM	Layer 3 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 3 IP address fields. This status is given only when one of these conditions is true: • All enabled layer 3 fields match and bypasses all enabled layer 4 fields. • All enabled filter fields match. When more than one filter matches, this field gives the layer 3 filter status of filter which bits[31:29] indicate. **NOTE** This status is not available when the flexible receive parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When HF becomes 0, it indicates that this field contains the MAC address register number that matches the received packet destination address. This field is valid only if the DAF field becomes 0. When HF = 1, it indicates that this field contains the hash value that MAC computes. A packet passes the hash filter when the field corresponding to the hash value is 1 in the hash filter register. **NOTE** This status is not available when the flexible receive parser is enabled.
18	HF	Hash Filter Status When this field is 1, it indicates that the packet passes the MAC address hash filter. Bits[26:19] indicate the hash value. **NOTE** This status is not available when the flexible receive parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the DA filter in MAC. When flexible receive parser is enabled, and this field is 1, it indicates that the packet parsing is incomplete (RXPI) due to ECC error. **NOTE** When this field is 1, RDES3 ES field is also 1.
16	SAF/RXPD	SA Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the SA filter in MAC.

Table continues on the next page...

Table 617. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		When flexible receive parser is enabled and this field is 1, it indicates that the parser drops the RXPD packet. **NOTE** When this field is 1, RDES3 ES field is also 1.
15	OTS	VLAN Filter Status When this field is 1, it indicates that the received packet VLAN tag passes the VLAN filter. This field redefines as an outer VLAN tag filter status (OTS). This field is valid for both single and double VLAN tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS) This field is valid only for double VLAN tagged frames, when double VLAN processing is enabled. See Filter status for more information.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this field is 1, it indicates that MAC did not generate the ARP reply for the ARP request packet it receives.. This field is 1 when MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This field is reserved when you do not select the enable IPv4 ARP offload option.
9:0	HL	L3/L4 Header Length Contains the length of the packet header which MAC splits at L3 or L4 header boundary which the MAC receiver identifies. This field is valid only when the first descriptor bit = 1 (FD = 1). You can write the header data to the buffer 1 address of corresponding descriptor. If the header length is zero, this field is not valid. It implies that MAC does not identify and split the header. This field is valid when you select the enable split header feature option.

75.18.4.1.5.4 RDES3 normal descriptor (Write-back format)

#unique_3965/unique_3965_Connect_42_id_9cde4392-a0c2-4731-bcb2-bf9dcd789aae describes the write-back format for the RDES3 normal descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 618. RDES3 normal descriptor (Write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. If this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor When this field is 1, it indicates that the current descriptor is a context type descriptor. DMA writes 1'b0 to this field for a normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 2’b00: Intermediate descriptor • 2’b01: First descriptor • 2’b10: Reserved • 2’b11: Descriptor error (due to all 1s) **NOTE** When descriptor error occurs, the receive DMA closes the receive descriptor indicating a descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA will write 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, as this is not marked as the last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	FD	First Descriptor When this field is 1, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet and if the size of the second buffer is also 0, the next descriptor will contain the beginning of the packet. See the CTXT bit description for more information on how to use the CTXT bit and FD bit together.
28	LD	Last Descriptor When this field is 1, it indicates that this descriptor buffers points to the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this field is 1, it indicates that the status in RDES2 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
26	RS1V	Receive Status RDES1 Valid When this field is 1, it indicates that the status in RDES1 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
25	RS0V	Receive Status RDES0 Valid When this field is 1, it indicates that the status in RDES0 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.

Table continues on the next page...

Table 618. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
24	CE	CRC Error When this field is 1, it indicates that a cyclic redundancy check (CRC) error occurs on the received packet. This field is valid only when the LD bit of RDES3 = 1.
23	GP	Giant Packet When this field is 1, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable = 1). **NOTE** Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this field is 1, it indicates that the receive watchdog timer expires when it receives the current packet. The current packet truncates after watchdog timeout.
21	OE	Overflow Error When this field is 1, it indicates that the received packet is damaged because of buffer overflow in receive FIFO. **NOTE** This field is 1 only when DMA transfers a partial packet to the application. This happens only when the receive FIFO operates in the Threshold mode. In the Store-and-Forward mode, all the partial packets drops completely in the receive FIFO.
20	RE	Receive Error When this field is 1, it indicates that the gmii_rxer_i signal asserts when the gmii_rxdv_i signal asserts during the packet reception. This error also includes carrier extension error in the GMII and Half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this field is 1, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This field is valid only in the MII mode.
18:16	LT	Length/Type Field Indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet. • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP request packet type • 3'b100: The packet is a type packet with VLAN tag • 3'b101: The packet is a type packet with double VLAN tag • 3'b110: The packet is a MAC control packet type • 3'b111: The packet is a OAM packet type

Table continues on the next page...

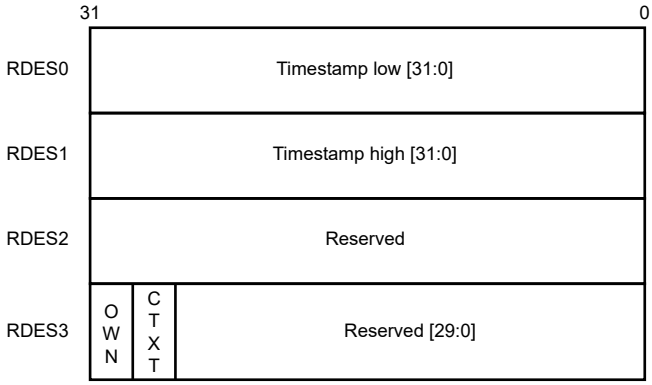
Table 618. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		• 3'b010: Reserved
15	ES	Error Summary When this field is 1, it indicates the logical OR of these bits, : • RDES3[24]: CRC error • RDES3[19]: Dribble error • RDES3[20]: Receive error • RDES3[22]: Watchdog timeout • RDES3[21]: Overflow error • RDES3[23]: Giant packet • RDES2[17]: Destination address filter fail, when the flexible receive parser is enabled • RDES2[16]: SA address filter fail, when flexible receive parser is enabled This field is valid only when the LD bit of RDES3 = 1.
14:0	PL	Packet Length Indicates the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 = 1 and overflow error bits becomes 0. The packet length also includes the two bytes that appends to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 = 1. When the last descriptor and error summary bits are not 1, this field indicates the accumulated number of bytes that are transferred for the current packet.

75.18.4.1.6 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

Figure 459. Receive context descriptor format



75.18.4.1.6.1 RDES0 context descriptor

Table 619. RDES0 context descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low DMA updates this field with least significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSH field of RDES1 show all-ones value, you must consider the timestamp as corrupt.

75.18.4.1.6.2 RDES1 context descriptor

Table 620. RDES1 context descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High DMA updates this field with the most significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, you must consider the timestamp as corrupt.

75.18.4.1.6.3 RDES2 context descriptor

Table 621. RDES2 context descriptor

Bit	Description
31:0	Reserved

75.18.4.1.6.4 RDES3 context descriptor

31	30	29	28:0
OWN	CTXT	DE	Rsvd

Table 622. RDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA clears this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor

Table continues on the next page...

Table 622. RDES3 context descriptor (continued)

Bit	Name	Description
		When this field is 1, it indicates that the current descriptor is a context descriptor. DMA writes 1'b1 to this field for context descriptor. DMA writes 2'b11 to indicate a descriptor error due to all = 1. When CTXT and DE bits are used together {CTXT, DE} • 2'b00: Reserved • 2'b01: Reserved • 2'b10: Context descriptor • 2'b11: Descriptor error Note: When descriptor error occurs, the receive DMA closes the receive descriptor indicating descriptor error. This receive descriptor is skipped and the buffer addresses does not write the packet data. The receive DMA writes 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, because this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	DE	Descriptor Error See the CTXT bit description for more information about how to use the DE bit along with CTXT bit.
28:0	Rsvd	Reserved

75.18.5 Enhanced descriptor for time-based scheduling

This feature needs 32 bytes enhanced descriptors to enable on all the DMA channels that uses this feature (write 1 to EDSE bit of DMA_CH(#i)_TX_Control register).

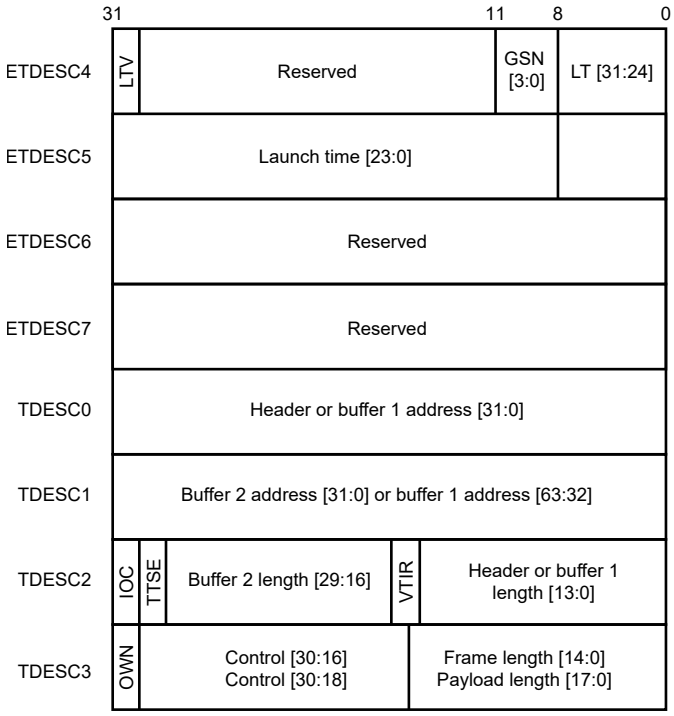
The structure of 32-byte descriptor for the context and the normal descriptor in read and write formats are described in the upcoming sections.

75.18.5.1 Enhanced normal descriptor - Read (32-bit mode)

These fields are present in the first 16 bytes of the enhanced descriptor format of normal descriptor:

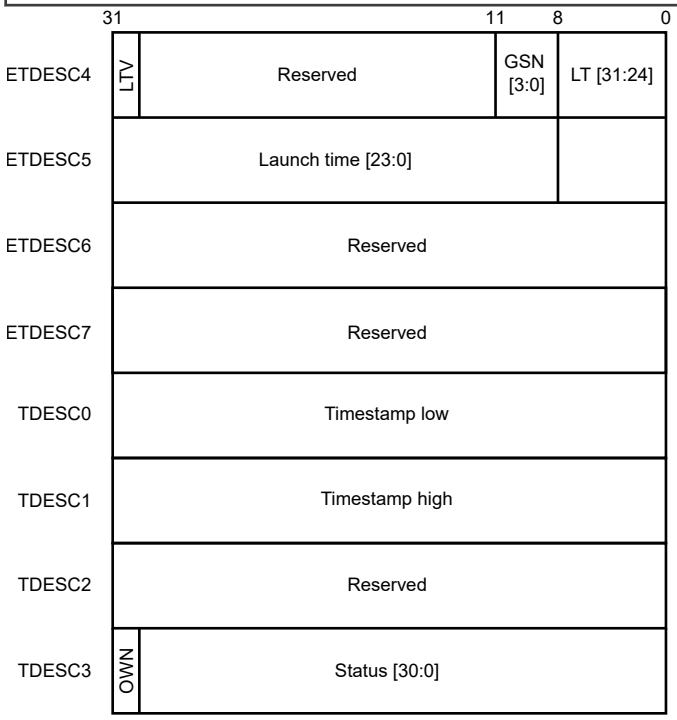
- LTV- Indicates that the launch time (LT) and GSN fields present in the descriptor are valid. The LTV must be = 1 only if the FD bit of the descriptor is not.
- GSN- Indicates the GCL slot number associated with the packet.
- LT- Indicates the launch time associated with the packet.

Figure 460. Enhanced normal descriptor - Read (32-bit mode)



75.18.5.2 Enhanced normal descriptor (Write, 32-bit mode)

Figure 461. Enhanced normal descriptor write (32-bit mode)



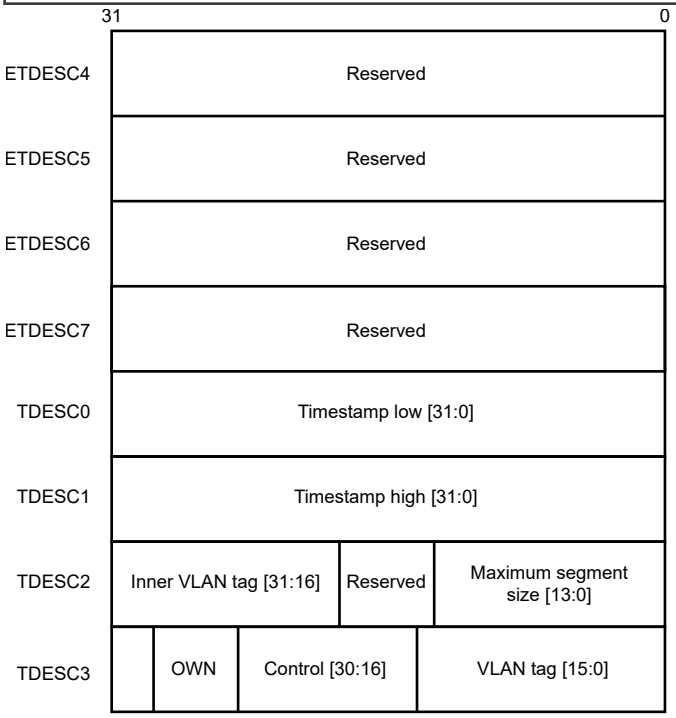
NOTE

- All the enhanced descriptors, example, assumes a 32-bit data width configurations. However, the same definitions are valid in 64-bit and 128-bit configurations.
- In both the write back formats, you cannot modify the extended 16 bytes. The remaining 16 bytes (TDESC0 to TDESC3) are written back per the previous 16 bytes descriptor format.
- When you enable the fetch time it overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding fetch, launch, and launch expiry because the CTR and BTR values get updated when the frame is processed

75.18.5.3 Enhanced context descriptor (Read, 32-bit mode)

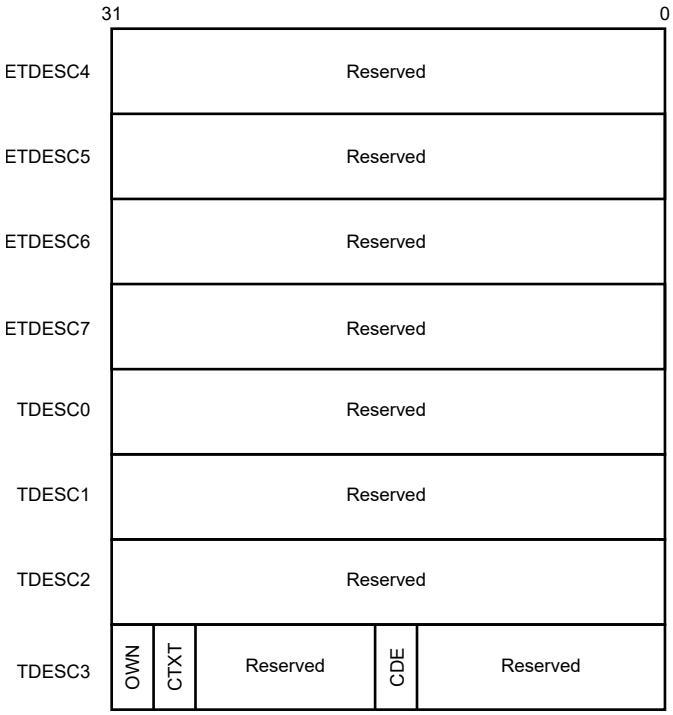
The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be = 0. The fields present in the last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

Figure 462. Enhanced context descriptor - Read



75.18.5.4 Enhanced context descriptor (Write, 32-bit mode)

Figure 463. Enhanced context descriptor - Write



75.19 Programming

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

75.19.1 Initializing DMA

Perform these steps to initialize DMA:

1. Provide a software reset. This resets all the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the reset process (poll bit 0 of DMA_Mode which is only clears after the reset operation completes) to complete.
3. Program these fields to initialize DMA_SysBus_Mode:
    a. DMA_SysBus_Mode[AAL]
    b. Fixed burst or undefined burst
    c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
    d. Select the maximum burst length possible on the AXI bus (bits [7:1]), if fixed length value is enabled.
4. Create a descriptor list for a transmit and receive. Also, ensure that DMA (write 1 to bit 31 of descriptor TDES3/RDES3) owns the descriptors. See Descriptors for more information about descriptors.
5. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= 1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= 1)). The programmed ring length must be at least 4.

    NOTE

    The descriptor address from the start to the end of the ring must not cross the 4 GB boundary.

6. Initialize the receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program the transmit and receive tail pointer registers that indicates DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer

(for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)).

NOTE

For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).

The tailpointer registers must advance to the location immediately after the descriptors that are set so that DMA is aware that the additional descriptors are available.

7. Program the settings of these registers for the parameters like maximum burst-length (PBL) which DMA initiates, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Program the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to enable the interrupts.
9. Write 1 to SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to start the receive and transmit DMAs.
10. Repeat steps 4 to 9 for all the transit DMA and receive DMA channels selected in the hardware.

75.19.2 Initializing MTL registers

The transaction layer (MTL) registers must initialize to establish the transmit and receive operating modes and commands.

Perform these steps to initialize the MTL registers:

1. Program MTL_Operation_Mode[SCHALG] and MTL_Operation_Mode[RAA] to initialize the MTL operation in case of multiple transit and receive queues.
2. Program the receive queue to DMA mapping in MTL_RxQ_DMA_Map0.
3. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode.
   a. MTL_TxQ0_Operation_Mode[TSF] or MTL_TxQ0_Operation_Mode[TTC] in case of Threshold mode.
   b. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0.
   c. MTL_TxQ0_Operation_Mode[TQS]
4. Program these fields to initialize the mode of operation in MTL_RxQ0_Operation_Mode:
   a. MTL_RxQ0_Operation_Mode[RSF] or MTL_RxQ0_Operation_Mode[RTC] in case of Threshold mode.
   b. Flow control activation and de-activation thresholds for MTL receive FIFO (MTL_RxQ0_Operation_Mode[RFA] and MTL_RxQ0_Operation_Mode[RFD]).
   c. Error Packet and undersized good Packet forwarding enable (MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]).
   d. MTL_RxQ0_Operation_Mode[RQS]
5. Repeat previous two steps for all MTL transit and receive queues selected in the configuration.

75.19.3 Initializing MAC

The MAC configuration registers establish the operating mode of MAC. These registers must initialize before initializing DMA.

You can perform these MAC initialization operations after DMA initialization. If the MAC initialization completes before DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, the received frames fill the receive FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled, , program the MAC addresses appropriately.

2. Program these fields to set the appropriate filters for the incoming frames in MAC_Packet_Filter:

a. Receive all

b. Promiscuous mode

c. Hash or perfect filter

d. Unicast, multicast, broadcast, and control frames filter settings

3. Program these fields for proper flow control in MAC_Q0_Tx_Flow_Ctrl:

a. Pause time and other Pause frame control bits

b. Transmit flow control bits

c. Flow control busy

4. Program MAC_Interrupt_Enable as required, and if applicable, for your configuration.

5. Program the appropriate fields in MAC_Configuration. For example Inter-packet gap when transmission and jabber disable.

6. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to start the MAC transmitter and receiver.

75.19.4 Performing normal receive and transmit operation

During normal operation of the module, read the normal and transmit interrupts, poll the descriptors, suspend the DMA (if it does not own descriptors), and read the values of the current host transmitter or receiver descriptor pointers for debugging.

For normal operation, perform these steps:

1. Read the interrupt status for normal transmit and receive interrupts. Then poll the descriptors, read the status of the descriptor which the host owns (either transmit or receive).

2. Set appropriate values for the descriptors, ensure that the DMA owns the transmit and receive descriptors to resume the data transmission and reception.

3. If DMA does not own the descriptors (or no descriptor is available), DMA enters into SUSPEND state. The transmission or reception can resume by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).

4. Read the current host transmitter or receiver descriptor address pointer values for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc regsiter).

5. Read the current host transmit buffer address pointer and receive buffer address pointer values for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Cur-rent_App_RxBuffer).

75.19.5 Stopping and starting transmission

Perform these steps to pause the transmission for some time. The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable) .

2. Wait for any previous frame transmissions to complete. Read the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01 and MTL_TxQ0_Debug[TXQSTS] = 0) to check this.

3. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and MAC receiver.

4. Disable the receive DMA (if applicable), after you ensure that the data in the receive FIFO transfers to the system memory (read the appropriate fields MTL_RxQ0_Debug[PRXQ] = 0 and MTL_RxQ0_Debug[RXQSTS] = 00).

5. Ensure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] = 0 and MTL_RxQ0_Debug[RXQSTS] = 0).

6. Restart the operation by first starting the DMAs, and then enable the MAC transmitter and receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. You can change these parameters only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA related configuration when transmit and receive DMA are active.

75.19.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the receive DMA as compared to the transit DMA. It is permitted when the RxDMA is in SUSPEND state as described below:

- RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND state because the descriptors are not available, a major failure occurs (you are not able to free the filled-up descriptors or buffers). If this issue does not rectify immediately, frames will be lost because of an RxFIFO overflow. Therefore, you can create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

75.19.7 Programming guidelines for multi-channel multi-queuing

75.19.7.1 Transmit

1. Program the transmit queue size in TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in TQS field, you can determine the queue size.

In the transmit operation, the number of channels is equal to the number of the queues, because of this reason, the channel-to-queue mapping is fixed.

2. Enable the queue in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode register to use the queue. In DMA configurations, enable the ST field of DMA_CH[n]_Tx_Con-trol register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode register.

3. Program the scheduling method in MTL_Operation_Mode[SCHALG].

4. Program MTL_TxQ[n]_Quantum_Weight register for DCB queue per the selected algorithm. In case of CBS algorithm in AVB queues program the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit, and MTL_TxQ[n]_LoCredit registers as required.

5. Program the MAC_TxQ_Prty_Map0 register to assign a fixed priority to the queue, if DCB is enabled and PFC function is required. You can use this assigned priority to determine if the corresponding queue must stop transmitting packet on the basis of the received PFC packet.

75.19.7.2 Receive

1. Program the receive queue size in RQS field of MTL_RxQ[n]_Operation_Mode register. Determine the size of the queue, based on the value programmed in RQS field.
2. Enable the receive queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 for AV or DCB. In DMA configurations, SR bit of statically or dynamically map DMA_CH[n]_Rx_Control register and the corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 is enabled.
3. Based on these packet types MAC routes the receive packets to the receive queues :
    a. AV PTP packets: Based on the programming of MAC_RxQ_Ctrl1[PTPQ].
    b. AV untagged control packets: Based on the programming of MAC_RxQ_Ctrl1[AVCPQ].

c. Data center bridging (DCB) related link layer discovery protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 to indicate MAC which queue should get the DCB packets.

d. VLAN tag priority field in VLAN tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 register for routing the tagged packets based on the received packets USP (user priority) field to the receive queues 0 to 7.

e. Route the AV tagged control and data packets based on PSRQ field of MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.

NOTE

The priorities set in PSRQ7-0 must be unique.

4. If multiple receive DMA channels are enabled, you must perform the following programming for proper arbitration and mapping:

a. Program MTL_Operation_Mode[RAA] to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.

b. Program the MTL_RxQ[n]_Control register to decide the weights and the packet arbitration for each RxQ.

c. If you program the static mapping in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH becomes 0), fields RXQx2DMA and others are programmed to select the channel to map each queue.

d. Write 1 to RXQ[n]DADMACH field in MTL_RxQ_DMA_Map0 to select the dynamic mapping of packets in each receive queue.

e. In dynamic channel mapping, the value of DCS field in the lowest MAC address registerthe decides the routing of a packet to a specific RxDMA channel.

75.19.7.2.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the receive DMA channel failure.

Perform these steps if you get bus error in the receive DMA channel:

1. Write 1 to DMA_CH0_Rx_Control[RPF]. This flushes all the packets one after the other.

This step is optional. However, writing 1 to this field prevents head-of-line blocking in the receive queues when packets sent to the RXDMA are stopped due to the bus error.

2. Re-program the specific registers of the DMA channel.

3. Start the DMA channel.

Recovering from the transmit DMA channel failure.

1. Stop the specific DMA channel, even if it is in active state.

2. Flush the corresponding MTL queue.

3. Re-program the specific registers of the DMA channel.

4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not be always successful in recovering from a bus error. If the module is not fully functional after reprogramming the DMA, you can issue a soft reset to recover from the bus error.

75.19.8 Programming guidelines for GMII link state transitions

75.19.8.1 Transmit and receive clocks running when link down

Perform these steps when the link is down but the transmit and receive clocks are running:

NOTE

The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable).

2. Write 0 to MAC_Configuration[RE] to disable the MAC receiver.

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01) or, flush the Tx FIFO for faster empty operation.

4. Write 0 to MAC_Configuration[TE] to disable the MAC transmitter.

5. Make sure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] and MTL_RxQ0_Debug[RXQSTS] are 0).

6. Read the PHY registers to know the latest configuration and accordingly program the MAC registers, after the link is up.

7. Start the transit DMA to restart the operation, and then enable the MAC transmitter and receiver.

You do not disable the receive DMA because the receiver is disabled and the FIFO does not get any data in the receive FIFO.

75.19.8.2 Transmit and receive clocks stopped when link down

Perform these steps when the link is down and the transmit and receive clocks are stopped:

NOTE

The steps are provided for channel 0.

1. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and receiver. This does not take effect immediately as the clocks are absent.

2. Wait until the link is up and the clocks are restored.

3. Wait for the transfer of any partial frame, if any to complete at time of stopping of the transmit or receive clock. To check this, read MAC_Debug (should be all-zero). Some old packets may still remain in the TXFIFO because the MAC transmitter is stopped.

4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.

5. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to restart the MAC transmitter and receiver.

75.19.9 Programming guidelines for IEEE 1588 timestamping

75.19.9.1 Initialization guidelines for system time generation

Write 1 MAC_Timestamp_Control[TSENA] to enable the timestamp feature. However, it is essential to initialize the timestamp counter after MAC_Timestamp_Control[TSENA] = 1. Perform these steps during the module initialization:

1. Write 0 to the bit 16 of MAC_Interrupt_Enable to mask the timestamp trigger interrupt.
2. Write 1 to MAC_Timestamp_Control[TSENA] to enable timestamping.
3. Program MAC_Sub_Second_Increment based on the PTP clock frequency.
4. Program MAC_Timestamp_Addend and write 1 to MAC_Timestamp_Control[TSADDREG], if you are using the fine correction approach.
5. Poll MAC_Timestamp_Control until MAC_Timestamp_Control[TSADDREG] = 0.
6. Program MAC_Timestamp_Control[TSCFUPDT] to select the fine update method (if required).

7. Program MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update with the appropriate time value.
8. Write 1 to MAC_Timestamp_Control[TSINIT].
9. Initialize the timestamp counter with the value written in the timestamp update registers so that the timestamp counter can start operation. If one-step timestamping is enabled
    a. Program Bit 27 of the TDES3 context descriptor, to enable one-step timestamping.
    b. Program MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If the timestamp operation is disabled by writing 0 to MAC_Timestamp_Control[TSENA], repeat all these steps to restart the timestamp operation.

75.19.9.2 System time correction

75.19.9.2.1 Coarse correction method

Perform these steps to synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the timestamp registers that is MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update.

2. Write 1 to MAC_Timestamp_Control[TSUPDT].

The value in the timestamp update registers is added to or subtracted from the system time when MAC_Timestamp_Control[TSUPDT] = 0.

75.19.9.2.2 Fine correction method

Perform these steps to synchronize or update the system time to reduce system-time jitter (fine correction method):

1. Calculate the rate by which you want to increment the system time slower or faster, with the help of the algorithm.

2. Update MAC_Timestamp_Addend with the new value and write 1 to MAC_Timestamp_Control[TSADDREG].

3. Wait for the time for which you want the new value of the addend register to be active. You can do this by enabling the timestamp trigger interrupt after the system time reaches the target value.

4. Program the required target time in MAC_PPS[n]_Target_Time_Seconds register and MAC_PPS[n]_Target_Time_Nanoseconds register.

5. Enable the timestamp interrupt in MAC_Interrupt_Enable[TSIE].

6. Write 1 to bit 4 in MAC_Timestamp_Control.

7. Read MAC_Interrupt_Status when this trigger causes an interrupt.

8. Reprogram MAC_Timestamp_Addend with the old value and write 1 to MAC_Timestamp_Control[TSADDREG] again.

75.19.10 Programming guidelines for AV feature

After you enable the AV feature in the module controller, follow these programming tasks:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

75.19.10.1 Initializing the DMA in audio video feature

The first step to program the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI/QOS-AXI4 configurations with AV feature.

1. Provide a software reset to reset all the QOS internal registers and logic (DMA_Mode[SWR]).

2. Wait for the reset process to complete. Poll DMA_Mode[SWR], which clears only after the reset operation completes.

3. Set the values in DMA_Mode to program the fields to initialize the DMA register.

4. Create a descriptor list for transmit and receive. In addition, ensure that the DMA owns the transmit and receive descriptors. When you use OSF mode, at least two transmit descriptors are required.

See Descriptors for more information about descriptors.

5. Ensure that you create three or more different transmit or receive descriptors in the list before reusing any descriptors.

6. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the transmit and receive tail pointer registers to indicate the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode:

a. MTL_TxQ0_Operation_Mode[TSF]

b. MTL_TxQ0_Operation_Mode[TTC]

c. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0

d. MTL_TxQ0_Operation_Mode[TQS]

9. Enable the interrupts by programming DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

10. Repeat steps 4 through 9 for all the additional channels of AV feature.

11. Program the AV queues CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers.

12. Write 1 to bit 0 of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register to start the receive and transmit DMA.

75.19.10.2 Enabling slot number checking

You can enable slot number checking feature if you specifies the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus.

You must complete these steps after step 11 and before step 12 of Initializing the DMA in audio video feature .

You can use the slot number check feature to specify the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus. This feature is useful for an uniform and periodic transfer of the AV traffic from the host memory and it is available only when you enable timestamping and programs MAC_Sub_Second_Increment. Perform these steps to enable the slot number checking:

1. Follow the steps described in Initialization guidelines for system time generation to enable timestamping.

2. Ensure that the SLOTNUM field (bits 22:19) of TDES3 normal descriptor (Read format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Func-tion_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

3. Write 1 to bit 0 (ESC) of the slot function control and status register of a channel to enable the slot number checking.

75.19.10.3 Enabling average bits per slot reporting

You can enable the reporting of average bits transmitted in a slot.

The CBS status register of the additional AV channels provide information about the average bits that are transmitted in a slot. You can asynchronously read this register to retrieve information about the average bits transmitted per slot. Perform these steps to enable average bits per slot reporting:

1. Follow the steps as described in the Initialization guidelines for system time generation to enable timestamping.

2. Program SLC bits [6:4], of the MTL_TxQ[n]_ETS_Control register of a channel with the number of slots over which the average transmitted bits per slot are computed.

3. Enable bit 9(ABPSSIE) of the MTL_Q[n]_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt generates at every 125 microsecond.
- You can disable this interrupt to stop the interrupt flooding, when it is not required.

4. Read ABS bits [16:0], of the MTL_TxQ[n]_ETS_Status register of a channel on each interrupt.

NOTE

You can read the ABS fields in the polling mode even if ABPSIE bit is not enabled. When bit 1 (ABPSIS) of the MTL_TxQ[n]_ETS_Status register is 1, it indicates that a new value is updated in the ABS field.

75.19.10.4 Disabling flow control for AV enabled queues

75.19.10.4.1 Transmit flow

Program the EHFC (Enable Hardware Flow Control) field of the corresponding receive queue's MTL_RxQ[n]_Operation_Mode register to 0.

75.19.10.4.2 Receive flow control

Program PSTQ[n] field, corresponding to AV enabled transit queue in MAC_TxQ_Prty_Map0/1 register to 0.

75.19.10.5 Programming guidelines for flexible pulse-per-second output

After you enable the flexible pulse-per-second output feature in the module controller, you can perform these tasks:

- Generating single pulse on PPS
- Generating next pulse on PPS
- Generating a pulse train on PPS
- Generating an interrupt without affecting the PPS

75.19.10.5.1 Generating single pulse on PPS

Perform these steps to generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5], of MAC_PPS_Control. This instructs MAC to use the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for a start time of the PPS signal output.
2. Program the start time value in the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= 3) register.

4. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0001. This instructs MAC to generate single pulse on the PPS signal output at the time programmed in the target time registers.

75.19.10.5.2 Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can give the cancel start command (PPSCMD=0011) before the programmed start time elapses to cancel the pulse generation. You can also program the behavior of the next pulse in advance.

Follow these steps to program the next pulse:

1. Program the start time for the next pulse in the target time registers. This time must be more than the time at which the falling edge occurs for the previous pulse.

2. Program the next PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

3. Program PPSCMD bits [3:0], of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs MAC to generate single pulse on the PPS signal output, at the time programmed in target time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

75.19.10.5.3 Generating a pulse train on PPS

Perform these steps to generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5] , of MAC_PPS_Control. This instructs MAC to use the target time registers for the start time of the PPS signal output.

2. Program the start time value in the target time registers.

3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_Interval (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

4. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

5. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0010. This instructs MAC to generate train of pulses on the PPS signal output with start time programmed in target time registers.

By default, the PPS pulse train is free-running unless the STOP pulse train at time or STOP pulse train immediately commands stop it.

6. Program the stop value in the target time registers. Ensure that bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register becomes 0 before programming the target time registers again.

7. Program PPSCMD field [bit 3:0] of MAC_PPS_Control to 0100. This stops the train of pulses on the PPS signal output after the programmed stop time specified in step 6 elapses.

You can program 0101 in PPSCMD field [bit 3:0] of MAC_PPS_Control to stop the pulse train at any time. Similarly, you can program 0110 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the time (programmed in step 6) elapses to cancel the stop pulse train command (given in Step 7). Also, program 0011 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the programmed start time (in Step 2) elapses to cancel the pulse train generation.

75.19.10.5.4 Generating an interrupt without affecting the PPS

MAC_PPS_Control TRGTMODSEL bits [6:5] enables you to program the target time registers to perform any one of these actions:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Perform these steps to program the target time registers to generate only interrupt event:

1. Program 00 (for interrupt) in MAC_PPS_Control TRGTMODSEL bits [6:5]. This instructs the MAC to use the target time registers for target time interrupt.

2. Program a target time value in the target time registers. This instructs the MAC to generate an interrupt when the target time elapses.

If TRGTMODSEL bits [6:5], are changed (for example, to control the PPS) then over-write the interrupt generation with the new mode and new programmed target time register value.

75.19.10.6 Programming guidelines for VLAN filtering on receive

Perform these steps to program VLAN filtering on receive:

1. Program MAC_VLAN_Tag register for the following fields to select the filtering method:

a. ETV: Enables 12-Bit VLAN tag comparison or 16-bit VLAN tag comparison.

b. VTHM: VLAN tag hash table match enable.

c. ERIVLT: Enables inner VLAN tag or outer VLAN Tag (to enable the inner or outer VLAN tag filtering, writing 1 to MAC_VLAN_Tag_Ctrl[EDVLP] enables the double VLAN processing).

d. ERSVLM: Enables receive S-VLAN match or C-VLAN match (write 1 to MAC_VLAN_Tag_Ctrl[ESVL] to enable S-VLAN processing).

e. DOVLTC: Ignores VLAN type for tag match

f. VTIM: Enables VLAN tag inverse match instead of the normal VLAN tag matching

2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.

3. Program MAC_VLAN_Hash_Table, if hash filtering of VLAN tag is enabled. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0, it indicates that the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and index the content of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] is 1, it indicates that the upper 4 bits of calculated CRC-32 of VLAN Tag index the content of MAC_VLAN_Hash_Table. For example, when MAC_VLAN_Tag_Ctrl[ETV] is 1, a hash value of 4b'1000 selects bit 8 of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0 a hash value of 4'b1000 selects bit 7 of MAC_VLAN_Hash_Table.

75.19.10.7 Programming guidelines for extended VLAN filtering and routing on receive

Perform these steps, for the indirect access of the per VLAN tag registers:

- Write
  - Write the required data into MAC_VLAN_Tag_Data.
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required filter register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a write command, set this field to 0.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0 to do the next write. This will guarantee that you have programmed the appropriate VLAN Tag Filter register.
- Read
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a read command, set this field to 1.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0. The appropriate value of the VLAN Tag Filter register is available in MAC_VLAN_Tag_Data.

75.19.10.8 Programming sequence for queue/channel based VLAN inclusion register

Perform these steps to program the queue/channel-based VLAN inclusion register:

NOTE

When MAC_VLAN_Incl[CBTI] = 1 you cannot access the indirect VLAN include registers.

1. Write 1 to MAC_VLAN_Incl[CBTI], to enable queue or channel based VLAN tag insertion on all the transmitted packets. This field must be 1 before any indirect access to the queue or channel specific MAC_VLAN_Incl(#i) register.

2. Program the VLAN tag and VLAN type to insert in packets from a particular queue or channel in MAC_VLAN_Incl[VLT] and MAC_VLAN_Incl[CSVL], corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Write 0 to MAC_VLAN_Incl[RDWR] to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_Incl initiates access to indirect access MAC_VLAN_Incl(#i) register.

3. Write 1 to MAC_VLAN_Incl[BUSY] via the module to indicate the progress of access to indirect access MAC_VLAN_Incl(#i) register. After the access completes, MAC_VLAN_Incl[BUSY] = 0. The application must not attempt subsequent access to MAC_VLAN_Incl(#i) register when the MAC_VLAN_Incl[BUSY] is 1.

4. Repeat step 2 and step 3 to program VLAN tag and VLAN type to insert in packets from the remaining queues or channels. The application must ensure that the required VLAN tag and VLAN type for all the queues or channels are programmed, otherwise an unintended VLAN tag and VLAN type might be inserted.

75.19.11 Programming guidelines for EST

Program the gate control values and time intervals in MTL_EST_Status[SWOL] along with the other EST related registers that are described in GMAC register descriptions to appropriate values. The upcoming sub-sections provide step by step details for programming the GCL and the other EST related registers.

75.19.11.1 Programming the GCL and GCL linked registers

Perform these steps to program the GCL and the four other registers implemented per GCL:

1. Access the GCL and the four other GCL-linked registers via indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data. MTL_EST_Status[SWOL] indicates whether the software owns GCL0 or GCL1.
2. Write the 32-bit write data to MTL_EST_GCL_Data, to program the GCL. Then program MTL_EST_GCL_Control to write the write address and other control information.
3. In MTL_EST_GCL_Data, write data consists of up to 8 bits (configurable) of gate controls and up to 24 bits (configurable) of time interval. Programming a 0 indicates gate close and programming a 1 indicates gate open. For a 4-TC and 20-bit time interval configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. You must write the data in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. Program MTL_EST_GCL_Control[SRWO] to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check that the hardware clears MTL_EST_GCL_Control[SRWO] to indicate that the previous operation completes before initiating a new read-write operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL completes.
7. Program the BTR, CTR, TER and LLR registers, using the same indirect addressing method as described above. Write 1 to MTL_EST_GCL_Control[GCRR] appropriately. MTL_EST_GCL_Control[GCRR] interprets the address field as belonging to these registers (instead of the GCL).

After the GCL and the related registers are programmed, program MTL_EST_GCL_Control to allow hardware to own and process the GCL. When the list length (as indicated in LLR) is 1, the associated time interval must be smaller than the cycle time register value. Otherwise, an error is reported (as described in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP system time is used, you must program the nanoseconds field to use the Digital Rollover mode. (The value of MAC_Timestamp_Control[TSCTRLSSR]must be 1)

75.19.11.2 Programming the EST registers

After the steps mentioned in "Programming the GCL and GCL Linked Registers" completes, program MTL_EST_Control

1. Write 1 to MTL_EST_Control[CTOV] and MTL_EST_Control[TILS]. Also, write 1 to MTL_EST_Control[EEST] and MTL_EST_Control[SWOL].

   NOTE

   The CTOV recommendations for GMII for SPRAM configurations are:

   - 96 * Tx clock period, for 32 and 64 bit data width configurations.
   - 128 * Tx clock period for 128 bit data width configurations.

   The CTOV recommendations for GMII for non-SPRAM configurations are:

   - 30 * Tx clock period, when SA/VLAN insertion is enabled.
   - 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. Enables the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Performs an appropriate action to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Write 1 to MTL_EST_Control[SSWL] to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when MTL_EST_Control[SSWL] = 1, because the hardware might be using the new GCL.

The hardware resets or clears MTL_EST_Control[SSWL] when it successfully switches to the new list. The hardware also flips MTL_EST_Status[SWOL] to indicate the new GCL that the software owns.

Program the GCL that software owns (MTL_EST_Status[SWOL] indicates) as described in "Programming the GCL and GCL Linked Registers" and then program MTL_EST_Control as described above, to install a new GCL. Ensure that the new BTR is set to an appropriate value to avoid BTR Error that may require software intervention in some cases.

The packet length (frame size) information must be available at all times, to avoid transmission overruns. Therefore, in the DMA configurations, program the packet length in the first descriptor of every transmit frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

The packet length provided in the transmit descriptor must account for the SA and VLAN insertion, to avoid transmission overruns, if applicable, that is, packet length must represent the actual packet length on the Ethernet line.

75.19.12 Programming the launch time in time-based scheduling

Configure the launch time in the enhanced normal transmit descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and launch time features are mutually exclusive and must not be used together. In case of a conflict (if OSTC = LTV = 1 in MTL configuration), give priority to OSTC and ignore the launch time.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV = 1, then the LTV is ignored.

75.19.13 Programming guidelines for media clock generation and recovery

75.19.13.1 Programming guidelines for media clock generation

These are the guidelines for the media clock generation:

1. Program the appropriate presentation time control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control, to define the PPS instance in Media clock generation mode.

2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].

3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_Target_Time_Seconds register. Then, mcgr_dma_req_o[#i] is set.

4. For every request which DUT generates, the module reads the corresponding MAC_PPS(#i)_Target_Time_Seconds register and asserts the corresponding mcgr_d-ma_ack_i[#i] to acknowledge the read request.

75.19.13.2 Programming guidelines for media clock recovery

These are the guidelines for the media clock recovery:

- Writing 1 to MAC_Timestamp_Control[PTGE] enables the CPT counter. In addition to configuring the initialization values for the system time, update MAC_Presn_Time_Updt with the equivalent presentation time initialization value, then MAC_Timestamp_Control[TSINIT] = 1.
- Use the increment values for the system time and also for the CPT because the increment value is in sub-seconds and sub-nanoseconds.
- Update MAC_Presn_Time_Updt with the equivalent presentation time update value (32 bit ns), when an update is requred, and also configure the updated values for the system time. Finally, MAC_Timestamp_Control[TSUPDT] must be 1 for the update.
- Program the MCGREN#i field of MAC_PPS_Control to enable the PPS instance to operate in MCGR mode.
- Program the appropriate presentation time control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance) or PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register, to set the PPS instance in Media clock recovery mode.
- After the PPS instance is set in Recovery mode, DUT sets the corresponding mcgr_dma_req_o[#i]. For every request which DUT generates, program the target presentation time into the MAC_PPS(#i)_Target_Time_Seconds register and assert the corresponding mcgr_dma_ack_i[#i] to acknowledge the request. Acknowledgment can be given before/after programming the Target presentation time.
- Observe the recovered media clock on the corresponding ptp_pps_o[#i].

75.19.14 Programming guidelines for ECC protection for memories

These are the guidelines for the ECC protection for memories:

- Write 1 to the appropriate field of MTL_ECC_Control to enable the ECC features for the respective memory.
- Generate a correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application, if any correctable, uncorrectable, or address errors are detected. DMA_Interrupt_Status or MTL_ECC_Interrupt_Status indicates an appropriate status.
- Provide debug mode for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise the false interrupts may trigger.

75.19.14.1 Programming guidelines for ECC hardware error injection (Debug mode)

Follow these steps for ECC hardware error injection:

- Write 1 to the appropriate field in MTL_DBG_CTL to enable the ECC error injection feature for MTL TX/RX and DMA TSO.
- Write 1 to the appropriate field in MTL_EST_GCL_Control to enable the ECC error injection feature for the EST memory.
- Write 1 to the appropriate field in MTL_RXP_Indirect_Acc_Control_Status to enable the ECC error injection for the receive parser memory. To access the receive parser memory in Debug mode, write 0 to MTL_RXP_Indirect_Acc_Control_Status[FRPE] to disable the receive parser feature.
- Ensure that all the CSR writes corresponding to one memory write must have the same value for the error injection control word, where multiple CSR writes are required for writing single data word into the memory.

75.19.15 Programming guidelines for on-chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Writing 1 to MTL_DPP_Control[EDPP] enables the parity generation and parity detection mismatch on datapath.
- Generates an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application if any parity mismatch is detected. DMA_Safety_Interrupt_Status or MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status indicates the appropriate status.
- Supports Debug mode for each parity generator to insert an error.

NOTE

Enable the datapath parity protection before the receive or transit traffic starts, to avoid the false safety interrupts.

75.19.16 Programming guidelines for FSM parity and timeout

Follow these steps to configure the FSM parity and timeout:

- Write 1 to MAC_FSM_Control[PRTYEN] and MAC_FSM_Control[TMOUTEN] to enable the FSM parity and timeout feature respectively.
- Force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to define with MAC_DPP_FSM_Interrupt_Status[FSMPES] for a parity error detection.
- Write 1 to the parity error injection using the [23:16] bits of MAC_FSM_Control to select the appropriate clock domain, for Error injection mode in FSM parity. Wait for the safety uncorrectable interrupt to be defined with MAC_DPP_FSM_Interrupt_Status[FSMPES].
- Configure the large and normal mode values which MAC_FSM_ACT_Timer[LTMRMD] and MAC_FSM_ACT_Timer[NTMRMD] indicates , for FSM timeouts.
- Use the [31:24] bits of MAC_FSM_Control to select the large or normal mode tic generation per clock domain.
- Write 1 to MAC_FSM_ACT_Timer[TMR] with the appropriate number of CSR clock cycles to generate 1us tic.
- Force the FSM in a particular clock domain to remain in an active state for timeout duration (for example, T-2T). You can check the safety interrupt and the status field for the corresponding clock domain that sets in the [15:8] bits of the MAC_DPP_FSM_Interrupt_Status .
- Select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control, for Error injection mode in FSM timeout. Wait for the safety uncorrectable interrupt to define with the corresponding error status in the MAC_DPP_FSM_Interrupt_Status .
- Use only normal mode tic generation, for application or CSR interface timeout. On the basis of the time-outs of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_Interrupt_Status is defined with the safety interrupt.

75.20 Glossary

AFM Address filtering module

ARI Application receive interface

ATI	Application transmit interface
AVB	Audio video bridging
AXI	Advanced extensible interface
BTR	Base time register
CPT	Current presentation time
CRC	Cyclic redundancy check
DA	Destination address
DCB	Data center bridging
DUT	Device under test
EOP	End of packet
FCS	A 32-bit cyclic redundancy check used to detect an in-transit corruption of data. Also marks the end of an Ethernet frame.
FIFO	First in first out
GCL	Gate control list
GMII	Gigabit media independent interface
MAC	Media access controller
MCI	MAC control tnterface
MDC	Management data clock
MDIO	Management data input/output
MII	Media independent interface
MRI	MAC receive interface
MTI	MAC transmit interface
MTL	MAC transmit layer
PBL	Programmable burst length
PHY	The physical interface transceiver that implements the OSI physical layer for an ethernet network. The IEEE 802.3 standard defines it.
RGMII	Reduced gigabit media independent interface
RMII	Reduced media independent interface
RMON	Remote network monitoring
SA	Source address
SFD	Start frame delimiter
SGMII	Serial gigabit media independent interface
SMA	Station management agent
TCP	Transmission control protocol
UDP	User datagram protocol
VLAN	Virtual local area network

Chapter 76
Low Power Universal Asynchronous Receiver/ Transmitter (LPUART)

76.1 Chip-specific LPUART information

76.1.1 LPUART instances and configuration

Table 623. LPUART instances

Instance	S32K314/S32K324/S32K44/S32K358	S32K311/S32K322/S32K342	S32K312
LPUART_0	Yes	Yes	Yes
LPUART_1	Yes	Yes	Yes
LPUART_2	Yes	Yes	Yes
LPUART_3	Yes	Yes	Yes

LPUART_13	Yes	No	No
LPUART_14	Yes	No	No
LPUART_15	Yes	No	No

Table 624. LPUART Configuration

Feature	Configuration			
	S32K344	S32K312	S32K342	S32K358
TX FIFO size	4 Words		16 Words (for instance 0,1) 4 Words (for instance 2,3)	16 Words (for instance 0,1) 4 Words (for instance 2 to 15)
RX FIFO size	4 Words		16 Words (for instance 0,1) 4 Words (for instance 2,3)	16 Words (for instance 0,1) 4 Words (for instance 2 to 15)
Functionality supported	Standard LPUART functionality with MODEM/IrDA		Standard LPUART functionality with MODEM/IrDA and MODBUS support.	
	LIN master and slave operation			

NOTE

LPUART instances are not available during Standby.

LPUART[0:2]_trg_input is coming from TRGMUX and you should take care of the pulse width of trigger. It should follow the requirement mentioned in section "Peripheral Triggers". These triggers are not present in S32K314, S32K324, S32K344.

76.2 Overview

The Low Power Universal Asynchronous Receiver/Transmitter (LPUART) module provides asynchronous, serial communication capability with external devices. LPUART supports non-return-to-zero (NRZ) encoding format and IrDA compatible infrared (low-speed) SIR format. The LPUART can continue operating while the processor is in low-power mode if an appropriate peripheral clock is available.

76.2.1 Block diagram

The following figure shows the transmitter portion of the LPUART.

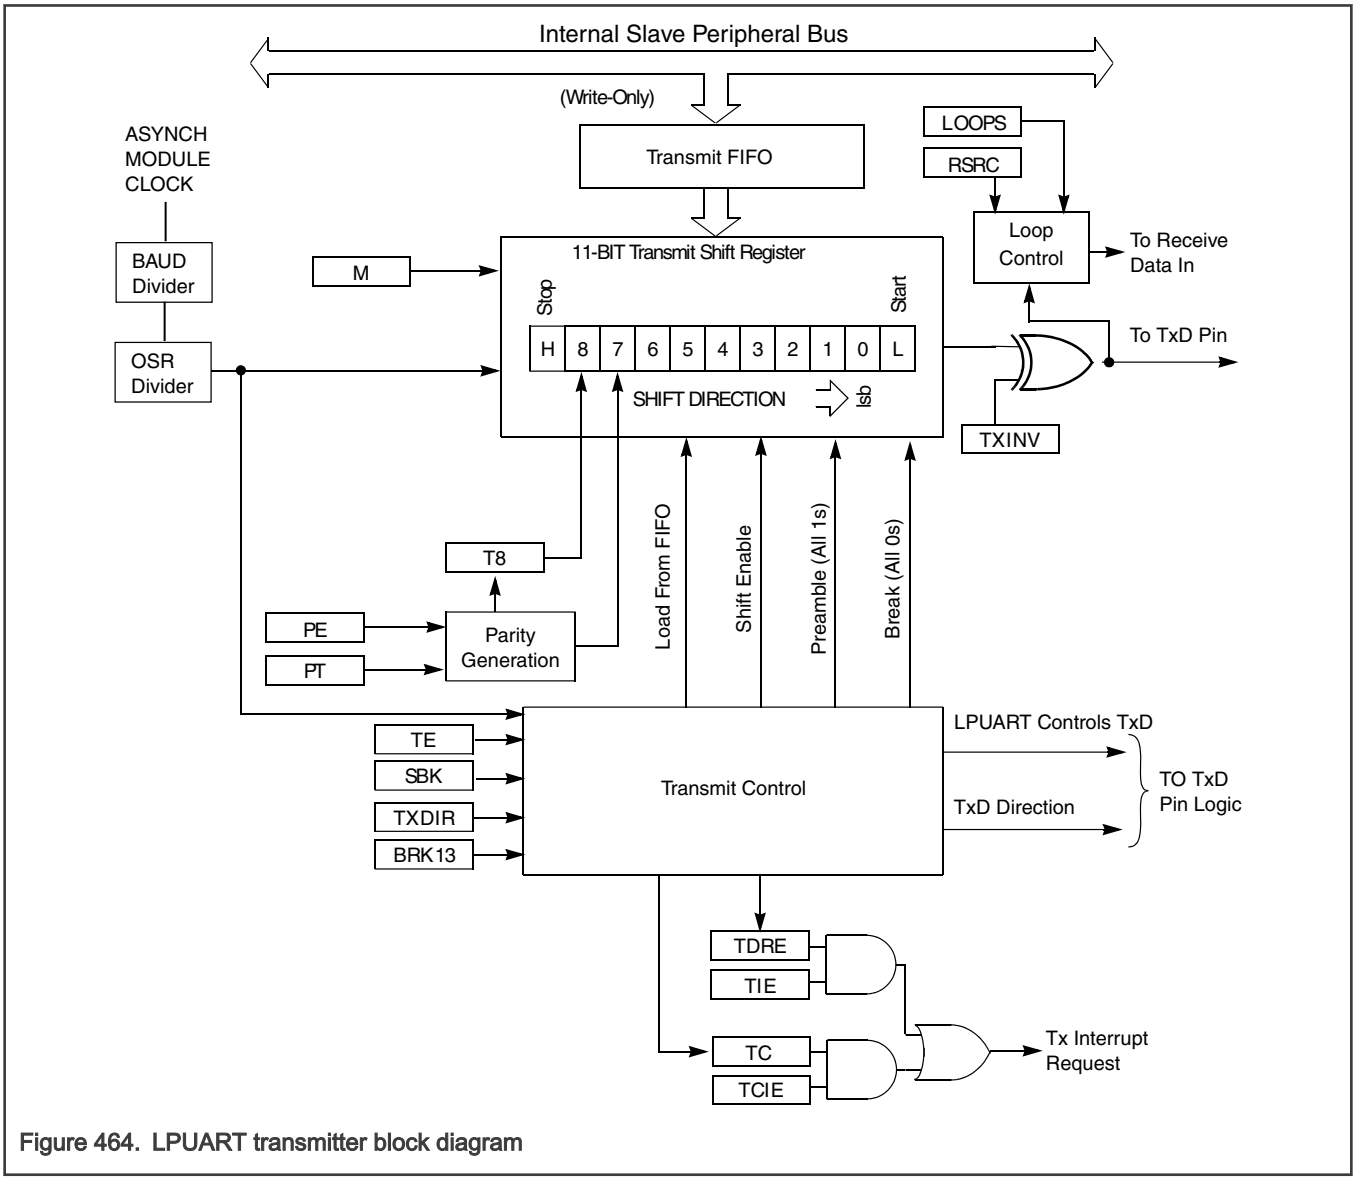

Figure 464. LPUART transmitter block diagram

The following figure shows the receiver portion of the LPUART.

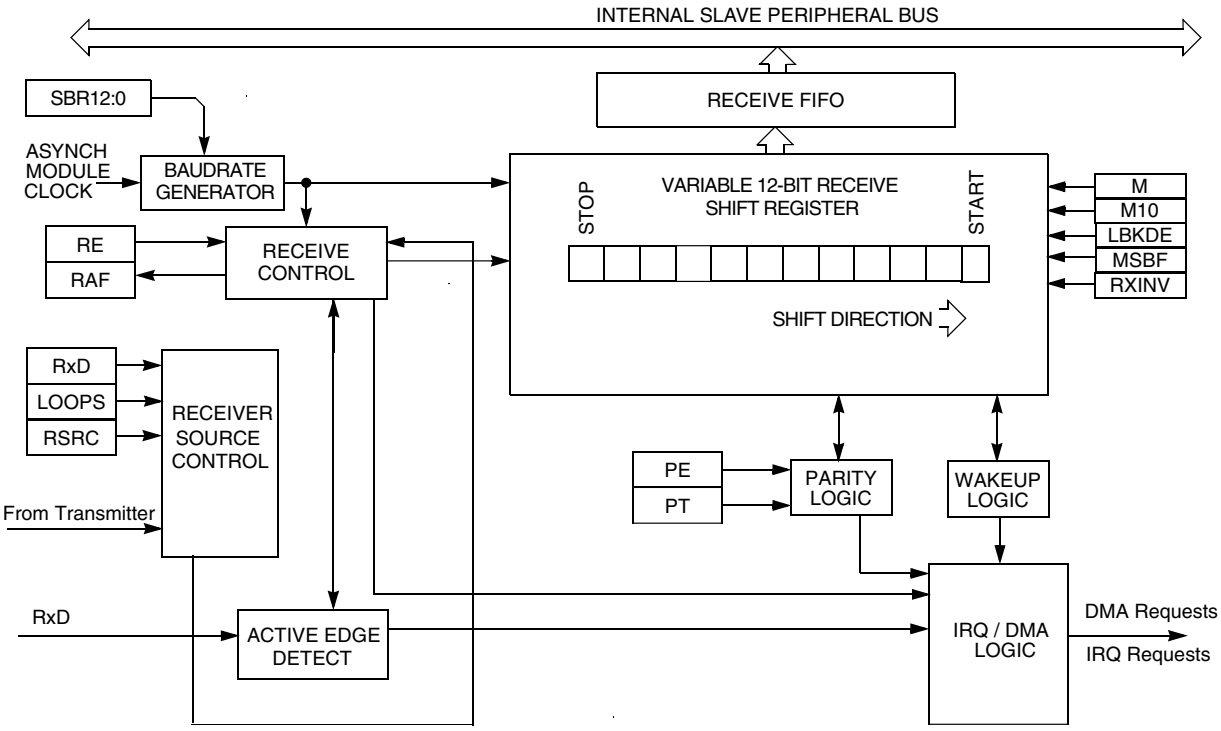

Figure 465. LPUART receiver block diagram

76.2.2 Features

Following are the features of the LPUART module.

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates(13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Asynchronous operation of transmit and receive baud rate with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in low-power modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wakeup methods:
  - Idle line wakeup

  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit/11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

76.3 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

76.3.1 Low-power modes

The LPUART remains functional during low power modes, provided the CTRL[DOZEEN] bit is clear and the LPUART functional clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from low power modes.

The LPUART can be configured to be disabled in low power modes, when the CTRL[DOZEEN] bit is set. In this case the transmitter and receiver finish transmitting/receiving the current word.

If the LPUART is disabled in low power modes, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

NOTE

See the chip-specific information to know the specific low-power modes available on your device.

76.3.2 Debug mode

The LPUART remains functional in debug mode.

76.3.3 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio (OSR). Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

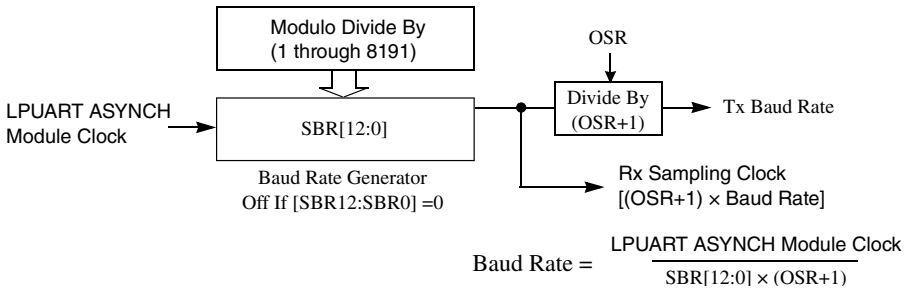

Figure 466. LPUART baud rate generation

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher oversampling ratio and/or sampling on both edges of the clock slightly improves the LPUART tolerance to baud rate mismatch between the received data and the LPUART configured baud rate. However, the three data samples in each bit will also be closer together which may impact noise sensitivity.

76.3.4 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted by setting CTRL[TXINV]. CTRL[TXINV] is cleared following reset. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit FIFO. Programs store data into the transmit FIFO by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the transmit shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit FIFO at the DATA register.

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter does not start transmitting another character.

76.3.4.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with DATA[FRETSC] set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 0, and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with DATA[FRETSC] and DATA[T9] set, and all other bits cleared. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

Table 625. Break character length

BRK13	M	M10	M7	SBNS	Break character length
0	0	0	0	0	10 bit times
0	0	0	0	1	11 bit times
0	0	0	1	0	9 bit times
0	0	0	1	1	10 bit times
0	1	0	X	0	11 bit times
0	1	0	X	1	12 bit times
0	X	1	X	0	12 bit times
0	X	1	X	1	13 bit times
1	0	0	0	0	13 bit times
1	0	0	0	1	13 bit times
1	0	0	1	0	12 bit times
1	0	0	1	1	12 bit times
1	1	0	X	0	14 bit times
1	1	0	X	1	14 bit times
1	X	1	X	0	15 bit times
1	X	1	X	1	15 bit times

76.3.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the clear-to-send operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register will be complete; any characters in the FIFO will wait for the CTS_B to assert again and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

76.3.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the request-to-send operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts one bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts one bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, the RTS_B asserts 1 bit time before the transmitter starts transmitting and negates 1 bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

The transmitter RTS_B negation can be delayed by up to 256 bit clock (baud rate) after the last stop bit by configuring the HDCR[RTSEXT] field to the desired length.

76.3.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

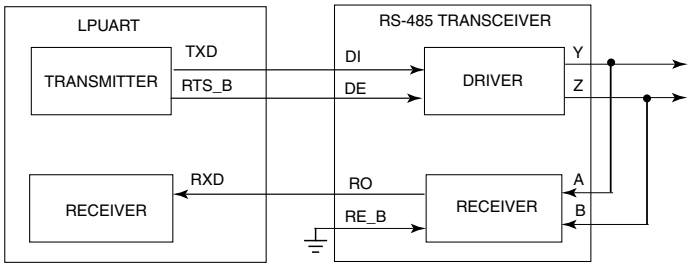

Figure 467. Transceiver driver enable using RTS_B

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

76.3.5 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to Data Modes. For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost.

Since the LPUART receiver is separate from the receive FIFO, the receive shift register can be receiving the next word when the receive FIFO is full and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to Interrupts and status flags for details about flag clearing.

76.3.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE]=1), the number of segments in each received bit is effectively doubled (from 1 to OSR×2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4× to 7× and is optional for higher oversampling rates.

The "synchronization" is a feature of the LPUART module to synchronize the internal oversampling counter with detected falling edge on Rx signal, and to adjust the data sampling window. The falling edge detection needs three consecutive '1' prior to '1'->'0' transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter once another falling edge is detected. This is called "resynchronization".

- When LPUART_BAUD[RESYNCDIS] = 0, this falling edge detection and resynchronization is performed not only for the start bit but also for the rest of character reception after the start bit.
- When LPUART_BAUD[RESYNCDIS] = 1, the falling edge detection and resynchronization is performed only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

  See the following table and figure.

Table 626. LPUART resynchronization

Resynchronization	LPUART_BAUD[RESYNCDIS]=0	LPUART_BAUD[RESYNCDIS]=1
For the starting bit falling edge	Yes	Yes
For every falling edges after the start bit	Yes	No

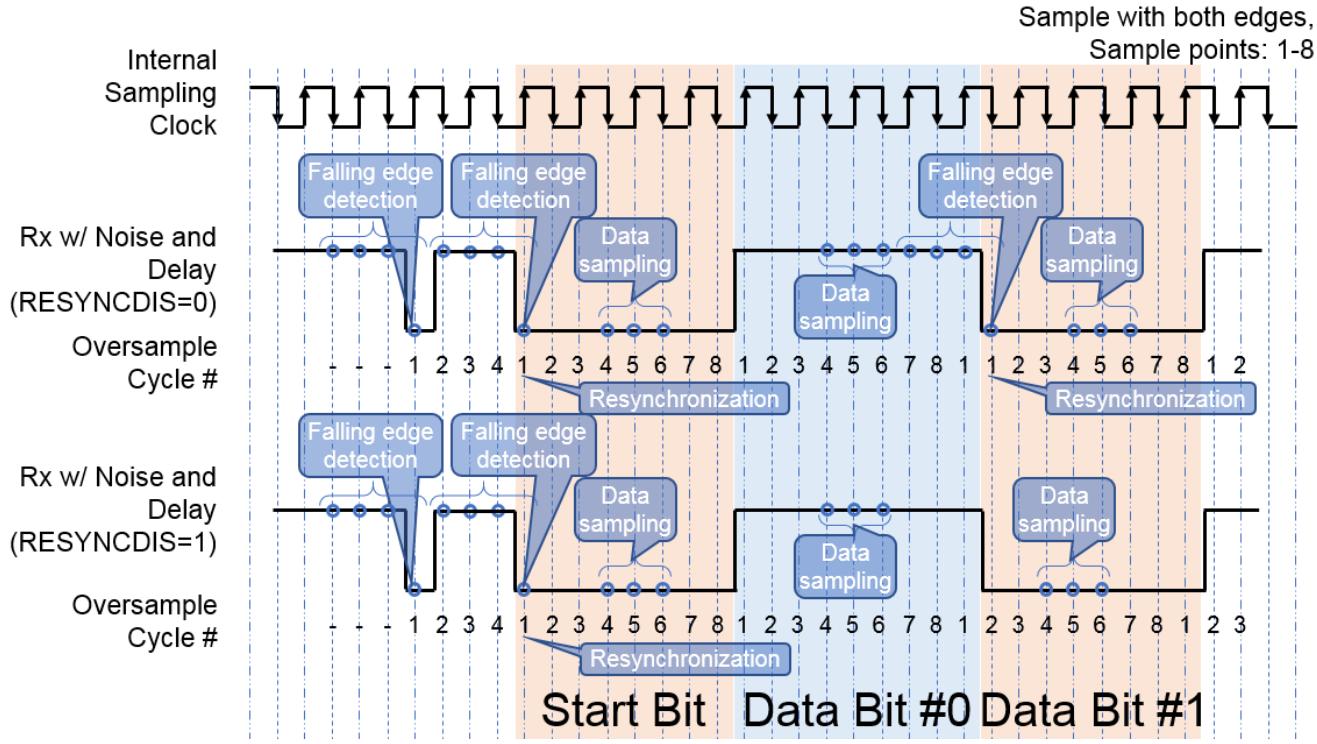

Figure 468. LPUART resynchronization

76.3.5.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 627. Receiver Wakeup Options

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
0	0	X	X	Normal operation
1	0	00	00	Receiver wakeup on idle line, IDLE flag not set
1	0	00	01	Receiver wakeup on idle line, IDLE flag set
1	0	00	10	Receiver wakeup on address mark

Table continues on the next page...

Table 627. Receiver Wakeup Options (continued)

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
1	1	11	10	Receiver wakeup on data match
0	1	00	X0	Address mark address match, IDLE flag not set for discarded characters
0	1	00	X1	Address mark address match, IDLE flag set for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match On and Match Off, IDLE flag not set for discarded characters
0	1	10	X1	Match On and Match Off, IDLE flag set for discarded characters

76.3.5.2.1 Idle-line wakeup

When CTRL[WAKE] is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7], and BAUD[M10] control bits select 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line.

- When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle.
- When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

76.3.5.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

76.3.5.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

76.3.5.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs then no transfer is made to the receive FIFO, and all following characters with logic zero in the most significant bit (or second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

76.3.5.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is transferred only to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive FIFO, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

76.3.5.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

NOTE

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

76.3.5.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS_B.

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS_B if the number of characters in the receiver data register is full or a start bit is detected that causes the receiver data register to be full.
- The receiver asserts RTS_B when the number of characters in the receiver data register is not full and has not detected a start bit that causes the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS_B remains deasserted.

76.3.6 Additional LPUART functions

The following sections describe additional LPUART functions.

76.3.6.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the 9th and 10th bit are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0], but if values in CTRL[T8] or CTRL[T9] do not need to change then it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to the DATA register.

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10-bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the 9th and 10th bit are held in CTRL[R8] and CTRL[R9] but should be read before reading the DATA register. A 16-bit or 32-bit read of the receive FIFO will return all 10-bits in the DATA register.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

76.3.6.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position (idle state, generally logic 1). The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit causes any discarded characters to be treated as if they were idle characters.

When the extended idle time is enabled for the receiver, an idle line condition can be configured using a 14-bit idle length register that specifies the number of bits (baud rate) since the last stop bit that is required for an idle condition to be detected. This replaces the ILT and IDLECFG configuration.

The extended idle time can also be enabled for the transmitter, in this case any idle character queued through the transmit FIFO will force the transmitter to have idled for the configured number of bit clocks before the idle character is read from the FIFO and the transmitter continues. Note that when the transmitter extended idle time is enabled, the transmitter does not automatically queue an idle character whenever it is enabled.

76.3.6.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help

isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

Loop mode will also internally connect the RTS_B output to the CTS_B input and the DTR_B output to the DSR_B input.

76.3.6.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

The Half Duplex Control Register replaces the CTRL[LOOPS] and CTRL[RSRC] implementation and can be used to configure various options for both single-wire operation or for half-duplex operation using independent RXD and TXD pins:

- HDCR[TXSTALL] replaces the CTRL[TXDIR] functionality and prevents the transmitter from becoming busy or asserting transmitter RTS_B when STATUS[RAF] is set.
- HDCR[RXSEL] configures for single-wire operation by selecting the TXD pin as the source for the receiver. When RXSEL is set, the TXD pin should be configured for open drain operation.
- HDCR[RXMSK] masks the receiver input when the transmitter RTS_B is asserted (this applies even when the transmitter RTS_B is not configured as an output).
- HDCR[RXWRMSK] blocks storing receive data to the receive FIFO when the transmitter RTS_B is asserted. The receiver idle functionality is not affected by this setting.
- HDCR[RTSEXT] delays the negation of the trasmitter RTS_B by the configured number of bit clocks (baud rate).

76.3.6.5 Timeout Counter

The LPUART implements 4 general purpose timeout counters, counters 0 and 1 are used to monitor the receiver and counters 2 and 3 are used to monitor the transmitter. When enabled, each counter can be configured to monitor one of the following conditions:

- Idle time in number of bits, starting to increment when first enabled and an idle condition is detected. Counter restarts whenever a character is received/transmitted.
- Idle time in number of bits, starting to increment after the next character is received/transmitted. Counter restarts whenever a character is received/transmitted.
- Idle time is more than the timeout interval in number of bits, but less than the extended idle timout. Counter restarts whenever a character is received/transmitted. Can be used to detect a gap between characters that is greater than a threshold (timeout) but less than the configured extended idle time. This configuration requires the extended idle feature for the transmitter or receiver to be enabled for proper operation.
- Number of characters received/transmitted is equal to the configured timeout. Will assert at the start of the character that equals the timeout value.

The timeout counters restart counting whenever the counter is disabled and then enabled. The timeout counters are disabled while the corresponding timeout status flag is set. If the timeout enable is still set after the status flag is cleared, then the timeout counter will restart as if the counter had been disabled and then enabled. Idle time is measured in bit times from the end of the last stop bit and until a start bit has been validated.

76.3.7 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared

communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. The LPUART IrDA support is limited to SIR mode which supports data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode (external to LPUART) and transformed to CMOS levels by the IR receive decoder. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

76.3.7.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

76.3.7.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

76.3.7.3 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

76.3.7.4 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

76.3.7.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

76.3.7.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

76.3.8 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit Data Register Empty (STAT[TDRE]) indicates when there is room in the transmit FIFO to write another transmit character to the DATA register. If the Transmit Interrupt Enable (CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to be set, the error flags — noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) — are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] is already set when a new character is ready to be transferred from the receive shifter to the receive FIFO, the overrun (STAT[OR]) flag is set instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

The MODEM Status Register can generate an interrupt from a configured status flag, this is indicated by STAT[MSF].

The Timeout Status Register can generate an interrupt from a configured status flag, this is indicated by STAT[TSF].

76.3.8.1 DMA Burst Support

To support efficient DMA transfers to the transmit FIFO, two alias regions are implemented to support incrementing 8-bit, 16-bit or 32-bit write accesses to the transmit FIFO.

- Transmit Command Burst Register is a 512-byte region that supports pushing 16-bit DATA into the transmit FIFO
- Transmit Data Burst Register is a 1024-byte region that supports pushing zero extended 8-bit DATA into the transmit FIFO

The two regions are contiguous, so a DMA transfer can start in the TCBR region to initialize the transfer including address mark, idle word or break character, and then complete the transfer in the TDBR region with the data to transmit, without changing the transfer size.

The transmit FIFO will block writes that overflow the FIFO, but this does not signal an error. Do not perform 32-bit writes to the TDBR unless there are 4 empty slots in the transmit FIFO. Do not perform 16-bit writes to the TDBR unless there are 2 empty slots in the transmit FIFO.

76.3.9 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

Output Triggers

The LPUART generates the following output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.

- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when the idle flag would set, and negates when the next valid start bit is detected.

Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

- The CTS function must be enabled. The input trigger can be connected in place of the CTS_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be a free running clock (carrier signal) generated from a timer or PWM source with a frequency that is greater than the bit clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

76.4 Clocking and Resets

Table 628. Clocks

LPUART Functional clock	The LPUART functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support transmit and/or receive, including low power wakeups.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

Table 629. Resets

Chip reset	The logic and registers for the LPUART transmitter and receiver are reset to their default state on a chip reset.
Software reset	Resets the LPUART logic and registers to their default state, except for the Global Register. The LPUART software reset is in the Global Register GLOBAL[RST].
FIFO reset	The LPUART implements write-only control bits that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO is empty.

76.5 External signals

Table 630.

Signal	Description	I/O
TXD	Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data.	I/O
RXD	Receive data.	I
CTS_B	Clear to send.	I
RTS_B	Request to send.	O

DCD_B	Data Carrier Detect.	I
RIN_B	Ring Indicator.	I

76.6 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module does not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

23 TDMAE	Transmitter DMA Enable TDMAE configures the transmit data register empty flag, STAT[TDRE], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable RDMAE configures the receiver data register full flag, STAT[RDRF], to generate a DMA request.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - DMA request disabled. 1b - DMA request enabled.
20 —	Reserved
19-18 MATCFG	Match Configuration Configures the match addressing mode used. This field should be changed only when the transmitter and receiver are both disabled. 00b - Address Match Wakeup 01b - Idle Match Wakeup 10b - Match On and Match Off 11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should be changed only when the receiver is disabled. 0b - Receiver samples input data using the rising edge of the baud rate clock. 1b - Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	Resynchronization Disable When set, this field disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should be changed only when the receiver is disabled. 0b - Resynchronization during received data word is supported. 1b - Resynchronization during received data word is disabled.
15 LBKDIE	LIN Break Detect Interrupt Enable LBKDIE enables the LIN break detect flag, STAT[LBKDIF], to generate interrupt requests. 0b - Hardware interrupts from STAT[LBKDIF] flag are disabled (use polling). 1b - Hardware interrupt is requested when STAT[LBKDIF] flag is 1.
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables the receive input active edge, STAT[RXEDGIF], to generate interrupt requests. Changing CTRL[LOOPS] or CTRL[RSRC] when RXEDGIE is set can cause the STAT[RXEDGIF] flag to set. 0b - Hardware interrupts from STAT[RXEDGIF] are disabled. 1b - Hardware interrupt is requested when STAT[RXEDGIF] flag is 1.
13	Stop Bit Number Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
SBNS	SBNS determines whether data characters have one or two stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0b - One stop bit. 1b - Two stop bits.
12-0 SBR	Baud Rate Modulo Divisor. The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) * SBR)". The 13-bit baud rate setting [SBR12:SBR0] must be updated only when the transmitter and receiver are both disabled (CTRL[RE] and CTRL[TE] are both 0).

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. Writing a 1 clears the LBKDIF field. 0b - No LIN break character has been detected. 1b - LIN break character has been detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge (falling if RXINV = 0, rising if RXINV=1,) on the RXD pin occurs. To clear RXEDGIF, write a 1 to the RXEDGIF field. 0b - No active edge on the receive pin has occurred. 1b - An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1b - MSB (identified as bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. .
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. This bit should be changed only when the receiver is disabled. **NOTE** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Receive data not inverted. 1b - Receive data inverted.
27 RWUID	Receive Wake Up Idle Detect For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should be changed only when the receiver is disabled. 0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match. 1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match.
26 BRK13	Break Character Generation Length BRK13 selects a longer transmitted break character length. The state of this bit does not affect the detection of a framing error. This bit should be changed only when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Break character is transmitted with length of 9 to 13 bit times. 1b - Break character is transmitted with length of 12 to 15 bit times.
25 LBKDE	LIN Break Detection Enable LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive FIFO. **NOTE** The LBKDE bit enables the LIN break detect circuit and disables writing receive data to FIFO. So it essentially ignores all characters except a LIN break. 0b - LIN break detect is disabled, normal break character can be detected. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).
24 RAF	Receiver Active Flag RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. 0b - LPUART receiver idle waiting for a start bit. 1b - LPUART receiver active (RXD input not idle).
23 TDRE	Transmit Data Register Empty Flag When the transmit FIFO is enabled, TDRE is set when the number of datawords in the transmit FIFO is equal to or less than the number indicated by WATER[TXWATER]. To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled, TDRE is set when the transmit DATA register is empty. To clear TDRE, write to the DATA register. TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Transmit FIFO level is greater than watermark. 1b - Transmit FIFO level is equal or less than watermark.
22 TC	Transmission Complete Flag TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active (sending data, a preamble, or a break). 1b - Transmitter idle (transmission activity complete).
21 RDRF	Receive Data Register Full Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive FIFO is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register. A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character continues to be received until an overrun condition occurs once the entire character is received. 0b - Receive FIFO level is less than watermark. 1b - Receive FIFO level is equal or greater than watermark.
20 IDLE	Idle Line Flag IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line. To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character is stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period. 0b - No idle line detected. 1b - Idle line is detected.
19 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received. While the OR flag is set, no additional data is stored in the receive FIFO even if sufficient room exists. To clear OR, write logic 1 to the OR flag. 0b - No overrun. 1b - Receive overrun (new LPUART data lost).
18 NF	Noise Flag The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register is received with noise detected within the character. To clear NF, write logic 1 to the NF field. 0b - No noise detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Noise detected in the received character in the DATA register.
17 FE	Framing Error Flag FE is set whenever the next character to be read from the DATA register is received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field. 0b - No framing error detected. This does not guarantee the framing is correct. 1b - Framing error.
16 PF	Parity Error Flag PF is set whenever the next character to be read from the DATA register is received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field. 0b - No parity error. 1b - Parity error.
15 MA1F	Match 1 Flag MA1F is set whenever the next character to be read from the DATA register matches MA1. To clear MA1F, write a logic 1 to the MA1F field. 0b - Received data is not equal to MA1 1b - Received data is equal to MA1
14 MA2F	Match 2 Flag MA2F is set whenever the next character to be read from the DATA register matches MA2. To clear MA2F, write a logic 1 to the MA2F field. 0b - Received data is not equal to MA2 1b - Received data is equal to MA2
13-10 —	Reserved
9 TSF	Timeout Status Flag Indicates that a flag in the Timeout Status Register is set and configured to generate an interrupt. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

7-2 —	Reserved
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers. This bit has no effect when configured for LSB first. This bit should be changed only when the transmitter and receiver are both disabled. 0b - Address mark in character is MSB. 1b - Address mark in character is last bit before stop bit (or parity bit when enabled) and stored in DATA register at MSB (or MSB-1 when parity bit enabled).

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 LBKFE	LIN Break Flag Enable Enables the LIN Break Flag to assert whenever a LIN break character is detected. Unlike LBKDE, this does not impact data being stored in the receive data buffer, but does cause LBKDIF to assert whenever a LIN break is detected. Since a LIN break is longer than a normal character, the LIN break will trigger a write to the receive data register with the data bits clear and the Framing Error set. The character following the LIN break has the LINBRK flag set to indicate the previous character was a LIN break. This bit should be changed only when the transmitter and receiver are both disabled. 0b - LIN break detect is disabled. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).

76.6.1.8 LPUART Control Register (CTRL)

Offset

Register	Offset
CTRL	18h

Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

Diagram

Fields

Field	Function
31 R8T9	Receive Bit 8 / Transmit Bit 9 R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading the DATA register. T9 is the tenth data bit transmitted when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing the DATA register. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written.
30 R9T8	Receive Bit 9 / Transmit Bit 8 R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading the DATA register T8 is the ninth data bit transmitted when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing the DATA register. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter finishes receiving the current character (if any) before the receiver starts receiving data from the TXD pin. 0b - TXD pin is an input in single-wire mode. 1b - TXD pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion Setting this bit reverses the polarity of the transmitted data output. **NOTE** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Transmit data not inverted. 1b - Transmit data inverted.
27 ORIE	Overrun Interrupt Enable This bit enables the overrun flag (OR) to generate hardware interrupt requests.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - OR interrupts disabled; use polling. 1b - Hardware interrupt is requested when OR is set.
26 NEIE	Noise Error Interrupt Enable This bit enables the noise flag (NF) to generate hardware interrupt requests. 0b - NF interrupts disabled; use polling. 1b - Hardware interrupt is requested when NF is set.
25 FEIE	Framing Error Interrupt Enable This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0b - FE interrupts disabled; use polling. 1b - Hardware interrupt is requested when FE is set.
24 PEIE	Parity Error Interrupt Enable This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0b - PF interrupts disabled; use polling). 1b - Hardware interrupt is requested when PF is set.
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests. 0b - Hardware interrupts from TDRE disabled. 1b - Hardware interrupt is requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0b - Hardware interrupts from TC disabled. 1b - Hardware interrupt is requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate interrupt requests. 0b - Hardware interrupts from RDRF disabled. 1b - Hardware interrupt is requested when RDRF flag is 1.
20 ILIE	Idle Line Interrupt Enable ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0b - Hardware interrupts from IDLE disabled; use polling. 1b - Hardware interrupt is requested when IDLE flag is 1.
19	Transmitter Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TE	Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit reads as 1 until the transmitter has completed the current character and the TXD pin is tristated. A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set. 0b - Transmitter disabled. 1b - Transmitter enabled.
18 RE	Receiver Enable Enables the LPUART receiver. When RE is written to 0, this register bit reads as 1 until the receiver finishes receiving the current character (if any). 0b - Receiver disabled. 1b - Receiver enabled.
17 RWU	Receiver Wakeup Control This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set and STAT[RWUID] is clear. **NOTE** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted. 0b - Normal receiver operation. 1b - LPUART receiver in standby waiting for wakeup condition.
16 SBK	Send Break Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK. If software takes too long to clear SBK (for example, it is not cleared by the end of the 1st break character), then a 2nd break character is sent. This is compared to queuing a break character through the transmit FIFO which guarantees only one is sent. A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0b - Normal transmitter operation. 1b - Queue break character(s) to be sent.
15	Match 1 Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
MA1IE	0b - MA1F interrupt disabled 1b - MA1F interrupt enabled
14 MA2IE	Match 2 Interrupt Enable 0b - MA2F interrupt disabled 1b - MA2F interrupt enabled
13-12 —	Reserved
11 M7	7-Bit Mode Select This bit should be changed only when the transmitter and receiver are both disabled. 0b - Receiver and transmitter use 8-bit to 10-bit data characters. 1b - Receiver and transmitter use 7-bit data characters.
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before the IDLE flag is set. 000b - 1 idle character 001b - 2 idle characters 010b - 4 idle characters 011b - 8 idle characters 100b - 16 idle characters 101b - 32 idle characters 110b - 64 idle characters 111b - 128 idle characters
7 LOOPS	Loop Mode Select When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function. 0b - Normal operation - RXD and TXD use separate pins. 1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0b - LPUART is enabled in Doze mode. 1b - LPUART is disabled in Doze mode , but remains active when not in Doze mode .
5	Receiver Source Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
RSRC	This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
LPUART_0	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. The DSR_B pin is not used and internally driven by the DTR_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
LPUART_1	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. The DSR_B pin is not used and internally driven by the DTR_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
LPUART_2	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
LPUART_3	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
LPUART_4	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
LPUART_5	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.

Table continues on the next page...

Table continued from the previous page...

Field	Function	
	Instance	Field value and description
	LPUART_6	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
	LPUART_7	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
	LPUART_8	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
	LPUART_9	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
	LPUART_10	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
	LPUART_11	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
	LPUART_12	0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. The CTS_B pin is not used and internally driven by the RTS_B output. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.

0b - Receiver and transmitter use 8-bit data characters.
1b - Receiver and transmitter use 9-bit data characters.</td></tr>
<tr><td>3
WAKE</td><td>Receiver Wakeup Method Select
Determines which condition wakes the LPUART when RWU=1 and MATCFG=00 (WAKE must be set when MATCFG=11):
• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character.
• An idle condition on the receive pin input signal.
0b - Configures RWU for idle-line wakeup.
1b - Configures RWU with address-mark wakeup.</td></tr>
<tr><td>2
ILT</td><td>Idle Line Type Select
Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.
NOTE
In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Idle character bit count starts after start bit. 1b - Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - No hardware parity generation or checking. 1b - Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of logic 1 bits in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity. 1b - Odd parity.

76.6.1.9 LPUART Data Register (DATA)

Offset

Register	Offset
DATA	1Ch

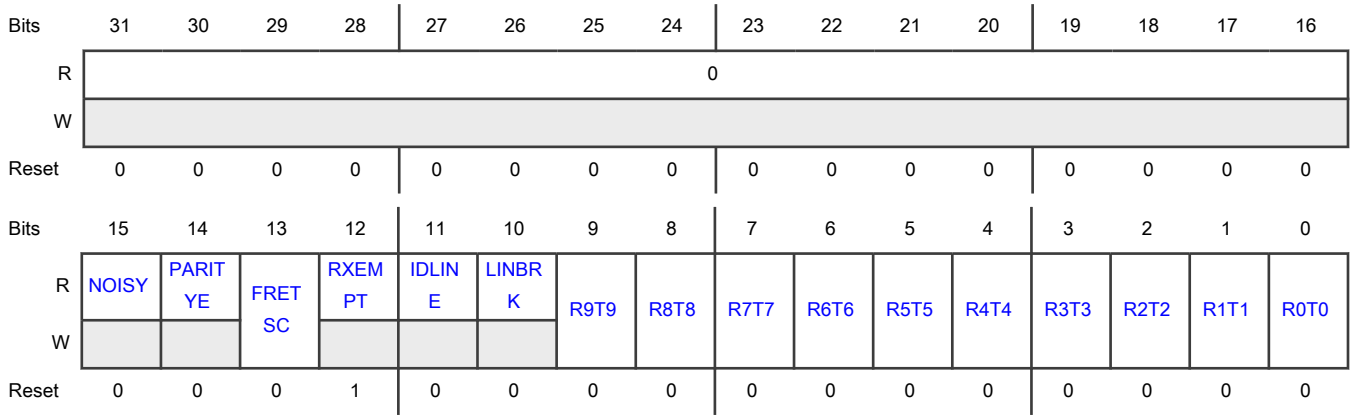
Function

NOTE

This register is two separate registers. Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags. This register can be written using 8-bit, 16-bit or 32-bit writes. An 8-bit write to DATA[7:0] will push { R8T9, R9T8, DATA[7:0] } the transmit FIFO with TSC clear. A 16-bit or 32-bit write will push the data written into the FIFO and does not update the value in R8T9 or R9T8.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 NOISY	Noisy Data Received The current received dataword contained in DATA[R9:R0] is received with noise. 0b - The dataword is received without noise. 1b - The data is received with noise.
14 PARITYE	Parity Error The current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - The dataword is received without a parity error. 1b - The dataword is received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0b - The dataword is received without a frame error on read, or transmit a normal character on write. 1b - The dataword is received with a frame error, or transmit an idle or break character on transmit.
12 RXEMPT	Receive Buffer Empty Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer contains valid data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0b - Receiver was not idle before receiving this character. 1b - Receiver was idle before receiving this character.
10 LINBRK	LIN Break Indicates the receiver line detected a LIN break before receiving the character in DATA[9:0]. This flag requires LBKDF to be set. 0b - Receiver did not detect LIN break before this character, or LIN break detect circuitry disabled. 1b - Receiver detected a LIN break before receiving this character.
9 R9T9	R9T9 Read receive FIFO bit 9 or write transmit FIFO bit 9.
8 R8T8	R8T8 Read receive FIFO bit 8 or write transmit FIFO bit 8.
7 R7T7	R7T7 Read receive FIFO bit 7 or write transmit FIFO bit 7.
6 R6T6	R6T6 Read receive FIFO bit 6 or write transmit FIFO bit 6.
5 R5T5	R5T5 Read receive FIFO bit 5 or write transmit FIFO bit 5.
4 R4T4	R4T4 Read receive FIFO bit 4 or write transmit FIFO bit 4.
3 R3T3	R3T3 Read receive FIFO bit 3 or write transmit FIFO bit 3.
2 R2T2	R2T2 Read receive FIFO bit 2 or write transmit FIFO bit 2.
1 R1T1	R1T1 Read receive FIFO bit 1 or write transmit FIFO bit 1.

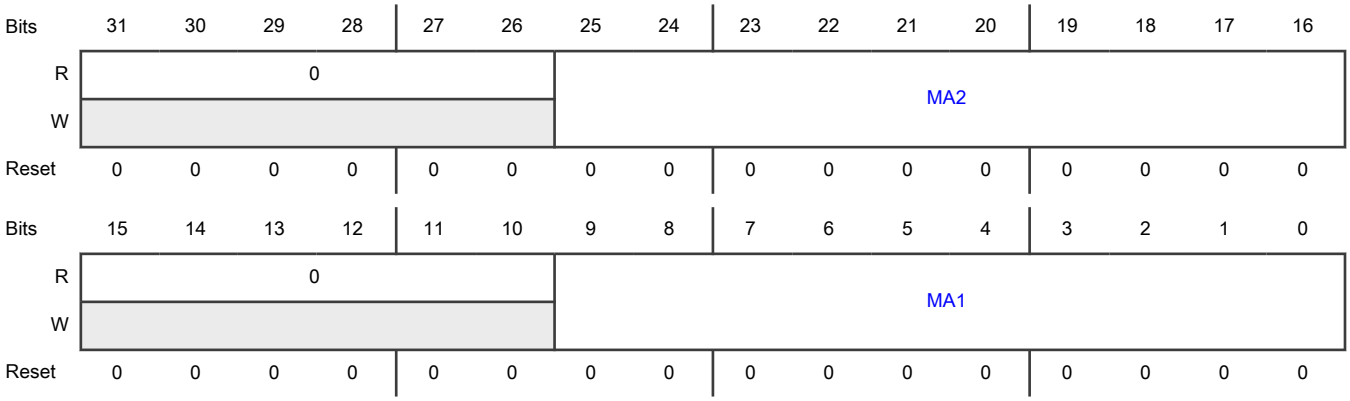
R0T0	Read receive FIFO bit 0 or write transmit FIFO bit 0.

76.6.1.10 LPUART Match Address Register (MATCH)

Offset

Register	Offset
MATCH	20h

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.
15-10 —	Reserved
9-0 MA1	Match Address 1 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.

76.6.1.11 LPUART Modem IrDA Register (MODIR)

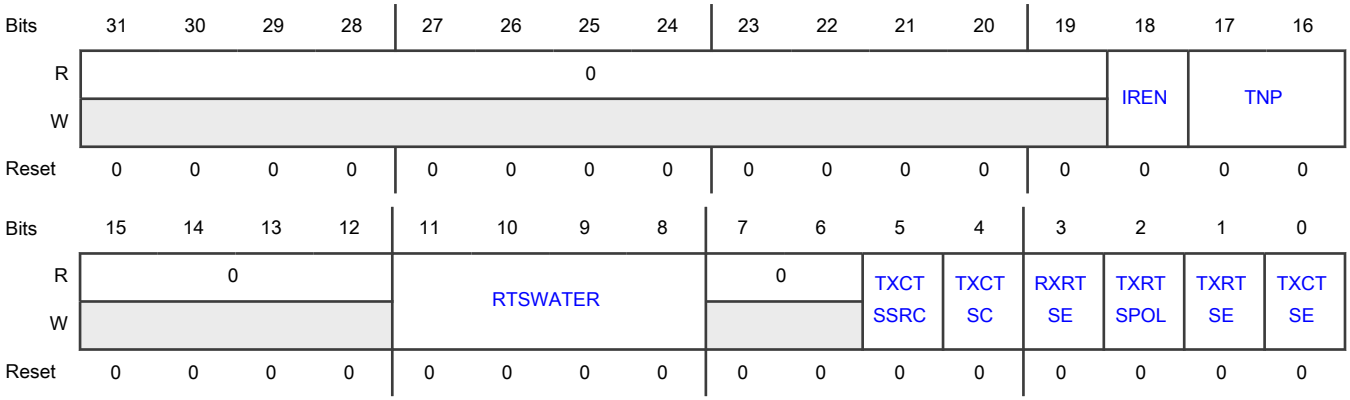
Offset

Register	Offset
MODIR	24h

Function

The MODIR register controls options for setting the modem configuration.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. This bit should be changed only when the transmitter and receiver are both disabled. 0b - IR disabled. 1b - IR enabled.
17-16 TNP	Transmitter narrow pulse Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should be changed only when the transmitter and receiver are both disabled. The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width. 00b - 1/OSR. 01b - 2/OSR.

11b - 4/OSR.</td></tr>
<tr><td>15-12
—</td><td>Reserved</td></tr>
<tr><td>11-8
RTSWATER</td><td>Receive RTS Configuration
Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match.
This field should be changed only when the receiver is disabled.
NOTE
This field is not supported in every instance. The following table includes only supported registers.</td></tr>

7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - CTS input is the CTS_B pin. 1b - CTS input is an internal connection to the receiver address match result.
4 TXCTSC	Transmit CTS Configuration Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0b - CTS input is sampled at the start of each character. 1b - CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should be changed only when the receiver is disabled. **NOTE** Do not set both RXRTSE and TXRTSE. 0b - The receiver has no effect on RTS. 1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS remains negated in the active low state unless TXRTSE is set. This bit should be changed only when the transmitter is disabled. 0b - Transmitter RTS is active low. 1b - Transmitter RTS is active high.
1	Transmitter request-to-send enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXRTSE	Controls RTS before and after a transmission. This bit should be changed only when the transmitter is disabled. 0b - The transmitter has no effect on RTS. 1b - When a character is placed into an empty transmit shift register, RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0b - CTS has no effect on the transmitter. 1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

76.6.1.12 LPUART FIFO Register (FIFO)

Offset

Register	Offset
FIFO	28h

Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the FIFO is empty.

Diagram

Register reset values

Register	Reset value
FIFO	LPUART_0,LPUART_1: 00C0_0033h LPUART_2–LPUART_15: 00C0_0011h

Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO/Buffer Empty Asserts when there is no data in the Transmit FIFO/Buffer. This field does not take into account data that is in the transmit shift register. 0b - Transmit buffer is not empty. 1b - Transmit buffer is empty.
22 RXEMPT	Receive FIFO/Buffer Empty Asserts when there is no data in the Receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer is not empty. 1b - Receive buffer is empty.
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates that more data has been written to the transmit FIFO than it can hold. This field asserts regardless of the value of TXOFE. However, an interrupt is issued to the host only if TXOFE is set. Write 1 to clear this flag. 0b - No transmit FIFO overflow has occurred since the last time the flag was cleared. 1b - At least one transmit FIFO overflow has occurred since the last time the flag was cleared.
16 RXUF	Receiver FIFO Underflow Flag Indicates that more data has been read from the receive FIFO than was present. This field asserts regardless of the value of RXUFE. However, an interrupt is issued to the host only if RXUFE is set. Write a logic 1 to clear RXUF. 0b - No receive FIFO underflow has occurred since the last time the flag was cleared. 1b - At least one receive FIFO underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO Flush

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Writing to this field causes all data that is stored in the transmit FIFO to be flushed. This does not affect data that is in the transmit shift register. 0b - No flush operation occurs. 1b - All data in the transmit FIFO is cleared out.
14 RXFLUSH	Receive FIFO Flush Writing to this field causes all data that is stored in the receive FIFO to be flushed. This does not affect data that is in the receive shift register. 0b - No flush operation occurs. 1b - All data in the receive FIFO/buffer is cleared out.
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. This feature is not supported when the receiver extended idle time is enabled. 000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters. 110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0b - TXOF flag does not generate an interrupt to the host. 1b - TXOF flag generates an interrupt to the host.
8 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0b - RXUF flag does not generate an interrupt to the host. 1b - RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built-in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of

Table continues on the next page...

Table continued from the previous page...

Field	Function
	depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Transmit FIFO is not enabled. Buffer depth is 1. 1b - Transmit FIFO is enabled. Buffer depth is indicated by TXFIFOSIZE.
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read-only. 000b - Transmit FIFO/Buffer depth = 1 dataword. 001b - Transmit FIFO/Buffer depth = 4 datawords. 010b - Transmit FIFO/Buffer depth = 8 datawords. 011b - Transmit FIFO/Buffer depth = 16 datawords. 100b - Transmit FIFO/Buffer depth = 32 datawords. 101b - Transmit FIFO/Buffer depth = 64 datawords. 110b - Transmit FIFO/Buffer depth = 128 datawords. 111b - Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	Receive FIFO Enable When this field is set, the built-in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Receive FIFO is not enabled. Buffer depth is 1. 1b - Receive FIFO is enabled. Buffer depth is indicted by RXFIFOSIZE.
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read-only. 000b - Receive FIFO/Buffer depth = 1 dataword. 001b - Receive FIFO/Buffer depth = 4 datawords. 010b - Receive FIFO/Buffer depth = 8 datawords. 011b - Receive FIFO/Buffer depth = 16 datawords. 100b - Receive FIFO/Buffer depth = 32 datawords. 101b - Receive FIFO/Buffer depth = 64 datawords. 110b - Receive FIFO/Buffer depth = 128 datawords. 111b - Receive FIFO/Buffer depth = 256 datawords.

76.6.1.13 LPUART Watermark Register (WATER)

Offset

Register	Offset
WATER	2Ch

Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

Diagram

13-0 IDTIME	Idle Time The extended idle feature is disabled when set to zero. Otherwise configures the transmitter idle time in number of bits (baud rate) whenever an idle character is queued through the transmit FIFO. When transmitter extended idle is enabled, an idle character is not automatically queued whenever the transmitter is enabled. The minimum supported extended idle time is equal to one idle character.

76.6.1.19 Half Duplex Control Register (HDCR)

Offset

Register	Offset
HDCR	50h

Function

This register provides control for half duplex related operations. This register can be used in place of the LOOPS, RSRC and TXDIR functions, although LOOPS can be used to loop-back the transmitter outputs to the receiver.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

76.6.1.23 Transmit Command Burst Register (TCBR0 - TCBR127)

Offset

For a = 0 to 127:

Register	Offset
TCBRa	200h + (a × 4h)

Function

The Transmit Command Burst Register is an alias of the DATA Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using aligned 8-bit, 16-bit or 32-bit writes. The size of the Transmit Command Burst Register is 512-bytes.

- An aligned 32-bit write in this region will push one entry into the transmit FIFO
- An aligned 16-bit write in this region to TCBRx[15:0] will push one entry into the transmit FIFO
- An 8-bit write in this region to TCBRx[7:0] will update DATA[7:0], but does not push the data into the transmit FIFO
- An 8-bit write in this region to TCBRx[15:8] will push the data written to DATA[15:8] plus the previously written DATA[7:0] into the transmit FIFO
- An 8-bit or 16-bit write in this region to TXBRx[31:16] will be ignored

76.6.1.24 Transmit Data Burst Register (TDBR0 - TDBR255)

Offset

For a = 0 to 255:

Register	Offset
TDBRa	400h + (a × 4h)

Function

The Transmit Data Burst Register is an alias of the DATA Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit or 32-bit writes. The size of the Transmit Data Burst Register is 1024-bytes.

- An aligned 32-bit write in this region will push four DATA byte entries into the transmit FIFO (DATA0 byte first). Note that the register access is extended by 3 wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word will push two DATA byte entries into the transmit FIFO (DATA0 or DATA2 first). Note that the register access is extended by 1 wait state.
- An 8-bit write in this region will push one DATA byte entry into the tranmit FIFO.

Note that byte writes to the DATA register will use the contents of R9T8 for the ninth data bit, R8T9 for the tenth data bit and zero extend the FRETSC bit.

NOTE

Each module instance supports a different number of registers.

76.7 Glossary

Baud rate	Number of bits transmitted or received per second by the LPUART
Break character	Break character is generated when the transmitter is holding the data line at the space level for at least 1 character time
Oversampling	Number of times the receive circuitry samples the receive input per baud period (i.e. per data bit)

Chapter 77
Quad Serial Peripheral Interface (QuadSPI)

77.1 Chip-specific QuadSPI information

77.1.1 QuadSPI configuration

Table 631. QuadSPI instances

Instance	S32K322/S32K342/S32K314/S32K324/S32K344/S32K358	S32K311/S32K312
QuadSPI	Yes	No

Table 632. QuadSPI configuration details

Configuration	S32K3x2/ S32K3x4	S32K358
QuadSPI Tx FIFO size	32 words	256 words
QuadSPI Rx FIFO size	32 words	32 words
Look Up Table Size	4 words	16 words
AHB Buffer Size	256 Bytes	1024 Bytes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to single serial flash devices, with up to four bidirectional data lines. The QuadSPI supports 4-pin Quad A interface only in SDR mode.

NOTE

Boot from QuadSPI is not supported but execution from external memory is supported.

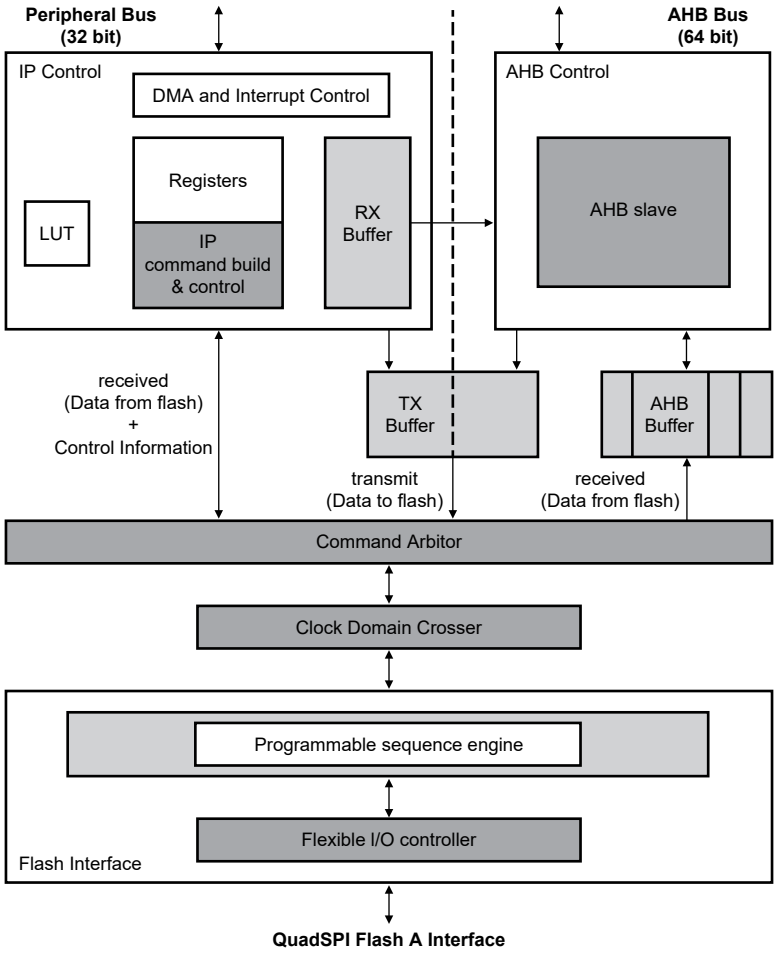

Figure 469. Block diagram

77.1.2 Supported read modes

The table below provides an overview of the QuadSPI read modes.

Table 633. QuadSPI read modes

Read modes		SDR support (QuadSPI_MCR [DDR_EN]=0)	QuadSPI_MCR [DQS_EN]	QuadSPI_MCR [DQS_FA_SEL]	DLL/Data learning support
DQS sampling method	Pad loopback	Yes	1	01	No

77.1.3 QuadSPI initialization sequence

Following initialization sequence should be followed for proper QuadSPI operation:

- Enable QuadSPI module by MC_ME peripheral clock enable (register PRTNx_COFBy_CLKEN present within MC_ME). Refer MC_ME chapter for peripheral mapping.
- Configure the SIUL2 registers MSCR[OBE] as 1 and MSCR[SSS] as 0 for QuadSPI_SCKFA pin.
- Initialize QuadSPI SCKFA by writing a sequence of 1010 to the SIUL2 register GPDO[PDO_a] for QuadSPI_SCKFA pin.
- Configure the SIUL2 register MSCR[OBE] back as 0 for the pins.

- Initiate a dummy flash read to reset all DQS flops by itself and any crossing from DQS domain to IPS/AHB is taken care by CDC logic.
- Initiate a peripheral software reset to QuadSPI controller by writing to QuadSPI controller's MCR.
- Post this initialization sequence, the QuadSPI will work in intended deterministic manner.

NOTE

QuadSPI initialization is to be done before using QuadSPI after each functional reset.

77.1.4 Pad clock loopback

This chip supports pad clock loopback. The QuadSPI can be configured to use clock loopback to sample input data. SCK is delayed by the SCK pin output delay, plus the SCK pin input delay using pad loopback, and is configured by setting QuadSPI config registers SOCCR[SOCCFG] and MCR[DQS_FA_SEL]. Enabling the loopback version of SCK can inprove the setup time of the input data from the Flash.

For details of these register, see QuadSPI register descriptions.

77.1.5 QuadSPI SOC Configuration register SOCCR[SOCCFG] implementation

The QuadSPI SOC Configuration register QuadSPI_SOCCR[SOCCFG] register is used to control dummy loopback pads and obe_pull_timing_relax_b. Below is the description of it's bits:

Table 634. SOCCR[SOCCFG] implementation

Bit	Description
Bit[0]	obe_pull_timing_relax_b : enables the timing relaxation by pulling obe for pad 1 for half cycle, if 0 then enabled else disabled.
Bit[1]	ibe of QSPIA_SCK_DUMMY pad. 0: Disable input reciever 1: Enable input reciever.
Bit[2]	obe of QSPIA_SCK_DUMMY pad. 0: Disable output driver 1: Enable output driver.
Bit[3]	dse of QSPIA_SCK_DUMMY pad. 0: Disable drive strength 1: Enable drive strength.
Bit[4]	pue of QSPIA_SCK_DUMMY pad. 0: Disable internal pullup or pulldown resistor 1: Enable internal pullup or pulldown resistor.
Bit[5]	pus of QSPIA_SCK_DUMMYpad. 0: Enable internal pulldown resistor if pue is set 1: Enable internal pullup resistor if pue is set.
Bit[6]	sre of QSPIA_SCK_DUMMY pad. 0: Disable slew rate control 1: Enable slew rate control.
Bit[31:7]	Reserved

To Enable the Quadspi dummy PAD loopback use following settings

For Flash-A: MCR[DQS_FB_SEL] = 0x2

SOCCR[SOCCFG] = 0x0000000E (ibe=1, obe=1, dse=1 and sre=0)

77.1.6 QuadSPI AHB Buffer write access control

In S32K3x4 and S32K3x2 devices, the QuadSPI AHB buffer does not support writes. A write to QuadSPI AHB buffer results in error response from QuadSPI.

QuadSPI might behave unexpectedly in case if its AHB buffer is written with QuadSPI MCR[MDIS] =1. In cases wherein QuadSPI is disabled with above MDIS control bit, XRDC must also be appropriately configured to block the accesses to QSPI AHB buffer and indicate an error response.

77.2 Introduction

The QuadSPI module acts as an interface to a single serial flash memory device, with up to eight bidirectional data lines.

77.2.1 Features

QuadSPI supports the following features:

- Flexible sequence engine to support various flash memory vendor devices. As there is no specific standard, the module supports various kinds of flash memories from different vendors. See Serial flash memory devices for example sequences.
- Single, dual, and quad modes of operation supported for Quad flash memories
- Octal and single IO modes of operation supported for Octal flash memories
- Support for HyperRAM
- Support for Macronix Octal Data integrity features such as ECC and R/W parity (CRC1)
- AHB master to read RX buffer data through AMBA AHB (64-bit width interface) or IPS registers space (32-bit access) and fill TX buffer via IPS registers space (32-bit access) or using AHB (64-bit width interface)
  - AHB master can be a DMA with a configurable inner loop size
- Multi-master accesses are allowed
  - Flexible and configurable buffer for each master—total available buffer size is 1024 bytes.
- All AHB accesses to flash/RAM memory devices are directly memory mapped to the chip system memory
- Programmable sequence engine to cater to future command/protocol changes and ability to support all existing vendor commands and operations. The software needs to select the corresponding sequence according to the connected flash memory device.
  - Support for 3-byte and 4-byte addressing

77.2.2 RX buffer push event

To add the valid entries into the RX buffer

By default, each buffer push event adds two entries to the RX buffer because the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash memory device, it is possible for the very last buffer push event that only one entry is added.

RBSR[RDBFL] is incremented by the number of entries added to the RX buffer.

77.2.3 RX buffer POP event

To remove valid entries from the RX buffer

Each buffer POP event removes (RBCT[WMRK] + 1) valid entries from the buffer. BSR[RDBFL] is decremented by the same number and RBSR[RDCTR] is incremented accordingly.

77.2.4 Block diagram

The following figure shows a block diagram of the QuadSPI module.

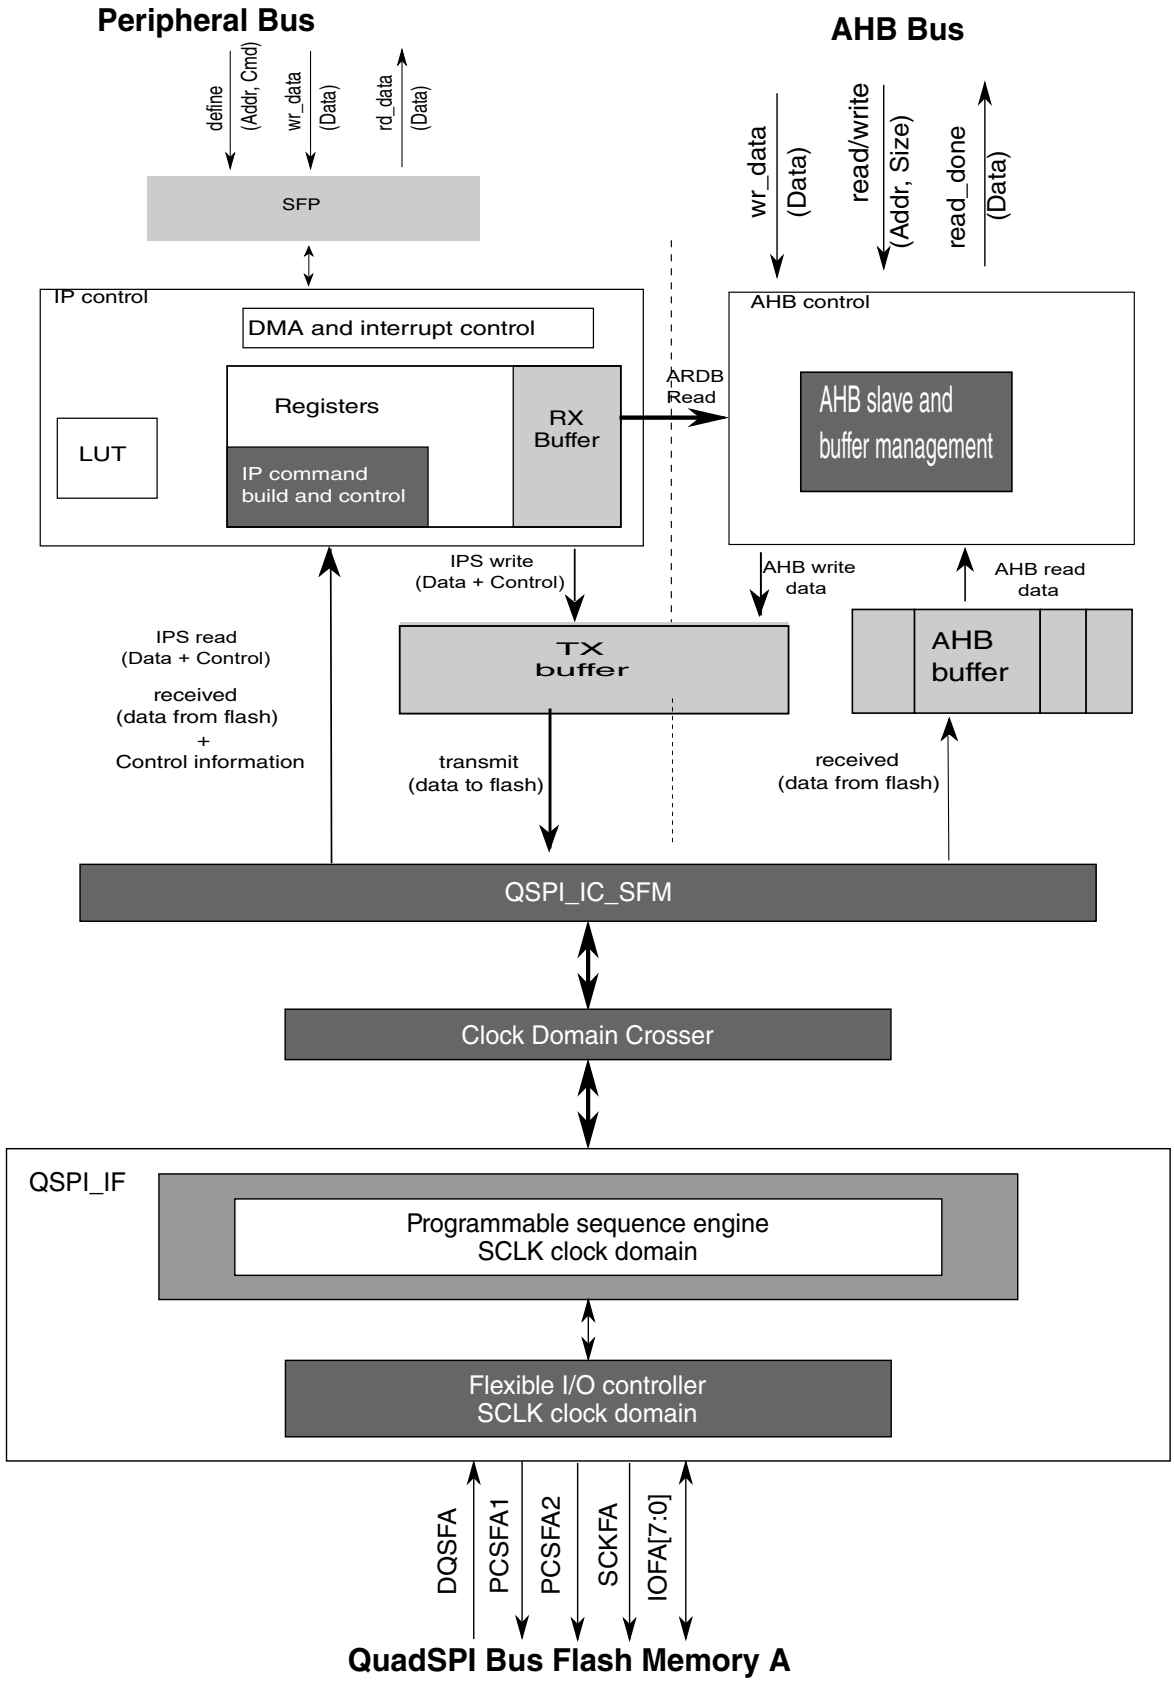

Figure 470. QuadSPI block diagram

77.2.5 QuadSPI modes of operation

QuadSPI supports the following modes of operation:

- Normal mode: You can use this mode for write or read accesses to an external serial flash memory device. See Normal mode for details.
  - Serial flash memory write: You can program data into the flash memory through the IP interface only. See Flash memory programming for details.
  - Serial flash memory read: Read the contents of the serial flash memory device. Two separate read channels are available through the RX buffer and AHB buffer. See Flash memory read for details.
- Module Disable mode: You can use this mode for disabling serial flash memory clock and AHB command. The clock to the non-memory mapped logic in QuadSPI can be stopped in the Module Disable mode. The module enters the mode by setting MCR[MDIS].

77.3 External signal description

This section provides the external signal information for the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

Table 635. Signal properties

Signal name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash Memory A1	O	This signal is the chip select for the serial flash memory device A1 that represents the first of the two flash memory devices that share IOFA.
PCSFA2	Peripheral Chip Select Flash Memory A2	O	This signal is the chip select for the serial flash memory device A2 that represents the the second of the two flash memory devices that share IOFA.
SCKFA	Serial Clock Flash Memory A	O	This signal is the serial clock output to the serial flash memory device A.
IOFA[7:0]	Serial I/O Flash memory A	I/O	These signals are the data I/O lines to/from the serial flash memory device A. See Driving external signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash memory device may change their function according to the SFM Command executed, leaving them as control inputs when single and dual instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1].
INTA	ECC error signal for Flash Memory A	I	Flash Memory A drives this signal to active low value in case of an ECC error.

NOTE

Please refer to chip specific information to check the configuration of QuadSPI block.

77.3.1 Driving external signals

Single/dual/quad/octal instructions

Depending on the serial flash memory device connected to the QuadSPI module, there are instructions using a different number of data lines:

- Single pad: Single line I/O with one data out and one data in line to/from the serial flash memory device

- Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPI module
- Quad pad: Quad line I/O with four bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPImodule
- Octal pad: Octal line I/O with eight bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPI module

The different phases of the serial flash memory access scheme are shown in the following figure.

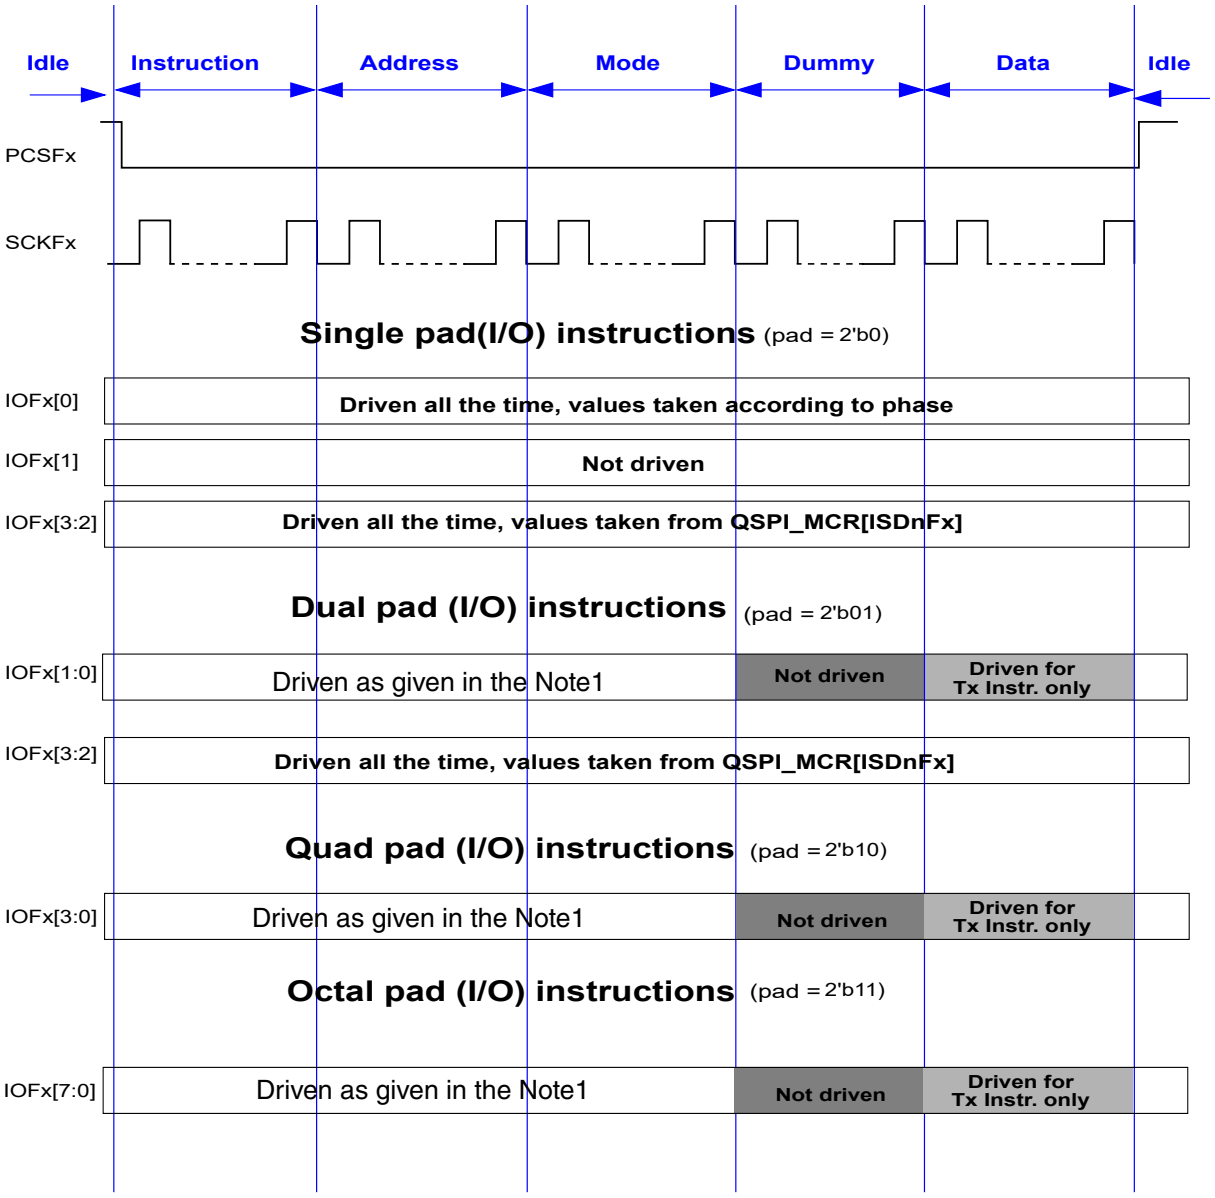

Figure 471. Serial flash memory access scheme

Note1:The IOs are driven from QuadSPI as per the number of pads configured for ongoing phase.

Note:The lines status will change based on command mode in case of instruction, address and mode phases. It can be either 1,2 or 4 lines

Following are the different phases and the I/O driving characteristics of the QuadSPI module:

- Idle: Serial flash memory device not selected – no interaction with the serial flash memory device and the IOFx signals are driven.
- Instruction: Serial flash memory device selected – the instruction is sent to the serial device and all the IOFx signals are driven.
- Address: Serial flash memory address is sent to the device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Mode: Mode bytes are sent to the serial flash memory device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Dummy: Dummy clocks are provided to the serial flash memory device. See Figure 471 for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

— This phase is not applicable for all the SFM commands.

— All read commands in Dual pad, Quad pad /or Octal pad modes must use dummy phase before read phase. Note that this restriction is not applicable to Single-pad mode.

- Data: Serial flash memory data are sent to or received from the serial flash memory device. See the preceding figure for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

This phase is not applicable for all the SFM commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases. In the individual flash memory mode, this applies to the selected flash memory device.

Access to a single, individual serial flash memory device

See Serial flash memory access schemes for details.

Read access to two serial flash memory devices attached to the QuadSPI module in parallel. See Serial flash memory access schemes for details.

77.4 Functional description

This section provides a functional description of the QuadSPI module.

77.4.1 Serial flash memory access schemes

In the individual flash memory mode, all supported commands are available.

77.4.2 Normal mode

This mode allows communication with an external serial flash memory device. Compared to the standard SPI protocol, this communication method uses up to eight bidirectional data lines operating at high-data rates. The communication to the external serial flash memory device consists of an instruction code and optional address, mode, dummy, and data transfers. The flexible programmable core engine described below is immune to a wide variety of command or protocol differences in the serial flash memory devices provided by various flash memory vendors.

77.4.2.1 Programmable sequence engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands are provided in the following table.

Table 636. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
CMD	1d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	8-bit command value	Provides the serial flash memory with the SFM command operand (Encoded) on the number of pads specified in STR mode.
ADDR	2d		Number of address bits to be sent (for example, 24d => 24 address bits required)	Provide the serial flash memory with address cycles according to the operand on the number of pads specified The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions.
DUMMY	3d		Number of dummy clock cycles (should be <= 64 and > 2 cycles)	Provide the serial flash memory with dummy cycles according the operand The PAD information defines the number of pads in input mode. For example, one pad implies that pad 1 is not driven, rest all are driven. **NOTE** If DLL is enabled and N dummy cycles are needed, you must program two back-to-back DUMMY instructions: DUMMY: N-2 followed by DUMMY:2.
MODE	4d		8-bit mode value	Provide the serial flash memory with 8-bit operand on the number of pads specified
MODE2	5d	N={0,1}d	2-bit mode value	Provide the serial flash memory with 2-bit operand on the number of pads[1] specified
MODE4	6d	N={0,1,2}d	4-bit mode value	Provide the serial flash memory with 4-bit operand on the number of pads[2] specified
READ	7d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	Read data size in bytes (for AHB transactions, your application should ensure that data size is a multiple of 8 bytes)	Read data from flash memory on the number of pads specified The data size can be overwritten by writing to the ADATSZ field of the BUFxCR registers for AHB-initiated transactions and to the IDATSZ field of the IP Configuration Register (IPCR) for IPS-initiated transactions.
WRITE	8		Write data size in bytes	Write data on the number of pads specified The data size can be overwritten by writing to the IDATSZ field of IP Configuration Register (IPCR).

Table continues on the next page...

Table 636. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
JMP_ON_CS [3]	9d	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion. **NOTE** This instruction is not supported if DLL is enabled.
DATA_LEARN	16d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	Operand[7]- • 1 - DDR mode • 0 - SDR mode Operand[6:0]- • Number of bits to be used for data learning. For example, if operand is 16 then a 16-bit data learning pattern is read and compared.	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the value of Sampling Register (SMPR) is ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern.[4]
JMP_TO_SEQ[3]	20d	NA	Sequence number	Every time CS is deasserted, jump to the LUT sequence is pointed to by the operand. This instruction allows the programmer to join two sequences and initiates the second flash memory transaction automatically. It can be used to join write-enables with flash memory write or data learn with read. **NOTE** This instruction is not supported if DLL is enabled.
STOP[3]	0d	NA	NA	Stop execution; deassert CS

1. For a one-pad instruction, MODE2 takes two serial flash memory clock cycles on the flash memory interface.
2. For a one-pad instruction, MODE4 takes four serial flash memory clock cycles on the flash memory interface. For a four-pad instruction, MODE4 takes one serial flash memory clock cycle on the flash memory interface.
3. Sequence ending with this instruction must have all remaining bits as 0s after it.

4. It is not recommended to have 0h or FFh as the data learning pattern.

The programmable sequence engine allows you to configure the QuadSPI module according to the serial flash memory connected on board. This flexible structure is compatible with new command or protocol changes from different vendors.

77.4.2.2 Flexible read xAHB buffers

To reduce the latency of the reads for AHB masters, the data read from serial flash memory is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 bytes and maximum size being the size of the complete buffer instantiated (1024 bytes). The size of buffer 0 ranges from 0 to BUF0IND. The size of buffer 1 ranges from BUF0IND to BUF1IND, buffer2 from BUF1IND to BUF2IND and, buffer 3 ranges from BUF2IND to the size of the complete buffer (1024 bytes).

Each flexible AHB buffer is associated with the following:

- An AHB master: Optionally, buffer3 may be configured as an "all master" buffer by writing 1 to BUF3CR[ALLMST]. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
- A datasize field representing the amount of data to be fetched from the flash memory on every missed access.

The master ID of every incoming request is checked and the data is returned or fetched into the corresponding associated buffer.See the "Chip-specific SMPU information" section in this document for the master IDs and their corresponding components. Every missed access to the buffer causes the controller to clear the buffer and fetch the BUFxCR[ADATSZ] amount of data from the serial flash memory. As such, you need not configure the buffer size to be greater than ADATSZ because the locations greater than ADATSZ are never used. For any AHB access, the sequence pointed to by BFGENCR[SEQID] is used for the initiated flash memory transaction. The data is returned to the master as soon as the requested amount is read from the serial flash memory. The controller; however, continues to prefetch the rest of the data in anticipation of a next consecutive request. See Figure 472 that shows flexible AHB buffers.

BFGENCR[SEQID] points to an index of the LUT. See LUT for details.

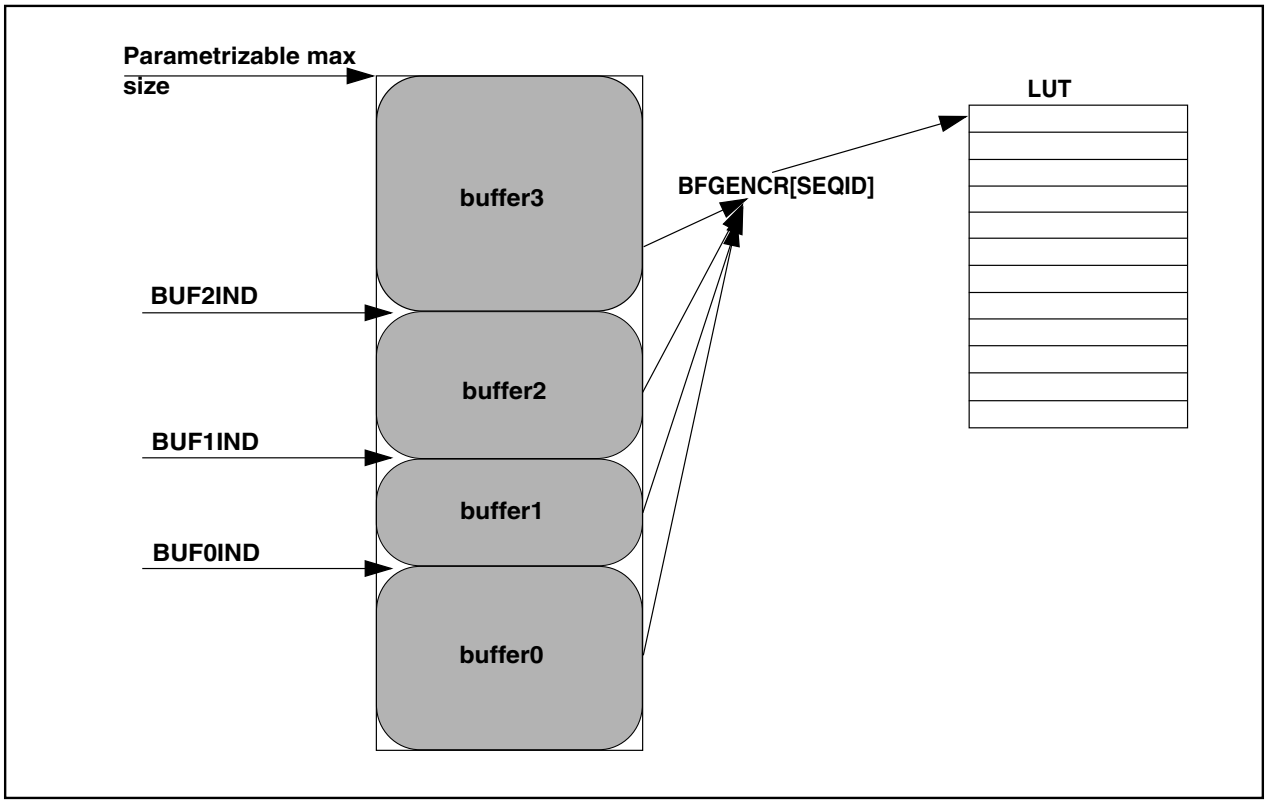

Figure 472. Flexible read AHB buffers

77.4.2.3 Abort mechanism during AHB read

Any ongoing read transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

77.4.2.4 HBURST support with AHB read

QuadSPI controller supports HBURST and HSIZE on the AHB read interface. HBURST indicates if the transfer forms part of a burst. Four, eight, and sixteen beat bursts are supported and the bursts might either be incrementing or wrapping. HSIZE indicates the size of the transfer, and supports 8-, 16-, 32-, and 64-bit data sizes. In case of WRAP accesses, QuadSPI generates aligned accesses to serial flash memory if there is no buffer hit for any incoming, non-sequential AHB read access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size, an error response is generated and the value of FR[AIBSEF] is configured as 1. The data prefetch size can be defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as 0. In case of wrap burst, data prefetch size must be greater than or equal to the wrap burst size + 32 bytes. A few examples are shown in the figure below:

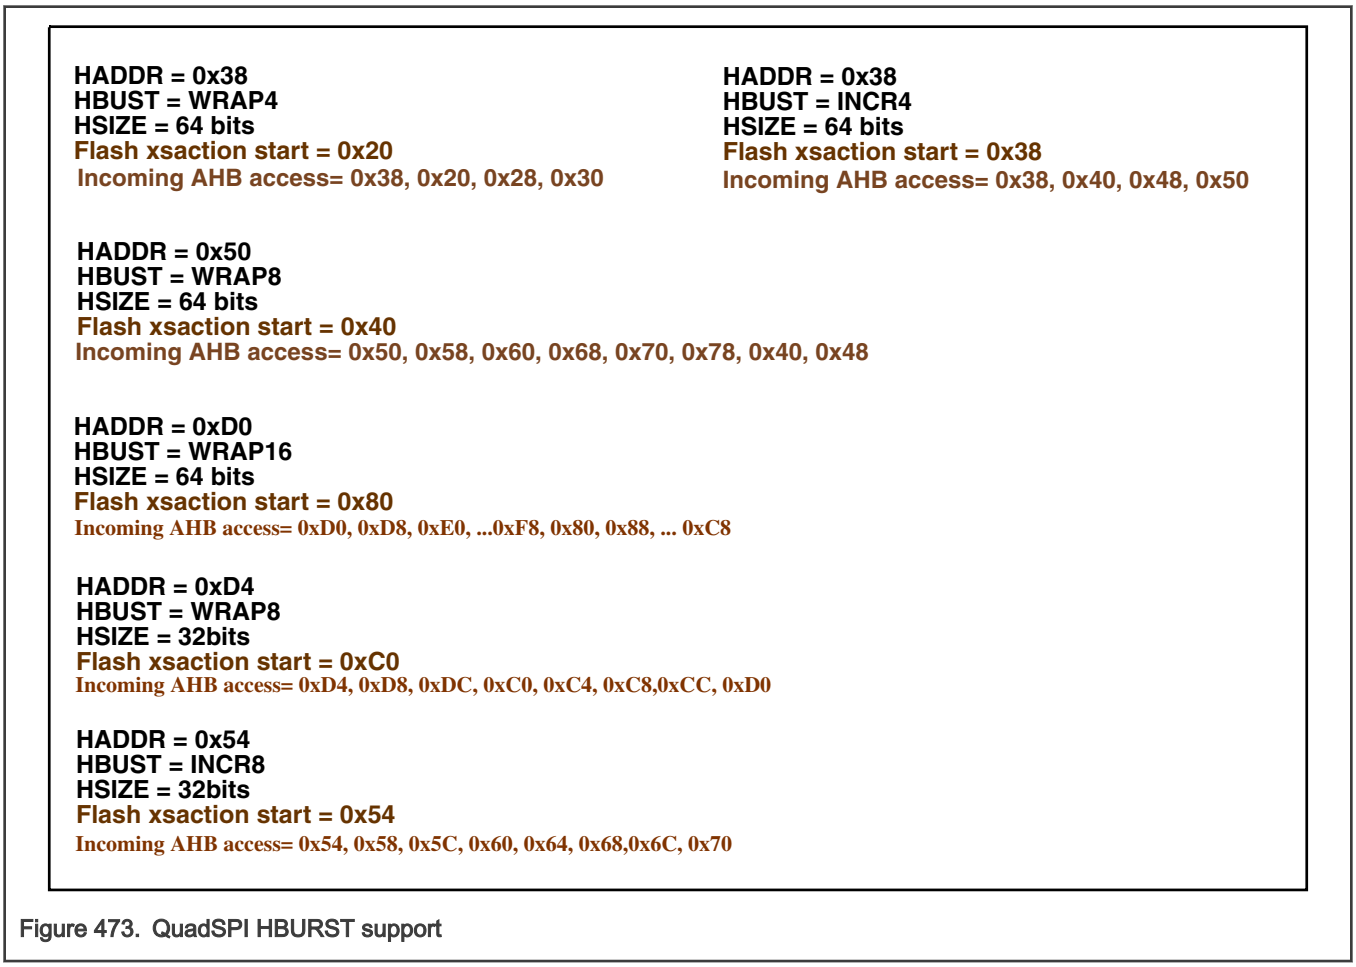

Figure 473. QuadSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

NOTE

Whenever a core accesses QuadSPI memory with cache enabled, the prefetch size must be configured as equal or more than the cache line size; otherwise, FR[AIBSEF] error appears.

77.4.2.5 LUT

The LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs, which when executed sequentially, generate a valid serial flash memory transaction. Each sequence can have a maximum of 10 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

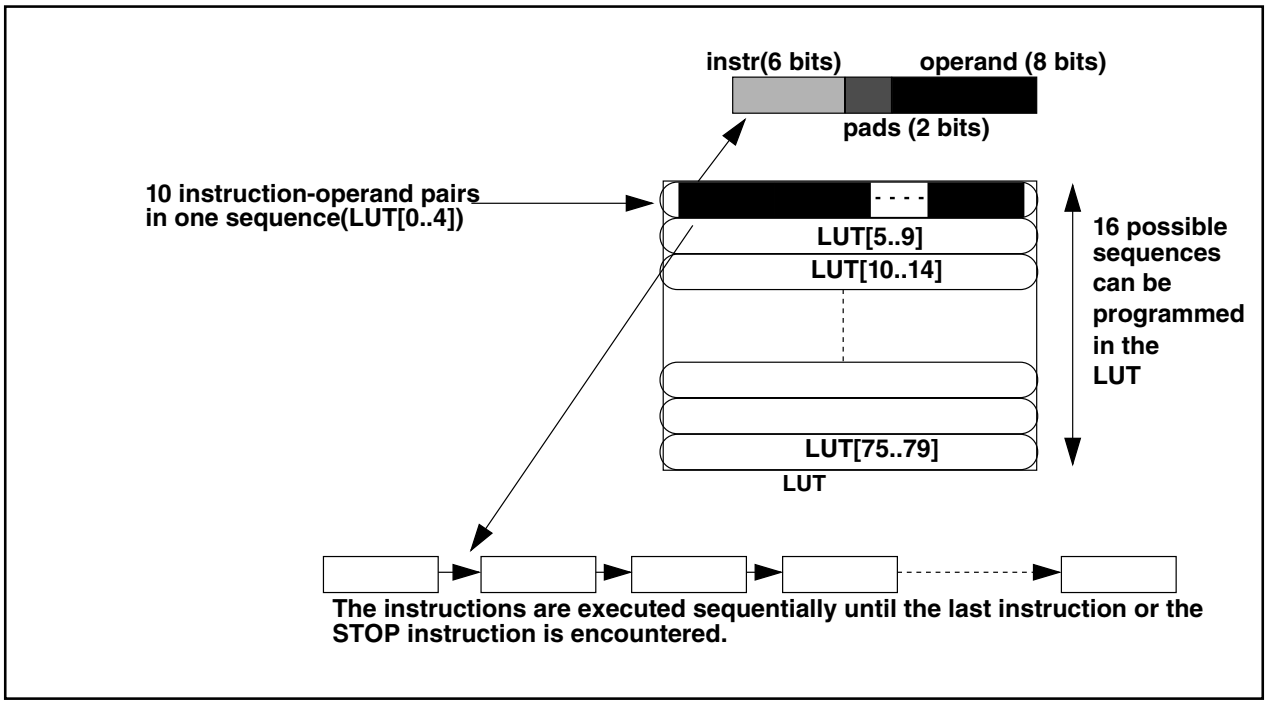

Figure 474. LUT and sequence structure

At reset, the index 0 of the LUT[0..4] is programmed with a basic read sequence as described in Reset sequence. After reset, the complete LUT may be reprogrammed according to the chip connected on board. To protect its contents, during a code runover, the LUT might be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is 5AF05AF0h, and the associated processes are as follows:

Locking the LUT

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued). A successful write to this register locks the LUT.

Unlocking the LUT

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b10 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write to this register unlocks the LUT.

The lock status of the LUT can be read from the LCKCR[UNLOCK] and LCKCR[LOCK] fields.

Some example sequences are defined in Example sequences. After reset the instruction sequence 0 is populated with the default read sequence shown in the table below.

Table 637. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0h	3h	Read data byte command on one pad
ADDR	0h	18h	24 address bits to be sent on one pad
READ	0h	8h	Read 64 bits
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

NOTE

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

77.4.2.6 Issuing SFM commands

Each access to the external device follows this sequence:

1. You must pre-populate the LUT with the serial flash memory command sequences that are required for the flash memory device being used.
2. The module executes the instructions in this sequence one by one. The transaction starts and the module configures the value of SR[BUSY].
3. Communication with the external serial flash memory device starts and the transaction executes.
4. After the transaction is complete (all transmit and receive operations with the external serial flash memory device are complete), the module resets SR[BUSY]. In case of an IP command, FR[TFF] is asserted.

For details, see Flash memory programming and Flash memory read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

Using IP commands

For IP commands, the required components need to be written into the following registers and in this sequence:

1. Write the serial flash memory address to be used as provided in the Serial Flash Address Register (SFAR). For IP commands not related to specific addresses, the base address of the related flash memory needs to be programmed. For example, for an instruction which does not require an address (that is, write enable instruction), the SFAR should be programmed with the base address of the memory the command is to be sent to.
2. Write the sequence ID and data size details in the IP Configuration Register (IPCR).
3. Note that writing a value to IPCR[SEQID] must be the last step of the sequence. It is possible to combine all the fields of the IPCR into one single write. See IP Configuration Register (IPCR) for details.

Using AHB commands

Any AHB memory-mapped access is routed to one of the buffers depending on the master ID of the request. If the access is a "miss," a new serial flash memory transaction is initiated. The transaction is based on the sequence pointed to by BFGENCR[SEQID] as described in Flexible read xAHB buffers.

An AHB access is considered memory mapped when the access is to the memory-mapped serial flash memories, as described in Memory Mapped Serial Flash Data - Individual Flash mode on Flash memory A.

77.4.2.7 Flash memory programming

In all NOR Flash devices memory sector to be written needs to be erased first. The programming sequence is then initiated in the following way:

1. Check that SR[BUSY] is de-asserted or the value of the BUSY field is 0, also, check that the TX buffer is empty. If you need to discard the data present in the TX buffer (SR[TXNE]) then the TX buffer must be cleared by writing 1 to MCR[CLR_TXF].
2. Program the address related to the command in SFAR.
3. Provide initial data for the program command into the circular buffer through the TBDR. At least one words of data must be written into the TX buffer up to a maximum of 256 entries.
4. Program the IPCR to trigger the command. IPCR[SEQID] should point to an index of the LUT that has the flash memory program sequence pre-programmed. Write an appropriate value to IPCR[IDATSZ] to denote the size of the write in bytes.
5. Repeat step 3, depending on the amount of data required, until all of the required data is written to the TBDR. SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, TBSR[TRCTR] can be read to check how many words have been written into the TX buffer.

After writing to IPCR[SEQID] (see step 4), the module starts executing the programmed sequence. The software ensures that the correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX buffer. It consists of 256 entries of 32-bit sizes and is organized as a circular FIFO, the read pointer for which is incremented after each fetch. When all the data is transmitted, the QuadSPI module returns from the busy state to the idle state. However, this is not true for the external device because the internal programming is still ongoing. You may monitor the relevant status information available from the serial flash memory device and ensure that the programming is done appropriately.

77.4.2.8 Flash memory read

Host access to the data stored in the external serial flash memory device is performed in two steps. First, the data must be read into the internal buffers and in the second step, these internal buffers can be read by the host.

Reading serial flash memory data into the QuadSPImodule internal buffers

A read access to the external serial flash memory device can be triggered in two different ways:

- IP command read: For reading flash memory data into the RX buffer, you must provide the correct sequence ID in IPCR[SEQID]. The sequence ID points to a sequence in the LUT. The software needs to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. You must program the SFAR , and IPCRs. All available read commands supported by the external serial flash memory are possible.

  Optionally, it is possible to clear the RX buffer pointer prior to triggering the IP command by writing a 1 to MCR[CLR_RXF]. This will invalidate the data currently present in the RX buffer and any new read data will overwrite the old one

  Using these inputs, the complete transaction is built when IPCR[SEQID] is written to. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash memory device into the RX buffer. As the read access is triggered by an IP command, the value of both SR[IP_ACC] and SR[BUSY] is set to 1.. A count of the number of entries currently in the Rx buffer can be obtained from RBSR[RDBFL].

  Communication with the external serial flash memory stops if the specified number of bytes are read (on successful completion of the transaction).

- AHB command read: For reading flash memory data into the AHB buffer, you must:
  - Set up a read access by a master to the address range in the system memory map, which the external serial flash memory devices are mapped to.
  -
  - Program the buffer registers corresponding to the AHB master initiating the request.
  - Provide the correct sequence ID in the BFGENCR. The software ensures that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. Flash memory device selection and access mode are determined by the address accessed in the AHB address space associated with the QuadSPI module (see Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

  On each AHB read access to the memory mapped area, the valid data in the AHB buffer is checked against the address requested in the actual read. When the AHB read request cannot be served from the content of the AHB buffer, the buffer is flushed and the controller executes the sequence pointed to by the sequence ID. The requested number of buffer entries

defined in BUFxCR[ADATSZ] is then fetched from the external serial flash memory device into the internal AHB buffer. As the read access is triggered through the AHB bus, the value of SR[AHB_ACC] is set, driving SR[BUSY] in turn, until the transaction is complete. Communication with the external serial flash memory stops when the specified number of entries is filled.

Data transfer from the QuadSPI module internal buffers

The data read out from the external serial flash memory device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data is loaded to. See Block diagram for details on the two available buffers, the RX buffer and the AHB buffer, in this module. The buffer appears transparent to you and is non-memory mapped. See the "Flexible AHB Buffer" section for details.

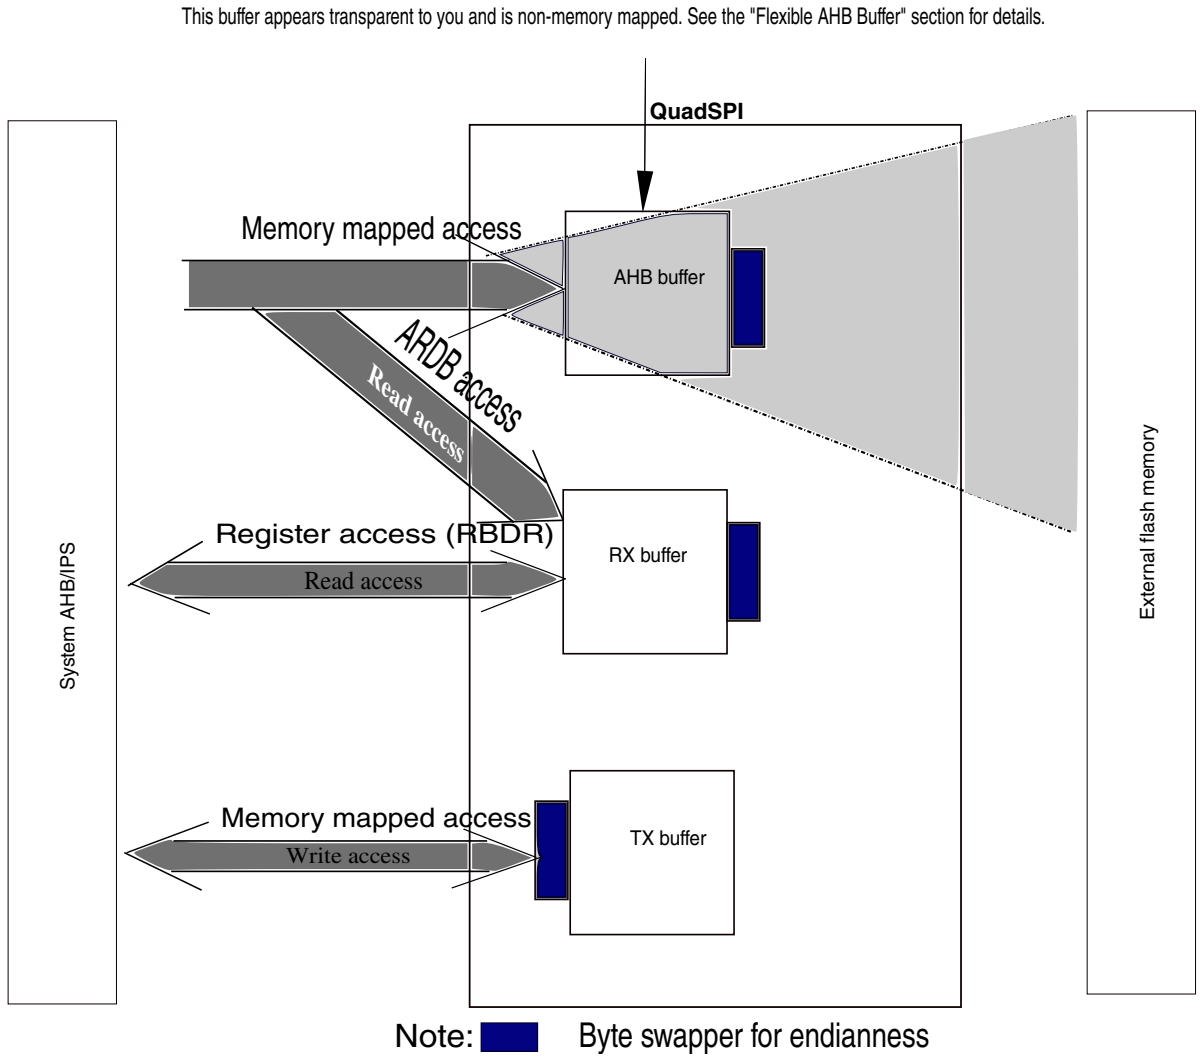

Figure 475. QuadSPI memory map

The RX buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas, both referring to identical data and the same physical memory:

- In the IPS address space in the area associated with RX Buffer Data Register (RBDR0 - RBDR31).
- In the AHB address space in the area associated with AHB RX Data Buffer Register (ARDB0 - ARDB31).Two successive entries are accessed with one single 64-bit AHB read operation.

The RX buffer operation can be summarized as follows:

- RBCT[WMRK] determines at which fill level SR[RXWE] is asserted and how many entries are removed from the RX buffer on each buffer POP operation.
- SR[RXWE] indicates that the configured number of data entries is available in the RX buffer and RBSR[RDBFL] indicates how many valid entries are available in total.
- The first entry (RBDR0 or ARDB0) always corresponds to the first valid entry in the RX buffer.

For details, see RX Buffer Data Register (RBDR0 - RBDR31) and AHB RX Data Buffer Register (ARDB0 - ARDB31).

- Flag-based data read of the RX buffer is performed by polling SR[RXWE]. When it is asserted, the valid entries can be read either via the IPS address space (RBDRn) or the AHB address space (ARDBn). A buffer POP operation must be triggered by the application by writing a 1 to FR[RBDF]. This automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer discards 16 bytes of data.
- DMA-controlled data read of the RX buffer is performed by using the DMA module. The application must ensure that the DMA controller of the related chip is programmed appropriately, as described in DMA usage.
- DMA-controlled read out is triggered fully automatically by the assertion of SR[RXWE]. The related buffer POP operation is also handled completely inside the QuadSPI module. As in the case explained here, accessing the RX buffer content either on RBDRn or ARDBn related addresses is equivalent.
- AHB buffer data read via memory-mapped access: This kind of access is performed by reading one of the addresses assigned to the external serial flash memory device(s) within the range specified in Table 674. If this is not the case, a memory-mapped AHB command read is triggered as described above. If the requested data is already available in the AHB buffer, it is provided directly to the host.

When an AHB access is made to the flash memory mapped address, the data is fetched and returned to the AHB interface. The AHB interface is stalled until the data is fetched. As soon as the data from the requested address is read by the QuadSPI module, the AHB read access is served. Therefore, it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless, this access scheme stalls the AHB bus for the time required to read the data from the serial flash memory device. If you know that the access is sequential, a better way is to have a prefetch enabled by programming the value of BUFxCR[ADATSZ] so that the data is fetched into the buffer before the next sequential AHB access.

As long as the host restricts its accesses to the data present in the buffer and to the data currently fetched from the serial flash memory, it is possible to run the host read from the AHB buffer simultaneously with the serial flash memory read into the AHB buffer.

77.4.2.9 AHB write

This module supports a single master AHB write with these burst types — INCR4, INCR8, INCR16, and INCR unspecified 4n bytes and single 4n bytes — and these burst types are supported with all Hsizes. An AHB write transaction size can be expressed in multiples of 4 bytes, and a single transaction must have a minimum of 4 bytes. In case of HyperRAM ,this limitation of minimum 4 bytes is not present. Also unspecified INCR and single transactions are supported without the limitation of 4n bytes in case of HyperRAM.

The following restrictions apply to the QuadSPI module with respect to AHB write transactions:

- AHB transactions of WRAP* types are not supported. For these unsupported access types, the controller returns an error response and does not initiate any flash memory transaction.
- Back to back, fixed address AHB write is not supported.
- Early burst termination is not supported for AHB transactions.

The QuadSPI controller queues back-to-back AHB writes with continuous address and sends them in a single flash memory transaction. However, in case the AHB address of a burst is not in continuous addressing sequence to previous write burst, a new flash memory transaction is initiated.

Following is the programming sequence for an AHB write:

1. Check that SR[BUSY] is deasserted or is 0 and check that the TX buffer is empty. If there is any residue data present in the TX buffer(SR[TXNE]), the buffer must be cleared by writing '1'1 to MCR[CLR_TXF].

2. Based on the type of flash memory device that is used for page programming, AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] need to be programmed.

   The default reset value for both the fields is 0 and allows writing to flash memory device assuming a very low T_{pp} (page program wait time) period. This period is very high for most of the flash memory devices. After any write to a flash memory device, the module waits for the write to finish before proceeding further.

   This is controlled by the AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] field configurations.
3. Configure trigger level AWRCR[AWTRGLVL] to an initial buffering level of the TX FIFO. Whenever this trigger level is reached by the AHB write, the QuadSPI module triggers a write to the flash memory.
4. Program the BFGENCR[SEQID] to point to the LUT where flash memory write sequence is stored.
5. AHB write master can now enable the transactions to be written to the flash memory. The AHB master must ensure data throughout to avoid underflow.
6. When a flash memory write completes and flash memory CS is deasserted, the software must poll SR[BUSY] for the deasserted value, which is 0. This indicates that the AHB write is complete. In case an underflow has occurred, flash memory CS is deasserted with (SR[TXNE])to know that an AHB write is pending with some residue data in the TX buffer.
7. Whenever flash memory CS is deasserted after an AHB write sequence, FR[PPWF] is set if any of AWRCR[PPW_RD/WR_DIS] is enabled. FR[PPWF] disables any further flash memory read/write based on AWRCR[PPW_RD]/AWRCR[WR_DIS]. After FR[PPWF] is set, it returns every incoming AHB transaction with an error response.
8. The software must clear FR[PPWF] to resume AHB transactions after the expiry of T_{pp} period of flash memory. It can also send IPS read command to the flash memory for checking if T_{pp} is over.
9. The software must ensure that the correct read and write LUT sequences are selected corresponding to the AHB read and write transactions. QuadSPI would malfunction if flash memory read sequence is selected during AHB write or vice versa.

77.4.2.10 Byte ordering of serial flash memory read data

The basic scheme is that the first byte read out of the serial flash memory device, which is addressed by SFAR[SFADR], corresponds to RBDR0[31:24] for IP command read. Similarly, to send a single byte it should be positioned in TBDR[0:7]. In contrast to that for AHB command read, the bytes are always positioned according to the byte ordering of the AHB bus.

- Byte ordering in individual flash memory mode

  The following table provides the byte ordering scheme of how the byte oriented data space of the serial flash memory device is mapped into one single 32-bit entry of the RX buffer or the AHB buffer. The table is valid within the following context:

  — Flash memory A in individual flash memory mode

  — All AHB data read commands with 32-bit access size

Table 638. Byte ordering in individual flash memory mode

Serial flash memory byte numbering	3	2	1	0
Buffer entry bit position [31:0] (32-bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

NOTE

For IP commands, the read size can be specified as number of bytes. If this number is not a multiple of four, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

  For AHB commands and reads, starting from an address not aligned to 32-bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- Buffer entry ordering for 64-bit read access

For read access via the AHB interface, a 64-bit access is possible. Each 64-bit access reads two 32-bit entries, simultaneously. The ordering of these 32-bit entries within the 64-bit word is provided in the following table.

Table 639. 64-bit read access buffer entry ordering

AHB read data bit position [63:0]	[63:32]	[31:0]
Buffer entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

77.4.2.11 Normal mode interrupt and DMA requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate an interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are associated with the Flag Register (FR).

Table 640. Interrupt and DMA request conditions

Condition	Flag (FR)	DMA
Data learn pattern failure	DLPFF	-
TX buffer fill	TBFF	-
TX buffer underrun	TBUF	-
Illegal instruction error	ILLINE	-
RX buffer drain	RBDF	X
RX buffer overflow	RBOF	-
AHB buffer overflow	ABOF	-
AHB sequence error	ABSEF	-
AHB illegal transaction error	AITEF	-
AHB illegal burst size error	AIBSEF	-
IP command trigger could not be executed error	IPIEF	-
IP command related transaction finished	TFF	-

Each condition has a corresponding field in Flag Register (FR) and a request enable field in DMA Request Select and Enable Register (RSER). FR[RBDF] has separate enable fields for generating IRQ and DMA requests. Note that not all the fields have an individual IRQ line. See the chip's Interrupt Vector table for details.

- Transmit buffer fill interrupt request

  This indicates that the TX buffer can accept new data. The buffer is asserted if FR[TBFF] is asserted and if the value of the corresponding enable field, RSER[TBFIE], is 1. See TX buffer Operation for details on the assertion of FR[TBFF].

  Apart from IRQ, it is possible to handle the TX buffer fill by using the DMA. If the value of RSER[TBFDE] is 1, a DMA request is triggered when the number of available space in the TX buffer is more than the TBCT[WMRK] valid entries and value of SR[TXWA] is set. The application must configure the environment appropriately (for example, the DMA controller) for the DMA transfer.

  In SFP Enabled configurations, program RSER[TBFDE] bit to 1 only when arbitration is won and TBDR access is unlocked after checking STATE field of FSMSTAT register. After TBDR programming is completed by DMA, reset this bit otherwise, QuadSPI SFM state will remain busy and no further IPS accesses can be served by that Target queue.

- Receive buffer drain interrupt or DMA request

This is derived from FR[RBDF], indicating that the RX buffer of the QuadSPI module has data available from the serial flash memory device to be read by the host. It remains set as long as RBSR[RXWE] is configured. Also, RSER[RBDIE] enables the related IRQ.

Apart from the IRQ, it is possible to handle the RX buffer drain by using the DMA. If the value of RSER[RBDDE] is 1, a DMA request is triggered when the RX buffer contains more than RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer overflow/underrun interrupt request

  This is a combination of the following fields (all located in the Flag Register (FR) with the related enable bits in the DMA Request Select and Enable Register (RSER)):

  — TBUF - TX buffer underrun, enabled by TBUIE

  — RBOF - RX buffer overflow, enabled by RBOIE

  — ABOF - AHB buffer overflow, enabled by ABOIE

  — The transmit buffer underrun indicates that an underrun condition in the TX buffer has occurred. It is generated when a write instruction is triggered whilst the TX buffer is empty and the the value of RSER[TBUIE] is 1.

  — The receive buffer overflow indicates that an overflow condition in the RX buffer has occurred. It is generated when the RX buffer is full, an additional read transfer attempts to write into the RX buffer, and the value of RSER[RBOIE] is 1.

  — The AHB buffer overflow indicates that an overflow condition in the AHB buffer has occurred. It is generated when the AHB buffer is full, an additional read transfer attempts to write into the AHB buffer and the value of RSER[ABOIE] is 1.

  — The data from the transfers that generated the individual overflow conditions is ignored.

- Serial flash memory command error interrupt request
- Transaction finished interrupt request

  The IP command transaction finished IRQ indicates the completion of the current IP command. It is triggered by FR[TFF] and is masked by RSER[TFIE].

77.4.2.12 TX buffer operation

The TX buffer provides the data used for page programming. For proper operation, it is required to provide at least one entry in the TX buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX buffer fast enough as long as the command is executed without a TX buffer overflow or underrun.

The QuadSPI module sets the FR[TBFF] field as long as the TX buffer is not full and can accept more data. At the end of write through TX buffer, you must clear FR[TBFF] to avoid unnecessary last TX buffer fill interrupt. However, there would always be a pending request asserted from QuadSPI controller at the end of any DMA transfer. When external DMA finishes transfer iteration, this request from QuadSPI is kept asserted for the next iteration loop.

NOTE

Even if the generation of DMA requests for filling the TX buffer is disabled by using RSER[TBFDE], the TX buffer still accepts a DMA transfer because of the last asserted pending request.

Disabling of DMA transfer should be controlled by an external DMA master.

When the QuadSPI module tries to pull data out of an empty TX buffer, FR[TBUB] signals the TX buffer underrun. The TX buffer underrun flag is also asserted when the TX buffer contains less than 32-bits of data and the QuadSPI module tries to pull out data from it. The current IP command leading to the underrun condition is continued until the specified number of bytes is sent to the serial flash memory device. Also, the data that is transferred is in the Fs format. This means, after the underrun flag is set under this condition, it returns Fs until the required number of bytes are not sent. This has been done to ensure that the software does not erase the whole sector after underrun and just reprogramming from failure point serves the purpose. When this sequence command is complete, FR[TBFF] is asserted, indicating that the TX buffer is ready to be written again.

The TX buffer overflow is not signaled explicitly, but TBSR[TRBFL] can monitor the TX buffer fill level.

For more information, see TX Buffer Status Register (TBSR) and Flag Register (FR).

77.4.2.13 Address scheme

Earlier, serial flash memories supported only a 24-bit address space, restricting the maximum memory size of the serial flash memory to 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to the legacy 24-bit address mode.

Extended address mode

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for the 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR commands should be programmed with 32d as the operand value . By default, QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (see the memory specification from memory vendors). For example, the command B7h sent to the Macronix flash memory enables it for the 32-bit address mode.

Extended address register

In this mode, the upper 8 bits of the 32-bit register are provided by the Extended address register in the memory, which provides a specific register that is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB consist of banks of 16 MB each. The 8 bits occupied in the extended address register effectively enable a bank. For example, in Spansion memory, when the extended address register is updated with a value of 1h, with the help of the 17h command, it opens Bank1 of the memory. The consequent 24-bit address commands lead to Bank1. The extended address register needs to be updated with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

This mode has been introduced for flash memories that need addresses segregated into rows and columns. The value in SFACR[CAS] defines the width of the column address required by a flash memory. The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions, if the value of SFACR[CAS] is 0. Otherwise, the actual address takes CAS into consideration. If the value of SFACR[CAS] is 3, then bits 26-3 of the programmed address are sent to the flash memory as its page address. This is in case the flash memory is operating in a 24-bit mode and bits 2-0 are sent as its column address. If a flash memory requirement for column address is less than the number of pads in which address has to be sent, then QuadSPI appends the remaining bits by 0. You must program the operand value in CADDR and CADDR_DDR command accordingly. It must be ensured that the total number of address bits requested by flash memory as its page and column address must not be more than 32 bits.

This mode has been introduced for flash memories, which have a word-addressable memory. This means, each address of the flash memory contains one word (two bytes) of data. The value of SFACR [WA] is configured to 1 to enter this mode. QuadSPI internally divides the incoming address in the AHB bus or the address in the SFAR to map it to a valid flash memory location. For example, if the incoming address is 2004h, the controller re-maps this address to access the flash memory location 1002h. If not in this mode, the incoming address 2004h is mapped to flash memory location 2004h.

77.4.3 Module Disable mode

Module Disable mode is a block-specific mode that the QuadSPI can enter to disable serial flash memory clock and AHB command. This mode can be entered by:

- The host software: by writing a '1' to MCR[MDIS]

Below are the condition that must be fulfilled to enter the Module Disable mode:

- SR[BUSY] = 0
- SR[AHBTRN] = 0
- RBSR[RDBFL] = 0
- SR[RXDMA] = 0
- SR[TXDMA] = 0
- None of the flags in FR are enabled as interrupts is set

The conditions mentioned above ensures the following:

- There is no SFM command currently being executed.
- All the data read into the RX buffer from the serial flash memory have been fetched by the application.
- There is no current AHB access.
- There is no active DMA request.
- There is no enabled interrupt that is pending.

Certain read or write operations have a different effect when the QuadSPI is in the Module Disable mode. In the Module Disable mode, not all of the status and flag bits of the QuadSPI module are updated, and writing to them has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

NOTE

It is illegal to issue a new SFM command starting two clock cycles prior to raising the request of entering the Module Disable mode until the QuadSPI stays in this mode.

77.4.4 Leaving Module Disable mode

In the Module Disable mode, the serial flash memory clock and AHB command to the QuadSPI module are switched off.

After the QuadSPI has left this mode and has returned to Normal mode, the execution of the first SFM command is deferred until the clock to drive that part of the module related to the serial flash memory device is available. Depending upon the point in time when the first SFM command is triggered, the actual execution of the command starts with a delay, respective with the re-enabling of the flash memory clock signal.

77.4.5 HyperRAM support

QuadSPI supports HyperRAM memories, and by virtue of this protocol, QuadSPI supports the following functionalities.

- Bidirectional data strobe/read write data strobe (RWDS)
  - If QuadSPI is configured to use the HyperRAM mode, the RWDS pad should be pulled down.
- Variable refresh latency
  - If the value of MCR[VAR_LAT_EN] is 1, based on the status of RWDS from HyperRAM during the command/address phase, QuadSPI includes an additional initial access latency. If RWDS is high, QuadSPI includes twice + 1 the latency mentioned in the dummy phase. If RWDS is low, latency mentioned in the dummy phase is not included.
  - In QuadSPI configuration register, read/write dummy is not a part of LUT programming. Therefore, the module does not consider the status of RWDS.
  - If the value of MCR[VAR_LAT_EN] is not set, fixed latency mentioned in the dummy phase is included.
- Read data strobe to latch data from HyperRAM
- Programming considerations for HyperRAM support:
  - Data masking during the AHB write is enabled when MCR[DQS_OUT_EN] bit is programmed as ’1’.
  - It is suggested that while using Hyper RAM program the SPTRCLR[PREFETCH_DIS] bit as ‘1’ so that every time a new AHB read transaction starts it reads new data from external memory instead of reading the data already stored in AHB buffers. This will ensure that the data read back after an AHB write is not a stale data.
  - AHB write doesn’t supports wrap transactions (WRAP4, WRAP8, WRAP16) even with HyperRAM.
  - If there is multiple switching between AHB read and write transactions then software should program AWRCR[AWTRGLVL] cautiously. It should ensure that during AHB write the data written to memory is more than the AWRCR[AWTRGLVL] programmed before switching over to AHB read transactions. This will ensure that IP is not left waiting for sufficient write data to be collected.

77.5 Initialization/application information

This section provides the initialization and application information of the QuadSPI module.

77.5.1 Power up and reset

The serial flash memory devices connected to the QuadSPI module might require special voltage characteristics of their inputs during power up or reset. The application must ensure this.

CAUTION

Erase or program commands should be completed before issuing a reset or power cycle to avoid corrupted flash pages. The application shall ensure there is a backup of critical data stored at a different location to enable recovery from corrupted flash pages.

Example: Flash reset sequence

Use the following sequence to reset flash A:

1. Make sure that the flash supports a reset for the condition CS#=high and IOF[3]=low.
2. Set MCR[SWRSTSD] and MCR[SWRSTHD] fields and then clear them.
3. Set MCR[MDIS] field.
4. Reset MCR[ISD3FA] field for flash A.
5. Clear MCR[MDIS] field.
6. Set MCR[MDIS] field.
7. Set MCR[ISD3FA] field for flash A.
8. Clear MCR[MDIS] field.

77.5.2 Available status/flag information

This section provides an overview of the different flags and statuses available, and their interdependencies for different use cases. The SR and FR are the related registers.

77.5.2.1 IP commands

See IP Configuration Register (IPCR) for additional details not explicitly covered in this paragraph.

- IP commands—normal operation

  Writing to IPCR[SEQID] triggers the execution of a new IP command. Given that this is a legal command, SR[IPACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts.

  After the instruction on the serial flash memory device is complete, these field deassert and FR[TFF] is configured.

- IP commands—error situations

  See Overview_of_Error_Flags for details.

77.5.2.2 AHB commands

See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic in theFlash Memory Read section for details.

- AHB commands—normal operation

  Memory-mapped read access to a serial flash memory address not contained in the AHB buffer triggers the execution of an AHB command. Given that this is a legal command, SR[AHB_ACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts. After the instruction on the serial flash memory device is complete, these fields are deasserted.

- IP commands—error situations

See Overview of FR error flags for details.

77.5.2.3 SFM commands

An SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash memory or results in an error. See Table 641 for details on errors.

77.5.2.4 Overview of error flags

The following table provides an overview of the different error flags in the FR and additional error-related details.

Table 641. Overview of FR error flags

Error category	Error flag in FR	Command execution on serial flash memory device TFF behavior (in case of IP commands only)	Description
AHB error flag	ABOF	Flash memory transaction continues until it finishes	Set when the module tries to push data into the AHB buffer that exceeds the size of the AHB buffer. Occurs only because of the wrong programming of BUFxCR[ADATSZ].
AHB error flag	AIBSEF	Flash memory transaction is aborted	Total burst size of the AHB transaction is greater than prefetch data size.
AHB error flag	AITEF	Flash memory transaction is aborted	No response is generated from QuadSPI to AHB bus in case of illegal transaction. Also, the watchdog timer expires.
Miscellaneous error flag	DLPFF	Flash memory transaction continues until it finishes	Set when the DATA_LEARN instruction is encountered in a sequence but no sampling point is found for the data learning pattern.
Miscellaneous error flag	ILLINE	Flash memory transaction aborted	Illegal instruction error flag - set when an illegal instruction is encountered by the controller in any of the sequences.
Command arbitration error	IPIEF	TFF not asserted in conjunction with that command	IP command error - caused when IP access is currently in progress (IP_ACC is set) and during: • Write attempt to RBCT register
Buffer-related error	RBOF	TFF is asserted on completion	• RX buffer overrun
Buffer-related error	TBUF	TFF is asserted on completion	• TX buffer underrun

Note that only the buffer-related errors are associated with a transaction on the external serial flash memory. All the other errors do not trigger an actual transaction.

77.5.2.5 IP bus and AHB access command collisions

There are following flags related to this topic: FR[IPIEF]. See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic of the Flash Memory read section for a description of the flags.

77.5.3 Flash memory device selection

Regardless of the SFM command (IP or AHB), the access mode is selected by specifying the 32-bit address value for the following SFM command.

For IP commands, the access mode is selected with the address programmed into the SFAR register. See Serial Flash Address Register (SFAR) for details.

For AHB commands, the access mode is determined by the memory-mapped address. See AMBA Bus Register Memory Map for details.

77.5.4 DMA usage

For a complete description of the DMA module, see the related DMA Controller chapter. This section only provides QuadSPI-specific DMA usage details.

77.5.4.1 DMA usage in normal mode

77.5.4.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash memory -> AHB bus / IP bus -> DMA controller) involved in the read/write data process is essential for a proper operation. Such analysis must take into account not only the data rate provided by the serial flash memory but also the data rate of the AHB bus and the performance of the DMA controller in reading/writing data from/to the RX/TX buffer.

Two figures must match for a proper operation, which means that the data rate provided by the serial flash memory device must not exceed the average RX buffer readout data rate. Otherwise, the longer this state persists, it results into an RX buffer overflow. Similarly, the data consumed by the serial flash memory device must not exceed the average TX buffer fill rate. If this persists, it leads to an underrun.

AHB bus side (data read)

The total number of bus cycles for each DMA minor loop completion is added from the following components:

The following table provides certain examples for typical use cases:

Case 1: DMA needs to read 4 bytes from SRAM and provide to QuadSPI. It costs total four bus clock cycles. Then, DMA handshake adds additional six bus clock cycles, resulting in a total of [6 + 4 * (32/4) = 38] bus clock cycles.

Table 642. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 60 MHz bus clock frequency
3	16	6+(16/4)*4 = 22	~366ns
7	32	6+(32/4)*4 = 38	~633ns
11	48	6+(48/4)*4 = 54	~900ns
15	64	6+(64/4)*4 = 70	~1166ns

Case 2: DMA needs to read 32 bytes from SRAM and provide to QuadSPI. DMA handshake takes an additional six bus cycles, with 32 bytes DMA read from SRAM costs (8 + 3) core clock cycles. DMA writes 32 bytes to QuadSPI, takes 2 * (32/4) = 16 bus cycles with one additional CPU access to QuadSPI, costing two bus clock cycles. This results in a total 6 + (8+3)/2 + 2 * (32/4) +2 = 30 bus clock cycles.

Table 643. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop >	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 80 MHz bus clock frequency
3	16	6 + (4+3) /2 + (16/4)*2 + 2 = 20	~333ns
7	32	6 + (8+3) /2 + (32/4)*2 + 2 = 30	~500ns
11	48	6 + (4+3)/2*3 + (48/4)*2 + 2 = 44	~733ns
15	64	6 + (8+3) + (64/4)*2 + 2 = 51	~810ns

NOTE

This table figure represents an ideal scenario; actual performance depends on how the chip integrates DMA and QuadSPI modules.

Serial flash memory device side (data read)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles is required to read 4 bytes, corresponding to one RX buffer entry (setup of command and address not considered): , two cycles for the Octal DDR mode in the individual flash memory mode, eight cycles for quad mode (SDR) instructions in individual flash memory mode, and so on.
- Overhead because of clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of RBCT[WMRK]:

Table 644. Access duration examples for serial flash memory side

RBCT[WMRK] setting	Num bytes per DMA loop [1]	Num SCKFx for 80 MHz SCKFx		Time duration of flash memory data readout for 80 MHz SCKFx (~12.5ns period)	
		IFM [2] quad	IFM quad DDR	IFM quad	IFM quad DDR
0	4	8	4	~100ns	~50ns
1	8	16	8	~200ns	~100ns
3	16	32	16	~400ns	~200ns
7	32	64	32	~800ns	~400ns
11	48	96	48	~1200ns	~600ns

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Individual flash memory mode

NOTE

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

A complementary example is when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be lesser than the time taken by the controller to push in the remaining entries in the buffer.

IPS bus side (data write)

The total number of bus cycles for each DMA minor loop completion are added from the following components:

- Overhead for each minor loop, given by DMA controller: assume 10 cycles
- Overhead because to clock domain crossing: assume two cycles
- Number of bus clock cycles required for 16 bytes (128-bit write size): assume four cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of TBCT[WMRK]; therefore, the overhead specified above distributes among (TBCT[WMRK]+1) write accesses of 32-bit each.

The following table provides some examples for typical use cases:

Table 645. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop [1]	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 80 MHz bus clock frequency
3	16	12+4 = 16	~200ns
7	32	12+8 = 20	~250ns

1. DMA loop refers to one minor loop completion that is equivalent to one.

NOTE

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

Serial flash memory device side (data write)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles required to write 16 bytes, corresponding to four TX buffer entry (setup of command and address not considered): Eight cycles for Octal DDR mode instructions in individual flash memory mode, 32 cycles for quad SDR writes in individual flash memory mode.
- Overhead due to clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of TBCT[WMRK]:

Table 646. Access duration examples for serial flash memory side

TBCT[WMRK] setting	Num bytes per DMA loop [1]	Num SCKFx		Time duration for consuming data at flash memory interface 100 MHz SCKFx (10 ns period)[2]		Time for FIFO to get empty[3]	
		IFM [4] quad	IFM octal DDR	IFM quad	IFM octal DDR	IFM quad	IFM octal DDR
3	16	32	8	320ns	80ns	2240ns	560ns
7	32	64	16	640ns	160ns	1920ns	480ns

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Not all flash memory devices support writes at 100 MH. See the flash memory data sheet for the actual page program frequency supported.
3. The assumption for these timings is that the TX Fifo is full when the transaction is initiated
4. Individual flash memory mode

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

Considering the examples provided in the two tables above for TX FIFO, it is evident that depending on the relationship between the bus clock and serial flash memory clock frequencies, there are settings possible where the serial flash memory consumes data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation occurs. To avoid TX buffer underrun, the data transaction size should be large enough.

77.5.5 Flash memory devices address mapping

QuadSPI is configured in Single mode for the supported flash memory port A

The sizes of the flash memory devices are mapped with the system memory space based on the configurations of the following registers:

- SFA1AD
- SFA2AD

The total memory region for the flash memory devices is mapped between QuadSPI_AMBA_BASE and TOP_ADDR_MEMA2 such that the corresponding CS is asserted based on SFA1AD and SFA2AD register configurations.

77.5.5.1 Single mode

For single-die flash memories, you must write the same value to SFA2AD register that you write to the SFA1AD register.

Following is a programming example for single mode single-die flash memory:

- QuadSPI_AMBA_BASE - 1000_0000h
- SFA1AD[TPADA1] - 2000_0000h
- SFA2AD[TPADA2] - 2000_0000h

The following figure illustrates the memory mapping for single mode QuadSPI configuration.

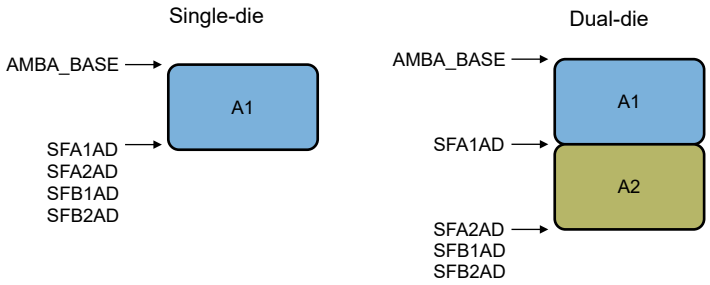

Figure 476. Memory map for Single mode

77.6 Byte ordering – endianness

The following topics show the byte ordering in 64-bit LE configuration for AHB buffer and 32-bit LE for TX/RX buffer.

77.6.1 Programming flash memory data

CPU writes instructions to the TBDR register, such as:

- Write TBDR: 4_03_02_01h
- Write TBDR: 8_07_06_05h

The following table shows the content against each TX buffer entry.

Table 647. Example of QuadSPI TX buffer

TX buffer entry	Content
0	4_03_02_01h
1	8_07_06_05h

Programming the TX buffer into the external serial flash memory device results in the following byte order to be sent to the serial flash memory:

- 01...02...03...04...05...06...07...08

77.6.2 Reading flash memory data into the RX buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

Table 648. Resulting RX buffer content

RX buffer entry	Content
0	4_03_02_01h
1	8_07_06_05h

77.6.2.1 Readout of the RX buffer through RBDRn

The RX buffer content appears at CPU read access through the peripheral bus interface in the following order:

- Read RBDR0: 4_03_02_01h
- Read RBDR1: 8_07_06_05h

77.6.2.2 Readout of the RX buffer through ARDBn

The RX buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit access: Read ARDB0: 4_03_02_01h
- 32-bit access: Read ARDB1: 8_07_06_05h
- 64-bit access: Read ARDB0: 8_07_06_05_04_03_02_01h

77.6.3 Reading flash memory data into the AHB buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

Table 649. Resulting AHB buffer content

AHB buffer entry	Content
0	8_07_06_05_04_03_02_01h

77.6.3.1 Readout of the AHB buffer through memory-mapped read

The AHB buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit read access: 4_03_02_01h
- 32-bit read access: 8_07_06_05h
- 64-bit read access: 8_07_06_05_04_03_02_01h

77.7 Driving flash memory control signals in single and dual modes

In single and dual modes, the serial flash memory devices that can connect to the QuadSPI module expect additional control signals on the inputs, which are connected to IOFA[3], IOFA[2] in the quad mode. For easy interfacing, the outputs IOFA[3:2] for flash memory A are driven to the logic state given by the configuration fields MCR[ISD3FA], MCR[ISD2FA].

These outputs are driven all the time to the logic level programmed in the MCR except the time when quad commands of the serial flash memory are executed. See the specifications of the related serial flash memory device for details about the inactive level.

77.8 Serial flash memory devices

Several different vendors make flash memory devices with a QuadSPI interface. At present, there is no set standard for the QuadSPI instruction set. The most common commands currently have the same instruction code for all vendors; however, some commands are unique to specific vendors. Some of the example sequences are provided in the following sections.

77.8.1 Example sequences

This section provides the example sequences of the QuadSPI module.

Table 650. Exit 4 x I/O read enhance performance mode (XIP) (Macronix) and read status

Instruction	Pad	Operand	Description
CMD	0h	EBh	4xIO read command
ADDR	2h	18h	24-bit address to be sent on four pads
MODE	2h	0h	2 mode cycles (exit XIP)
DUMMY	0h	4h	4 dummy cycles
READ	2h	8h	Read 64 bits
CMD	0h	5h	Read Status register
READ	0h	1h	Status register data
STOP	0h	0h	Stop, instruction over

77.8.1.1 Read command (hyperflash memory/HyperRAM)

This section provides the read command sequences (hyperflash memory/HyperRAM) of the QuadSPI module.

Table 651. Read command (hyperflash memory/HyperRAM)

Instruction	Pad	Operand	Comment
CMD_DDR	3h	A0h	Read command with continuous burst type
ADDR_DDR	3h	18h	24-bit row address

Table continues on the next page...

Table 651. Read command (hyperflash memory/HyperRAM) (continued)

CADDR_DDR	3h	10h	16-bit column address with lower 3 bits valid and rest 0
Dummy	3h	0hF	15 dummy cycles
READ_DDR	3h	4h	32-bit data read on 8 pads
STOP	3h	0h	Stop, instruction over

Hyperflash memory/HyperRAM is a word addressable flash memory. This means that each address accesses a word-wide (two-byte) data value. The software should ensure that when Hyperflash memory/HyperRAM is connected to the controller, the value of SFACR[WA] must be 1. With this value, the controller remaps a byte addressable access to a word addressable access.

77.8.1.2 Read status register (hyperflash memory/HyperRAM)

This section provides details related to the read status register of the QuadSPI module.

Table 652. Read status register (hyperflash memory/HyperRAM)

Instruction	Instruction sequence	Pad	Operand	Description
CMD_DDR	Read Pre Command	3h	0h	Write command with wrapped burst type
ADDR_DDR		3h	18h	24-bit row address (0000AAh)
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits valid and rest 0(0005h) treated as command
CMD_DDR		3h	0h	Write command with wrapped burst type
CMD_DDR		3h	70h	Write data to be sent to flash memory as pre-command
CMD_DDR	Command phase (fourth/final chip select phase)	3h	A0h	Read command with continuous burst type
ADDR_DDR		3h	18h	24-bit row address
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits as valid and rest 0
DUMMY		3h	0hF	15 dummy cycles
READ_DDR		3h	4h	32-bit data read on 8 pads
STOP		3h	0h	Stop, instruction over

77.8.1.3 Word program (hyperflash memory/HyperRAM)

This section provides the word program (hyperflash memory/HyperRAM) of the QuadSPI module.

Table 653. Word program (hyperflash memory/HyperRAM)

Instruction	Instruction sequence	Pad	Operand	Description
CMD_DDR	Unlock sequence 1 (first chip select phase)	3h	0h	Write command with wrapped burst type
CMD_DDR		3h	0h	8-bit address 00h treated as command
CMD_DDR		3h	0h	8-bit address 00h treated as command
CMD_DDR		3h	AAh	8-bit address AAh treated as command
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits valid and rest 0(0005h) treated as command
CMD_DDR		3h	0h	Write command with wrapped burst type
CMD_DDR		3h	AAh	Write data to be sent to flash memory as pre-command
CMD_DDR	Unlock sequence 2 (second chip select phase)	3h	0h	Write command with wrapped burst type
CMD_DDR		3h	0h	8-bit address 00h treated as command
CMD_DDR		3h	0h	8-bit address 00h treated as command
CMD_DDR		3h	55h	8-bit address 55h treated as command
CADDR_DDR		3h	10h	16-bit column address with lower 3-bits valid and rest 0(0002h) treated as command
CMD_DDR		3h	0h	Write command with wrapped burst type
CMD_DDR		3h	55h	Write data to be sent to flash memory as pre-command
CMD_DDR	Program setup phase (third chip select phase)	3h	0h	Write command with wrapped burst type
CMD_DDR		3h	0h	8-bit address 00h treated as command
CMD_DDR		3h	0h	8-bit address 00h treated as command

Table continues on the next page...

Table 653. Word program (hyperflash memory/HyperRAM) (continued)

CMD_DDR		3h	AAh	8-bit address AAh treated as command
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits valid and rest 0(0005h) treated as command
CMD_DDR		3h	0h	Write command with wrapped burst type
CMD_DDR		3h	A0h	Write data to be sent to flash memory as pre-command
CMD_DDR	Command phase (fourth/final chip select phase)	3h	0h	Write command with wrapped burst type
ADDR_DDR		3h	18h	24-bit row address
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits as valid and rest as 0
WRITE_DDR		3h	2h	2-byte data written on 8 pads (D1D2)
STOP		3h	0h	Stop, instruction over

77.8.1.4 Fast read sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flash memories.

Table 654. Fast read sequence

Instruction	Pad	Operand	Description
CMD	0h	Bh	Fast read command = 0Bh
ADDR	0h	18h	24 address bits to be sent on one pad
DUMMY	0h	8h	Eight dummy cycles
READ	0h	4h	Read 32 bits on one pad
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

NOTE

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

77.8.1.5 Fast read quad output (Winbond)

The following table shows the fast read quad output sequence for Winbond memories

Table 655. Fast read quad output sequence

Instruction	Pad	Operand	Description
CMD	0h	6Bh	Fast read quad output command = 6Bh
ADDR	0h	18h	24 address bits to be sent on one pad
DUMMY	0h	8h	Eight dummy cycles
READ	2h	4h	Read 32 bits on four pads
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

NOTE

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

77.8.1.6 4 x I/O read enhance performance mode (XIP) (Macronix)

The following table shows the 4 x I/O read enhance performance mode for Macronix flash memories. The enhanced performance mode is also known as XIP mode.

Table 656. Fast read quad output sequence

Instruction	Pad	Operand	Description
CMD	0h	EBh	4xI/O read command = EBh
ADDR	2h	18h	24 address bits to be sent on four pads
MODE	2h	A5h	Two mode cycles
DUMMY	0h	4h	Four dummy cycles
READ	2h	4h	Read 32 bits on four pads
JMP_ON_CS	0h	1h	Jump to instruction 1 (ADDR)

When in XIP mode, the software must ensure that all the flash memories connected to the controller are in this mode. As a part of initializing the controller, all the flash memories might be enabled with XIP by carrying out dummy reads.

77.8.1.7 Dual command page program (Numonyx)

The following table shows the dual command page program sequence for Numonyx flash memories.

Table 657. Dual command page program sequence

Instruction	Pad	Operand	Description
CMD	1h	2h	Dual command page program = 02h on 2 pads
ADDR	1h	18h	24 address bits to be sent on two pads
WRITE	1h	20h	Write 32 bytes on two pads

Table continues on the next page...

Table 657. Dual command page program sequence (continued)

Instruction	Pad	Operand	Description
STOP	0h	0h	Stop, instruction over

77.8.1.8 Sector erase (Macronix/Numonyx/Spansion)

The following table shows the Sector erase sequence for the Macronix/Numonyx/Spansion flash memories.

Table 658. Sector erase sequence

Instruction	Pad	Operand	Description
CMD	0h	20h	Sector erase command = 20h
ADDR	0h	18h	24 address bits to be sent on one pad
STOP	0h	0h	Stop, instruction over

77.8.1.9 Read status register (Macronix/Numonyx/Spansion/Winbond)

The following table shows the read status register sequence for Macronix/Numonyx/Spansion/Winbond flash memories.

Table 659. Read status register sequence

Instruction	Pad	Operand	Description
CMD	0h	0h5	Read status register command = 05h
READ	0h	0h1	Read status register data
STOP	0h	0h	Stop, instruction over

77.8.1.10 Data learn instruction sequence

The following table shows the data learn sequence for 4 I/O flash memory.

Table 660. Data learn instruction sequence (4 I/O)

Instruction	Pad	Operand	Description
CMD	0h	6Bh	Fast read quad command = 6Bh
ADDR_DDR	2h	18h	24 address bits in the DDR mode to be sent on four pads
DUMMY	2h	8h	8-cycle dummy
DATA_LEARN	2h	1h	1-byte data learn
READ_DDR	2h	6h	Read 6 bytes in 4 pads[1]
JMP_ON_CS	0h	0h	Jump to Inst 0 (CMD)

1. Data learn instruction needs to be followed by a read DDR instruction of minimum 6 bytes in case of 4 I/O mode.

NOTE

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

The following table shows the data learn sequence for 8 I/O (hyperflash memory) flash memory.

Table 661. Data learn instruction sequence (8 I/O)

Instruction	Pad	Operand	Description
CMD_DDR	3h	AOh	Read command for hyperflash memory
ADDR_DDR	3h	18h	24-bit row address[1]
CADDR_DDR	3h	10h	16-bit column address
DUMMY	3h	Fh	15-cycle dummy
DATA_LEARN	3h	1h	1-byte data learn
READ_DDR	3h	Ch	Read 12 bytes in 8 pads[2]
STOP	3h	0h	Stop, instruction over

1. The address needs to be aligned, which means, no latency should be there between the RWDS edges.
2. The data learn instruction needs to be followed by a read DDR instruction of minimum 12 bytes in case of 8 I/O mode.

The following table shows the data learn sequence for 4 I/O flash memory.

Table 662. Data learn instruction sequence (4 I/O)

Instruction	Pad	Operand	Description
CMD	0h	6Bh	Fast read quad command = 6Bh
ADDR_DDR	2h	18h	24 address bits in DDR mode to be sent on four pads
DUMMY	2h	8h	8 dummy cycles
DATA_LEARN	2h	1h	1-byte data learn
READ_DDR	2h	6h	Read 6 bytes in 4 pads
JMP_ON_CS	0h	0h	Jump to Inst 0 (CMD)

NOTE

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

The following table shows the data learn sequence for 8 I/O (Hyperflash) flash memory.

Table 663. Data learn instruction sequence (8 I/O)

Instruction	Pad	Operand	Description
CMD_DDR	3h	AOh	Read command for hyperflash memory
ADDR_DDR	3h	18h	24-bit row address[1]
CADDR_DDR	3h	10h	16-bit column address
DUMMY	3h	Fh	15-cycle dummy

Table continues on the next page...

Table 663. Data learn instruction sequence (8 I/O) (continued)

Instruction	Pad	Operand	Description
DATA_LEARN	3h	1h	1-byte data learn
READ_DDR	3h	8h	Read 8 bytes in 8 pads
STOP	3h	0h	Stop, instruction over

1. The address needs to be aligned, which means, no latency should be there between the RWDS edges.

NOTE

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

77.9 Sampling of serial flash memory input data

77.9.1 Basic description

QuadSPI is used to read data from the serial flash memory device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash memory device. See the following figure for an overview of this scheme.

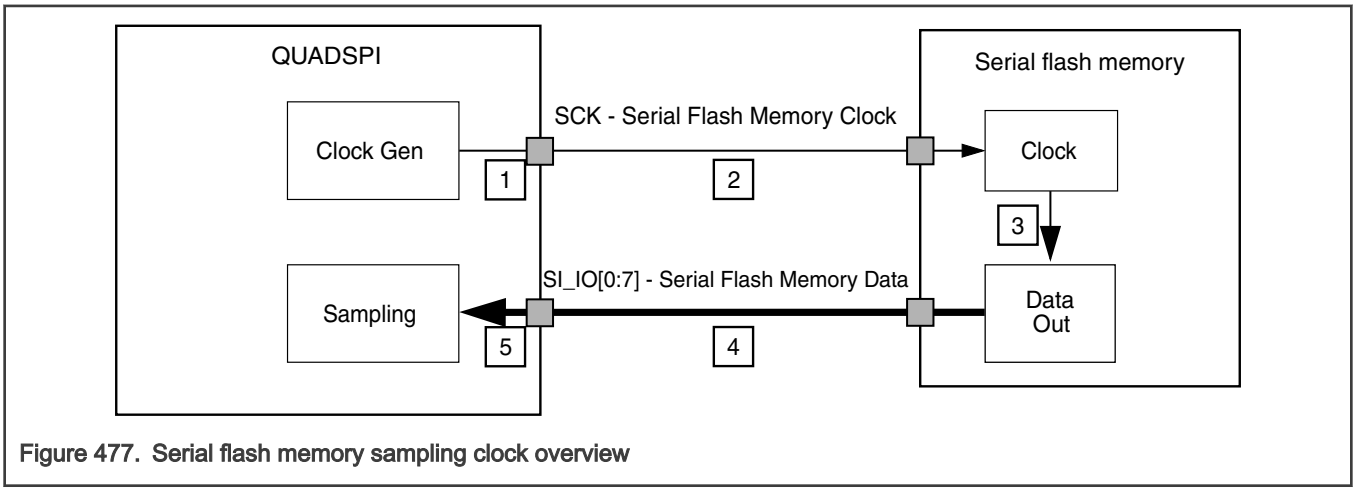

Figure 477. Serial flash memory sampling clock overview

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash memory. After a time of t_{total_delay} the data arrives at the internal sampling stage of the QuadSPI module. Considering the figure provided here, the following parts of the delay chain contribute to t_{total_delay}:

- Output delay of the serial flash memory clock output of the device containing the QuadSPI module
- Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash memory device
- Clock to data out delay of the external serial flash memory device, including input and output delays
- Wire delay of application/PCB from the external serial flash memory device to the device containing the QuadSPI module
- Device delay corresponding to the input data

NOTE

The t_{total_delay} is specific to the characteristics of the actual implementation. Also, the serial flash memory device clock (SCK) is inverted with respect to the QuadSPI internal reference clock.

77.9.2 DQS sampling method

77.9.2.1 Basic description

In the DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash memory move in the same direction; therefore, it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on the rising edge of the strobe signal.

The next figure shows the sampling read data in the SDR mode using the DQS.

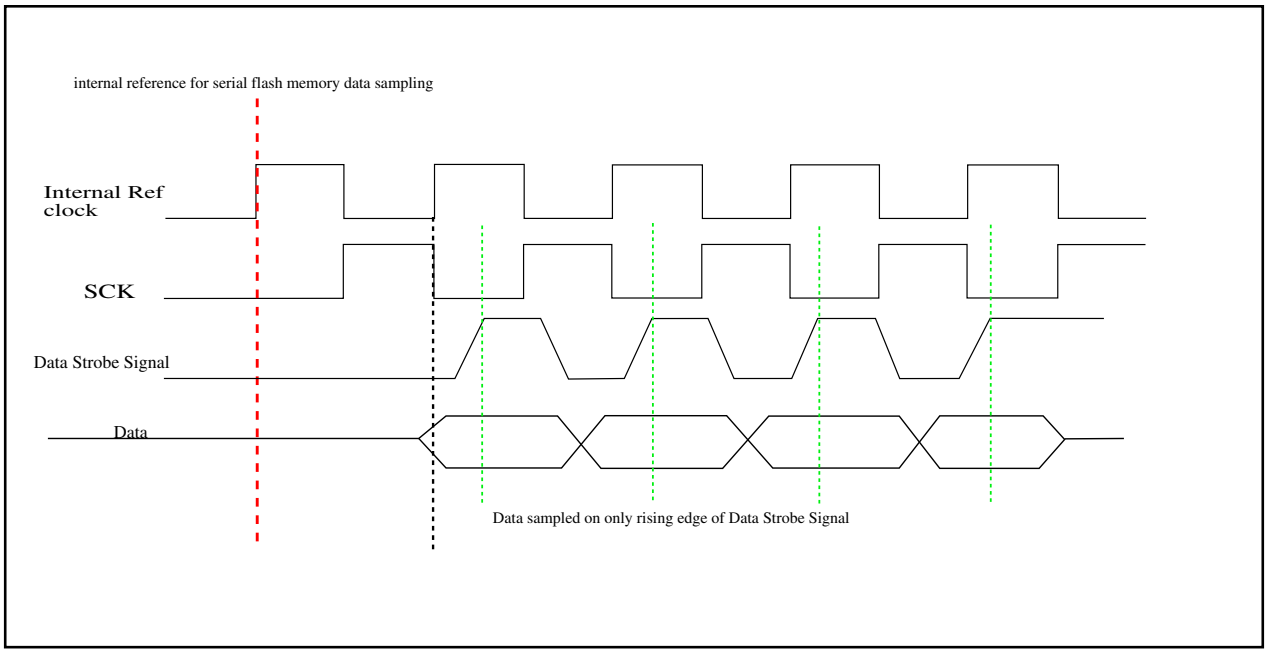

Figure 478. Data strobe functionality in SDR mode for read operation.

NOTE

Consider "Data Strobe Signal" as "Data Strobe Signal driven by memory" and "Data" as "Data from memory".

NOTE

Refer to the Datasheet for specific timing waveforms of QuadSPI

NOTE

For Specific details - Refer to the Data Sheet specification of QuadSPI module.

77.9.2.2 Dummy Pad loopback

The internal clock is loop-backed from the dummy internal pad to compensate data pad delays. This can be enabled by configuring the value of MCR[DQS_FA_SEL] as "01" for flash memory A. This mode can be used with the following configuration:

- High/low frequency delay chain manual programming in bypass mode using DLLCRA[SLV_DLY_COARSE] and DLLCR[FREQEN].
- DLL-assisted sampling only using DLLCRA[DLLEN]

  NOTE

  Refer to DS or "Chip-specific section" of QSPI for Fixed sampling Tap specific settings/details with out without DLL (in bypass mode)

- DLL-assisted auto data learning using DLLCRA[DLLEN] and along with MCR[DLPEN]

NOTE

Refer to Auto-DataLearning (4x Sampling method) section with DLL for further details

NOTE

This mode may not be available on the chip. See the "Supported read modes" section in the chip-specific QuadSPI information for the read modes that this chip supports.

77.10 Data learning

77.10.1 Basic description

Data learning is used to manage varying data valid windows from the flash memory as well as any variations in the chip based on PVT conditions in the DDR mode. QuadSPI provides this feature via the DATA_LEARN instruction for all flash memories, irrespective of whether the flash memory supports it. The DATA_LEARN instruction accepts an operand that defines the number of bits of the known pattern for which the data learning has to be done. The known pattern is provided in the DLPR register.

QuadSPI supports the following data learning:

- DQS

The following sections explain data learning in detail.

77.10.2 DQS sampling method

The semi-automatic data learning is supported in the DQS sampling method. To start data learning:

1. Configure a known pattern in the Data Learn register inside flash memories that support data learning. The pattern should be selected to have multiple low and high transitions in the data bus.

   NOTE

   Certain flash memories provide data learning as a feature for DDR data reads.

2. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash memory returns the data learning pattern in between dummy cycles in every read command. Each I/O gives the same DLP value for every clock edge.

   NOTE

   For flash memories that *do not* support data learning, configure a known location in flash memory with a known pattern. The pattern should not have 0h or FFh included. The pattern should be selected to have multiple low and high transitions in the data bus. et up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction. The address in the SFAR register should point to the known location within the pattern. Configure the known pattern in DLPR[DLPV]. See Programming the data learning pattern in flash memory for details on how the data has to be ordered in memory for correct operation.

3. Select a sampling point. See chip-specific QuadSPI information for selection of the sampling point.
4. Initiate the read via a peripheral transaction.
5. QuadSPI reads the data from the flash memory. It then encounters the DATA_LEARN instruction and samples the incoming data on both edges (rising and falling) of the DQS.

   NOTE

   If the data from the flash memory does not match the data learning pattern, the FR[DLPFF] flag is set. The QuadSPI module reports no sampling point automatically.

6. Repeat steps 2-7 with varying VT conditions for a particular process until FR[DLPFF] is set. The sampling points where no FR[DLPFF] is set signify a valid setting.

In the case of multiple valid settings, the software should select the middle point. The sampling point should be fixed within the above selected point for the next READ transactions.

NOTE

Ensure that QuadSPI is not accessed during calibration.

This feature might be used to auto-calibrate the sampling point for DDR reads, and auto-calibration might be triggered at fixed intervals, or depending on a change in PVT conditions.In case the sampling point needs to be changed based on initiating options (such as, DLL lock status, time period, or software forced interrupt), data learn instruction has to be re-initiated.

The following figure shows data learning in DQS mode.

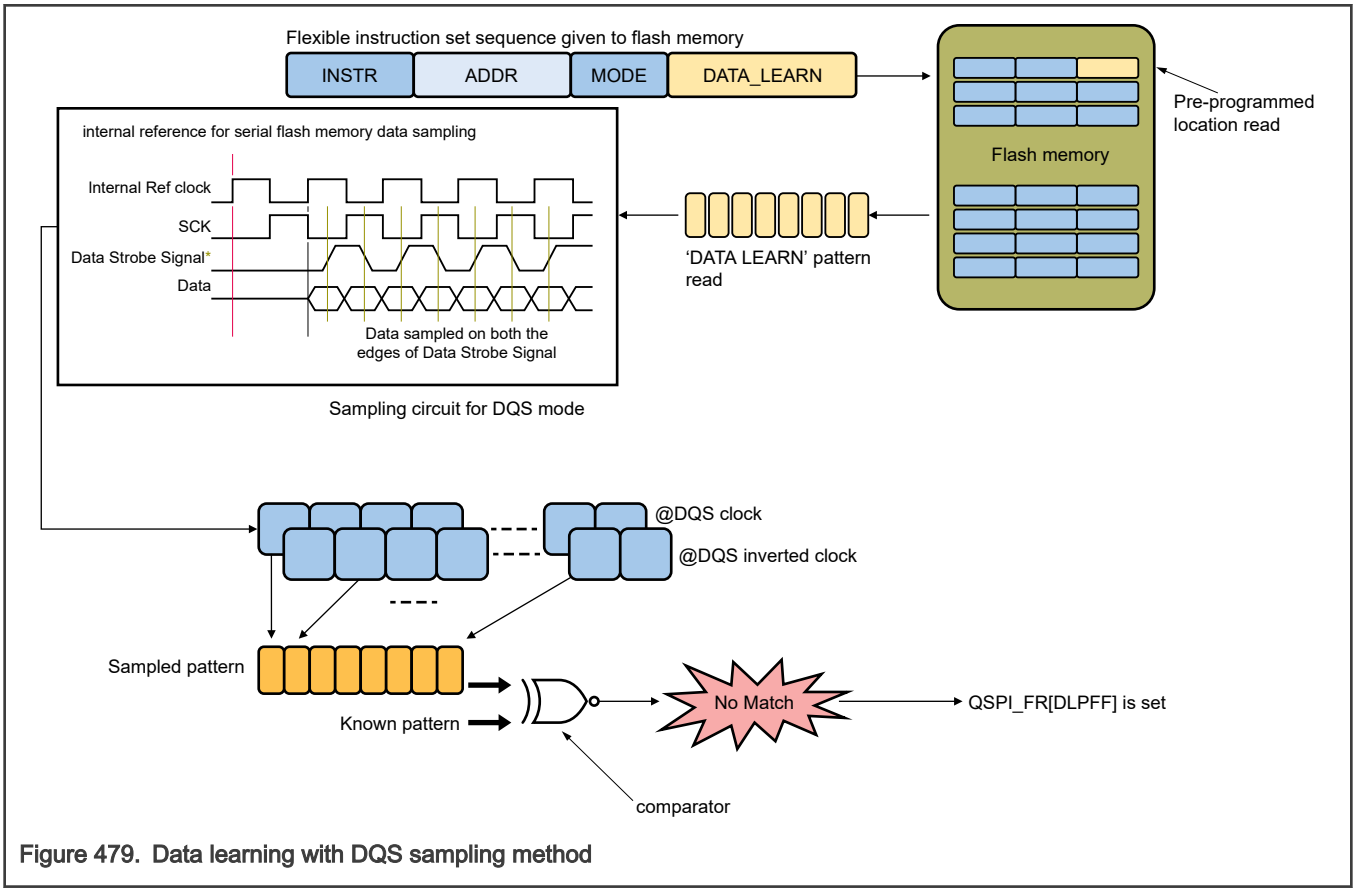

Figure 479. Data learning with DQS sampling method

NOTE

This mode might not be available on the chip. See the chip-specific QuadSPI information for the read modes that this chip supports.

77.10.3 Programming the data learning pattern in flash memory

Example scenario: If the value of DLPR[DLPV] is 43h, QuadSPI tries to match this sample on every incoming data line for single, dual, quad, or octal configurations. The following table shows the data programmed in flash memory with endianness taken into consideration.

Table 664. Programming the data learning pattern in flash memory

Endianness	Single IO	Dual IO	Quad IO	Octal IO
BE	43h	300Fh	0F0000FFh	00FF00000000FFFFh
LE	43h	0F30h	FF00000Fh	FFFF0000000000FFh

77.11 DLL and delay chain usage

The DLL is a general-purpose, dynamically adaptive clock delay module. It provides the ability to select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT). The DLL is suitable for applications where accurate delay adjustment is required, such as in case of DDR interfaces.

DLL working concept

The DLL control loop consists of a counter, reference delay line, and phase detector which operate on the ref_clock reference clock input. The reference clock (clk_ref) is fed into the reference delay line. After reset, a single delay tap is selected. A phase detector is used to detect the condition where a half shift has occurred. In addition to this, signals are generated to either increment or decrement the counter, which controls the delay line (if the half-phase detect condition is not met). Any changes in the delay of the individual elements of the delay chain (because of PVT) automatically cause the phase detector logic to determine if a change in the counter value is required. After the half-phase shift is detected, an internal lock signal is generated, and after a lock event occurs, the slave delay chain is ready to be updated based on a triggering event.

Slave delay chain programming sequence—

Following is the programming sequence for DLL bypass mode.

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=1, and DLLCRA[SLAVE_AUTO_UPDT]=0.
2. Program the following fields to provide the desired DQS delay for sampling: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_COARSE], and DLLCR[FREQEN]. See the chip-specific QuadSPI information for the supported programming settings.
3. Program DLLCRA[SLV_UPD]=1 to load these values in the slave delay chain.
4. Check the slave delay chain update status by polling DLLSR[SLVA_LOCK]=1 and clear DLLCRA[SLV_UPD] after confirming the update state.

Following is the programming sequence for DLL auto update mode.

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=0, and DLLCRA[SLAVE_AUTO_UPDT]=1.
2. Program the DLL configuration by using DLLCRA[DLL_REFCNTR] and DLLCRA[DLLRES]. See the chip-specific QuadSPI information for the supported DLL configuration settings.
3. Program the slave settings to delay DQS by using these fields: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_OFFSET], and DLLCR[FREQEN]. See the chip-specific QuadSPI information for the supported settings.
4. If offset delay needs to be updated on the slave chain, program DLLCRA[SLV_UPD]=1.
5. Enable DLL by programming DLLCRA[DLLEN]=1 and reset DLLCRA[SLV_UPD]=0. Slave delay chain is updated automatically and can be checked by polling DLLSR[SLVA_LOCK]==1

77.12 Secure flash protection

This secure flash module enforces access control policies based on the MGID, privilege and secure attributes of the IPS transactions. All accesses throughout the flash device need to be monitored to determine the validity of all accesses. If transaction from a given master has appropriate access rights, it is forwarded to flash, else the access is denied, and an error is generated.

There are two level of checks present in this module, based on MDAD and FRAD descriptors programmed. First level checks the input transactions based on secure attribute and MGID associated with that transaction which are checked according to MDAD. Second level check selects the appropriate FRAD based on address range of transaction. And each FRAD allows the transaction to pass through only when secure, privilege and other MGID related attributes are matching. Else the transaction is not forwarded and IPS bus error/interrupt is generated. Flash regions can be programmed to cover the entire address space to provide a default set of access permissions. For flash read transactions only first level of check is enabled.

Software can bypass both or anyone of these checks by writing to MGC[GVLDFRAD], MGC[GVLDMDAD] and MGC[GVLD] fields.

The IPS masters should write on QuadSPI register (SFAR, IPCR and TBDR) addresses for generating transfers to flash. SFP block monitors these IPS transfers and checks if the write is being done on SFAR or IPCR registers and forwards them for MDAD and FRAD checks. If the transaction passes both checks then it is passed through to QuadSPI register else bus error or interrupt is

generated. FRAD check is only done for flash write transactions not for read. Actual write on QuadSPI SFAR and IPCR register is done by SFP module only after the transaction passes MDAD and FRAD checks. There is only a single IPS slave interface which can be used for QuadSPI IPS register access and SFP IPS register access.

An IPS master transaction is secure if IPS_NONSECURE_ACCESS attribute is set to 0 for that transaction. An IPS master transaction is privileged if IPS_SUPERVISOR_ACCESS attribute is set to 1 for that transaction.

QuadSPI SFP related register sets are present here.

77.12.1 MDAD

These descriptors form the first level of checks on the input IPS transaction. There are two target group queues (TG0 and TG1) present in SFP block and each of these queues can be programmed with different set of MGAD descriptors checks in TG*n*MDAD registers. These registers are under access control and can only be programmed by privilege masters. These descriptors (one or both) should be programmed before start of any flash transaction else any IPS write on SFAR, IPCR or TBDR registers will generate an IPS bus error. After programming the target group descriptor the TG*n*MDAD[VLD] should be set to 1 for that register.

There are two target group queues (TG0 and TG1) so two transactions by different master ID can be stored inside SFP block while one of them is being processed by QuadSPI.

77.12.1.1 MDAD checks

- Secure check – This is decided by the TG*n*MDAD[SA] field of the MDAD descriptor. If the fields are set to 01 then queue is reserved for only non-secure transactions. If set to 10 then queue is reserved for only secure transactions. If the bits are set to 11 then this check is bypassed.
- MasterID check – This check compares themasterID of the input transaction with the MID match value set inTG*n*TG*n*MDAD[MIDMATCH]fields and allows only matching transactions inside the queue. There are 6 mask fields (TG*n*TG*n*MDAD[MASK]) inside the descriptor. If the mask type (TG*n*TG*n*MDAD[MASKTYPE]) is set to 0 then the input transactions master ID is ANDed with the mask bits before comparing with the MID match value. If the mask type is set to 1 then the input master ID is ORed with the masks bits and then compared with the MID match bits. Multiple master IDs can be allowed inside the queue using this mask.

When an IPS write is done to SFAR or IPCR registers then SFP block checks the attributes with MDAD descriptors of both the queues. If the attributes match with descriptor of any queue, then the value is written inside that queue and master ID is assigned to that queue. The queue is considered locked once the SEQID bits of IPCR register are written. So software should ensure that IPCR SEQID bits are written only after SFAR and other IPCR bits like DATSZ are written in that queue. The queue will be unlocked when flash transfer is completed for that transaction.

Once a master ID is assigned to a queue then transactions with only that master ID are allowed inside the queue. Any write of SFAR/IPCR is mapped to this queue even if other queue is free. So same master ID cannot have transaction on both queues at a time. The data in the queue is cleared once the flash transaction is finally completed by the QuadSPI.

The data path for input IPS writes to SFAR or IPCR registers are shown in the following figure.

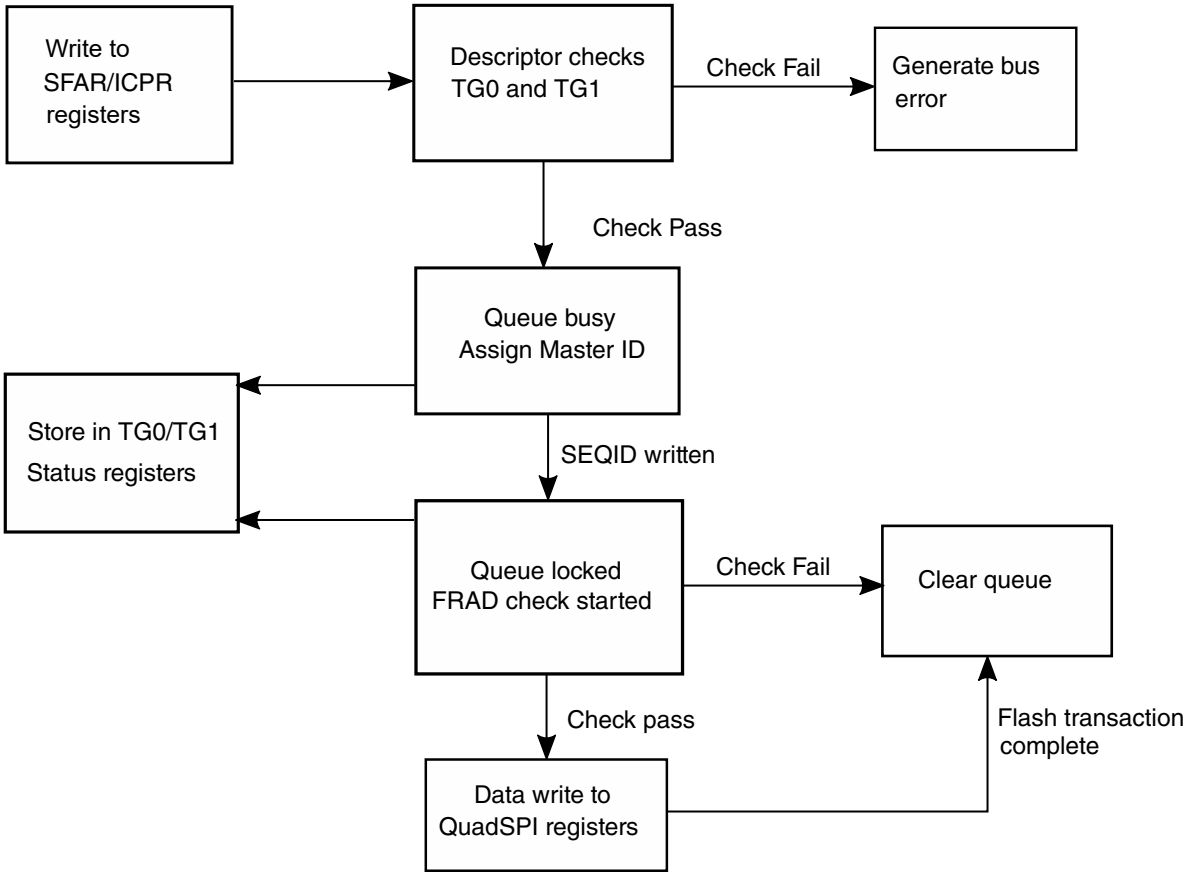

Figure 480. Data path for input IPS write to QuadSPI SFAR or IPCR registers

If the SFAR write passes first level of MDAD checks then the value is written in SFP register TG*n*SFAR and valid bit is set in TG*n*SFARS register and queue is considered as busy. Similarly when ICPR write passes the checks, its value is written into TG*n*IPRCS register and TG*n*IPRCS[VLD] field is set to 1 and queue is considered as locked. It is mandatory that IPCR is written only after SFAR has been written for a queue and queue is busy. If IPCR is written before SFAR then it will result in IPS transfer error. Master should ensure that it completes the programming sequence for flash access request (write SFAR and IPCR with SEQID) so that target queue is not left after writing SFAR or IPCR without the SEQID. Both queues TG0 and TG1 are processed in round robin arbitration. The queue receiving the data first is processed first and next queue is processed after the first transfer completes.

NOTE

TBDR register write is not allowed until the SFAR and IPCR entries of that master has passed MDAD and FRAD checks and the transaction is queued for writing to QuadSPI. If TBDR registers are written before arbitration win, transfer error will be generated. IPS master can read FSMSTAT register to check the status of their transaction. TBDR access is allowed when FSMSTAT[VLD] field is set and for the master whose master ID matches with fields [11:8] of this register, and field [1:0] are set to 01 or 10. IPCR and SFAR registers are forwarded to QuadSPI only after the TX buffer is filled till watermark level in case of write transactions. IPCR should be written only after SFAR has been written successfully to a queue.

77.12.1.2 Error conditions

The error conditions for first level of MDAD checks and the response is given in table below. These error conditions can occur when SFAR, IPCR or TBDR registers are being written.

NOTE

Queue is considered busy if it has been written successfully once with any of the values SFAR, IDATSZ or PAR.
Queue is considered locked when SEQID has been written successfully by passing MDAD checks.

Table 665. MDAD check error conditions

Error condition	Response	Common/Queue error
None of the queue descriptors are programmed	IPS transfer error is generated	Common error
Both queues are locked	IPS transfer error is generated	Common error
Both queues are busy and another master writes whose master ID is not matching with either queue.	IPS transfer error is generated.	Common error
Queue busy and same master writes SFAR or IPCR registers with wrong security attribute	IPS transfer error is generated and queue is cleared (SFAR and IPCR needs to be written again for transfer to start).	Queue error
Queue is locked and same master writes	IPS transfer error is generated	Common error
If master ID of transaction doesn't qualify MID check of any of the queues	IPS transfer error is generated	Common error
If both the queues are empty and security attribute of transaction doesn't match with any of the queues	IPS transfer error is generated	Common error
TBDR register is written before SFAR and IPCR SEQID qualifies MDAD checks	IPS transfer error is generated	-
If none of FRAD descriptors are programmed	IPS transfer error is generated	Common error
IPCR is written before SFAR	IPS transfer error is generated	Common Error - If the transaction doesn't matches the security attribute check or MID check of any MDAD. No common or queue error - If it matches security and MID attribute of any queue.

When a common error is generated its details are latched in IPSERROR register and corresponding error field is set to 1. This register will tell if the transaction failed because of queue locked, MID mismatch or security failure along with the master ID of that transaction. This register will keep the last error transaction latched unless cleared by writing 1 to CLR bit of this register. Then from next cycle onwards this register can latch new errors. Common error will also be generated if none of the FRAD descriptors are programmed. In case a queue is busy and same master writes IPCR or SFAR with wrong security attributes the queue is cleared, the Target Group n SFAR Status (TG0SFARS - TG1SFARS) valid bit goes low. In this case the master should write the SFAR an IPCR again for proper transaction to start.

In case of queue error the details are latched in Target Group n IPCR Status (TG0IPCRS - TG1IPCRS) or Target Group n SFAR Status (TG0SFARS - TG1SFARS) registers. These registers will also keep the error status latched until cleared by writing 1 to CLR bit of respective registers.

77.12.2 FRAD

These descriptors form the second level check for IPS flash write and flash erase transactions. IPS read transaction are not processed by this level of check and are passed through after MDAD checks. There are 8 FRADs which can be programmed by privilege masters. So the access checks can be programmed for up to 8 unique address ranges. Each of the address range

is equipped with different access attribute checks and based on this write access can be controlled for the flash region. These descriptors must be programmed before starting transactions on flash.

After programming the FRAD*n*_WORD0, FRAD*n*_WORD1, FRAD*n*_WORD2 and FRAD*n*_WORD3 registers, FRAD*n*_WORD3[VLD] field should be written 1. SFP block doesn't consider the FRAD descriptors which are not valid. If none of the FRAD are programmed, then error interrupt will be generated if enabled, and transaction is not forwarded to QuadSPI.

There is a descriptor lock feature to prevent spurious changes to the FRAD. FRAD*n*_WORD3[LOCK] can be programmed to make all FRAD registers as read only or to allow write access to all or some masters with specific master ID.

77.12.2.1 FRAD checks

- Address range checks – Start and end address for FRAD region are programmed in FRAD*n*_WORD0 and FRAD*n*_WORD1 registers. Start address of IPS flash transaction written in SFAR register and data size programmed in IPCR register, is used to check if the transaction lies within any of the FRAD address ranges. This address range match will be used to select the corresponding FRAD from which other access checks will be done. The start and end address are programmed around 64 KB boundary so 16 MSB are only used for range check..

  The data size should not be programmed as 0 in IPCR register for normal data transfers to flash and actual size should be programmed. In the cases where only flash instruction has to be send and no data has to be written in TBDR register, this DATSZ can be programmed as 0. In case the DATSZ is programmed as 0 in IPCR, SFP module blocks the write access to TBDR register and if any write is done then that generates IPS transfer error.

- Exclusive access lock – Exclusive master access lock can be enabled over any flash address defined under a FRAD. The master ID of the master which enables/owns the exclusive access is captured in FRAD*n*_WORD2[EALO] fields. Once enabled, the exclusive lock can be released only by the same master which enabled the lock by writing on FRAD*n*_WORD3[EAL] fields. The exclusive write access permissions of a flash region are decided as given in table below:

Table 666. Exclusive access lock

FRAD*n*_WORD3[EAL]	Write permissions
00	No lock. The write permissions are decided as set in FRAD*n*_WORD2[MDnACP] fields for respective master domain.
10	Write permissions are revoked for all masters. Any write transaction coming to this flash address region will not be forwarded through and will result in an error.
11	Write permissions are revoked for all masters except the master ID matching the ID specified by FRAD*n*_WORD2[EALO] fields.

- Flash region privilege checks – If the FRAD*n*_WORD3[EAL] fields are set to 00 then flash write access permissions for any IPS master is decided based on the settings done in FRAD*n*_WORD2[MDnACP] fields as given in table below. MD0ACP permission checks are done for transaction coming through target group 0 queue (TG0) and MD1ACP permission checks are for transactions coming through target group 1 queue (TG1).

Table 667. Flash region privilege checks

MDxACP value	Privilege access	Secure access	Write access
111	No	No	Not allowed
	No	Yes	Not allowed
	Yes	No	Allowed
	Yes	Yes	Allowed
110	No	No	Allowed
	No	Yes	Allowed

Table continues on the next page...

Table 667. Flash region privilege checks (continued)

MDxACP value	Privilege access	Secure access	Write access
	Yes	No	Allowed
	Yes	Yes	Allowed
101	No	No	Not allowed
	No	Yes	Not allowed
	Yes	No	Not allowed
	Yes	Yes	Allowed
100	No	No	Not allowed
	No	Yes	Allowed
	Yes	No	Not allowed
	Yes	Yes	Allowed
0xx	-	-	Not allowed

If any transaction fails FRAD check then error interrupt is generated if enabled.

FRAD status registers keep the details of last transaction which lie within the address range of that respective FRAD and will be updated only when a new transaction comes which falls within the same address range.

Flash Region Compare Address Status (FRAD0_WORD4 - FRAD7_WORD4) register stores the flash start address that was compared and Flash Region Compare Status Data (FRAD0_WORD5 - FRAD7_WORD5) contains the master ID, privilege and secure attributes of the transaction. The transaction details are stored in FRAD register for which the address compare check passed. These status registers are not updated in case of read transfers or when FRAD check is disabled. For example, if the transaction address lies in the range set in FRAD2_WORD0 and FRAD2_WORD1 then the transaction details will be stored in FRAD2_WORD4 and FRAD2_WORD5 registers and valid field [30] will be set. If transaction fails, the security or privilege attribute check for the corresponding FRAD then error field [29] is set in FRADx_WORD5 status register. This bit and other transaction details will remain latched unless cleared by writing '1' to W1C bit of corresponding FRAD in ERRSTAT register.

If transaction address doesn't match any of the FRAD address range or if matches with multiple FRAD address ranges, then also error interrupt is generated but the details will not be stored in any of the FRAD status registers.

FRAD checks are done only for flash write transactions, flash read transactions are passed through to QuadSPI if MDAD checks are passed. At least one FRAD region should be made valid (if the FRAD check is enabled from MGC register) for flash read instructions to go through even when FRAD check is not done for read instructions. SFP module checks if a transaction is read or write from the SEQID written in IPCR register and LUT table programmed inside QuadSPI. Master Read Command (MRC) register shows the read command code which SFP block identifies. There are two command codes which are predefined READ_DDR and READ commands. Software can program two other command code as per its convenience by writing into fields [21:16] or [29:24] and then writing respective valid bit as 1.

77.12.2.2 Error conditions

Any transaction passing the MDAD checks will be checked for FRAD checks and can lead to following error scenarios.

Table 668. Error conditions

Error condition	Response
None of the FRAD are programmed	IPS transfer error will be generated and status will be latched in IPS_ERROR register

Table continues on the next page...

Table 668. Error conditions (continued)

Error condition	Response
Transaction address doesn't fall within any of the FRAD address range	Error interrupt will be generated if enabled
Transaction match with multiple FRAD address range	Error interrupt will be generated if enabled. Error bit will be set, and status will be stored in FRADx_WORD5 status registers for whom the address check passed
Transaction passes FRAD address check but fails privilege or security checks	Error interrupt will be generated if enabled. Error bit will be set, and status will be stored in FRADx_WORD5 status registers for whom the address check passed
Transaction passes FRAD address check but range was locked by EAL bits	Error interrupt will be generated if enabled. Error bit will be set, and status will be stored in FRADx_WORD5 status registers for whom the address check passed
Read transaction	No FRAD check will be done and no error will be generated for FRAD failure. But if FRAD check is enabled in MGC then at least one FRAD should be valid else it will give error during SFAR/IPCR write

77.12.2.3 Atomic commands considerations

For security reasons, the atomic commands (where flash's internal configuration region is accessed) like flash erase etc. should always be programmed in last 6 SEQID locations of LUT. FRAD0 has access to all the LUT locations including these last 6 SEQID. Remaining FRAD regions will not allow write access if the IPCR SEQID is set for any of the last 6 locations of LUT. It will result in FRAD access error and it will set in FRAD status registers. Also the software must set the FRAD0 MDACP to 101 so that write access is allowed only for secure privilege masters. This is done to ensure that no other master can use the atomic commands like flash erase to change the contents of flash. So when any master wants to use these atomic command programmed in last 6 locations of LUT it will have to write FRAD0 start address in SFAR and keep IPCR DATSZ such that it falls under FRAD0 address region and MDACP programmed in FRAD0 are checked.

For flash configuration in case of dual-die the software needs to change the address range of FRAD0 accordingly so that address goes to second die. Similar consideration to be taken in case of dual flash where Port A and B are being used.

77.12.3 TBDR register write lock

SFP module keeps the TBDR write locked for IPS transactions by default. When a IPS master writes SFAR and IPCR transactions and this transaction passes MDAD and FRAD checks then the accesses are unlocked for that master ID. Lock and unlock procedure is shown with an example in figure below:

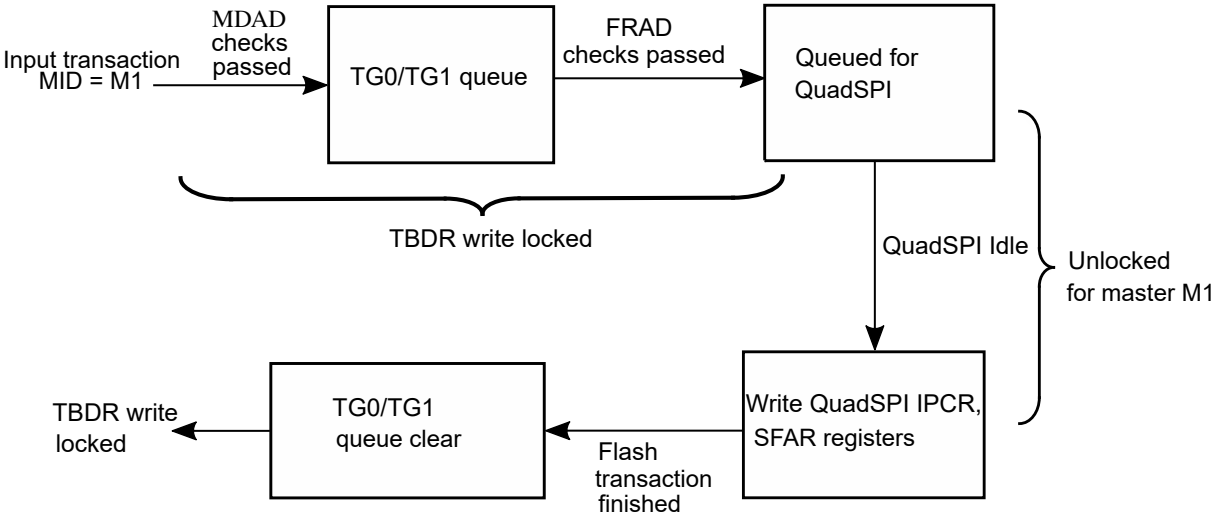

Figure 481. TBDR lock and unlock procedure

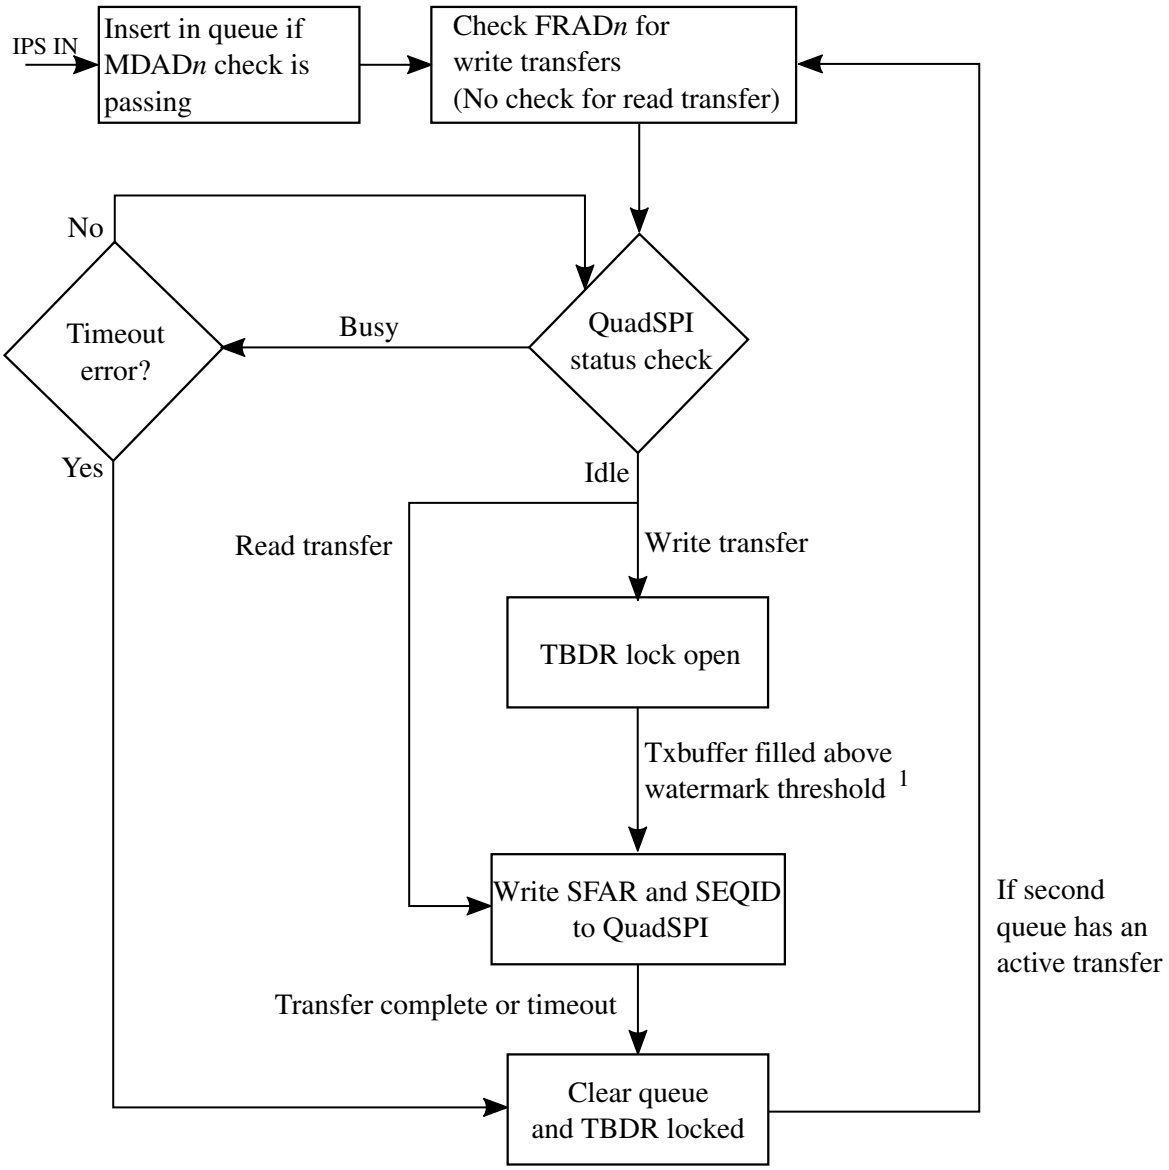
If any master writes on TBDR register when it is not unlocked for that master ID it will result in IPS transfer error. IPS master should ensure that it writes the TBDR register once QuadSPI registers have been written by the SFP module. This can be checked by reading FSM Status (FSMSTAT). Bits [11:8] of this register tells which master ID is currently active, and if the value of bits [1:0] is 01 or 10 and bit 31 is set as 1, then the TBDR lock is open for write transactions. It is advisable that for write transactions where IDATSZ is non zero, master clears the TBDR buffer from any residue data and program the TBCT[WMRK] watermark once its request is granted in arbitration (FSMSTAT bit [1:0] are 01). In case of transfers having IDATSZ programmed as 0 the TBDR register remains locked and data can't be written to this register. In case DMA is being used to fill the TBDR buffer, program RSER[TBFDE] field to 1 only when write access is granted and TBDR access is unlocked after checking FSMSTAT[STATE] field. Once DMA completes the TBDR write reset, this field is set back to 0. After this, the SFP will write SFAR and IPCR to QuadSPI triggering the flash transfer. It should be made sure that the DMA should have same master ID as the master which won the arbitration.

77.12.4 Transaction status registers

SFP module has two registers (FSM Status (FSMSTAT) and FlashSeq Request (FLSEQREQ)) which shows the current and last transaction status. These registers are updated only after MDAD and FRAD check are passed.

- FSM Status (FSMSTAT) register shows the current transaction which is queued for QuadSPI when valid field [31] is set. Field [16] of this register if set to 1 then it is a non-read instruction sequence and it is set to 0 then it means that this is a read sequence. Fields [11:8] show the master ID from which this transaction is generated. Fields [1:0] show the current state of active transaction when valid field [31] is set.

  The figure below shows the IPS transaction flow inside SFP block along with various values of bits [1:0]:



Note:
1. If the DATSZ programmed in TG0/TG1 IPCR register is more than the TX buffer watermark threshold value (256- Watermark programmed in TBCT) then it waits for threshold to cross before writing the SFAR and IPCR registers to QuadSPI. Else SFP block waits for one entry to be written to TBDR register and after that it writes the SFAR and IPCR to QuadSPI thus triggering the transfer. In case of read transfers, SFAR and IPCR are written as soon as QSPI is IDLE.

Figure 482. Transaction status

FSM state values in FSM Status (FSMSTAT) for different states are in the following table:

Table 669. FSMSTAT register field details

FSMSTAT register fields	
VLD	0 - No IPS transfer is queued for launch to QuadSPI 1 - IPS transfer is queued or running in QuadSPI
STAT	00 - QuadSPI is busy with AHB transfer, any DMA transfer is pending, RDBFL has residue data or any interrupt is pending. 01 - TBDR lock is open. QuadSPI considers IPS transfer. AHB transfer should not start. 10 - TX buffer filled above threshold. Write transfer is triggered. SEQID is written. 11 - Read transfer is triggered. SEQID is written.

For flash write transfers which passes MDAD and FRAD checks and QuadSPI is not busy with any previous transfer, TBDR lock is opened and bits [1:0] shows value of 01. Once the IPS master fills the TX buffer till the level where free entires in TX buffer are less than the watermark threshold set in TX Buffer Control Register (TBCT) and SR[TXWA] flag is de-asserted, SFP block writes the SFAR and IPCR entries to QuadSPI registers and transaction is triggered. To avoid underrun, program the watermark accordingly for size of the data to be transferred. This programming can be done when TBDR access is allowed after arbitration is granted. TBCT Watermark can be programmed as 256-(IDATSZ/4-1) in most of the scenarios. If the DATSZ entry written in IPCR is less such that TX buffer can never be filled till watermark threshold, in such cases SFP block does not wait for the TBCT[WMRK] to trigger and writes the SFAR and ICPR registers as soon as one data entry is written to TBDR register. When the SFAR and IPCR register are written, bits [1:0] are set to 10. In case of flash memory read transfers SFAR and IPCR entries are written to QuadSPI as soon as QuadSPI is IDLE and bits [1:0] are set to 11. QuadSPI is considered IDLE only if no AHB/IPS transfer is ongoing, any DMA transfer is not pending, RDBFL doesn't have residue data and any interrupt is not pending. Valid bit [31] goes to 0 once the IPS transfer is completed. IPS master should clear the TX buffer before writing to TBDR register to ensure that no data from previous transaction is left in TX buffer.

If the IPS transaction has passed the MDAD and FRAD checks but QuadSPI is busy with some AHB transfer, then the bits [1:0] are set to 00. Other than ongoing AHB transfer QuadSPI can be busy because of other reasons also like if any TXDMA or RXDMA pending, if read buffer has data pending or if any QuadSPI interrupt is enabled and pending for servicing. So IPS master should ensure that no interrupt is pending or previous read transfer is completed. If the QuadSPI remains busy for a longer time it may result in timeout error.

Software must take care that no AHB transaction is launched when any IPS transactionis ongoing, TBDR lock is open or IPS transaction is getting executed on QuadSPI. It can be checked by reading this FSM status register. if the valid bit is 1 and bits [1:0] are set to 01, 10 or 11 then no AHB transfer should be generated towards QuadSPI.

For any IPS initiated RW transaction which needs two separate transactions at flash interface, like Write-Enable transaction followed by Write-data transaction (Data-Learn flash transaction followed by Read-data transaction) at flash interface must be joined together with JMP_2_SEQ instruction.

- FlashSeq Request (FLSEQREQ) register holds the details of transaction which was last send to QuadSPI. After a flash transaction is completed this register is updated and its valid field [31] is set to 1. This register holds the command type (read or write), transaction master ID (fields [3:0]), target group queue (TG0 or TG1) from which this transaction passed in field [4], privilege and secure attributes for the transaction, SEQID (fields [19:16]) and number of flash descriptor FRAD within whose address range the transaction lies (fields [14:12]).

  This register also contains a timeout error field [27] which is set when a timeout error occurs, and transaction is aborted. When the error occurs this register keeps the status latched unless it is cleared by writing 1 to clear field [29].

77.12.5 Timeout error

MTO register can be programmed with a timeout value above which the transaction should be aborted. When the transaction passes MDAD and FRAD level checks and QuadSPI is idle (no AHB transaction is ongoing, no DMA transfer is pending, RDBFL doesn't have any residue data from last transfer and any interrupt is not pending) this counter is started. If the transaction is not

completed before this timeout counter reaches the value programmed in MTO register the transaction is considered aborted by SFP and an error interrupt is generated if enabled. The error bit is also set in FLSEQREQ register along with the transaction details. After the timeout error, next transaction is written to QuadSPI register which was queued in another target group queue once SR[BUSY] flag goes low.

77.12.6 Arbitration lock

The arbitration lock feature is used to lock the arbitration for a particular queue. This lock can be requested by a master by writing '1' into IPCR[ARB_LOCK] field. Once the transaction passes both the checks (MDAD & FRAD) and wins the arbitration, this lock will be granted. After this, the transaction from the other queue will not be granted unless the arbitration is unlocked by previous queue. The master which locked the arbitration can unlock it by writing '1' to IPCR[ARB_UNLOCK] field. Once the transaction with unlock bit 1 passes the MDAD and FRAD checks, it will unlock the arbitration. After this transaction is finished, the other queue will be granted the arbitration which was waiting.

This arbitration lock feature can be used by software while doing any transaction to flash which may result in a waiting period. For example, in case of NOR flash, after a write is issued to flash there is a waiting period (TPP) for which the flash is inaccessible. In this case, the software should ensure that while writing this SEQID to IPCR register it should lock the arbitration so that transaction coming to other queue is not passed to flash controller which may result in failure. Once the software ensures that waiting period at flash is over, it can read the flash configuration/status registers to confirm. And after getting confirmation, it can send another read command to same configuration register with IPCR[ARB_UNLOCK] field set to '1'. This will ensure that the transaction waiting in another queue are granted. If the flash being used does not have a waiting period attached with transactions, then this ARB_LOCK field can be always kept to 0.

In case software uses this LOCK functionality RWW support will not be available. Because in this case, all the transaction from other queue which was blocked from arbitration will be blocked irrespective of read or write access. So, RWW support (read can go through even when flash is in waiting state) will not be available. The master which has arbitration lock granted can still send read accesses to flash during the waiting period in case the flash supports it.

77.12.7 Soft reset consideration with SFP

In case the soft reset is being used for QSPI, software should take some considerations so that correct functionality is maintained. if the soft reset is asserted when a transaction is being executed by SFP (FSM_STATE [1:0] bits are 01, 10 or 11) then this transaction will be aborted. Different conditions that can occur in case of soft reset are listed in table below:

Table 670. Soft reset conditions

Condition at time of soft reset	FSM state register at time of soft reset	Result	Timeout scenario
Some AHB transaction was ongoing and SFP/IPS is in waiting state.	FSM_STATE[1:0] = 00	After the soft reset if de-asserted the SFP will schedule its transaction over QSPI. FSM_STATE[1:0] will change to other values than 00. Software can fill TBDR in case it is a write transfer or start reading from RBDR.	In this case software doesn’t writes to TBDR or read from RBDR it will result in timeout error.
QSPI was IDLE and SFP transaction has been arbitrated. TBDR is being filled and SFAR, IPCR are not currently written to QSPI.	FSM_STATE[1:0] = 01	Currently TBDR was being filled after soft reset all the entries in TBDR are flushed. So it is expected from software that it will start filling TBDR from start after the reset has de-asserted. SFP will write SFAR and IPCR to QSPI once its normal conditions are met (when number of available spaces in the TX buffer is greater than or equal to the value provided by TBCT[WMRK] or single TBDR write in case watermark check is disabled)	Timeout will occur if TBDR is not filled again after the soft reset is lifted.

Table continues on the next page...

Table 670. Soft reset conditions (continued)

Condition at time of soft reset	FSM state register at time of soft reset	Result	Timeout scenario
SFP has written just SFAR to QSPI IPCR is not written yet. (For a read transfer or write transfer with data size 0)	FSM_STATE[1:0] = 01	After the soft reset is lifted the SFP will write ICPR to QSPI module and FSM_STATE will change to 11 (read) or 10(write). Transaction will finish normally.	Timeout conditions will be same as that for normal transfer.
SFP has written just SFAR to QSPI IPCR is not written yet. (Write data size is non 0)	FSM_STATE[1:0] = 01	After soft reset is lifted the SFP will write IPCR to QSPI module once software fill TBDR (from start) and FSM_STATE will change to 10.	Timeout conditions will be same as that for normal transfer.
SFP has written SFAR and IPCR to QSPI.	FSM_STATE[1:0] = 10 or 11	After the soft reset is de-asserted the current transaction will be deemed aborted. FSM_STATE valid will go low as transfer has finished.	No timeout.

So to conclude in case the soft reset is asserted when FSM_STATE[31] bit is 1 and state bits are 10 or 11 current transaction will be aborted & the next transaction will proceed as normal. In case the state bits are 00 or 11 then it is advisable that software doesn't writes into TBDR after the reset is de-asserted and waits for timeout error to be generated to know when current ongoing SFP transaction is aborted. After clearing the timeout error a new transaction can be launched to SFP or if already a new transaction is present in another queue it will be arbitrated.

77.12.8 Error Interrupt Enable

INT_EN register allow software to disable or enable the interrupt signal generation in case of any of the listed error conditions. This interrupt is generated on 'ipi_int_ored' interface signal of QuadSPI.

- Time out error (INT_EN[TO_ERR])
- IPCR register write error (INT_EN[TG*n*IPCR])
- SFAR register write error (INT_EN[TG*n*SFAR])
- IPS common error (INT_EN[IPS_ERR])
- FRAD access error (INT_EN[FRAD*n*ACC])
- No FRAD address range match error (INT_EN[FRADMTCH])

If the respective field is set to 1 for any of the error conditions, then the interrupt signal is set to 1 when that error occurs and it remains set until the error is cleared by writing 1 to error clear bit as listed in register descriptions.

77.13 Memory map and register definition

This section provides the memory map and register definitions for the QuadSPI module.

77.13.1 Register write access

Following are the write access restriction terms that apply to all the registers:

- Register write access restriction

  For each register field, the write access conditions are specified in the detailed register description.

  The following table provides a description of the write access conditions. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 671. Register write access restrictions

Condition	Description
Anytime	No write access restriction
Disabled mode	Write access only if MCR[MDIS] = 1
Normal mode	Write access only if the module is in the normal mode

- Register write access requirements

  You can access all registers using 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16-bit or 32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each affected register.

77.13.2 QuadSPI register descriptions

This section provides the memory map and register definitions for the QuadSPI module.

Access to the following addresses does not result in a transfer error:

- 4h
- 64h
- 104h
- 138h
- 168h
- 188h
- 18Ch

77.13.2.1 QuadSPI memory map

77.13.2.2 Module Configuration Register (MCR)

Offset

Register	Offset
MCR	0h

Function

This register holds configuration data associated with the QuadSPI operation.

Special write-access is permitted in different modes:

- DQS_FA_SEL: Disabled mode
- ISD3FA, ISD2FA: Disabled mode
- All other fields: Anytime

Diagram

17 ISD3FA	Idle signal drive IOFA[3] flash memory A Determines the logic level that the IOFA[3] output of the QuadSPI module is driven to in the inactive state. See Driving flash memory control signals in single and dual modes for details. 0b - IOFA[3] is driven to logic L 1b - IOFA[3] is driven to logic H
16 ISD2FA	Idle signal drive IOFA[2] flash memory A Determines the logic level that the IOFA[2] output of the QuadSPI module is driven to in the inactive state. See Driving flash memory control signals in single and dual modes for details.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - IOFA[2] is driven to logic L. 1b - IOFA[2] is driven to logic H.
15 —	Reserved
14 MDIS	Module disable Allows the clock to the non-memory mapped logic in the QuadSPI to be stopped. 0b - Enable QuadSPI clocks 1b - Allow external logic to disable QuadSPI clocks
13 —	Reserved
12 DLPEN	Data learning pattern enable Write 1 to this field to enable data learning mechanism.
11 CLR_TXF	Clear TX FIFO/buffer This is a self-clearing field that invalidates the TX buffer content. **NOTE** Software must wait for at least five system cycles and three flash cycles after writing '1' to this field. 0b - No action 1b - Read and write pointers of the TX buffer are reset to 0 and TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO This is a self-clearing field that invalidates the RX buffer content. 0b - No action 1b - Read and write pointers of the RX buffer are reset to 0 and RBSR[RDBFL] is reset to 0.
9 —	Reserved
8 VAR_LAT_EN	Variable latency Is used to enable the variable latency feature in the controller. This field is valid for HyperRAM where data strobe acts as an output from the memory during the command and address (CA) cycles of a read or write transaction. This is to indicate whether additional initial access latency is needed to perform a dynamic memory refresh operation. For details, see HyperRAM support. 0b - Fixed latency: Twice + 1 latency enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Variable latency: "Once" or "twice + 1" the initial latency based on data strobe during the CA phase. If enabled, you need to ensure that the value of FLSHCR[TCSS] is >= 2.
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 DQS_OUT_EN	DQS as an output Is valid when data strobe is also used as an output from controller during the write data phase. This is valid for HyperRAM where the data strobe acts as a Read Write Data Strobe (RWDS). For details, see HyperRAM support. 0b - DQS as an output from controller is disabled. 1b - DQS as an output from controller is enabled.
3-2 —	Reserved
1 SWRSTHD	Software reset for AHB domain 0b - De-assert Software reset 1b - AHB domain flops are reset. This field does not reset configuration registers. It is advisable to reset both the serial flash memory domain and AHB domain at the same time. Resetting only one domain might lead to side effects. **NOTE** The software resets need the clock to be running to propagate to the design. The value of MCR[MDIS] should be 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTHD] to 0), it is recommended to set the value of MCR[MDIS] to 1. After the software resets have been deasserted, the normal operation can be started by setting MCR[MDIS] to 0. **NOTE** Software must wait for at least three system cycles and three flash cycles after changing the value of this field.
0 SWRSTSD	Software reset for serial flash memory domain 0b - De-assert Software reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Serial flash memory domain flops are reset. This field does not reset configuration registers. It is advisable to reset both the serial flash memory domain and AHB domain at the same time. Resetting only one domain might lead to side effects. **NOTE** The software resets need the clock to be running to propagate to the design. The value of MCR[MDIS] should therefore be 0 when the software reset bits are asserted. Also, before they can be deasserted again (by specifying 0 as the value for MCR[SWRSTSD]), it is recommended to specify 1 as the value for MCR[MDIS]. After the software resets are deasserted, the normal operation can be started by specifying 0 as the value for MCR[MDIS]. **NOTE** Software must wait for at least three system cycles and three flash cycles after changing the value of this field.

77.13.2.3 IP Configuration Register (IPCR)

Offset

Register	Offset
IPCR	8h

Function

This register provides all the configuration required for an IP-initiated command, which can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash memory is initiated per the sequence pointed to by this field. See Normal mode for details on command triggering and command execution.

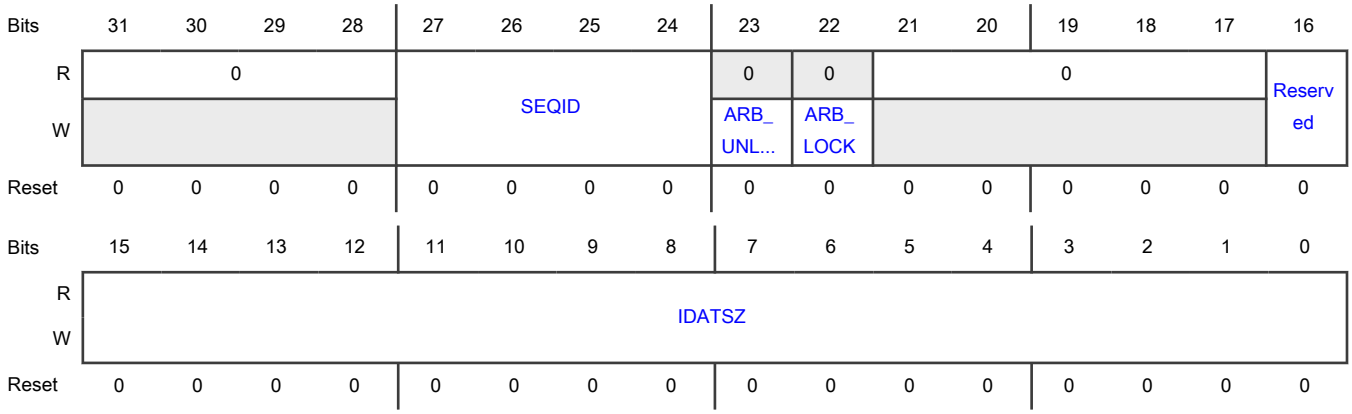
Special write-access is permitted if:

- SR[IP_ACC]=0

NOTE

Only one of the fields should be written '1' at a time out of ARB_LOCK and ARB_UNLOCK. If both the fields are written '1' at same time then it will invert the lock status. If the arbitration was already locked, it will unlock it and vice-versa.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 SEQID	Points to a sequence in the LUT This field contains the sequence index of the LUT. See LUT for details. Each sequence index can accommodate up to 10 instructions (2 instructions per register). A write to this field triggers a transaction on the serial flash memory interface.
23 ARB_UNLOCK	Arbitration Unlock Writing 1 to this bit unlocks the arbitration. Writing 0 will have no effect. The arbitration unlock will be done only if the transaction passes both MDAD and FRAD checks. To lock the arbitration write 1 to ARB_LOCK bit. This bit is always read as 0.
22 ARB_LOCK	Arbitration Lock Writing 1 to this bit locks the arbitration for that specific target queue. Writing 0 will have no effect. The arbitration lock will be granted only if the transaction passes both MDAD and FRAD checks. To unlock the arbitration write 1 to ARB_UNLOCK bit. This bit is always read as 0.
21-17 —	Reserved
16 —	Reserved
15-0 IDATSZ	IP data transfer size This field defines the data transfer size, in bytes, of the IP command.

77.13.2.4 Flash Memory Configuration Register (FLSHCR)

Offset

Register	Offset
FLSHCR	Ch

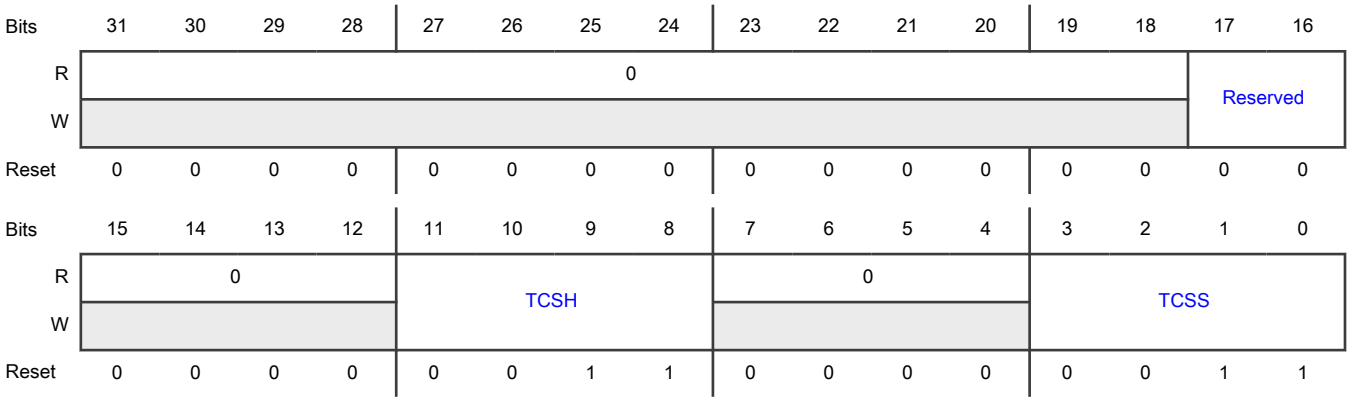
Function

This register contains the timings that are specific to the flash memory device. The QuadSPI controller must meet these timings for the device to function correctly.

Special write-access is permitted if:

- SR[AHB_ACC] = 0
- SR[IP_ACC] = 0

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 —	Reserved
15-12 —	Reserved
11-8 TCSH	Serial flash memory CS hold time This hold time is in terms of serial flash memory clock cycles, and it must be greater than or equal to five flash memory clock cycles. Refer the chip Datasheet for the exact value.
7-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
3-0 TCSS	Serial flash memory CS setup time This setup time is in terms of serial flash memory clock cycles, and it must be greater than or equal to two flash memory clock cycles. Refer the chip Datasheet for the exact value.

77.13.2.5 Buffer 0 Configuration Register (BUF0CR)

Offset

Register	Offset
BUF0CR	10h

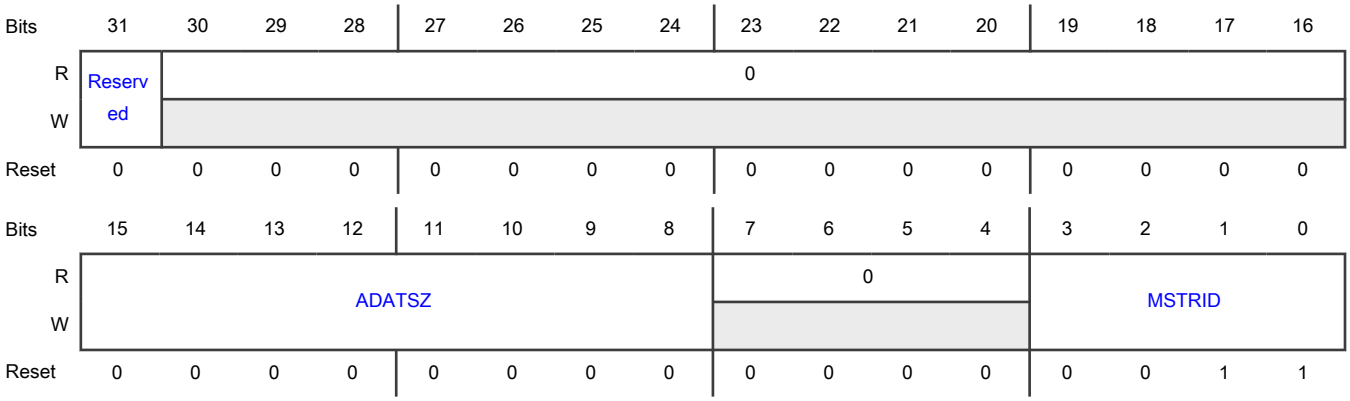
Function

This register provides the configuration for any read access routed to buffer0, which happens when the master ID of the incoming AHB request matches BUF0CR[MSTRID]. Any buffer "miss" leads to a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31 —	Reserved
30-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-8 ADATSZ	AHB data transfer size Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of the buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 0 Any AHB read access with this master ID is routed to this buffer. You must ensure that the master IDs associated with all buffers are different. **NOTE** See the "Chip-specific SMPU information" section in this document for the master IDs and their corresponding components.

77.13.2.6 Buffer 1 Configuration Register (BUF1CR)

Offset

Register	Offset
BUF1CR	14h

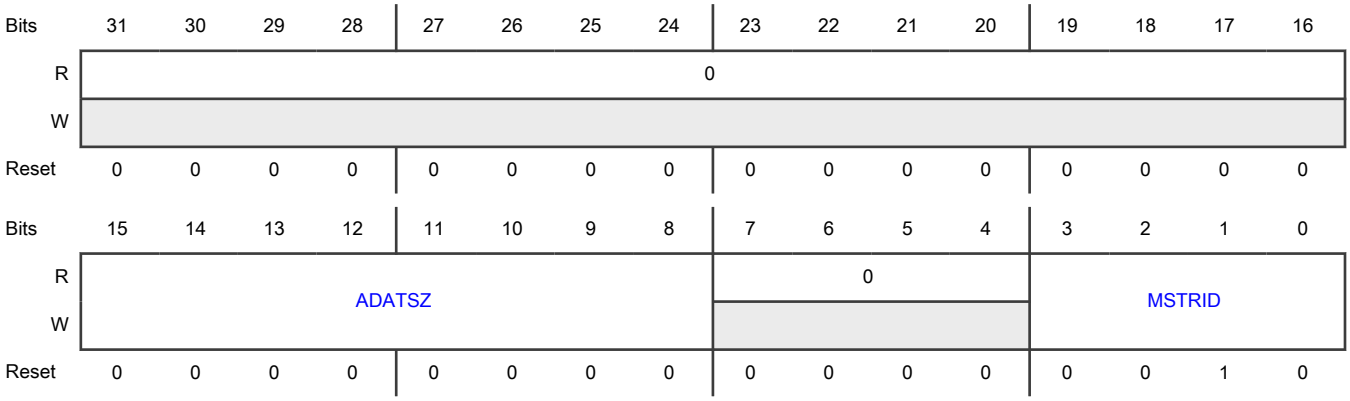
Function

This register provides the configuration for any access routed to buffer 1, which happens when the master ID of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 ADATSZ	AHB data transfer size This field defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets the transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 1 Any AHB read access with this master ID is routed to this buffer. You must ensure that the master IDs associated with all buffers are different. **NOTE** See the "Chip-specific SMPU information" section in this document for the master IDs and their corresponding components.

77.13.2.7 Buffer 2 Configuration Register (BUF2CR)

Offset

Register	Offset
BUF2CR	18h

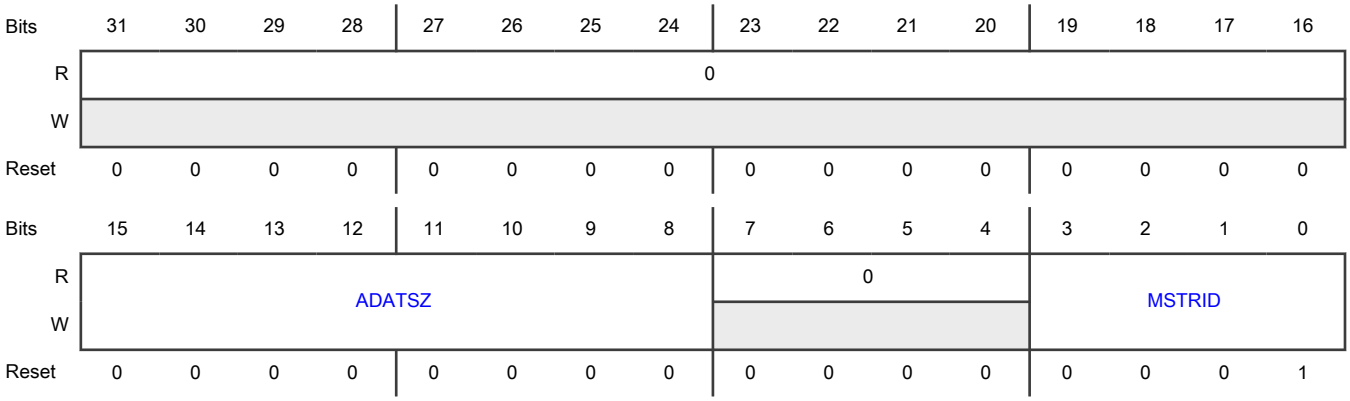
Function

This register provides the configuration for any access routed to buffer 2, which happens when the master ID of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 ADATSZ	AHB data transfer size This field defines the read data transfer size in 8 bytes of an AHB triggered read access to the serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID The ID of the AHB master associated with BUFFER2. Any AHB read access with this master ID is routed to this buffer. It must be ensured that the master IDs associated with all buffers are different. **NOTE** See the "Chip-specific SMPU information" section in this document for the master IDs and their corresponding components.

77.13.2.8 Buffer 3 Configuration Register (BUF3CR)

Offset

Register	Offset
BUF3CR	1Ch

Function

This register provides the configuration for any access to buffer 3.

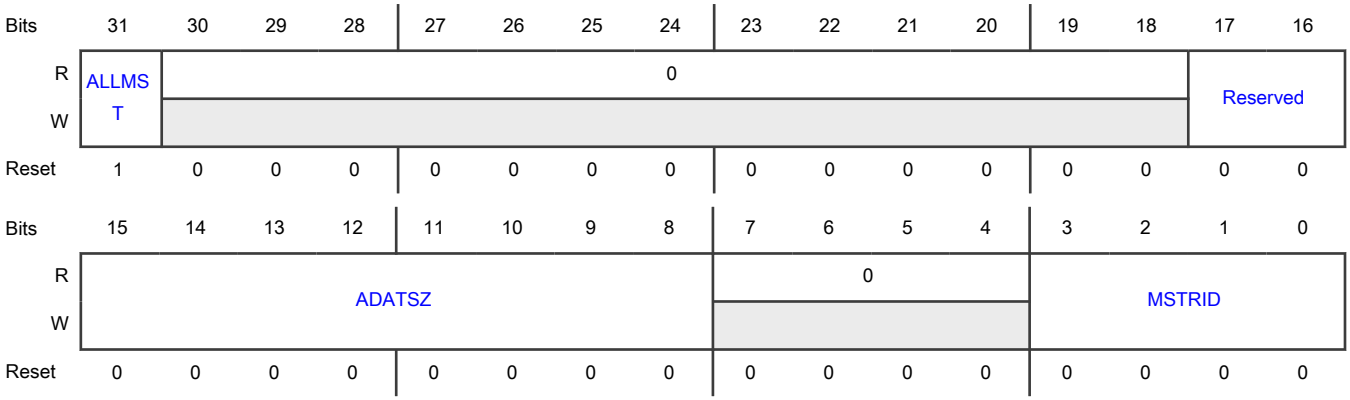
An access is routed to buffer 3 when the master ID of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

In case the value of the ALLMST field is not 1, any such transaction (where master ID does not match any of the MSTRID fields) is returned with an ERROR response.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31 ALLMST	All master enable When set, buffer3 acts as an all-master buffer. Any AHB access with a master ID not matching with the master ID of buffer0, buffer1, or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30-18 —	Reserved
17-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 ADATSZ	AHB data transfer size Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value.
7-4 —	Reserved
3-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 3. Any AHB read access with this master ID is routed to this buffer. You must ensure that the master IDs associated with all buffers are different. **NOTE** See the "Chip-specific SMPU information" section in this document for the master IDs and their corresponding components.

77.13.2.9 Buffer Generic Configuration Register (BFGENCR)

Offset

Register	Offset
BFGENCR	20h

Function

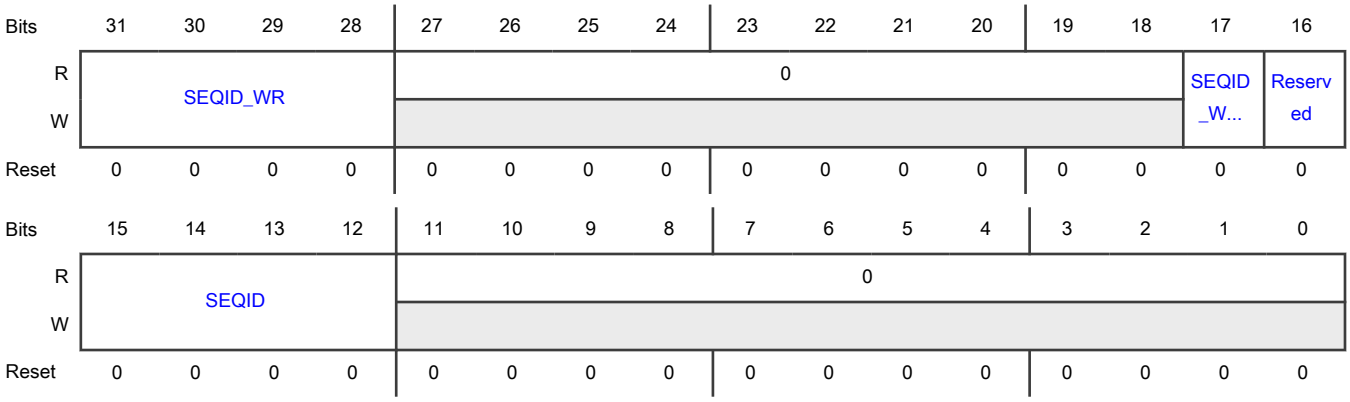
This register provides generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by the SEQID field.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

This register is access controlled and can only be programmed by privilege masters.

Diagram



Fields

Field	Function
31-28 SEQID_WR	Write Sequence ID This field points to write seq-id of LUT and would be selected in case of AHB write transaction, if SEQID_WR_EN==1.
27-18 —	Reserved
17 SEQID_WR_EN	Enable Write Sequence ID
16 —	Reserved
15-12 SEQID	Points to a sequence in the LUT. This field contains the sequence index of the LUT. and would be selected in case of AHB read transaction (and AHB write transactions if SEQID_WR_EN==0).. See LUT. **NOTE** If the sequence pointer differs in the new and the previous sequences, you should reset it. See sequence pointer clear register for more information.
11-0 —	Reserved

77.13.2.10 SOC Configuration Register (SOCCR)

Offset

Register	Offset
SOCCR	24h

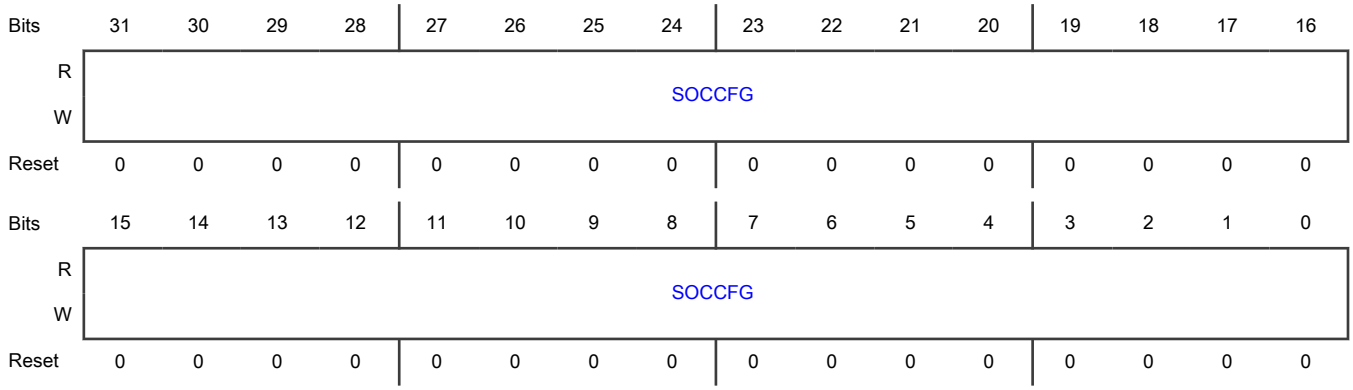
Function

This register is programmed at the chip level for QuadSPI delay chain configuration. For details, see chip-specific QuadSPI information.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-0 SOCCFG	SOC configuration This field configuration is specific to chip. For details, see chip-specific QuadSPI information.

77.13.2.11 Buffer 0 Top Index Register (BUF0IND)

Offset

Register	Offset
BUF0IND	30h

Function

This register specifies the top index for buffer 0, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The register value should be set to the desired number of bytes. For example, setting BUF0IND[31:3] to 0 gives 0 bytes, setting the value to 1 gives 8 bytes, and so on.

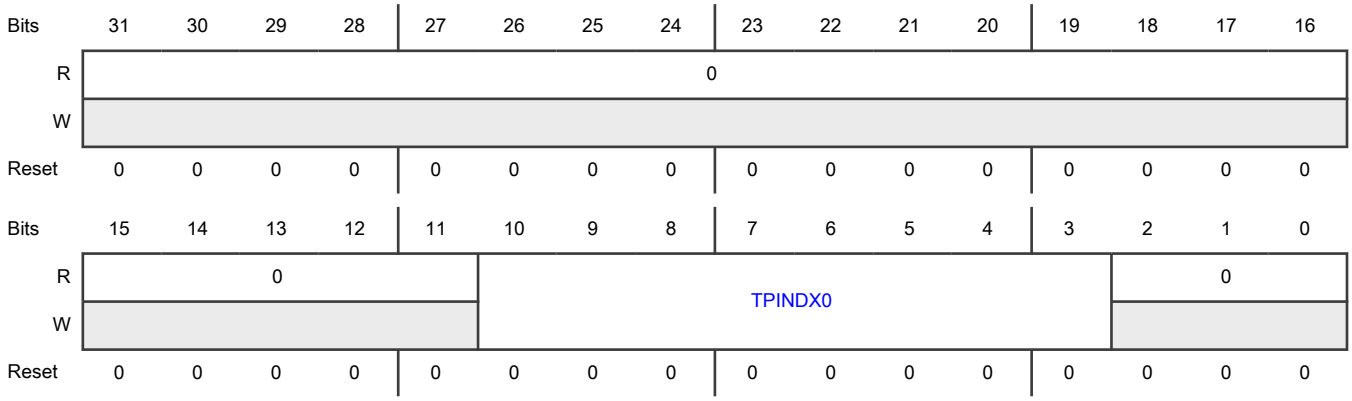
The size of buffer 0 is the difference between BUF0IND and 0.

The software must ensure that the value of TPINDX0 is not greater than the size of buffer 0.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-11 —	Reserved
10-3 TPINDX0	Top index of buffer 0
2-0 —	Reserved

77.13.2.12 Buffer 1 Top Index Register (BUF1IND)

Offset

Register	Offset
BUF1IND	34h

Function

This register specifies the top index of buffer 1, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

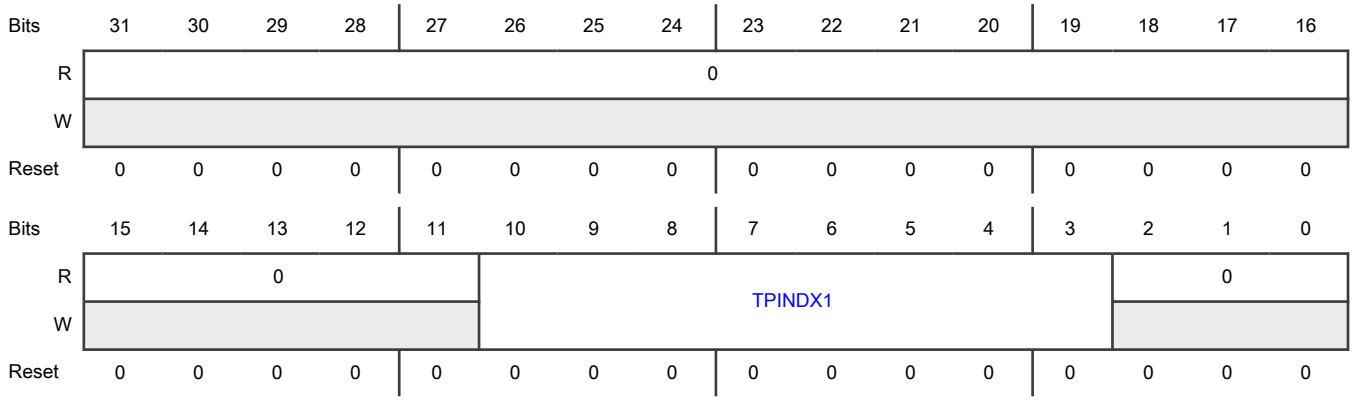
The size of buffer 1 is the difference between BUF1IND and BUF0IND. The register value should be entered in bytes. For example, if BUF0IND = 0x100, then setting BUF1IND = 0x130 sets the size of buffer 1 to 0x30 bytes.

The software must ensure that the value of TPINDX1 is not greater than the size of buffer 1.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-11 —	Reserved
10-3 TPINDX1	Top index of buffer 1
2-0 —	Reserved

77.13.2.13 Buffer 2 Top Index Register (BUF2IND)

Offset

Register	Offset
BUF2IND	38h

Function

This register specifies the top index of buffer 2, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

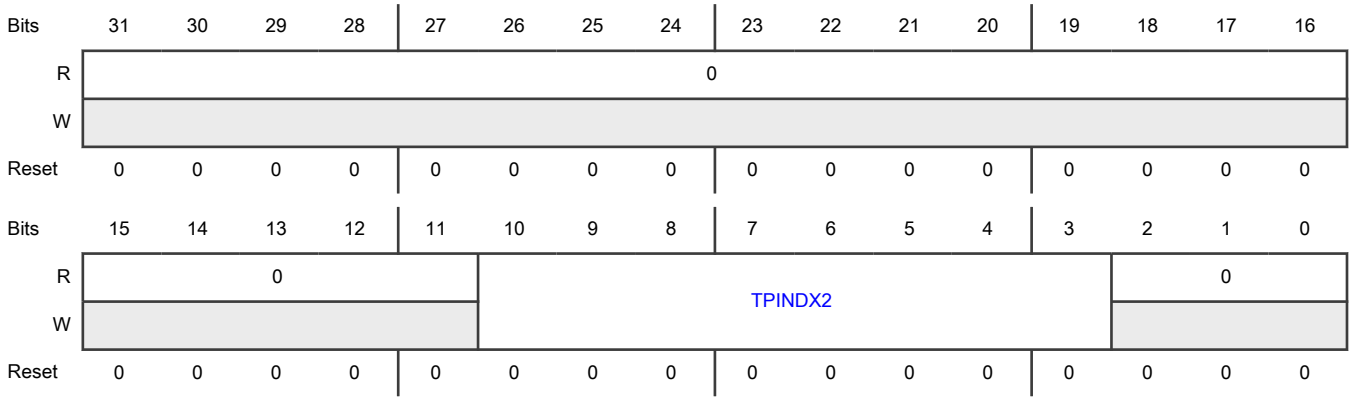
The size of buffer 2 is the difference between BUF2IND and BUF1IND. The register value should be entered in bytes. For example, if BUF1IND = 0x130 then setting BUF2IND = 0x180 sets the size of buffer 2 to 0x50 bytes.

The software must ensure that the value of TPINDX2 is not greater than the size of buffer 2.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-11 —	Reserved

2-0 —	Reserved

77.13.2.14 AHB Write Configuration Register (AWRCR)

Offset

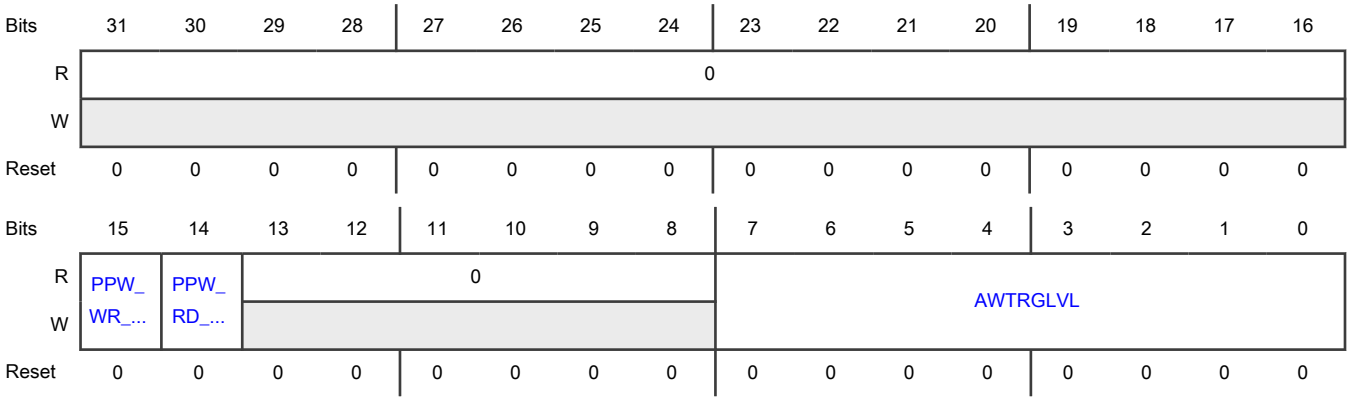
Register	Offset
AWRCR	50h

Function

Special write-access is permitted if:

- SR[AWRACC] = 0

Diagram



Fields

Field	Function
31-16 —	Reserved
15 PPW_WR_DIS	Page program wait write disabled 0b - Enables subsequent writes 1b - Disables subsequent writes to the flash memory. After the first write transaction, AHB write is returned with an error response.
14 PPW_RD_DIS	Page program wait read disabled 0b - Enables subsequent reads 1b - Disables subsequent reads to the flash memory. After the first write transaction, AHB read is returned with an error response.
13-8 —	Reserved
7-0 AWTRGLVL	AHB write trigger level Defines a trigger level of TX FIFO in terms of a 4-byte entry. AHB write to the flash memory is triggered when either of the following happens: • TX FIFO crosses the level defined by this field • AHB transaction completes This is done to prevent an underrun in the flash memory.

77.13.2.15 DLL Flash Memory A Configuration Register (DLLCRA)

Offset

Register	Offset
DLLCRA	60h

Function

This register configures DLL and slave delay chain for flash memory A.

The value of the DLLEN field must be 1 after all reference (FREQEN, DLL_REFCNTR, DLLRES, SLAVE_AUTO_UPDT) delay chain configurations are programmed.

See DLL and delay chain usage for the programming sequence.

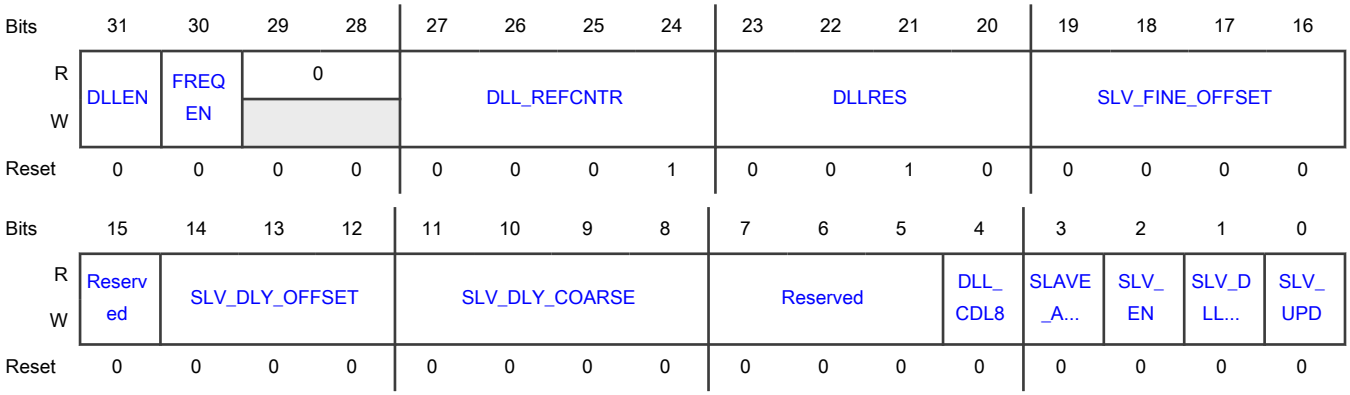
NOTE

See the chip data sheet for information on programming register fields.

NOTE

Please see the chip specific section of QuadSPI DLLCRA register for delay elements data

Diagram



Fields

Field	Function
31 DLLEN	DLL enable 0b - DLL reference logic remains in reset and should be 0 for at least three flash memory clock cycles for reset. 1b - Enables DLL logic. Set it to 1 after all the configuration for DLLCR reference settings is complete.
30 FREQEN	Frequency enable 0b - Selects delay chain for low frequency of operation 1b - Selects delay chain for high frequency of operation
29-28 —	Reserved
27-24 DLL_REFCNTR	DLL reference counter Select the "n+1" interval of DLL phase detection and reference delay updating interval (minimum recommended value = 1).
23-20	DLL resolution

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLLRES	Minimum resolution for DLL phase detector to remain locked/unlocked based on flash memory clock jitter. The minimum value is 2, and should be programmed to a more suitable value, such as 6.
19-16 SLV_FINE_OFFSET	Fine offset delay elements in incoming DQS This field sets the number of fine offset delay elements up to 16 in incoming DQS, and the default must be 1 element.
15 —	Reserved
14-12 SLV_DLY_OFFSET	T/16 offset delay elements in incoming DQS This field sets the number of T/16 offset delay elements in incoming DQS; default is 0.
11-8 SLV_DLY_COARSE	Delay elements in each delay tap This field sets the number of delay elements in each delay tap. The field is used to overwrite DLL-generated delay values and works when the value of SLV_DLL_BYPASS is 1. Note : Please refer to the QuadSPI datasheet for more details.
7-5 —	Reserved
4 DLL_CDL8	DLL CDL8 Enable 0b - DLL is implemented to support within 2x variation 1b - DLL is implemented to support within 3x variation (BCS -> WCS)
3 SLAVE_AUTO_UPDT	Slave chain update This field automatically updates the slave chain as soon as DLL is locked. 0b - Auto-update feature is disabled. 1b - Auto-update feature is enabled.
2 SLV_EN	Slave enable 0b - DLL slave logic remains in reset, and its value should be 0 for at least three flash memory clock cycles for reset. 1b - Enables DQS slave delay chain, and should be 1 before any slave configuration settings take place.
1 SLV_DLL_BYPASS	Slave DLL bypass This field enables selection of the number of delays in each slave delay tap. 0b - Disables manual selection of coarse delays in the slave delay chain. 1b - Enables selection of number of delays in each slave delay tap, based on DLLCRA[SLV_DLY_COARSE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 SLV_UPD	Slave update You must program this field only after slave delay chain configuration takes place. 0b - Disables any further update on DQS slave delay chain. 1b - Updates the DQS slave delay chain with either ref-delay or bypass slave delay value, and should be set in the absence of the DQS clock.

77.13.2.16 Parity Configuration Register (PARITYCR)

Offset

Register	Offset
PARITYCR	6Ch

Function

This register replicates the parity related configuration programming performed on the flash memory configuration registers.

You must write 1 to PARITYCR[CRCEN_FA] and PARITYCR[CRCEN_FB] after all parity configuration bits are programmed. However, you can program PARITYCR[BYTE_SIZE_FA] and PARITYCR[BYTE_SIZE_FB] at any time.

20-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 CRC_WNDW_FA	CRC address window configuration 0b - Calculates parity (CRC) over fixed address window within the denoted flash memory A chunk size boundary. 1b - Calculates parity (CRC) over incremental window of flash memory A chunk size, irrespective of address.
14-9 CHUNKSIZE_FA	Chunk size for flash memory A Defines the chunk size (in terms of 4 bytes) after parity is inserted and compared by the QuadSPI controller for flash memory A. Values 0x1, 0x2, and so on indicate 4 bytes, 8 bytes, and so on.
8 BYTE_SIZE_FA	Byte size for flash memory A This field can be programmed any time. It enables single-byte, read/write parity with flash memory A configuration register. The field overrides the chunk size used for flash memory data array. You must write 1 to this field before any read/write operation on the flash memory internal registers. And you must write 0 to this field before reading flash memory data array.
7 CRCEN_FA	CRC parity checker logic 0b - Disables parity mechanism. In case of parity error, set it to 0 to clear parity error. Only supported for DDR Octal commands. 1b - CRC parity checker logic for flash memory A read paths. Configure this field after programming CHUNK_SIZEA, CRCBEN_FA and CRCBIN_FA.
6 CRCBEN_FA	Adds CRC bar parity from flash memory A output to QuadSPI controller
5 CRCBIN_FA	Adds CRC bar parity to flash memory A input from QuadSPI controller
4-0 —	Reserved

77.13.2.17 Serial Flash Memory Address Register (SFAR)

Offset

Register	Offset
SFAR	100h

Function

The module automatically translates this address on the memory map to the address on the flash memory. When operating in a 24-bit mode, only bits 23-0 are sent to the flash memory. In the 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 . See Table 673 for the mapping between the access mode and the SFAR content and Normal mode for details on command triggering

and command execution. The software must ensure that the serial flash memory address provided in the SFAR register lies in the valid flash memory address range, as defined in Table 673.

Special write-access is permitted if:

- SR[IP_ACC] = 0

Diagram

77.13.2.18 Sampling Register (SMPR)

Offset

Register	Offset
SMPR	108h

Function

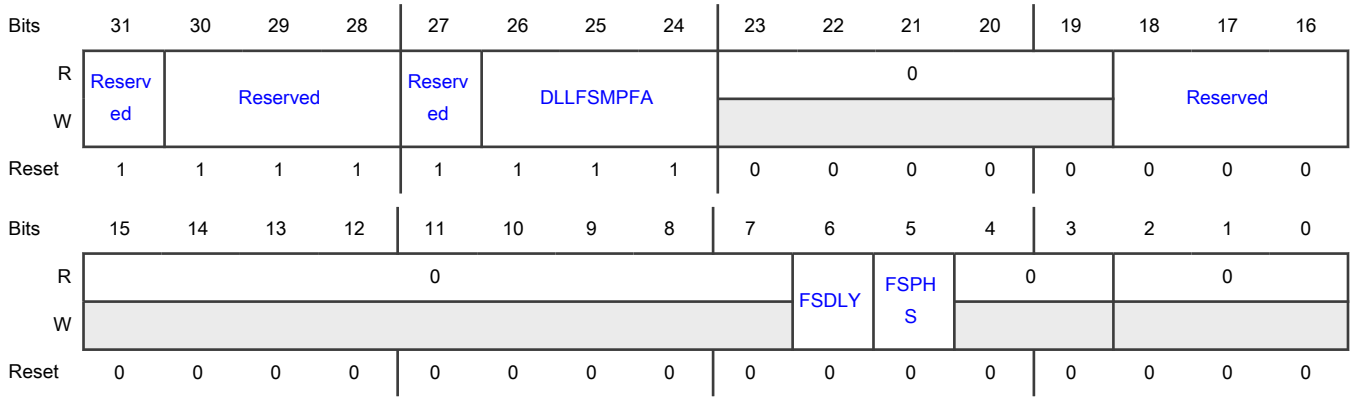
This register allows configuration of how the incoming data from the external serial flash memory devices is sampled in the QuadSPI module.

NOTE

See the chip data sheet for programming the register fields.

Special write-access is permitted in the disabled mode.

Diagram



Fields

Field	Function
31 —	Reserved
30-28 —	Reserved
27 —	Reserved
26-24 DLLFSMPFA	Selects the nth tap provided by slave delay chain for flash memory A The value of *n* can vary from 0 to 7, with each tap delay based on the DLLCRA register.

2-0 —	Reserved

77.13.2.19 RX Buffer Status Register (RBSR)

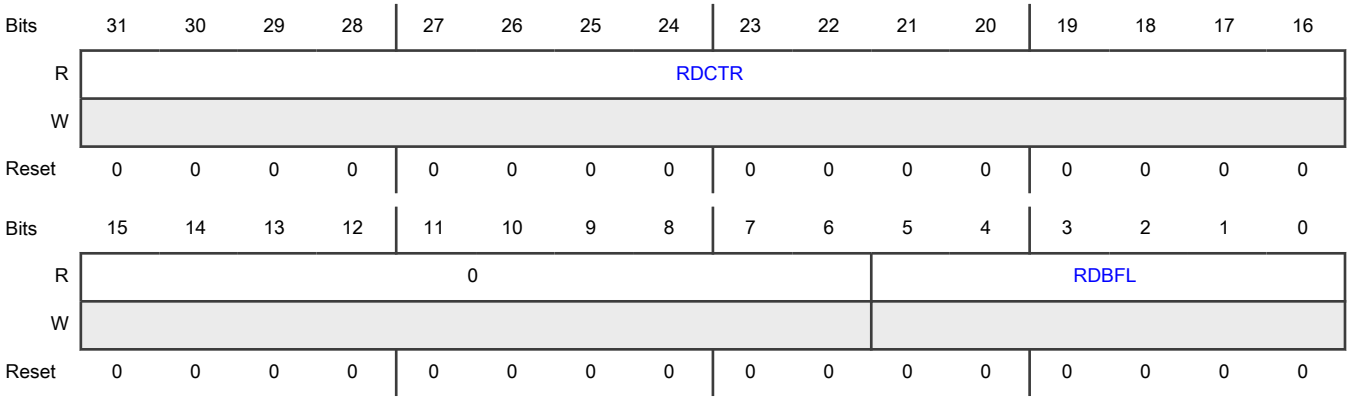
Offset

Register	Offset
RBSR	10Ch

Function

This register contains information related to the receive data buffer.

Diagram



Fields

Field	Function
31-16 RDCTR	Read counter Indicates the number of 4-byte entries removed from the RX buffer. For example, a value of 0x2 indicates that 8 bytes have been removed. It is incremented by the number (RBCT[WMRK] + 1) on RX buffer POP event. The RX buffer can be popped using DMA or FR[RBDF]. The RSER[RBDDE] defines which pop should be pursued. For details, see AHB RX Data Buffer Register (ARDB0 - ARDB31) and Data Transfer from the QuadSPI Module Internal Buffers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-6 —	Reserved
5-0 RDBFL	RX buffer fill level Indicates the number of 4-byte entries available in the RX buffer. For example, a value of 0x2 indicates 8 bytes are available.

77.13.2.20 RX Buffer Control Register (RBCT)

Offset

Register	Offset
RBCT	110h

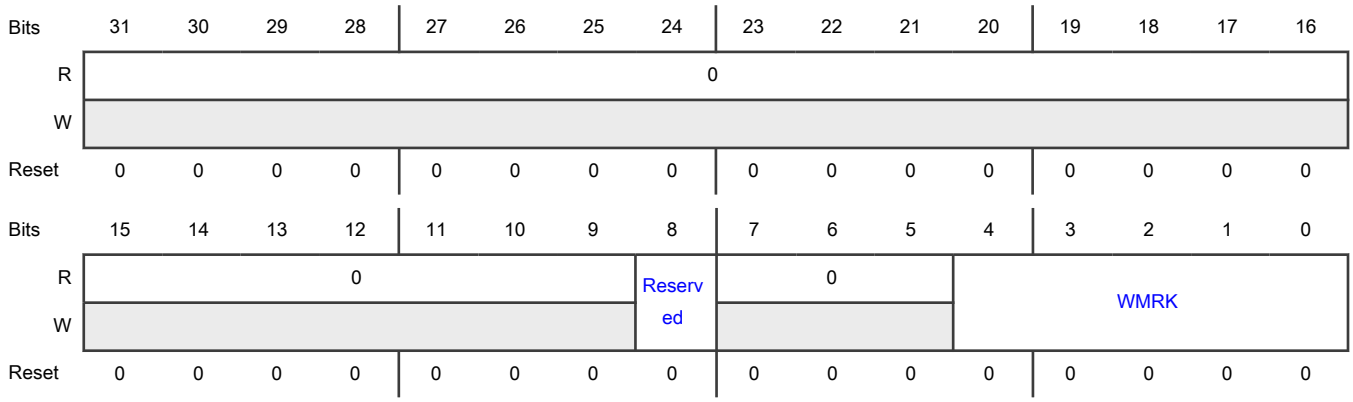
Function

This register contains control data related to the receive data buffer.

Special write-access is permitted if:

- SR[IP_ACC] = 0

Diagram



Fields

7-5 —	Reserved
4-0 WMRK	RX buffer watermark This field determines when the readout action of the RX buffer is triggered. When the number of valid entries in the RX buffer is equal to or greater than the number provided by (WMRK+1), the SR[RXWE] flag is asserted. The value should be entered as the number of 4-byte entries minus 1. For example, a value of 0x0 sets the watermark to 4 bytes, 1 to 8bytes, 2 to 12 bytes, and so on. For details, see DMA usage. **NOTE** This field should never be programmed above 63 because there are only 64 memory mapped RBDR registers. If watermark is programmed above 63, data above 64 words will be lost.

14 SLVA_LOCK	Slave high lock status High-frequency slave delay chain locked. The field is configured when the slave decoder is updated with DLLCRA[SLV_UPD] and is reset after you configure SLV_UPD to 0.
13 DLLA_RANGE_ERR	DLL master delay chain The value 1 indicates that DLL master delay chain is working out of delay range because of incorrect DLL configuration.
12 DLLA_FINE_UNDERFLOW	Fine delay chain underflow The value 1 indicates that fine delay chain underflow has occurred.
11-8 —	Reserved
7-4 DLLA_SLV_FINE_VAL	Fine delay cells in slave delay chain This value indicates the total number of fine delay cells (1 delay unit) selected in the slave delay chain.
3-0 DLLA_SLV_COARSE_VAL	Coarse delay cells in slave delay chain This value indicates the total number of coarse delay cells (16 delay units) selected in the slave delay chain.

77.13.2.23 Data Learning Configuration Register (DLCR)

Offset

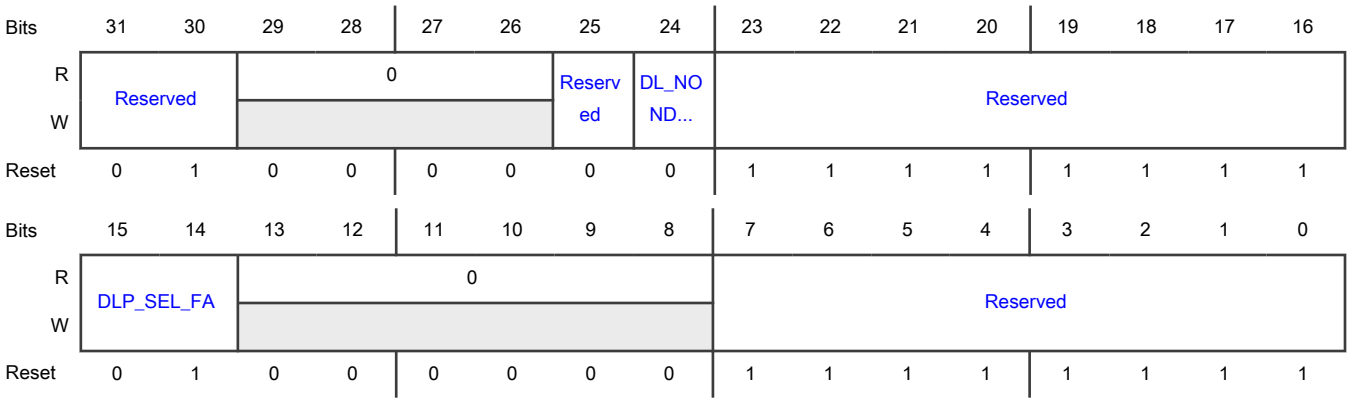
Register	Offset
DLCR	130h

Function

This register is used for programming the data learning settings.

- A flash memory device that supports data learning but cannot provide more than 10 bits of data learn pattern must be considered as non-DLP Flash. For Non-DLP flash devices, you must read at least 16 bits data learn pattern from a known location.
- You must program different learning pattern on the two data pins–IO1 and IO3. This is required to accommodate pessimistic data skew between the different IO lines.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-26 —	Reserved
25 —	Reserved
24 DL_NONDLP_FLSH	Data learning enabled for non-DLP flash memory Configure the value of this field as 1 to enable data learning for flash memories that do not provide a data learning pattern. For a non-DLP flash memory, execute a one-time data learning through the IPS to select a tap before an AHB read operation.
23-16 —	Reserved
15-14 DLP_SEL_FA	Selects pattern matching IO pads 00b - Pattern matching is ignored. This is only for debugging purpose and should not be programmed. 01b - IO1 is used for matching

Table continues on the next page...

Table continued from the previous page...

13-8 —	Reserved
7-0 —	Reserved

77.13.2.24 Data Learning Status Flash Memory A Register (DLSR_FA)

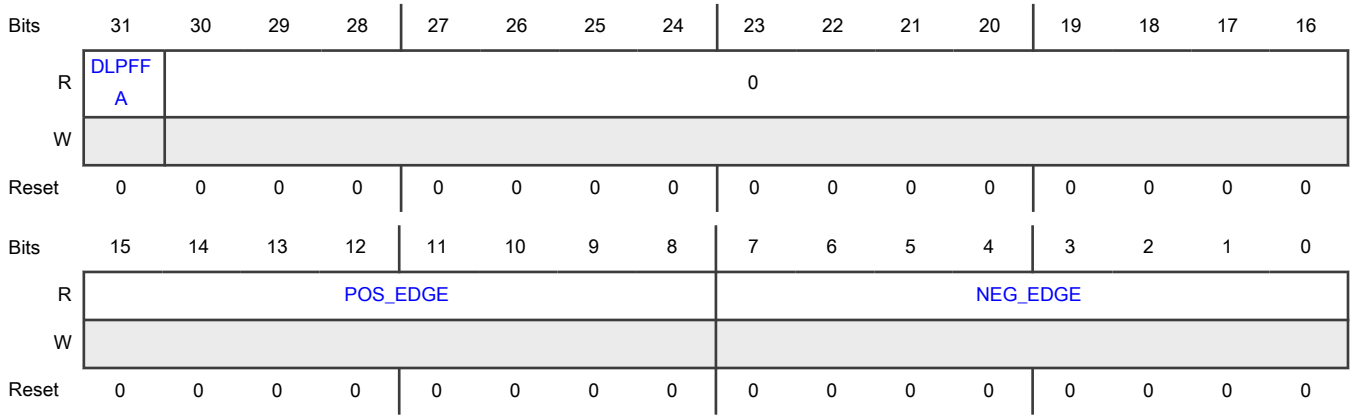
Offset

Register	Offset
DLSR_FA	134h

Function

This register shows sampling point selected by data learning algorithm when the value of DLSR_FA[DLPFFA] is 0. Otherwise, it shows the pattern matching outline.

Diagram



Fields

Field	Function
31 DLPFFA	Data learning pattern fail This field asserts when data learning fails at flash memory A.

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-16 —	Reserved
15-8 POS_EDGE	DLP positive edge match signature for flash memory A
7-0 NEG_EDGE	DLP negative edge match signature for flash memory A

77.13.2.25 TX Buffer Status Register (TBSR)

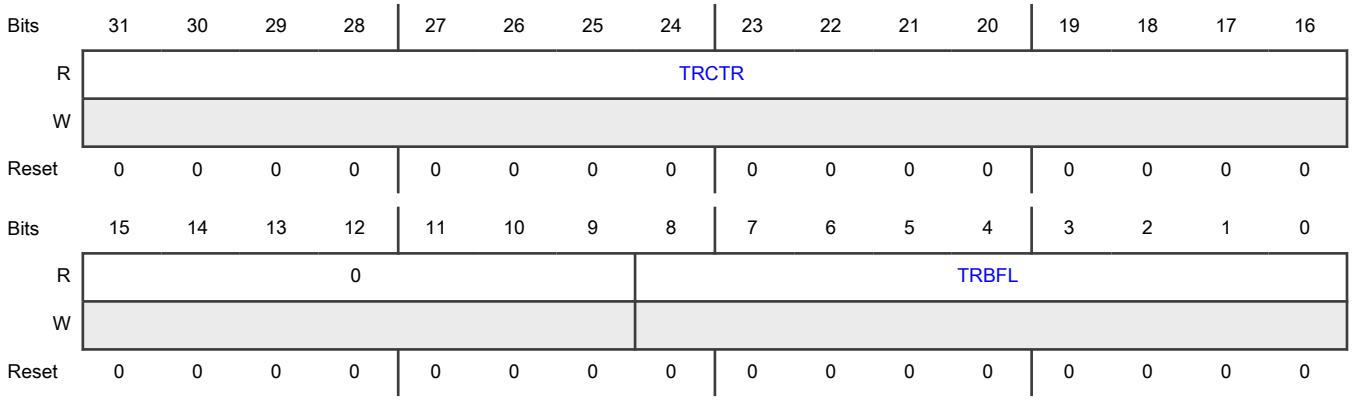
Offset

Register	Offset
TBSR	150h

Function

This register contains information related to the transmit data buffer.

Diagram



Fields

Field	Function
31-16 TRCTR	Transmit counter This field indicates how many entries of 4 bytes have been written into the TX buffer by host accesses. It is reset to 0 when a 1 is written to MCR[CLR_TXF]. It is incremented on each write access to the TBDR register when another word has been pushed onto the TX buffer. When it is not cleared, the TRCTR field wraps around to 0. See TX Buffer Data Register (TBDR) for details.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-9 —	Reserved
8-0 TRBFL	TX buffer fill level This field contains the number of entries of 4 bytes each available in the TX buffer for the QuadSPI module to transmit to the serial flash memory device. The value of this field can reach maximum up to the total TX buffer size.

77.13.2.26 TX Buffer Data Register (TBDR)

Offset

Register	Offset
TBDR	154h

Function

This register provides access to the circular TX buffer of depth 256, so the total size is 256 * 4 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash memory device. See Table 638 for the byte ordering scheme. A write transaction on the flash memory with data size of less than 32 bits leads to the removal of one data entry from the TX buffer. The valid bits are used and the rest of the bits are discarded.

Special write-access is permitted if:

- SR[TXFULL] = 0

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0	TX data

Table continues on the next page...

Field	Function
TXDATA	On write access, the data is written to the next available entry of the TX buffer and TBSR[TRBFL] is updated accordingly. On a read access, the last data written to the register is returned.

77.13.2.27 TX Buffer Control Register (TBCT)

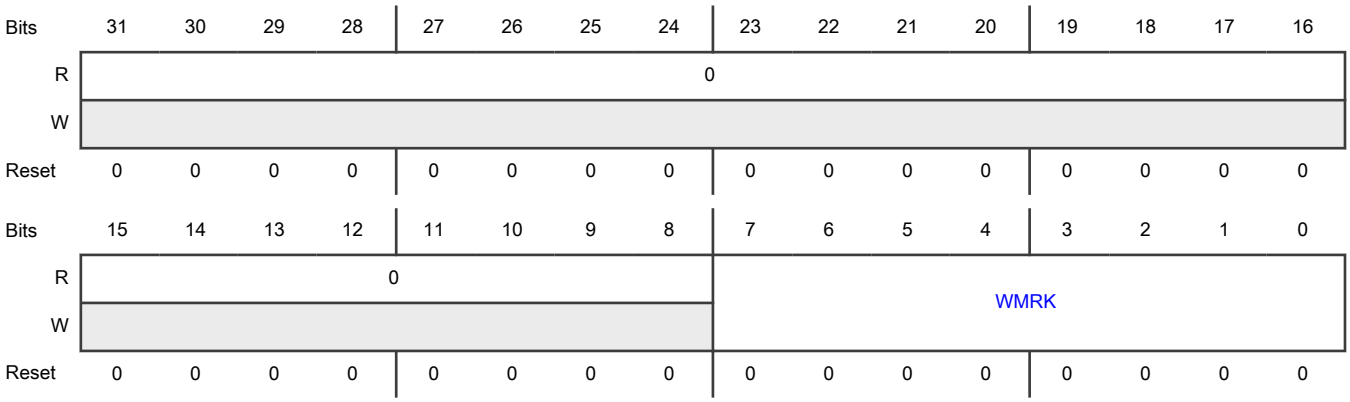
Offset

Register	Offset
TBCT	158h

Function

This register contains control information for transmit data buffer.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 WMRK	Watermark for TX buffer Determines the watermark for the TX buffer When the number of available space in the TX buffer is greater than or equal to the number provided by WMRK (number of 4-byte entries), SR[TXWA] is asserted. For example, a value of 0x1 sets the watermark to 4 bytes, 0x2 sets it to 8 bytes, 0x3 sets it to 12 bytes, and so on. For details, see DMA usage. WMRK = 0 is invalid.

77.13.2.28 Status Register (SR)

Offset

Register	Offset
SR	15Ch

Function

This register provides all the available status information about SFM command execution and arbitration, the RX buffer, TX buffer, and the AHB buffer.

Diagram

Fields

Field	Function
31-29 —	Reserved
28 —	Reserved
27 TXFULL	TX buffer full Asserted when the FIFO level reaches TX buffer size
26 TXDMA	TX DMA Asserted when the TXFIFO fill via DMA is active and DMA is requested or running
25 TXWA	TX buffer watermark available Asserted when the number of available spaces in the TX buffer is greater than or equal to the value provided by TBCT[WMRK] Example: When TBCT[WMRK]=1, SR[TXWA] is de-asserted when TX FIFO has 256 entries.

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 TXNE	TX buffer not empty Asserted when TX buffer contains data
23 RXDMA	RX buffer DMA Asserted when RX buffer read out via DMA is active; that is, when DMA is requested or running
22-20 —	Reserved
19 RXFULL	RX buffer full Asserted when the RX buffer is full; that is, when RBSR[RDBFL] is equal to 32
18-17 —	Reserved
16 RXWE	RX buffer watermark exceeded Asserted when the number of valid entries in the RX buffer exceeds the number provided in RBCT[WMRK]
15 —	Reserved
14 AHB3FUL	AHB 3 buffer full Asserted when AHB 3 buffer is full
13 AHB2FUL	AHB 2 buffer full Asserted when AHB 2 buffer is full
12 AHB1FUL	AHB 1 buffer full Asserted when the AHB 1 buffer is full
11 AHB0FUL	AHB 0 buffer full Asserted when the AHB 0 buffer is full
10 AHB3NE	AHB 3 buffer not empty Asserted when the AHB 3 buffer contains data
9 AHB2NE	AHB 2 buffer not empty Asserted when the AHB 2 buffer contains data
8 AHB1NE	AHB 1 buffer not empty Asserted when the AHB 1 buffer contains data
7	AHB 0 buffer not empty

Table continues on the next page...

Table continued from the previous page...

Field	Function
AHB0NE	Asserted when the AHB 0 buffer contains data
6 AHBTRN	AHB access transaction pending Asserted when there is a pending request on the AHB interface. See Flash memory mapped AMBA bus.
5 —	Reserved
4 AWRACC	AHB write access Asserted when AHB write access is enabled
3 —	Reserved
2 AHB_ACC	AHB read access Asserted when the currently executed transaction is initiated by the AHB bus
1 IP_ACC	IP access Asserted when transaction currently executed is initiated by the IP bus
0 BUSY	Module busy Asserted when module is currently busy handling a transaction to an external flash memory device

77.13.2.29 Flag Register (FR)

Offset

Register	Offset
FR	160h

Function

This register provides all available flags about SFM command execution and arbitration, which may serve as the source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash memory device itself but only to the behavior and conditions visible in the QuadSPI module.

Special write-access is permitted in the enabled mode.

Diagram

Fields

Field	Function
31 DLPFF	Data learning pattern failure flag This field is set when the DATA_LEARN instruction is encountered in a sequence, but no sampling point is found for the data learning pattern.
30 —	Reserved
29 —	Reserved
28 DLLABRT	DLL abort 1b - This field is set whenever DLL is unlocked while reading data from the flash memory.
27 TBFF	TX buffer fill flag Before writing to the TX buffer, this field should be cleared. Then, it should be read back. If it is set, the TX buffer can include more data. If the field remains cleared, the TX buffer can be considered as full. See TX buffer operation for details.
26 TBUF	TX buffer underrun flag This field is set if the module tries to pull data when the TX buffer is empty. The IP command leading to the TX buffer underrun is continued (data sent to the serial flash memory device is undefined). Here, a valid underrun means that it should have occurred during the transaction so that few bytes (that is, less than 4 bytes) are left in FIFO and the remaining are filled with "FFFFh". The software should initiate a TX transaction only when 128 bits are written in the TX buffer. This field does not set if transfer is less than 128 bits. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF]. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF].
25 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 DLLUNLCK	DLL unlock 1b - This field is set whenever DLL unlock event occurs, irrespective of flash memory access.
23 ILLINE	Illegal instruction error flag This field is set when an illegal instruction is encountered by the controller in any of the sequences. As soon as the field is set, you must assert MCR[SWRSTSD] and MCR[SWRSTHD]. That is, reset the flash memory and AHB domain after reconfiguring the correct sequence instruction. See Table 636 for a list of legal instructions.
22-21 —	Reserved
20 —	Reserved
19-18 —	Reserved
17 RBOF	RX buffer overflow flag This field is set when no more data can be pushed into the RX buffer from the serial flash memory device. The IP command leading to this condition is continued until the number of bytes in IPCR[IDATSZ] are read from the serial flash memory device. The content of the RX buffer remains unchanged.
16 RBDF	RX buffer drain flag This field is set if SR[RXWE] is asserted. Writing 1 to this field triggers one of the following actions: • If the RX buffer has up to RBCT[WMRK] valid entries, then the flag is cleared. • If the RX buffer has more than RBCT[WMRK] valid entries and the RSER[RBDDE] field is not set (flag driven mode), an RX buffer POP event is triggered. The flag remains set if the RX buffer contains more than RBCT[WMRK] valid entries after the RX buffer POP event is complete. The flag is cleared if the RX buffer contains less than or equal to RBCT[WMRK] valid entries after the RX buffer POP event is complete. See the "Receive Buffer Drain Interrupt or DMA Request" section in Normal mode interrupt and DMA requests for details.
15 —	Reserved
14	AHB illegal transaction error flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
AITEF	This is set whenever there is no response generated from QuadSPI to AHB bus in case of an illegal transaction and the watchdog timer expires. The timer value is considered as a parameter.
13 AIBSEF	AHB illegal burst size error flag This is set whenever the total burst size (size x beat) of an AHB transaction is greater than the prefetch data size, which is defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field in case ADATSZ = 0. See HBURST support with AHB read details on HBURST feature.
12 ABOF	AHB buffer overflow flag This is set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if BUFxCR[ADATSZ] is programmed incorrectly. The AHB command leading to this condition is continued until the number of entries according to BUFxCR[ADATSZ] have been read from the serial flash memory device. The content of the AHB buffer is not changed.
11 —	Reserved
10 CRCAEF	Sets when there is CRC or ECC error for flash memory A 0b - CRCEF interrupt is not generated. 1b - CRCEF interrupt is generated.
9 —	Reserved
8 PPWF	Page-program wait flag after flash memory write flag This field indicates page-program wait flag after flash memory write.
7 —	Reserved
6 IPIEF	IP command trigger could not be executed error flag This is set when the SR[IP_ACC] and SR[AWRACC] fields are set (that is, an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the RBCT
5 —	Reserved
4 —	Reserved
3-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
0 TFF	IP command transaction finished flag This field is set after the QuadSPI module completes a running IP command. If an error occurs, and the related error flags are valid in the same clock cycle, the TFF flag is asserted.

77.13.2.30 Interrupt and DMA Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	164h

Function

This register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each field of the FR enabled as source for an interrupt prevents the QuadSPI module from entering the Stop mode or Module Disable mode when this flag is set.

Special write-access is permitted in the "Anytime" mode.

4 —	Reserved
3-1 —	Reserved
0 TFIE	Transaction finished interrupt enable flag This field indicates the transaction finished interrupt enable flag. 0b - No TFF interrupt is generated. 1b - TFF interrupt is generated.

77.13.2.31 Sequence Pointer Clear Register (SPTRCLR)

Offset

Register	Offset
SPTRCLR	16Ch

Function

This register provides fields to reset the IP and buffer sequence pointers. The sequence pointer contains the index of instructions within the LUT entry that is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index is stored as 2.

The software should reset the sequence pointers defined by JMP_ON_CS operand whenever the sequence ID is required to be changed by updating the SEQID field in the IPCR or BFGENCR.

0 BFPTRC	Buffer pointer clear This is a self-clearing field. 1b - Clears the sequence pointer for AHB read accesses as defined in BFGENCR.

77.13.2.32 Serial Flash Memory A1 Top Address Register (SFA1AD)

Offset

Register	Offset
SFA1AD	180h

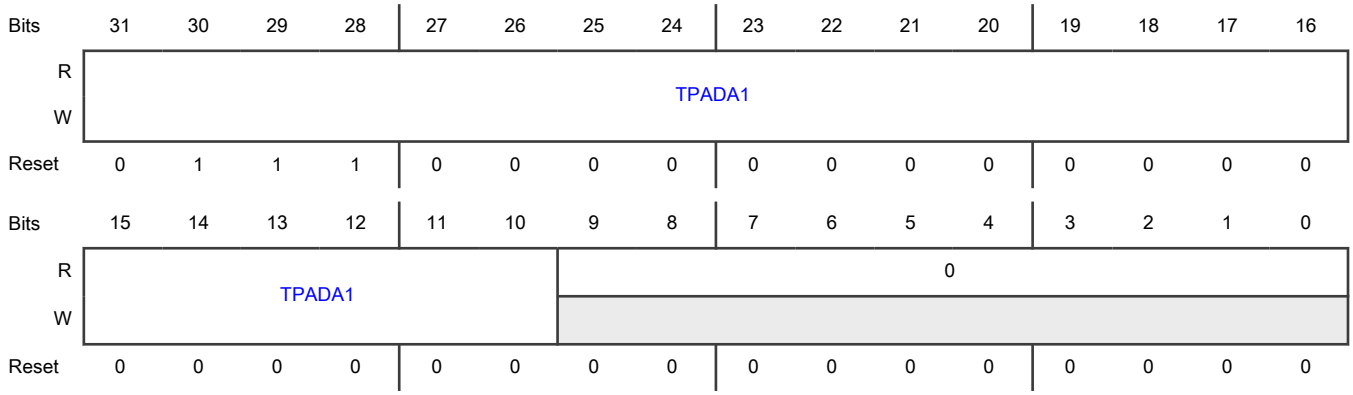
Function

This register provides the address mapping for serial flash memory A1. The difference between SFA1AD[TPADA1] and AMBA_BASE defines the size of the memory map for serial flash memory A1.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-10 TPADA1	Top address for serial flash memory A1 In effect, TPADxx is the first location of the next memory.
9-0 —	Reserved

77.13.2.33 Serial Flash Memory A2 Top Address Register (SFA2AD)

Offset

Register	Offset
SFA2AD	184h

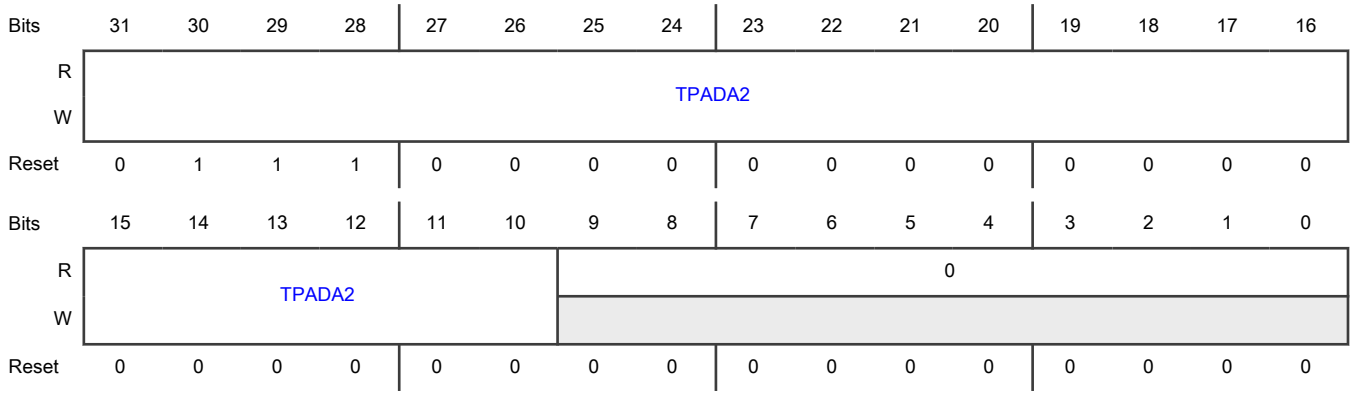
Function

This register provides the address mapping for serial flash memory A2. The difference between SFA2AD[TPADA2] and SFA1AD[TPADA1] defines the size of the memory map for serial flash memory A2.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-10 TPADA2	Top address for serial flash memory A2 In effect, TPxxAD is the first location of the next memory.
9-0 —	Reserved

77.13.2.34 Data Learn Pattern Register (DLPR)

Offset

Register	Offset
DLPR	190h

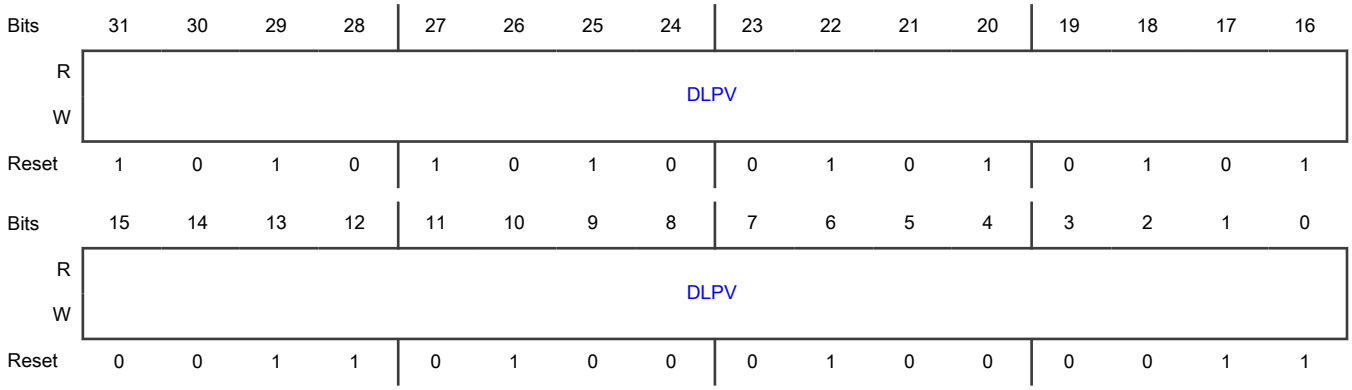
Function

This register contains the information of the data to be used for data learning.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-0 DLPV	Data learning pattern value This value is used for data learning in the DDR and DQS modes. For example, if you request for more than 32 bits of data learning, the value is repeated in the register. For example, if 64-bit data learning is requested by any flash memory and the value of DLPR is aa55_3443, then the 64-bit value is aa55_3443_aa55_3443. This value is used for data learning in SDR/DDR modes along with DATA_LEARN instruction. Different patterns can be matched at selected IOs. That is, IO1 and IO3 using DLCR[DLP_SEL_FA], DLPR[31:16] for IO3, and DLPR[15:0] for IO1. DLP pattern for IO1 and IO3 should be stored, bit-wise, in the little endian format. For details, see Data learning.

77.13.2.35 RX Buffer Data Register (RBDR0 - RBDR31)

Offset

For a = 0 to 31:

Register	Offset
RBDRa	200h + (a × 4h)

Function

These registers provide access to individual entries in the RX buffer. See Table 638 for the byte ordering scheme.

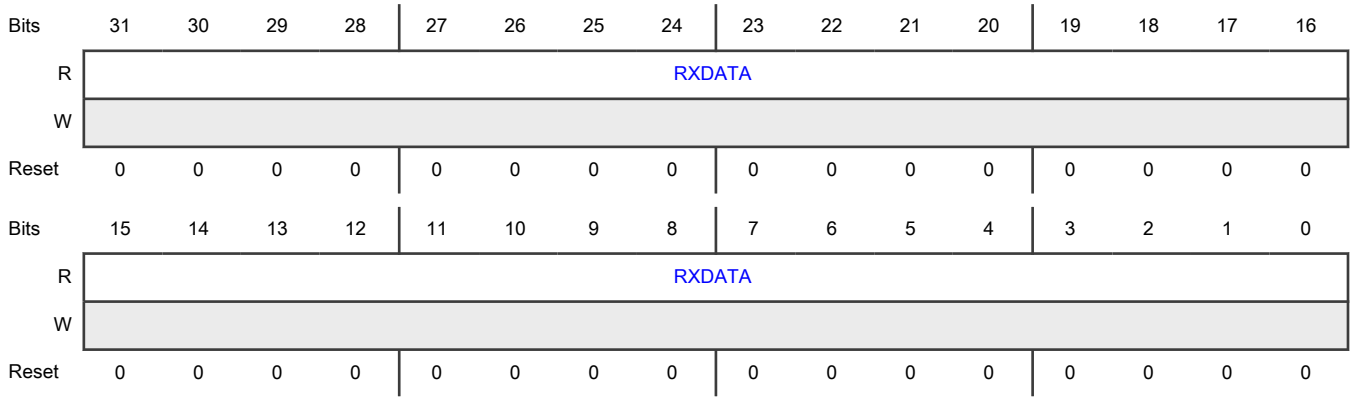
RBDR0 corresponds to the actual position of the read pointer within the RX buffer. The number of valid entries available depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

Example 1 - RX buffer filled completely with 32 words: In this case, the address range for valid read access extends from RBDR0 to RBDR31 RBDR63.

Example 2 - RX buffer filled with five valid words: RX buffer fill level of RBSR[RDBFL] is 5. In this case, access to RBDR4 provides the last valid entry.

Any access beyond the range of valid RX buffer entries provides undefined results.

Diagram



Fields

Field	Function
31-0 RXDATA	RX data This field contains the data associated with the related RX buffer entry. For data format and byte ordering, see Byte ordering of serial flash memory read data.

77.13.2.36 LUT Key Register (LUTKEY)

Offset

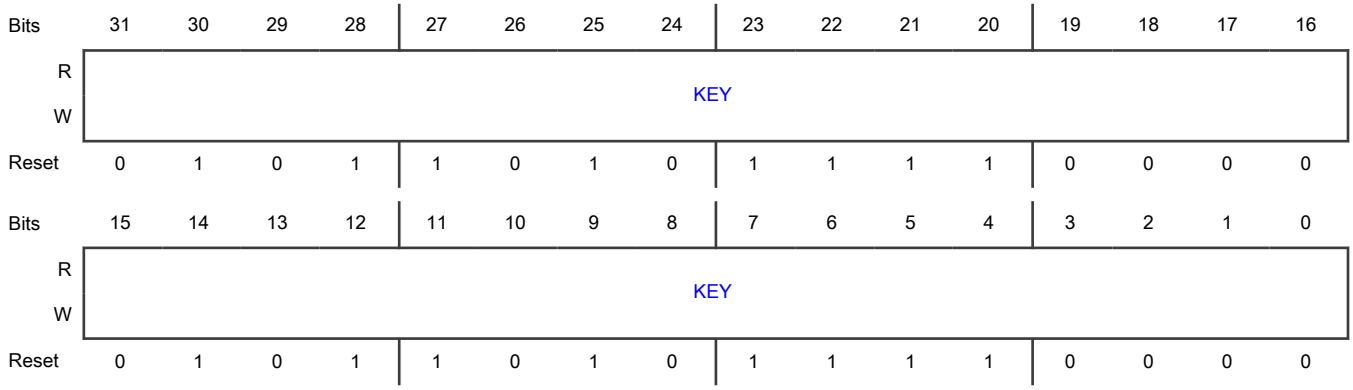
Register	Offset
LUTKEY	300h

Function

This register contains the key to lock and unlock the LUT. See LUT for details.

Special write-access is permitted in the "Anytime" mode.

Diagram



Fields

Field	Function
31-0 KEY	Key to lock or unlock the LUT The key is 0x5AF05AF0 and the read value is always 0x5AF05AF0.

77.13.2.37 LUT Lock Configuration Register (LCKCR)

Offset

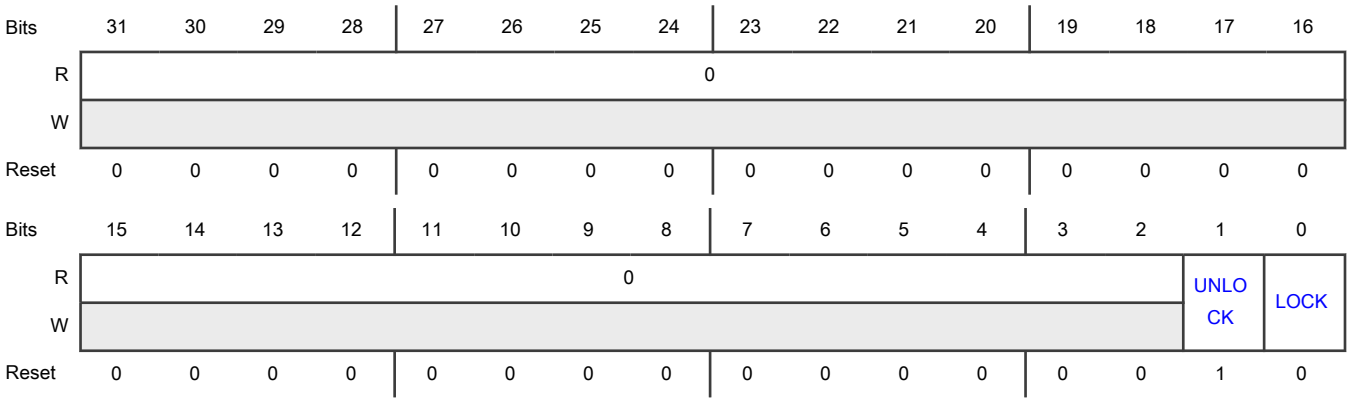
Register	Offset
LCKCR	304h

Function

This register is used along with the LUTKEY register to lock or unlock the LUT. This register should be written immediately after the LUTKEY register for the lock or unlock operation to be successful. See LUT for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Special write access is permitted after writing the LUT key register.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 UNLOCK	Unlock LUT Unlocks the LUT when the following two conditions are met: • This register is written just after the LUT Key Register (LUTKEY). • The LUT key register was written with the 0x5AF05AF0 key.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 LOCK	Lock LUT Locks the LUT when the following conditions are met: • This register is written just after the LUT Key Register (LUTKEY). • The LUT key register is written with the 0x5AF05AF0 key.

77.13.2.38 LUT Register (LUT0)

Offset

Register	Offset
LUT0	310h

Function

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence preprogrammed by Program Sequence Engine in the LUT is referred to by its index. The LUT registers act as lookup tables for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash memory transaction. There are a total of 80 LUT registers. These 80 registers are divided into groups of 5 registers that make a valid sequence. Therefore, LUT[0], LUT[5], LUT[10] ..... LUT[75] are the starting registers of a valid sequence. Each of these sets of 5 registers can have a maximum of 10 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT79. A maximum of 16 sequences can be defined at one time. See LUT that describes the LUT registers in detail.

Special write-access is permitted if the LUT is unlocked.

This register is access controlled and can only be programmed by privilege masters. Last six LUT SEQID locations should be used for programming SEQID for atomic commands (where flash's internal config region is accessed) like flash erase etc. where data transfer is not required. These 6 SEQID can be send to QSPI using only FRAD0 and can't be qualified using any other FRAD. For details, see Atomic commands considerations.

77.13.2.44 Flash Region Lock Control (FRAD0_WORD3 - FRAD7_WORD3)

Offset

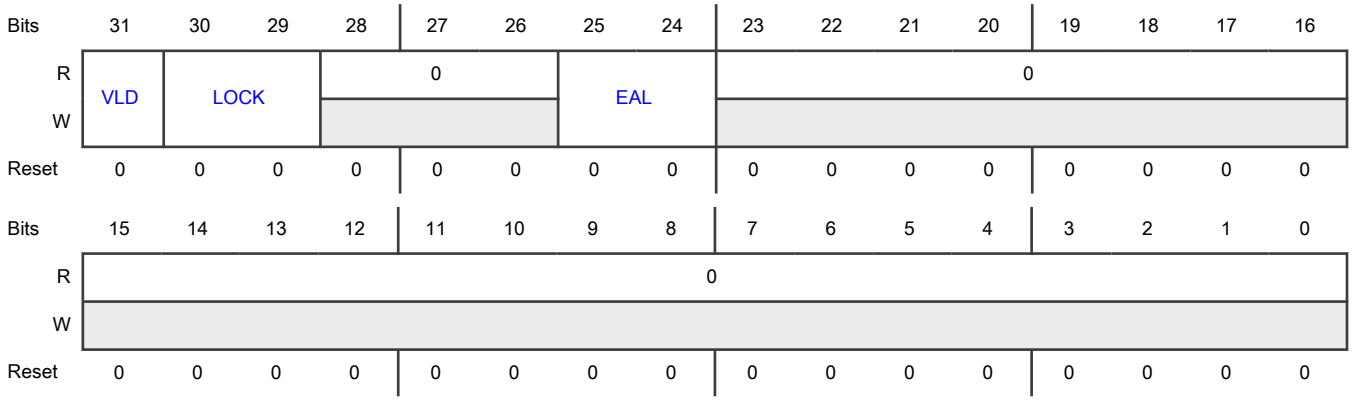
For n = 0 to 7:

Register	Offset
FRADn_WORD3	80Ch + (n × 20h)

Function

This register is access controlled and can only be programmed by privilege masters.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates whether the FRAD Descriptor for a specific flash region is valid. This field can not be written in same cycle if EAL field is being written as 10 or 11. **NOTE** You must enable this field after programming FRAD0_WORD0, FRAD0_WORD1, FRAD0_WORD2 and FRAD0_WORD3 registers. 0b - FRAD-Assignment is invalid 1b - FRAD-Assignment is valid
30-29 LOCK	Descriptor Lock This field enables masking of accidental write on FRAD registers. Lock is enabled/disabled by Secure/ Privileged master. Lock functionality does not affects the EAL bits of FRAD. They can still be written even if FRAD descriptors are locked. 00b-01b - Lock disabled. Descriptor registers can be written by any master 10b - Lock enabled. Descriptors are read-only. MDnACP fields can be programmed only by the master with ID matching the MID check of their respective Target group MDAD. If the Target group MDAD is not valid then MDnACP fields also become read-only. 11b - Lock enabled. Descriptor registers are read-only.
28-26 —	Reserved
25-24 EAL	Exclusive Access Lock This field provides exclusive write lock over a FRAD region based on MD*n*ACP. 00b - No lock. Write permissions available for all masters based on their MDxACP evaluation. 01b - NA

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Lock enabled. Write permissions revoked for all domains. It can only be changed to 11b and can't directly be changed to 00b. 11b - Lock enabled. Exclusive write permission for master with master ID given in FRADn_WORD3[EALO] fields based on its MDxACP evaluation. Write disabled for other masters. Exclusive lock can be taken by a master only if it its ID matches the master ID check of any of the MDAD target queue, which is valid. MDxACP field corresponding to that target queue is not programmed as 0b. when a master writes 11b on this field it will be written only if above condition is met and then the master ID will be stored in FRADn_WORD3[EALO]. No transfer error will be generated in case the master does not satisfies the check.
23-0 —	Reserved

77.13.2.45 Flash Region Compare Address Status (FRAD0_WORD4 - FRAD7_WORD4)

Offset

For n = 0 to 7:

Fields

Field	Function
31 VLD	Valid Indicates whether the IPCR-IDATZ, IPCR-SEQID and PAR stored in this target group queue is valid and queue is locked. This bit will not be set in case ERR is set. 0b - IPCR-assignment is invalid 1b - IPCR-assignment is valid and queue is locked.
30-29 ERR	Error Indicates whether the IPCR stored by a Master with required access attributes wrt target group MDAD 00b - IPCR programming with required attributes 01b - IPCR-DATZ programming without required attributes 10b - IPCR-SEQID programming without required attributes 11b - IPCR-DATZ and SEQID both programming without required attributes
28 CLR	Clear Clears the status in IPCR Status register. This register can only be cleared by the master having security attribute defined by TGnMDAD[SA]. After clearing if there is any valid transaction present in MDAD queue it will again get updated in this register else it will be cleared. It will not be cleared if TGxMDAD[SA] bits are set to 00.
27-23 —	Reserved
22	Arbitration Unlock

Table continues on the next page...

Table continued from the previous page...

Field	Function
ARB_UNLOCK	Specifies if the arbitration unlock is requested for TGn. 0b - No effect 1b - Arbitration unlock is requested
21 ARB_LOCK	Arbitration Lock Specifies if the arbitration lock is requested for TGn. 0b - No effect 1b - Arbitration lock is requested
20 PAR	Parallel Mode Enable Value Indicates the parallel mode enable value programmed in the target group queue.
19-16 SEQID	SEQID Value Indicates the SEQID value programmed in target group queue.
15-0 IDATSZ	IDATSZ Value Indicates the IDATSZ value programmed in target group queue.

77.13.2.51 Master Global Configuration (MGC)

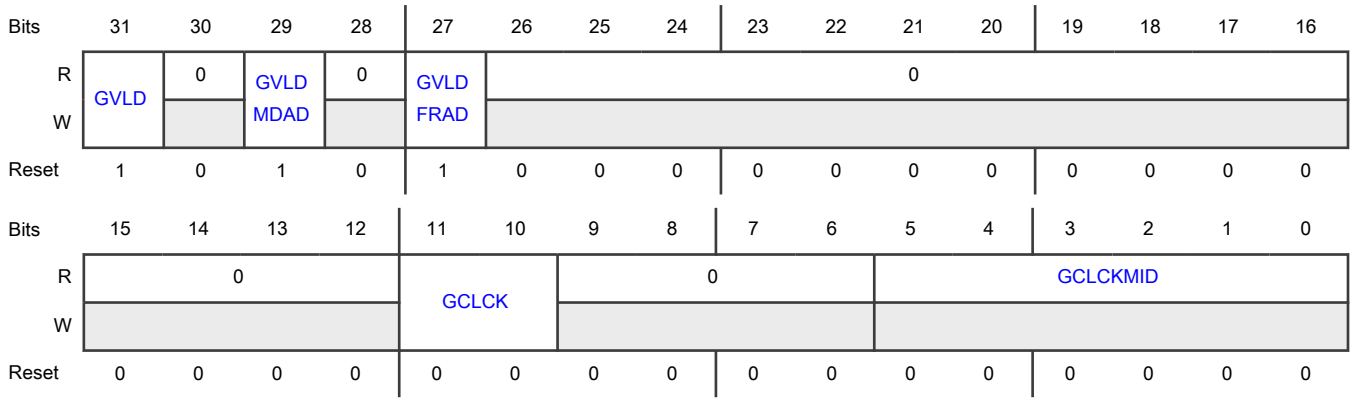
Offset

Register	Offset
MGC	920h

Function

This register is access controlled. It can only be programmed by master with master ID equal to 000011b. For MGC, MRC and MTO registers access checks master ID is being used. For transaction level checks inside MDAD and FRAD domain IDs are being used.

Diagram



Fields

Field	Function
31 GVLD	Global Valid access control 0b - Access controls are disabled. No descriptor comparison check. All transactions are allowed. 1b - Access controls are enabled.
30 —	Reserved
29 GVLDMDAD	Global Valid MDAD 0b - MDADs are disabled 1b - MDADs are enabled
28 —	Reserved
27 GVLDFRAD	Global Valid FRAD 0b - FRADs are disabled 1b - FRADs are enabled
26-12 —	Reserved
11-10 GCLCK	Global Configuration Lock This field provides a mechanism to limit write access to descriptors specific registers (MGC, MRC and MTO registers). 00b - Global Lock disabled. Registers can be written based on individual register acccess attribute. 01b - NA 10b - Lock enabled. Only the global configuration lock owner can write to the registers. 11b - Lock enabled. All registers are read only until unlocked
9-6 —	Reserved
5-0 GCLCKMID	Global configuration Lock Owner Status This fields specifies the 6-bit Master-ID of Global configuration Lock owner (which set MGC[GCLCK]=10). Input value of Global Master-ID is provided by sideband signals.

77.13.2.52 Master Read Command (MRC)

Offset

Register	Offset
MRC	924h

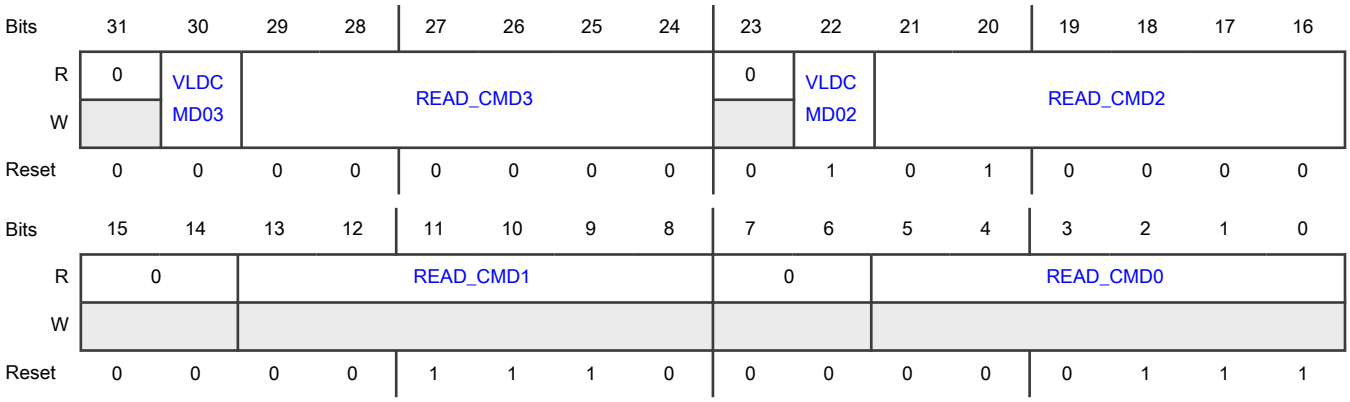
Function

This register is access controlled. It can only be programmed by master with master ID equal to 000011b.

NOTE

In case of Sequence Auto Join instruction in LUT, SFP will parse only first sequence. Second sequence will not be parsed for checking Read commands.

Diagram



Fields

Field	Function
31 —	Reserved
30 VLDCMD03	Valid command 0b - READ_CMD3 value invalid 1b - READ_CMD3 value valid
29-24 READ_CMD3	Read Command 3 Programmes the additional READ Instruction/Command encoding information, if applicable
23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - READ_CMD2 value invalid 1b - READ_CMD2 value valid
21-16 READ_CMD2	Read Command 2 Stores the existing instruction—DATA_LEARN command encoding information. Can be overritten with additional read command, if required.
15-14 —	Reserved
13-8 READ_CMD1	Read Command 1 Stores the existing instruction—READ_DDR command encoding information.
7-6 —	Reserved
5-0 READ_CMD0	Read Command 0 Stores the existing instruction—READ command encoding information.

77.13.2.53 Master Timeout (MTO)

Offset

Register	Offset
MTO	928h

Function

This register is access controlled. It can only be programmed by master with master ID equal to 000011b.

Diagram

Fields

Field	Function
31-0 WRITE_TO	Write Timeout Maximum timeout value to abort the ongoing write or read command. The timeout counter starts after the access from any target queue has won the arbitration and QSPI is IDLE (FSM_STAT state field is not 00). SFP queue is cleared once this timeout value has been reached and interrupt is generated if enabled.

77.13.2.54 FlashSeq Request (FLSEQREQ)

Offset

Register	Offset
FLSEQREQ	92Ch

Function
This register is access controlled and can only be programmed by privilege masters.

5-0 REQ_MID	FlashSeq Request Master ID Indicates the master-ID of last executed FlashSeq request.

77.13.2.55 FSM Status (FSMSTAT)

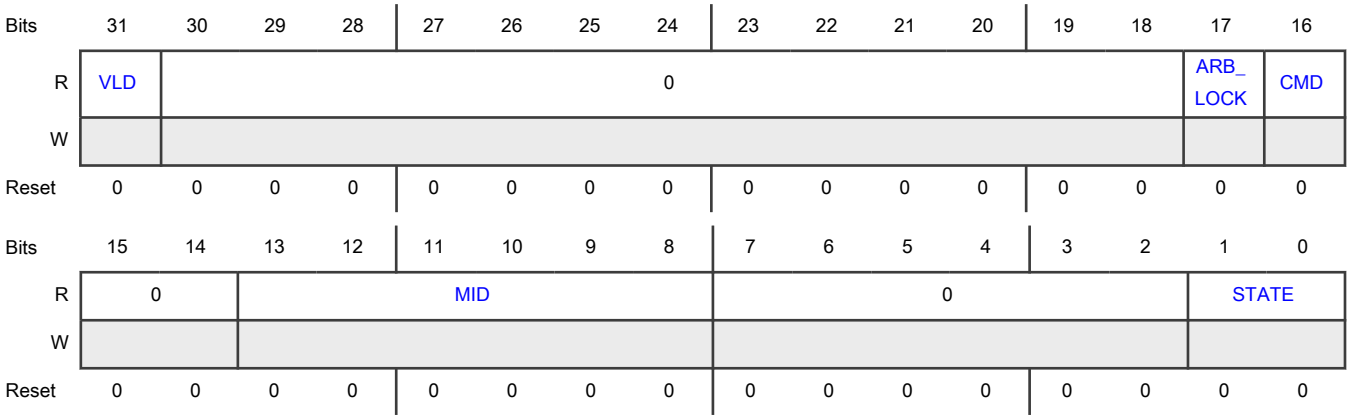
Offset

Register	Offset
FSMSTAT	930h

Function

This register is access controlled and can only be programmed by privilege masters.

Diagram



Fields

Field	Function
31 VLD	Valid Indicates whether the FSM Status is valid. 0b - Status is invalid. No IPS transfer is queued. 1b - Status is valid. IPS transfer is queued or execution on QuadSPI.
30-18 —	Reserved
17 ARB_LOCK	Arbitration Lock Arbitration lock status for present request. 0b - Arbitration not locked 1b - Arbitration locked
16 CMD	Command Instruction type of currently initiated Flash transaction on QuadSPI. 0b - Read instruction sequence 1b - Non-read instruction sequence
15-14 —	Reserved
13-8 MID	Master ID Indicates the Master-ID of the currently initiated FlashSeq transaction on QuadSPI.
7-2 —	Reserved
1-0	FSM State Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
STATE	00b - Transaction is Queued, but QuadSPI is busy with AHB transfer, any previous DMA transaction is ongoing, any residue data left in RDBFL or if any interrupt is pending.. 01b - TBDR lock is open. IPS master can write in TBDR. 10b - Write transfer is triggered. SEQID is written to QuadSPI. 11b - Read transfer is triggered. SEQID is written to QuadSPI.

77.13.2.56 IPS Error (IPSERROR)

Offset

Register	Offset
IPSERROR	934h

Function

This register contains the error status of IPS write on SFAR or IPCR registers if they are not qualified for any of the target group queues.

This register is access controlled and can only be programmed by privilege masters.

Diagram

Fields

Field	Function
31-15 —	Reserved
14 TO_ERR	Timeout Error This field is set if any flash transaction generated on QuadSPI results in timeout error and is aborted by SFP module. This field can be cleared by writing 1 to FLSEQREQ[CLR]. 0b - No timeout Error generated 1b - Timeout error is generated
13-12 TGnIPCR	TGn IPCR Error This field is set if any IPCR write generates error while being written to Target group queue. This field can be cleared by writing 1 to TG*n*IPCRS[CLR]. 0b - No Error generated 1b - Error is generated
11-10 TGnSFAR	TGn SFAR Error This field is set if any SFAR write generates error while being written to Target group queue. This field can be cleared by writing 1 to TG*n*SFARS[CLR]. 0b - No Error generated 1b - Error is generated
9 IPS_ERR	IPS Error Some common error occurred and IPS bus transfer error is also generated. The details of the IPS error can be found in IPSERROR register. This field can be cleared by writing 1 to IPSERROR[CLR].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No Error generated 1b - Error is generated
8-1 FRADnACC	FRADn Access Error This bit is set when the transaction address lies within the address range of this FRAD but it doesnâ€™t qualifies the access permission checks for this FRAD or this FRAD was under exclusive lock (FRAD*n*_WORD3[EAL] = 10 or 11) by another master. It may also be set if the transaction address qualifies for multiple FRAD regions. 0b - No valid Error transaction 1b - Transaction is with error and taret queue is cleared
0 FRADMTCH	No FRAD Match Error Transaction address does not lie within address range of any FRAD descriptor. 0b - No Error generated 1b - Transaction does not lie within any FRAD address range and error is generated

77.13.2.58 Interrupt Enable (INT_EN)

Offset

Register	Offset
INT_EN	93Ch

Function

This register is access controlled and can only be programmed by privilege masters.

NOTE

In case Queue Specific Error Interrupt bits (TG0SFAR,TG1SFAR,TG0IPCR,TG1IPCR) are enabled, ensure that the core executing interrupt handler can clear the Queue specific TGxSFARS and TGxIPCRS registers only when core's security attribute matches the queue. In case there is a mismatch in security attribute, you must change the TGMDADx.SA attribute of that queue to match the core SA attribute. After that, core can clear the error and then revert the changes in TGMDADx.SA field.

77.13.3 Serial flash memory address assignment

The serial flash memory address assignment can be modified by writing into Serial Flash Memory A1 Top Address Register (SFA1AD) and Serial Flash Memory A2 Top Address Register (SFA2AD) for device A

Table 673. Serial flash memory address assignment

Parameter	Function	Access mode
QuadSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address First address of the serial flash memory device as presented to the QuadSPI controller. This might be the base of the serial flash memory in the system address map or it may be a remapping, for instance to 0h, performed by the system. (See the system address map file attached to this document)	
QuadSPI_ARDB_BASE	First address of the QuadSPI Rx buffer on system memory map	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash memory A1 (the first of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QuadSPI_AMBA_BASE is routed to serial flash memory A1.
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash memory A2 (the second of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 is routed to serial flash memory A2.

77.14 Flash memory mapped AMBA bus

QuadSPI_AMBA_BASE defines the address to be used as the start address of the serial flash memory device, as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash memory in the system. See the system address map for details.

Table 674. QuadSPI AMBA bus memory map

Address	Register name
QuadSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 1h)	• See Memory-mapped serial flash memory data—individual flash memory mode on flash memory A. • For information about byte ordering, see Table 638 and Table 639.
QuadSPI_ARDB_BASE to... (32 * 4 Byte) QuadSPI_ARDB_BASE + 1FFh	• See AHB RX Data Buffer Register (ARDB0 - ARDB31). • For information about the byte ordering, see Table 638.

NOTE

Any read access to non-implemented addresses provides undefined results.

In individual flash memory modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash memory address are determined by SFADR[23:0] or SFADR[31:0] as provided in the table shown above.

77.14.1 AHB bus access read considerations

Note that all logic in the QuadSPI module implementing the AHB bus access is designed to read the content of an external serial flash memory device. Therefore, the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- AHB bus read access types—NONSEQ and BUSY—are fully supported.
- AHB read access type—SEQ—is treated in the same way as NONSEQ. See Flash memory mapped AMBA bus for details.
- Early burst termination is not supported for AHB transactions.
- An AHB error response is provided on occurrence of:
  - Parity error
  - ECC error from flash memory
  - Data learning failure

  Also, interrupts (if enabled) are provided along with the AHB error response.

77.14.2 Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

Starting with address QuadSPI_AMBA_BASE, the content of the first external serial flash memory device is mapped into the address space of the device containing the QuadSPI module. Serial flash memory byte address 0h corresponds to bus address, QuadSPI_AMBA_BASE, in an increasing order. . See the following table for the address mapping. The byte ordering for 32-bit access is provided in Table 638 and for 64-bit read access, the byte ordering is provided in Table 639.

Table 675. Memory-mapped individual flash memory mode—flash memory A address scheme

Memory-mapped address 32-bit access	Memory-mapped address 64-bit access	Serial flash memory byte address	Flash memory device
QuadSPI_AMBA_BASE + 0h	QuadSPI_AMBA_BASE + 0h	0h to 3h	A1
QuadSPI_AMBA_BASE + 4h		4h to 7h	
...	...	...	
TOP_ADDR_MEMA1 - 8h	TOP_ADDR_MEMA1 - 8h	(TOP_ADDR_MEMA1- 8h) to (TOP_ADDR_MEMA1 - 0h4 -0h1)	
TOP_ADDR_MEMA1 - 4h		(TOP_ADDR_MEMA1 - 4h) to (TOP_ADDR_MEMA1 - 0h1)	
TOP_ADDR_MEMA1 + 4h	TOP_ADDR_MEMA1 + 0h	0h to 3h	A2
TOP_ADDR_MEMA1 + 0h4		4h to 7h	
...	...	...	
TOP_ADDR_MEMA2 - 8h	TOP_ADDR_MEMA2 - 8h	(TOP_ADDR_MEMA2 - 8h) to (TOP_ADDR_MEMA2 - 4h - 1h)	
TOP_ADDR_MEMA2 - 4h		(TOP_ADDR_MEMA2 - 4h) to (TOP_ADDR_MEMA2 - 1h)	

The available address range depends on the size of the external serial flash memory device. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read.

77.14.3 ARDB register descriptions

NOTE

See the system memory map in this document for the base address of the QuadSPI AHB RX data buffer.

77.14.3.1 ARDB memory map

QuadSPI_ARDB base address: 6800_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 7Ch	AHB RX Data Buffer Register (ARDB0 - ARDB31)	32	RO	0000_0000h

77.14.3.2 AHB RX Data Buffer Register (ARDB0 - ARDB31)

Offset

For a = 0 to 31:

Register	Offset
ARDBa	0h + (a × 4h)

Function

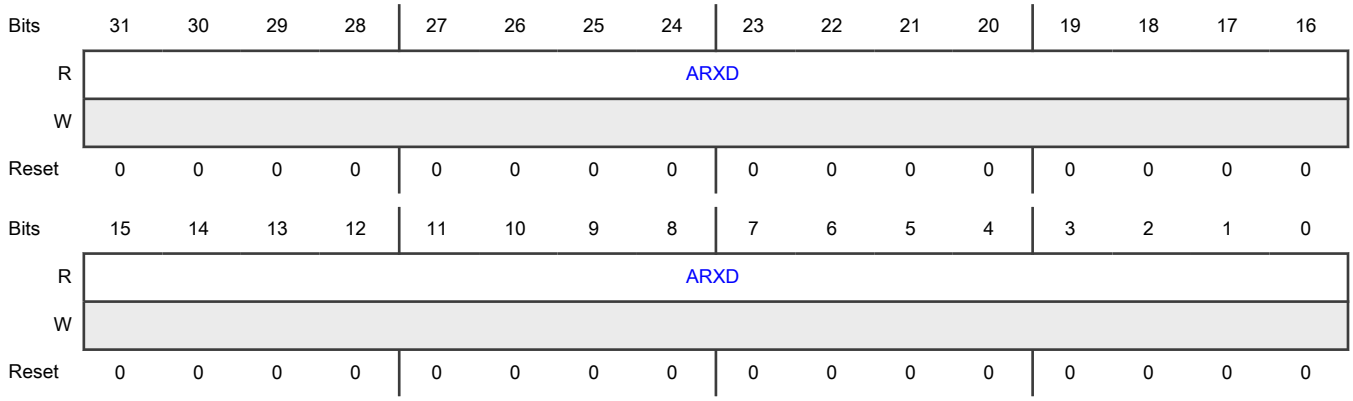
This register is used to read the buffer content of the RX buffer from successive addresses. ARDB0 corresponds to the RX buffer register entry corresponding to the current value of the read pointer in an increasing order.

The increment of the read pointer depends on the access scheme (DMA or flag-driven). See Flash memory read, RX buffer, data read through register interface, and AHB read for the description of successive accesses to the RX buffer content. See Byte Ordering of Serial Flash Memory Read Data for the byte ordering scheme.

Valid address range accessible in the ARDB*n* range depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

- Example 1 - RX buffer filled completely with 32 words: In this case, the address range for valid read access extends from ARDB0 to ARDB31 .
- Example 2 - RX buffer filled with five valid words; RX buffer fill level RBSR[RDBFL] is 5. In this case, an access to ARDB4 provides the last valid entry.

Diagram



Fields

Field	Function
31-0 ARXD	ARDB provided RX buffer data Byte order (endianness) is identical to the RX buffer data registers.

Ultra Secured Digital Host Controller (uSDHC)

78.1 Chip-specific uSDHC information

78.1.1 uSDHC instances and configuration

This chip supports up to one instance of uSDHC module.

Table 676. uSDHC instances

Instance	S32K358	S32K3x2/ S32K3x4/ S32K3x1
uSDHC	Yes	No

Table 677. Features supported

Features	Notes
MMC	• System specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1 • Bit Widths x1/x4/x8 • Full Speed Mode upto 25MHz • High Speed SDR upto 50MHz • High Speed DDR mode (50MHz both edges)
SD/ SDIO	• Card Specification version 2.0/3.0 • Bit Widths x1/x4 • Full Speed Mode upto 25MHz • High Speed Mode upto 50MHz
FIFO	128 x 32 external FIFO supported
External DMA	Supported
Write Protect WP system implementation	Supported
Voltage support	3.3 V

NOTE

Card clock pin should have weak pull down enabled when configured for uSDHC function.

This chip doesn't support the following features:

- MMC HS400 MODE
- Card Detection (CD) System Implementation
- LED control (LCTL) output signal
- IO power Voltage selection Signal (VSELECT)
- Input clock for eMMC HS400 mode (STROBE)

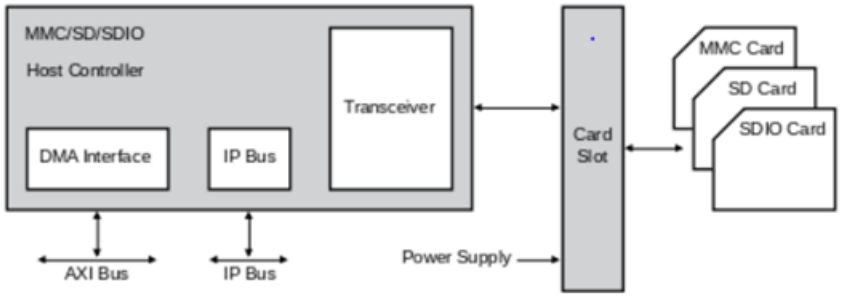

Figure 483. System connection of uSDHC

78.2 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the eMMC, SD card, and SDIO card as shown in Figure 485. The module acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO card by sending commands and performing data accesses to/from the cards. It handles the SD card/SDIO card/eMMC protocols at the transmission level.

78.2.1 Block diagram

The following figure illustrates the block diagram for uSDHC.

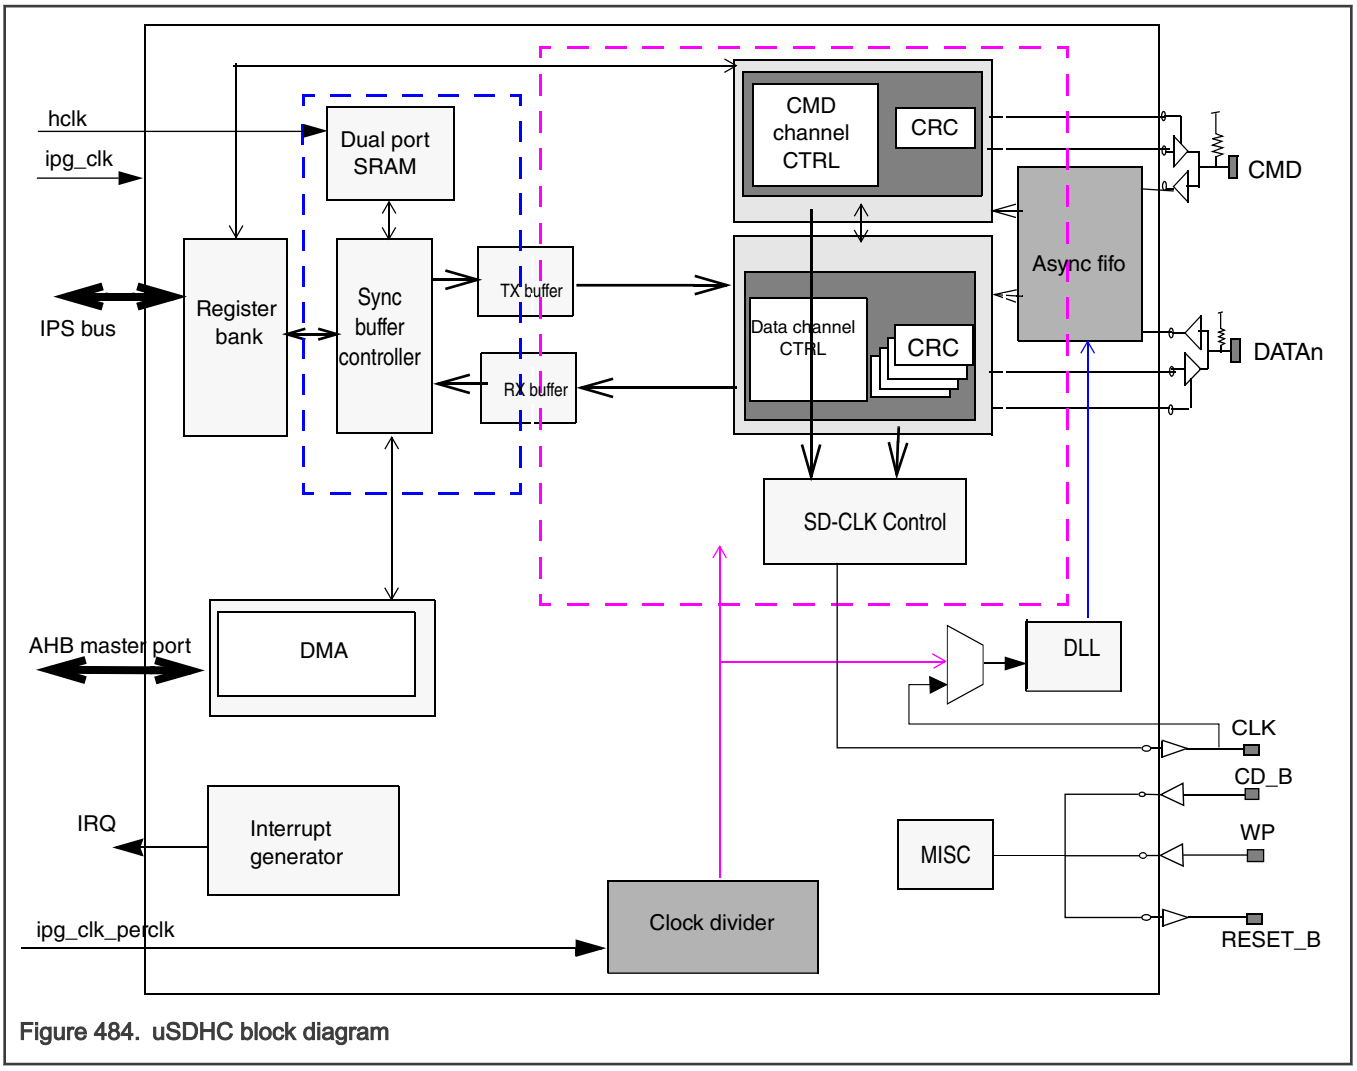

Figure 484. uSDHC block diagram

The figure below shows the System connection of uSDHC:

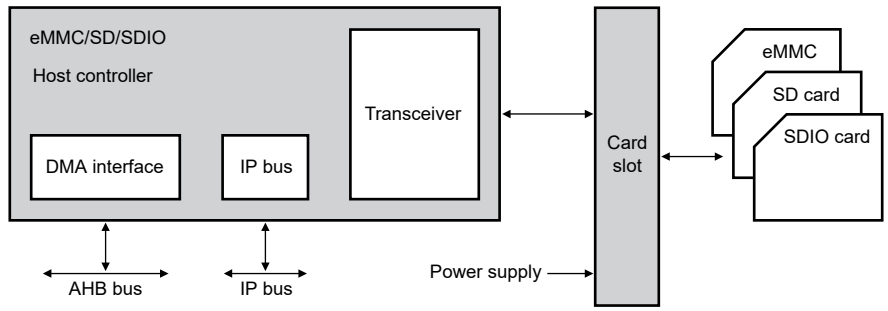

Figure 485. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Embedded MultiMediaCard (eMMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous eMMC were based on a 7-pin serial bus with a single data pin, while the new high speed eMMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

- The Secure Digital Card (SD) is an evolution of the old eMMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old eMMC (with some additions).
- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low-power consumption for mobile electronic devices.

78.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0
- Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, eMMC, eMMC plus, and eMMC RS cards
- Card bus clock frequency up to 104 MHz
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit eMMC modes
  - Up to 200 Mbps of data transfer for SDIO cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 200 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 416 Mbps of data transfer for eMMC using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 832 Mbps of data transfer for eMMC using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Supports voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

78.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

78.3.1 Modes and operations

78.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- eMMC 1-bit
- eMMC 4-bit
- eMMC 8-bit
- Identification mode (up to 400 kHz)
- eMMC full-speed mode (up to 26 MHz)
- eMMC high-speed mode (up to 52 MHz)
- eMMC DDR mode (52 MHz both edges)
- SD or SDIO cards full-speed mode (up to 25 MHz)
- SD or SDIO cards high-speed mode (up to 50 MHz)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

78.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced high-performance bus (AHB) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. The burst lengths for read and write are also configurable and can range between 1 to 31 words. The next figure provides the uSDHC buffer scheme as buffer control and buffer RAM wrapper.

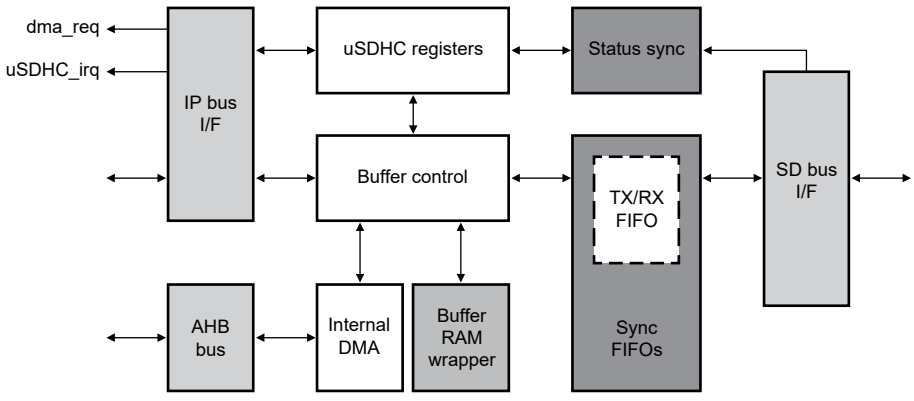

Figure 486. uSDHC buffer scheme

Here are 3 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in WTMK_LVL[RD_WML], a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Data Buffer Access Port (DATA_BUFF_ACC_PORT). If the number of words in the buffer after the current burst meets or exceeds RD_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the buffer as there are in the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in WTMK_LVL[RD_WML], the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always the INCR mode and the burst length depends on the shortest of the following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 KB address boundary defined in the AHB protocol

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

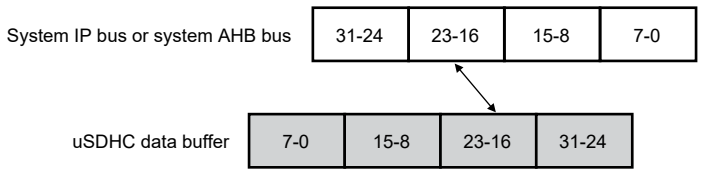

Figure 487. Data swap between system bus and uSDHC data buffer in the byte little endian mode

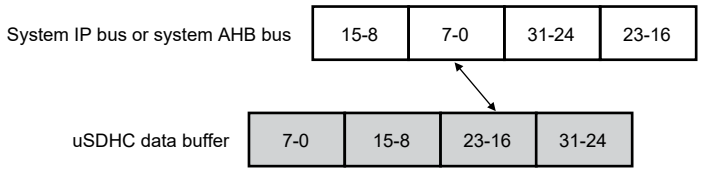

Figure 488. Data swap between system bus and uSDHC data buffer in half word big endian mode

78.3.2.1 Write operation sequence

There are 3 ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in WTMK_LVL[WR_WML] and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

78.3.2.2 Read operation sequence

There are 3 ways to read data from the buffer when the data is received from the card:

- External DMA through uSDHC DMA request signal
- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any read transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

78.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. For both read and write, the watermark level can range between 1 to 128 words. For both read and write, the burst length can range between from 1 to 31 words. The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

78.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the division of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

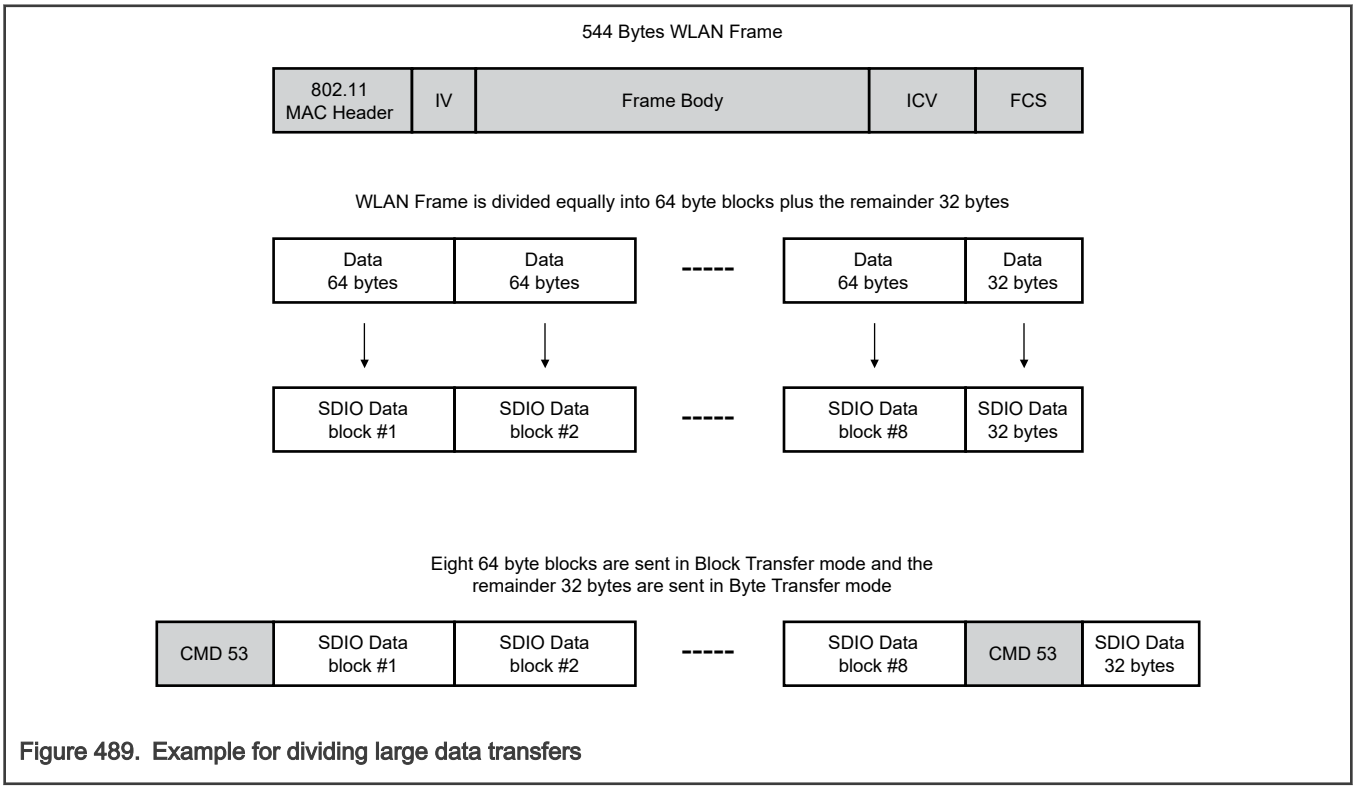

Figure 489. Example for dividing large data transfers

78.3.2.5 External DMA request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal uSDHC_dreq_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Buffer Access Port (DATA_BUFF_ACC_PORT) are made while the buffer's free space can't meet the watermark condition (free space> write watermark level).

On read operation, when the number of RD_WML words are already in the buffer, the signal uSDHC_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in

the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLK_ATT[BLKSIZE] will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See DMA burst length for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via Data Buffer Access Port (DATA_BUFF_ACC_PORT), the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLK_ATT[BLKSIZE] fields. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

78.3.3 DMA AHB interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See the figure below for an illustration of the DMA AHB interface block.

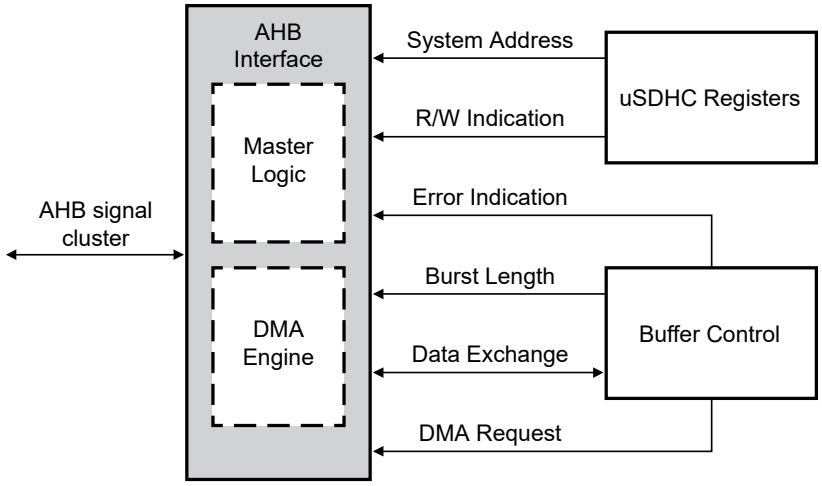

Figure 490. DMA AHB interface block

78.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AHB interface. Meanwhile, the external DMA request signal (uSDHC_dreq_b) is disabled.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

78.3.3.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can range between 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. See the example in Internal DMA request. After six words are read, the burst length is two words, then the next burst length is six words. This is because the next block starts, which is 31 bytes, more than six words. The host driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length is the same.

78.3.3.3 AHB master interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

78.3.3.4 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

78.3.3.4.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor

- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 491. Format of the ADMA1 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA1.

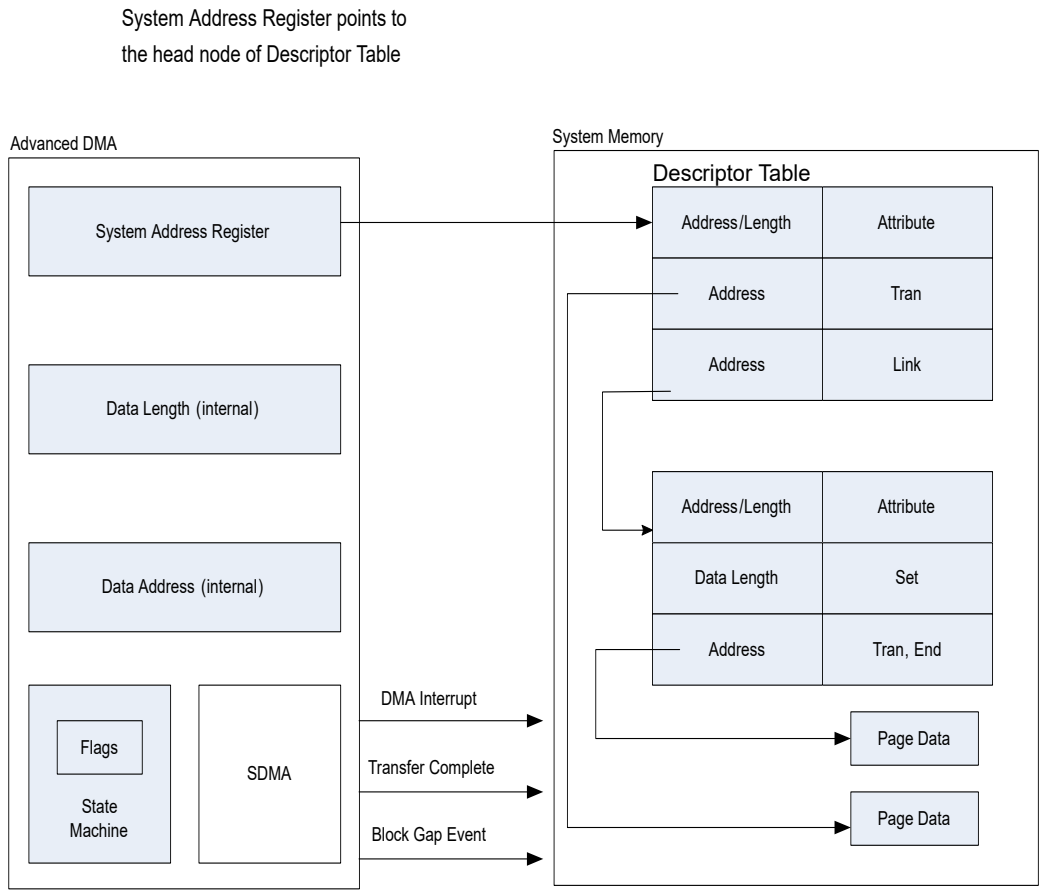

Figure 492. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 493. Format of the ADMA2 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA2.

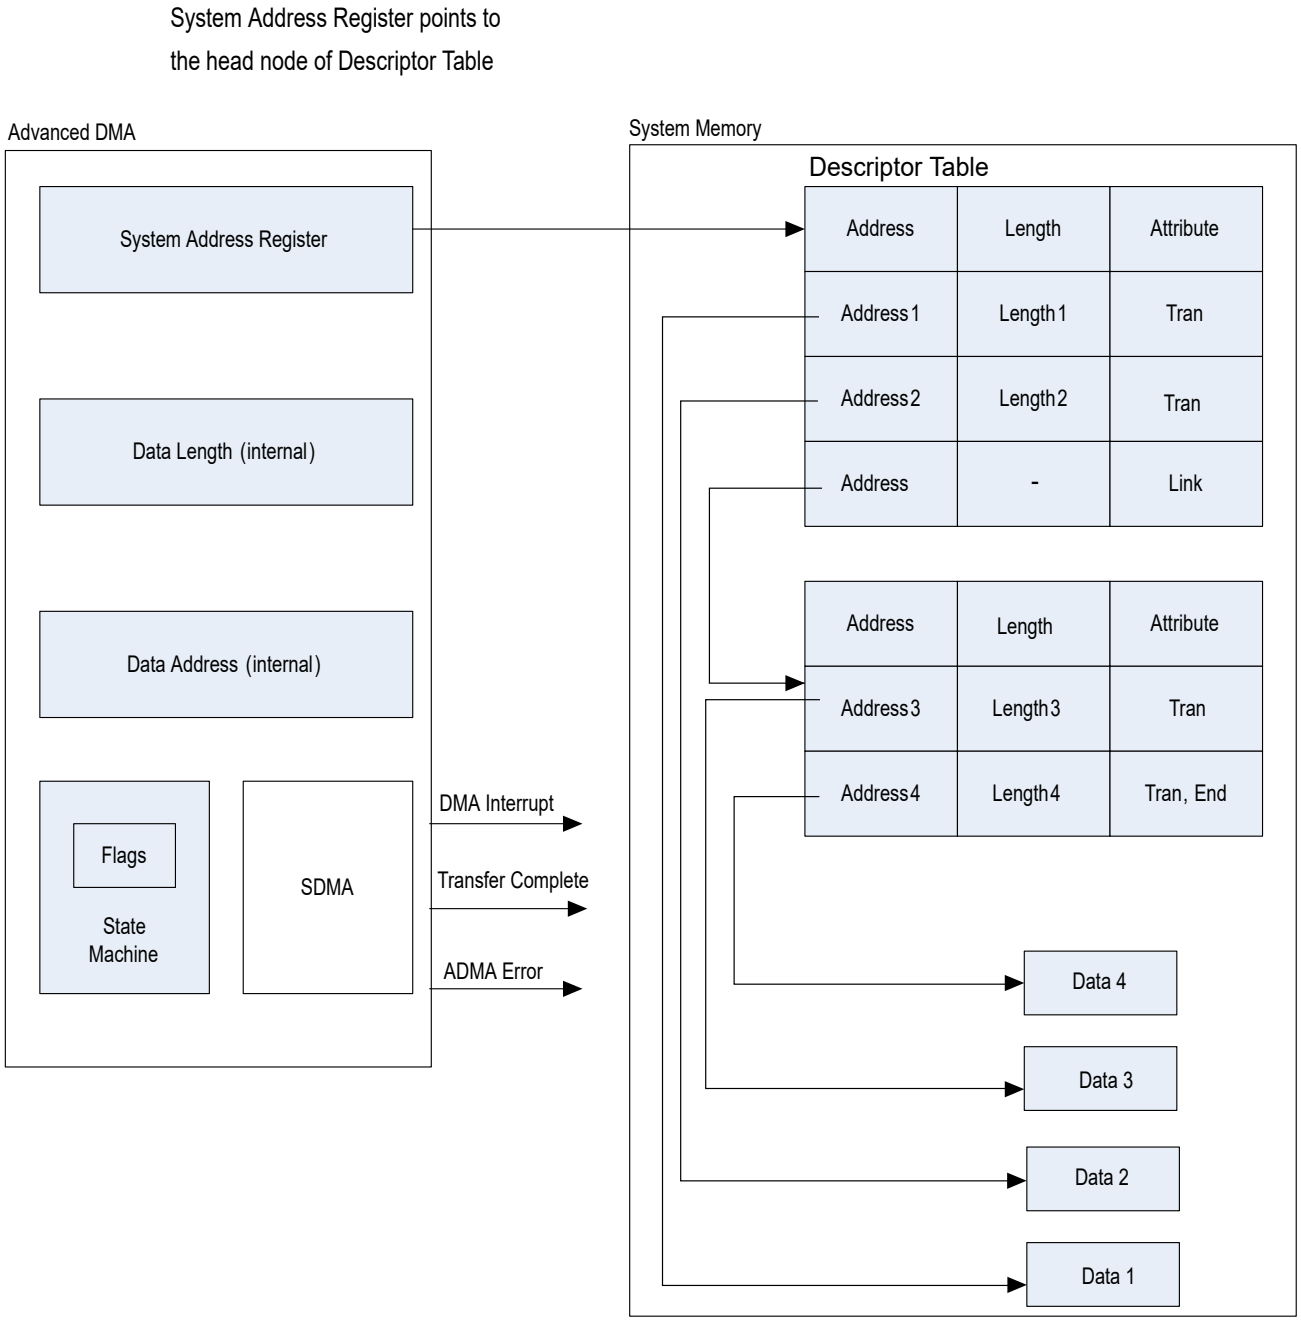

Figure 494. Concept and access method of the ADMA2 descriptor table

78.3.3.4.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.

- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

78.3.3.4.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

78.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See the figure below for the block diagram.

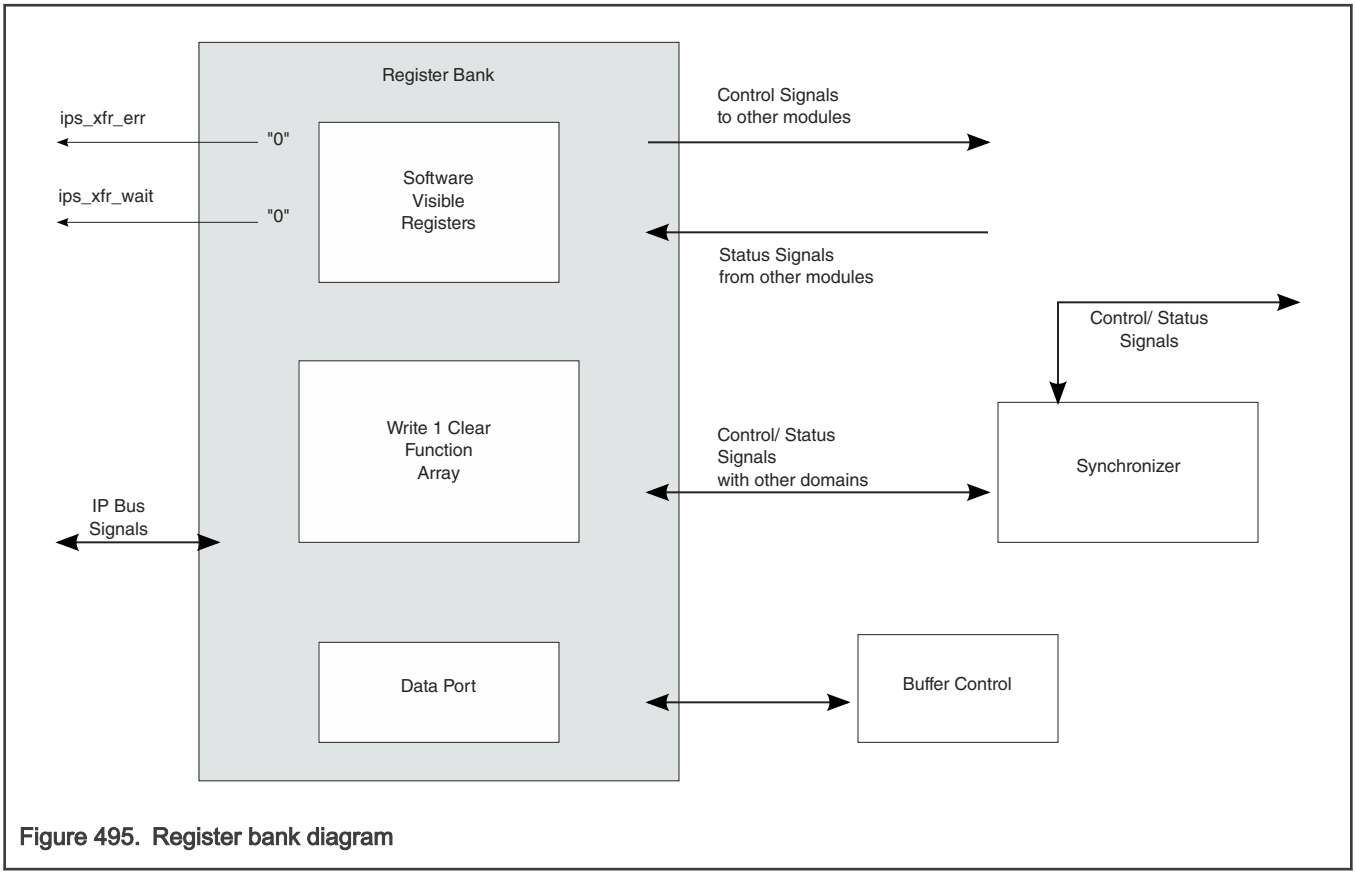

Figure 495. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

78.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD control misc
- Command control
- Data control
- Clock control

78.3.4.2 SD control misc

In the SD control misc unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is active, writes to memory and combo cards are ignored.

78.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

78.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC shift register.

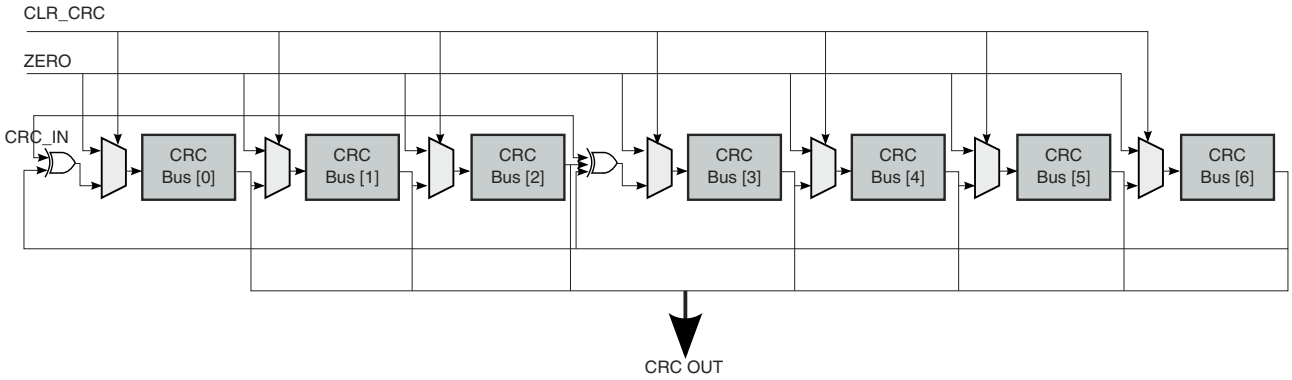

Figure 496. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

78.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

78.3.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the eMMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

78.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

78.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

78.3.7 eMMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (eMMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 setting, please see the eMMC4.3 specification.

78.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal eMMC initialization sequence by sending CMD1.

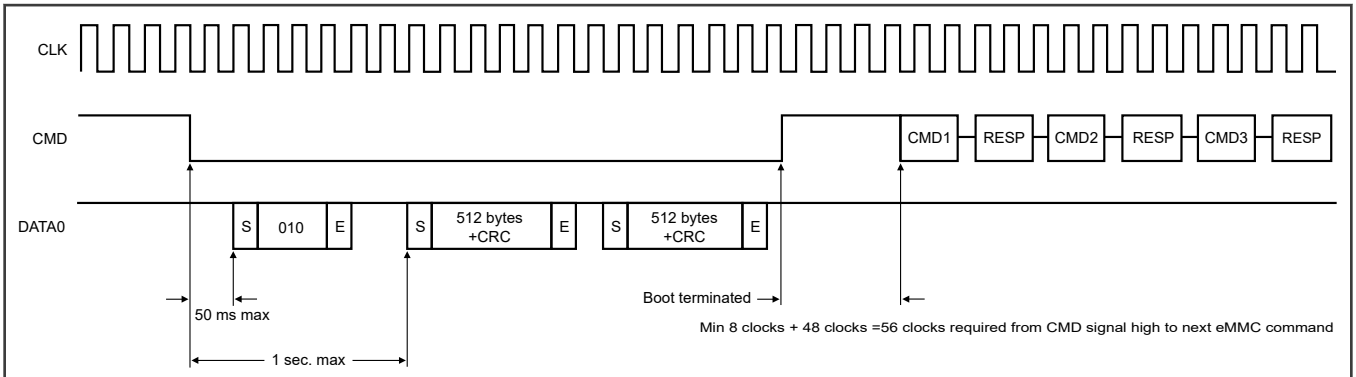

Figure 497. Embedded MultiMediaCard state diagram (normal boot mode)

78.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave must send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal eMMC initialization sequence by sending CMD1.

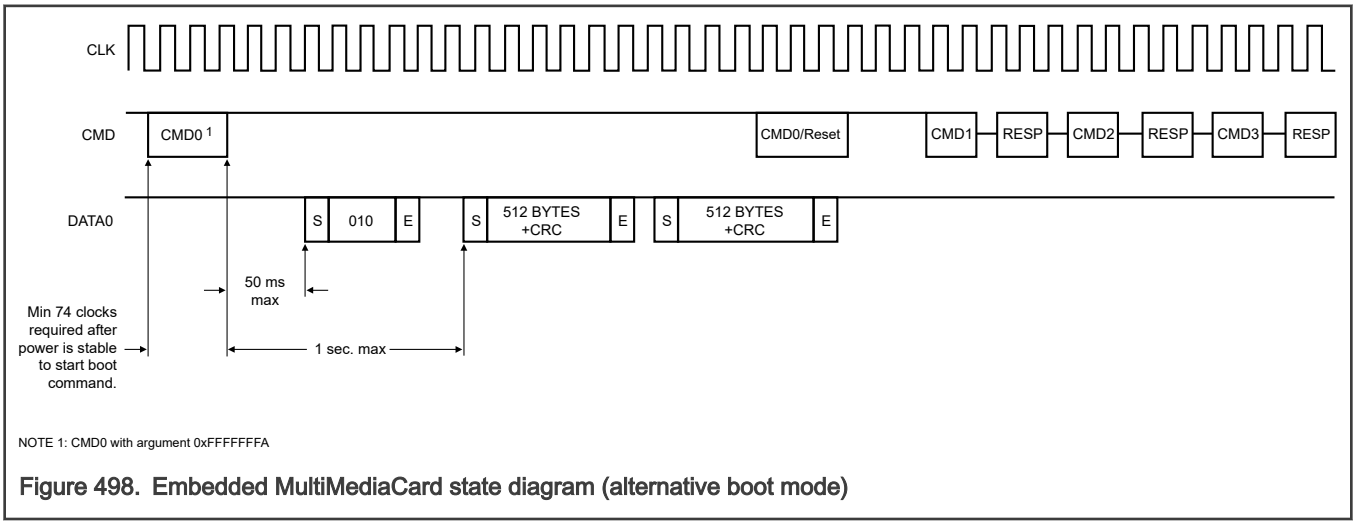

Figure 498. Embedded MultiMediaCard state diagram (alternative boot mode)

78.3.8 Commands for SD card, SDIO card, and eMMC

A table containing the list of commands for the eMMC/SD card/SDIO card is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the eMMC:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 678. Commands for eMMC/SD card/SDIO card

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all eMMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all eMMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set			Embedded MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.

Table continues on the next page...

Table 678. Commands for eMMC/SD card/SDIO card (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	Reserved				
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.

Table continues on the next page...

Table 678. Commands for eMMC/SD card/SDIO card (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the eMMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				

Table continues on the next page...

Table 678. Commands for eMMC/SD card/SDIO card (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				

Table continues on the next page...

Table 678. Commands for eMMC/SD card/SDIO card (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for eMMC and SD cards. For eMMC, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed eMMC and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed eMMC. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 679.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 679. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.

Table continues on the next page...

Table 679. EXT_CSD access modes (continued)

10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

78.3.9 Clocks

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 680. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock for register access
ipg_clk_perclk	Base clock

78.3.10 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

78.3.11 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

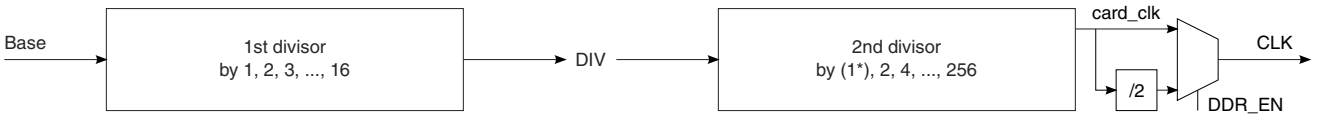

Figure 499. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 486) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

- In the DDR mode, CLK is equal to card_clk/2.

78.3.12 SDIO card interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

78.3.12.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

78.3.12.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10 for further information about the SDIO card interrupt.

78.3.12.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

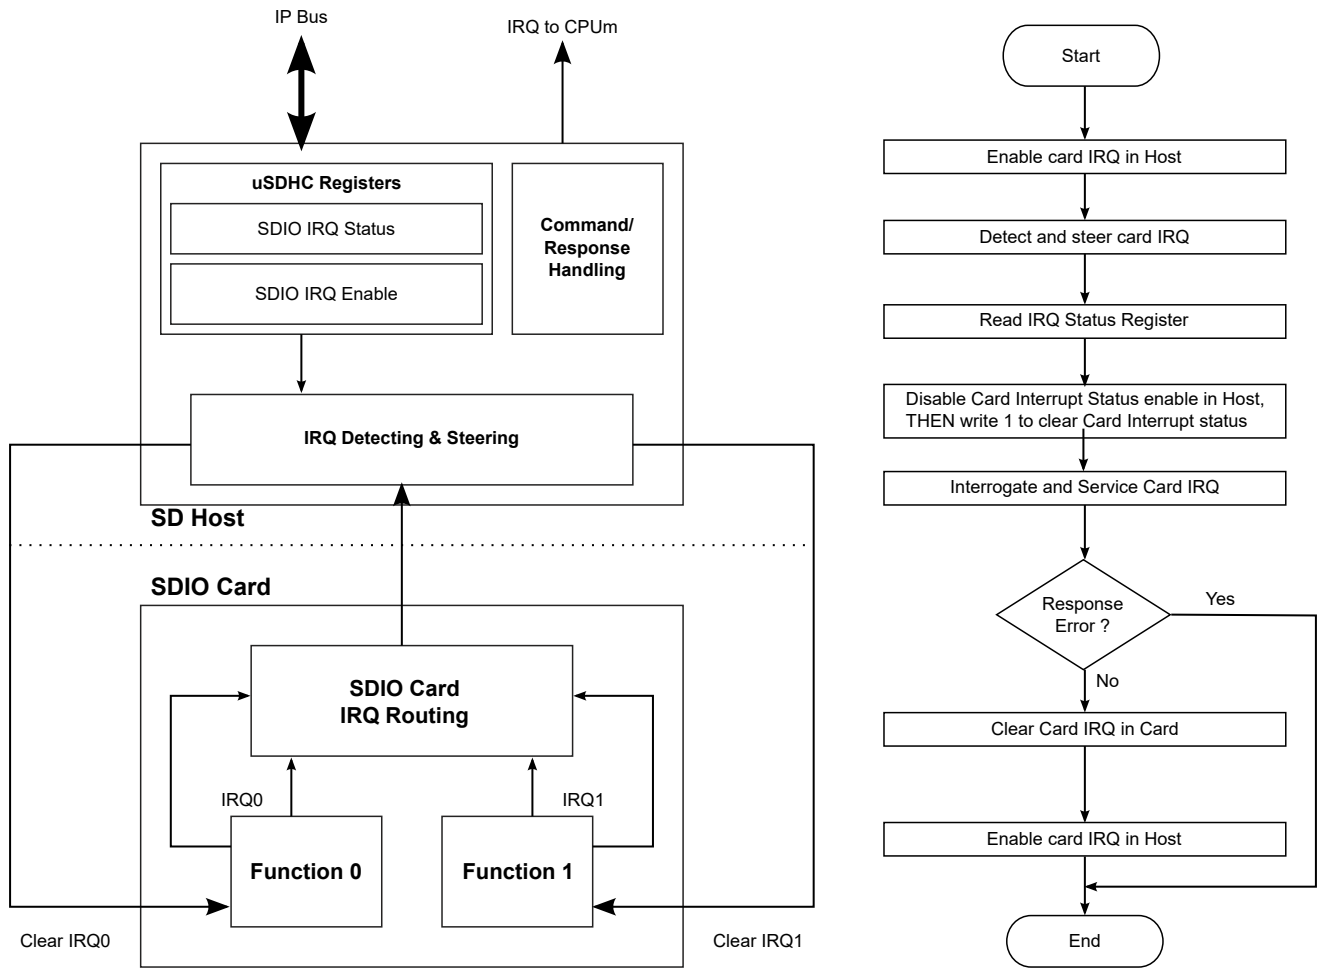

Figure 500. Card interrupt scheme, card interrupt detection, and handling procedure

78.4 External signals

The following table describes the uSDHC external signals:

Table 681. uSDHC external signals

Signal	Description	Direction
CLK	Clock for eMMC/SD card/SDIO card	O
CMD	CMD line connect to card	I/O
DATA7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DATA6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DATA5	DAT5 line in the 8-bit mode —	I/O

Table continues on the next page...

Table 681. uSDHC external signals (continued)

Signal	Description	Direction
	Not used in other modes	
DATA4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
DATA3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DATA2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DATA0	DAT0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection pin If not used (for the embedded memory), tie low to indicate that there is a card attached.	I
WP	Card write protect detect If not used (for the embedded memory), tie low to indicate that it is not write protected.	I
RESET_B	Card hardware reset signal, active low	O

78.4.1 Signals overview

uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the eMMC, SD card, and SDIO card.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC module and the card.
- The CD is card detection signal directly routed from the socket. This signal is active low (0). A low on CD# means that a card is inserted. It is optional for system implementation.
- The WP is write protection signals directly routed from the socket. This signal is active low (0). A high on WP means that the write protect switch is active. It is optional for system implementation.
- RST is an output signal used to reset the eMMC.

If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

78.5 Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for SD card, SDIO card, and eMMC for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. Refer to Commands for SD card, SDIO card, and eMMC for the commands of ac and adtc categories.

78.5.1 Command send and response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)

{

WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is

recommended to implement in a bit-field manner

wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>

set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;

if (internal DMA is used) wCmd |= 0x1;

if (multi-block transfer) {

          set MSBSEL bit;

          if (finite block number) {

                    set BCEN bit;

                    if (auto12 command is to use) set AC12EN bit;

          }

}

write_reg(CMDARG, <cmd_arg>); // configure the command argument

write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command

}

wait_for_response(cmd_index)

{

while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set

read IRQ Status register and check if any error bits about Command are set

if (any error bits are set) report error;

write 1 to clear CC bit and all Command Error bits;
```

```
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

78.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for eMMC.

78.5.2.1 Card detect

See the figure below for a flow diagram showing the detection of eMMC, SD card, and SDIO card using uSDHC.

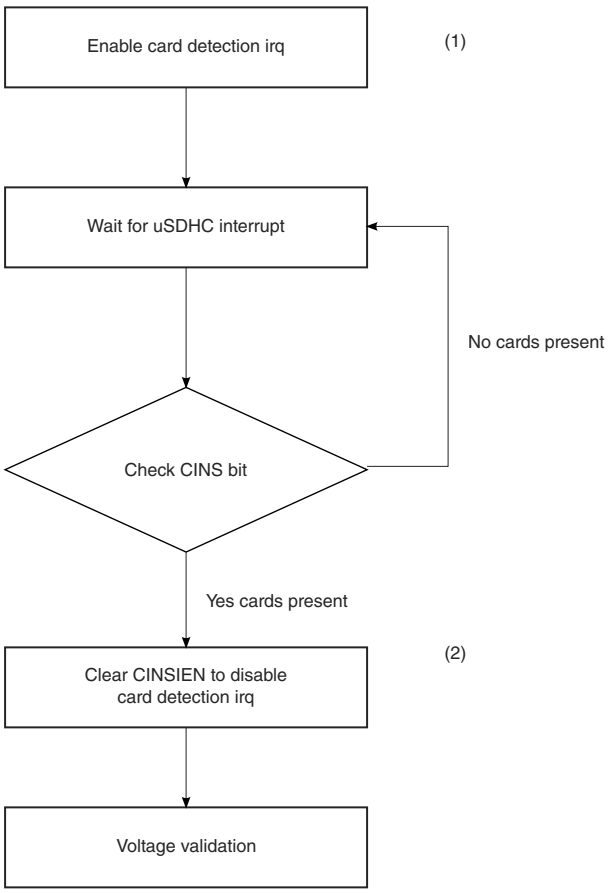

Figure 501. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

78.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of eMMC and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO card, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

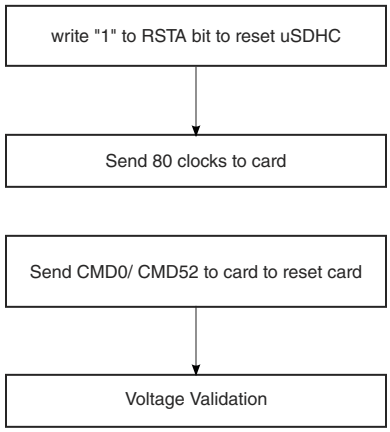

Figure 502. Flow chart for resetting uSDHC and SD I/O card

```
software_reset() {
set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and SDCLKFS bit fields to get the CLK of
frequency around 400kHz
                        //configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB
                        //bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0 or
send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

78.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for eMMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range

must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_argument) {
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation
voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card)
            Label the card as SDCombo; //this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labelled as SDIO card)
        return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific CMD
prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range for
memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN)
            label the card as SD;
        return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be eMMC
        if (card is already labelled as SDCombo) { // change label re-label the card as SDIO;
            ignore the error or report it;
            return; // card is identified as SDIO card
        } //of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if(RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either label
the card as UNKNOWN;
            return;
        } // of if (RESP_TIMEOUT ...
    } // of else
}
```

78.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the eMMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each

card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For eMMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using eMMC:

```
card_registry() {
    do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if(RESP_TIMEOUT == wait_for_response(ALL_SEND_CID))
                break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as eMMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; //arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as eMMC...
    } while (response is not time-out);
}
```

78.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

78.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

78.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For eMMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

78.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.

3. Set the eMMC to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC bus with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

78.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for the SDIO card. This is because when such a command is sent, uSDHC interprets the system that switches to another function on the SDIO card and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and

BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

78.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

78.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

78.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC, block length can be set to only 512 bytes.

2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC to high-speed mode and use SWITCH (CMD6).
4. Set the eMMC bus with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

78.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

78.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the eMMC and SD cards DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are two DLLs, PARTS DLL and STROBE DLL.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

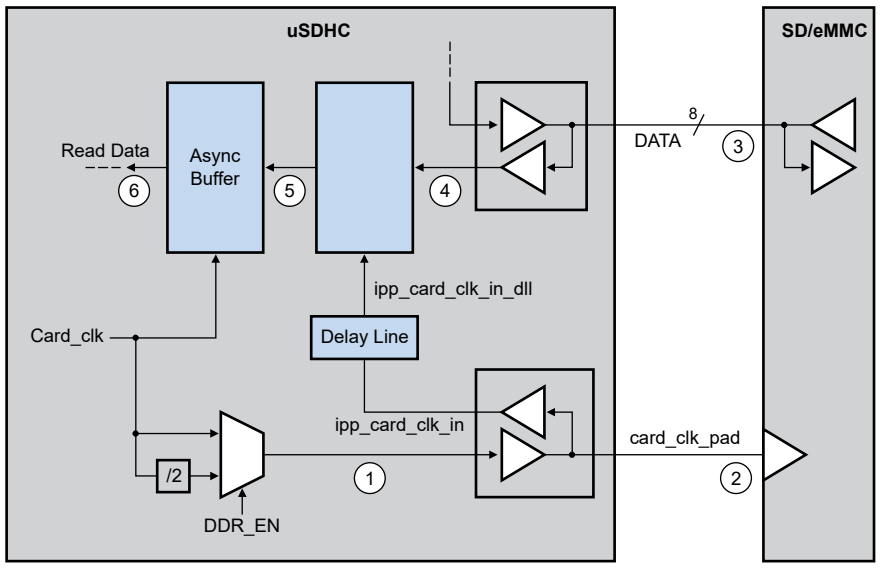

Figure 503. DLL in read path

78.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

78.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

78.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

78.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

78.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

78.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

78.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AHB bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, the previous burst length and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

78.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AHB transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

78.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

78.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

78.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the eMMC and SD cards. The eMMC and SD cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO cards, the high-speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For eMMC, the high-speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of eMMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

78.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

78.5.4.2 Query, enable, and disable SD high-speed mode/DDR50/SDR50/SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
```

```
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;(high
speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

78.5.4.3 Query, enable, and disable eMMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this eMMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report eMMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

78.5.4.4 Set eMMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

78.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

78.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

78.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
```

```
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

78.5.6 Fast boot operation

78.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure eMMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure eMMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

78.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the eMMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

78.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during eMMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that

is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.

7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the eMMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

78.6 Software restrictions

78.6.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

78.6.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

78.6.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

78.6.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

78.6.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

78.6.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

78.6.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

78.6.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for eMMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

78.7 uSDHC memory map/register definition

78.7.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

78.7.1.1 uSDHC memory map

78.7.1.2 DMA System Address (DS_ADDR)

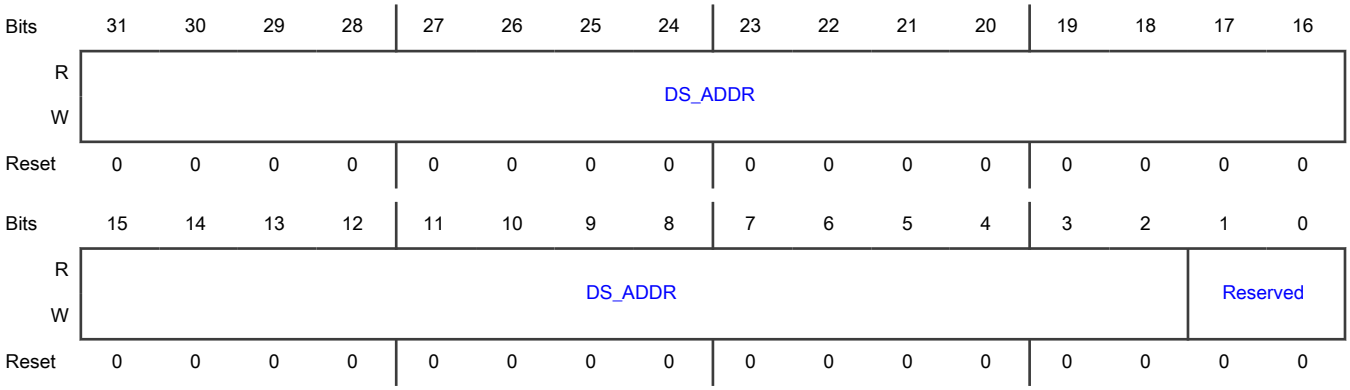
Offset

Register	Offset
DS_ADDR	0h

Function

This register contains the physical system memory address used for DMA transfers.

Diagram



Fields

Field	Function
31-2 DS_ADDR	DMA system address This field contains the memory address for a DMA transfer. Because the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When uSDHC stops a DMA transfer, this field points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this field before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this field. This field is protected during a data transfer. When data lines are active, write to this field is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this field. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Also, because AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC automatically changes SEQ burst type to NSEQ. Because this field supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this field when TC field is set. Such restriction is also listed in Software restrictions.
1-0 —	Reserved

78.7.1.3 Block Attributes (BLK_ATT)

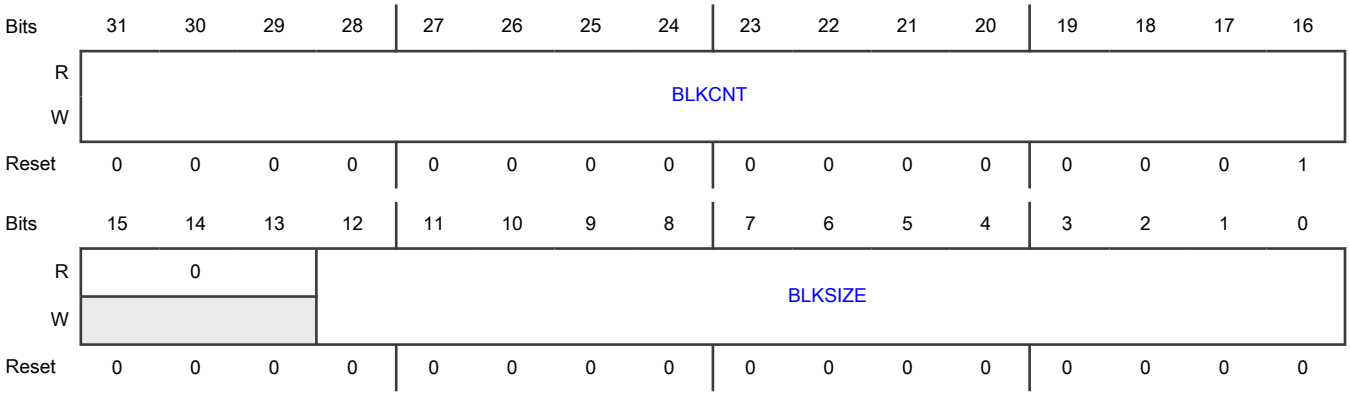
Offset

Register	Offset
BLK_ATT	4h

Function

This register is used to configure the number of data blocks and the number of bytes in each block.

Diagram



Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000_0000_0000_0000b - Stop count 0000_0000_0000_0001b - 1 block 0000_0000_0000_0010b - 2 blocks 1111_1111_1111_1111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0_0000_0000_0000b - No data transfer 0_0000_0000_0001b - 1 byte 0_0000_0000_0010b - 2 bytes 0_0000_0000_0011b - 3 bytes 0_0000_0000_0100b - 4 bytes 0_0001_1111_1111b - 511 bytes 0_0010_0000_0000b - 512 bytes 0_1000_0000_0000b - 2048 bytes 1_0000_0000_0000b - 4096 bytes

78.7.1.4 Command Argument (CMD_ARG)

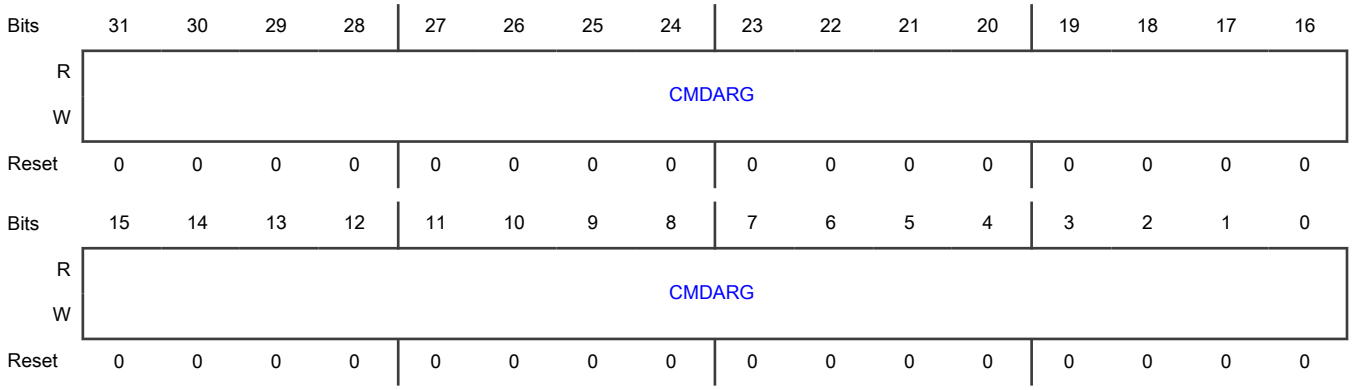
Offset

Register	Offset
CMD_ARG	8h

Function

This register contains the SD/eMMC command argument.

Diagram



Fields

Field	Function
31-0 CMDARG	Command argument The SD/eMMC command argument is specified as bits 39-8 of the command format in the SD or eMMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

78.7.1.5 Command Transfer Type (CMD_XFR_TYP)

Offset

Register	Offset
CMD_XFR_TYP	Ch

Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC

does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 682. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

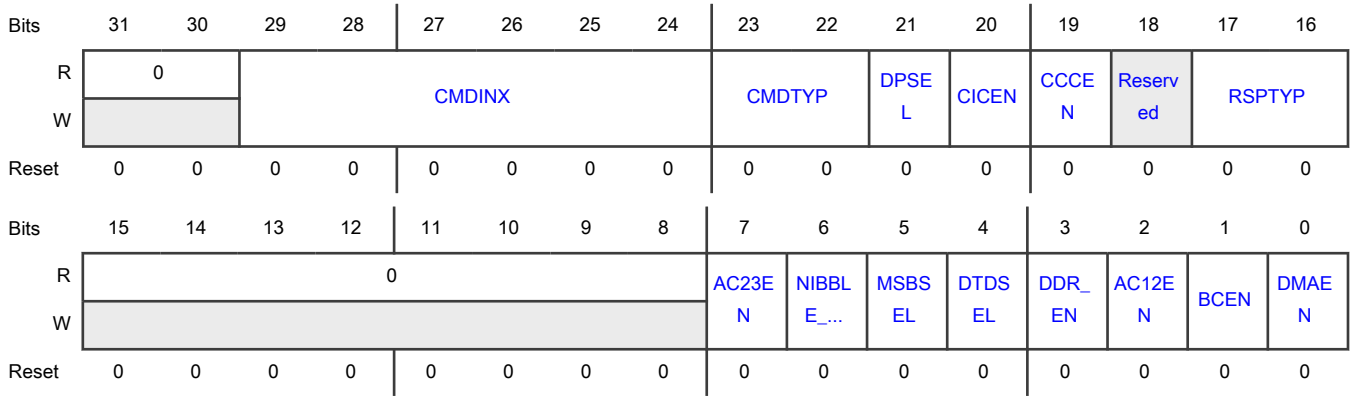
The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 683. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-8 —	Reserved
7 AC23EN	AC23EN This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register. 0b - Disable 1b - Enable
6 NIBBLE_POS	NIBBLE_POS This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
5 MSBSEL	MSBSEL This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Disable 1b - Enable
4 DTDSEL	DTDSEL This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Disable 1b - Enable
3 DDR_EN	DDR_EN Dual data rate mode selection. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0b - Disable 1b - Enable
2 AC12EN	AC12EN Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	BCEN This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0	DMAEN

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMAEN	This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

78.7.1.6 Command Response0 (CMD_RSP0)

Offset

Register	Offset
CMD_RSP0	10h

Function

This register is used to store part 0 of the response bits from the card.

Field	Function
31-0 CMDRSP1	Command response 1 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

78.7.1.8 Command Response2 (CMD_RSP2)

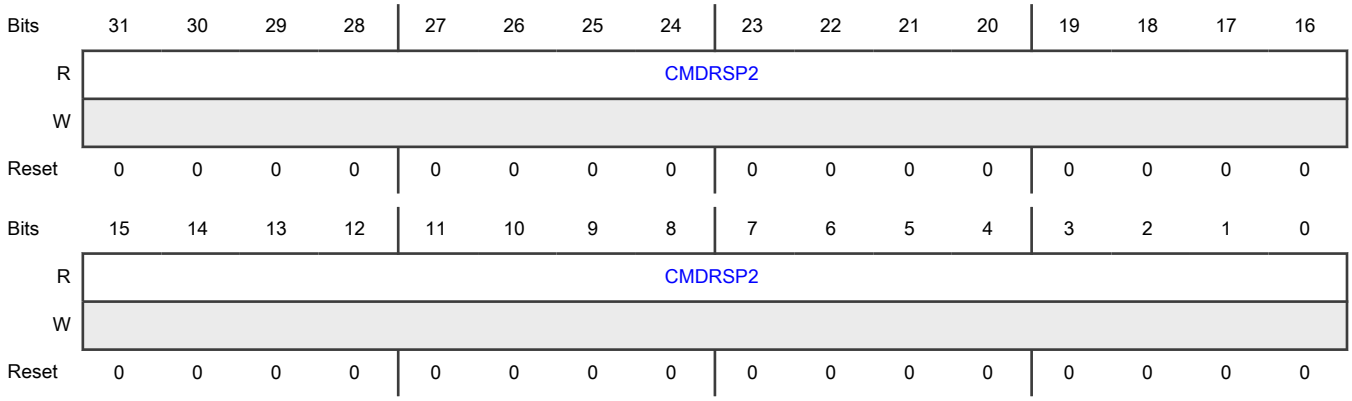
Offset

Register	Offset
CMD_RSP2	18h

Function

This register is used to store part 2 of the response bits from the card.

Diagram



Fields

Field	Function
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

78.7.1.9 Command Response3 (CMD_RSP3)

Offset

Register	Offset
CMD_RSP3	1Ch

Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 684. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}

Table continues on the next page...

Table 684. Response bit definition for each response type (continued)

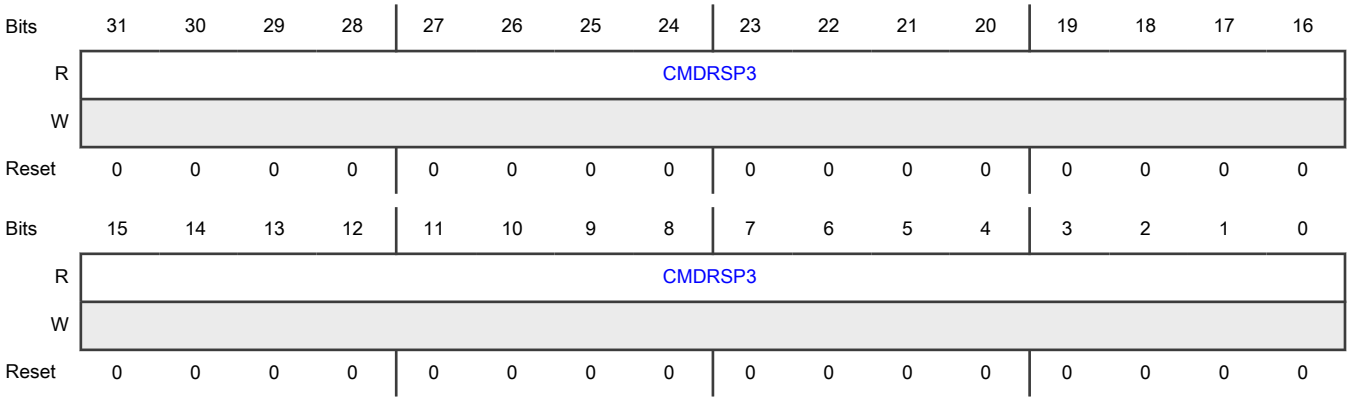
Response type	Meaning of response	Response field	Response register
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Diagram



Fields

Field	Function
31-0 CMDRSP3	Command response 3 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

78.7.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

Function

The Buffer Data Port register is for 32-bit data access by the Arm platform or the external DMA. When the internal DMA is enabled, any write to this field is ignored, and any read from this field always yields 0s.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 DATCONT	Data content This field is used to access the internal buffer.

78.7.1.11 Present State (PRES_STATE)

Offset

Register	Offset
PRES_STATE	24h

Function

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Diagram

Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 0000_0000b - Data 0 line signal level 0000_0001b - Data 1 line signal level 0000_0010b - Data 2 line signal level 0000_0011b - Data 3 line signal level 0000_0100b - Data 4 line signal level 0000_0101b - Data 5 line signal level 0000_0110b - Data 6 line signal level 0000_0111b - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19	Write protect switch pin level

Table continues on the next page...

Table continued from the previous page...

Field	Function
WPSPL	The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0b - Write protected (WP = 1) 1b - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable 1b - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0b - No valid data 1b - Transferring data
7-4 —	Reserved
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / eMMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / eMMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

78.7.1.12 Protocol Control (PROT_CTRL)

Offset

Register	Offset
PROT_CTRL	28h

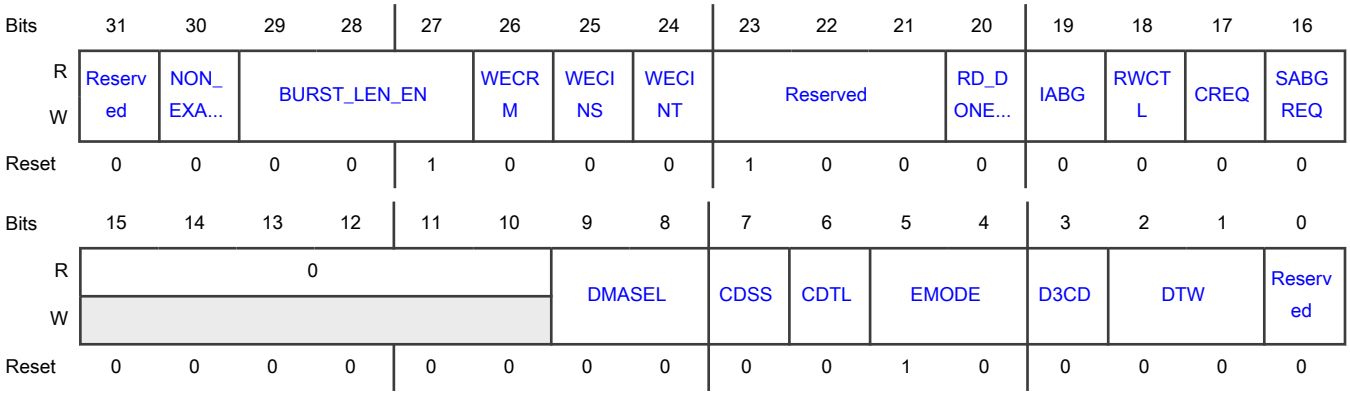
Function

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Diagram



Fields

Field	Function
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP This field is used to enable or disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLEs on the AXI side. 1xxb - Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP. x1xb - Burst length is enabled for INCR4 / INCR8 / INCR16. xx1b - Burst length is enabled for INCR.
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25	Wakeup event enable on SD card insertion

Table continues on the next page...

Table continued from the previous page...

Field	Function
WECINS	This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/eMMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO cards. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. If the card does not support

Table continues on the next page...

Table continued from the previous page...

Field	Function
	read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that the SDIO card support read wait. Therefore, the host driver does not set this field during read transfers unless the SDIO card supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - ADMA2 is selected. 11b - Reserved
7 CDSS	Card detect signal selection This field selects the source for the card detection. 0b - Card detection level is selected (for normal purpose). 1b - Card detection test level is selected (for test purpose).
6 CDTL	Card detect test level This field is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0b - Card detect test level is 0, no card inserted 1b - Card detect test level is 1, card inserted
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode 11b - Reserved
0 —	Reserved

78.7.1.13 System Control (SYS_CTRL)

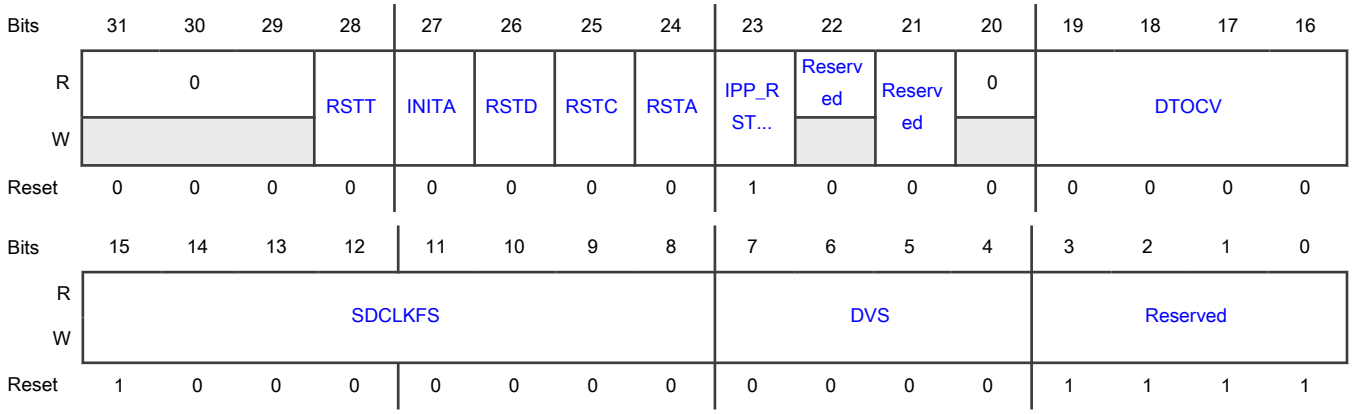
Offset

Register	Offset
SYS_CTRL	2Ch

Function

This register provides control of the system. See detail in the field description.

Diagram



Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26	Software reset for data line

Table continues on the next page...

Table continued from the previous page...

Field	Function
RSTD	Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable — Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0b - No reset 1b - Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This field's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 —	Reserved
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000b - SDCLK x 2^{14} 0001b - SDCLK x 2^{15} 0010b - SDCLK x 2^{16} 0011b - SDCLK x 2^{17} 0100b - SDCLK x 2^{18} 0101b - SDCLK x 2^{19}

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0110b - SDCLK x 2^{20} 0111b - SDCLK x 2^{21} 1000b - SDCLK x 2^{22} 1001b - SDCLK x 2^{23} 1010b - SDCLK x 2^{24} 1011b - SDCLK x 2^{25} 1100b - SDCLK x 2^{26} 1101b - SDCLK x 2^{27} 1110b - SDCLK x 2^{28} 1111b - SDCLK x 2^{29}
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

78.7.1.14 Interrupt Status (INT_STATUS)

Offset

Register	Offset
INT_STATUS	30h

Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 685. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 686. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 687. uSDHC status for command CRC error/command timeout error bit combinations

Command CRC error	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning. This field is relevant in combination with the bus error only and must be cleared prior to all the write and read transactions.
25 —	Reserved
24 AC12E	Auto CMD12 error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18	Command end bit error

Table continues on the next page...

Table continued from the previous page...

Field	Function
CEBE	Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process. 0b - No error 1b - Time out
15 ERR_INT_STATUS	Error Interrupt Status This bit is set when any of the error status bit DMAE, AC12E, DEBE, DCE, DTOE, CIE, CEBE, CCE and CTOE is set.
14 TP	Tuning pass:(only for SD3.0 SDR104 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 —	Reserved
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11 —	Reserved
10-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from the SDIO card does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as

Table continues on the next page...

Table continued from the previous page...

Field	Function
	specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete 1b - Command complete

78.7.1.15 Interrupt Status Enable (INT_STATUS_EN)

Offset

Register	Offset
INT_STATUS_EN	34h

Function

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

78.7.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

Offset

Register	Offset
INT_SIGNAL_EN	38h

Function

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

78.7.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 688. Relationship between command CRC error and command timeout error for auto CMD12

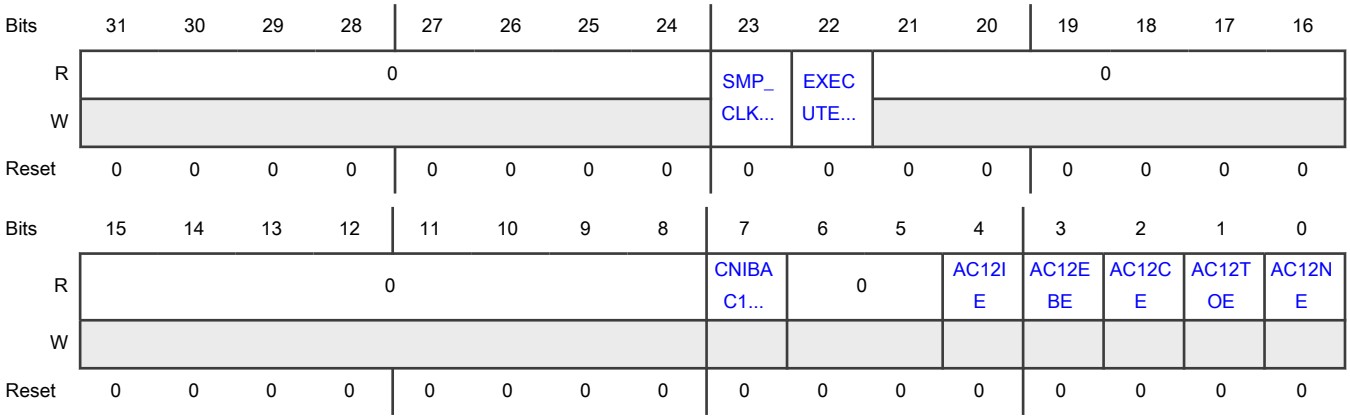
Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4
  - Set fields 1-4 corresponding to detected errors
  - Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform

Table continues on the next page...

Table continued from the previous page...

Field	Function
	the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0b - Tuning procedure is aborted 1b - Start tuning procedure
21-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
2 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
1	Auto CMD12 / 23 timeout error

Table continues on the next page...

Table continued from the previous page...

Field	Function
AC12TOE	Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

78.7.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

Offset

Register	Offset
HOST_CTRL_CAP	40h

Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

Diagram

78.7.1.19 Watermark Level (WTMK_LVL)

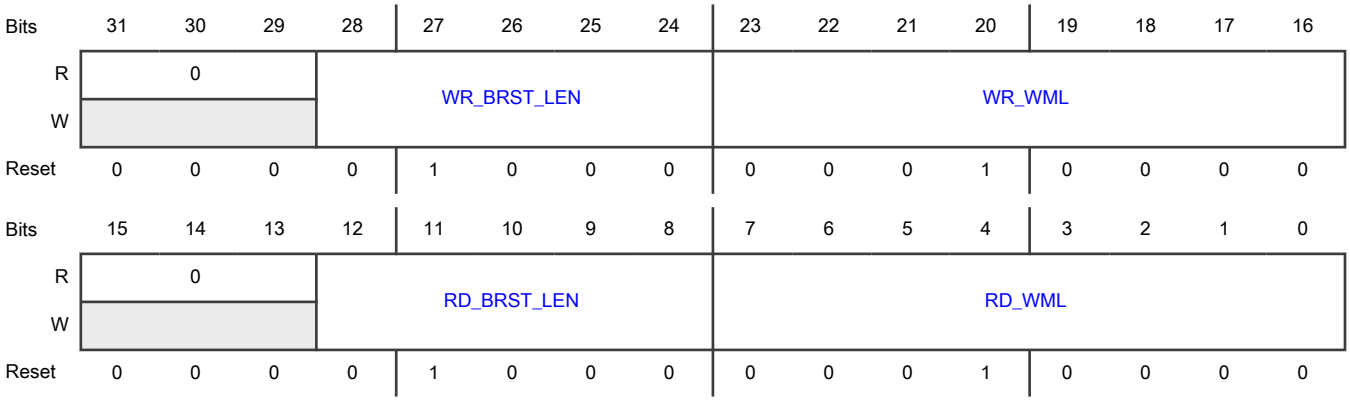
Offset

Register	Offset
WTMK_LVL	44h

Function

This register indicates configurability of write and read watermark levels (FIFO threshold). Their value can range from 1 to 128 words. Both write and read burst lengths are also configurable. Their value can range from 1 to 31 words.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 WR_BRST_LEN	Write burst length due to system restriction, the actual burst length might not exceed 16 This field indicates the number of words uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer is in back-to-back mode. On reset, this field is 8. Writing 0 to this field results in '01000' (that is, it is not able to clear this field).
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 —	Reserved
12-8 RD_BRST_LEN	Read burst length due to system restriction, the actual burst length might not exceed 16

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates the number of words uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer is in back-to-back mode. On reset, this field is 8. Writing 0 to this field results in '01000' (that is, it is not able to clear this field).
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

78.7.1.20 Mixer Control (MIX_CTRL)

Offset

Register	Offset
MIX_CTRL	48h

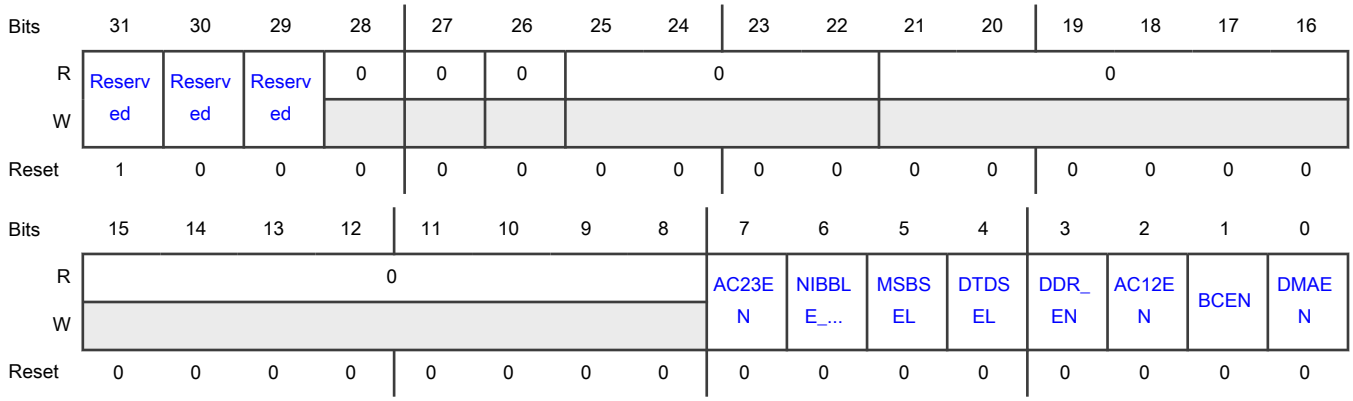
Function

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 689. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Diagram



Fields

Field	Function
31 —	Reserved Always write as 1.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 0.
28 —	Reserved
27 —	Reserved
26 —	Reserved
25-22 —	Reserved
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Single block 1b - Multiple blocks

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Write (Host to card) 1b - Read (Card to host)
3 DDR_EN	Dual data rate mode selection This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only.
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

78.7.1.21 Force Event (FORCE_EVENT)

Offset

Register	Offset
FORCE_EVENT	50h

Function

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding field of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

Diagram

78.7.1.22 ADMA Error Status (ADMA_ERR_STATUS)

Offset

Register	Offset
ADMA_ERR_STATUS	54h

Function

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 690. ADMA error state coding

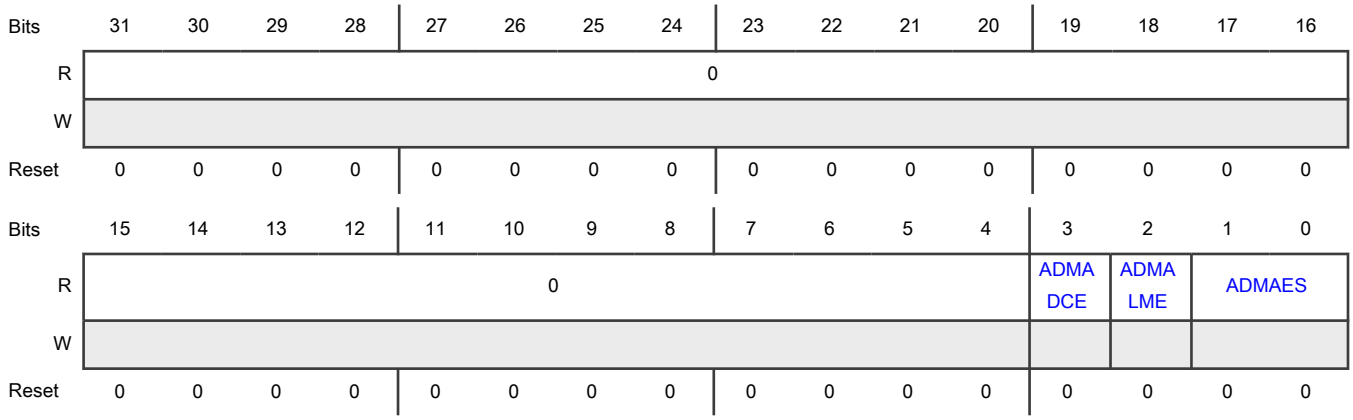
D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated

Table continues on the next page...

Table 690. ADMA error state coding (continued)

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

Diagram



Fields

Field	Function
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

78.7.1.23 ADMA System Address (ADMA_SYS_ADDR)

Offset

Register	Offset
ADMA_SYS_ADDR	58h

Function

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Field	Function
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

78.7.1.24 DLL (Delay Line) Control (DLL_CTRL)

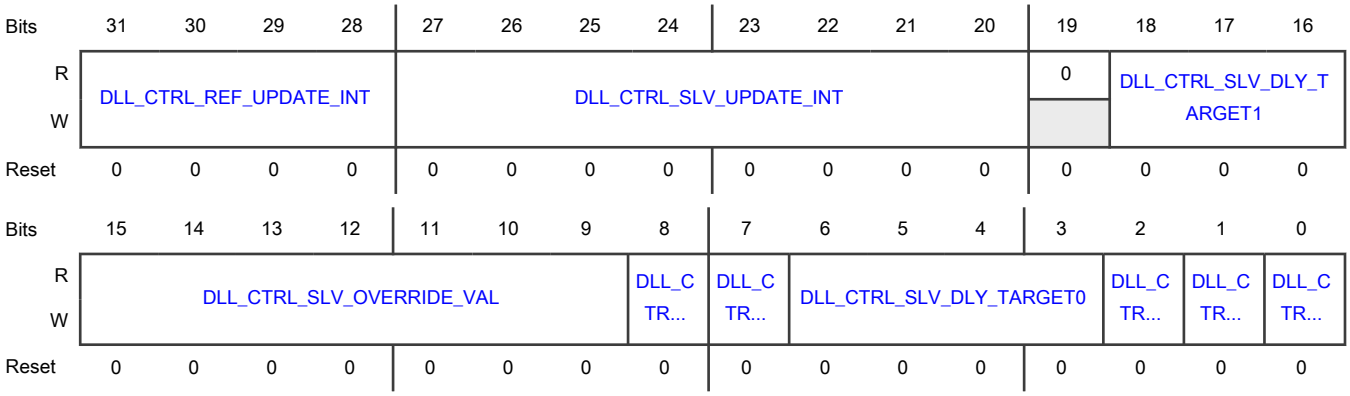
Offset

Register	Offset
DLL_CTRL	60h

Function

This register contains control fields for DLL.

Diagram



Fields

Field	Function
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4. **NOTE** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

78.7.1.25 DLL Status (DLL_STATUS)

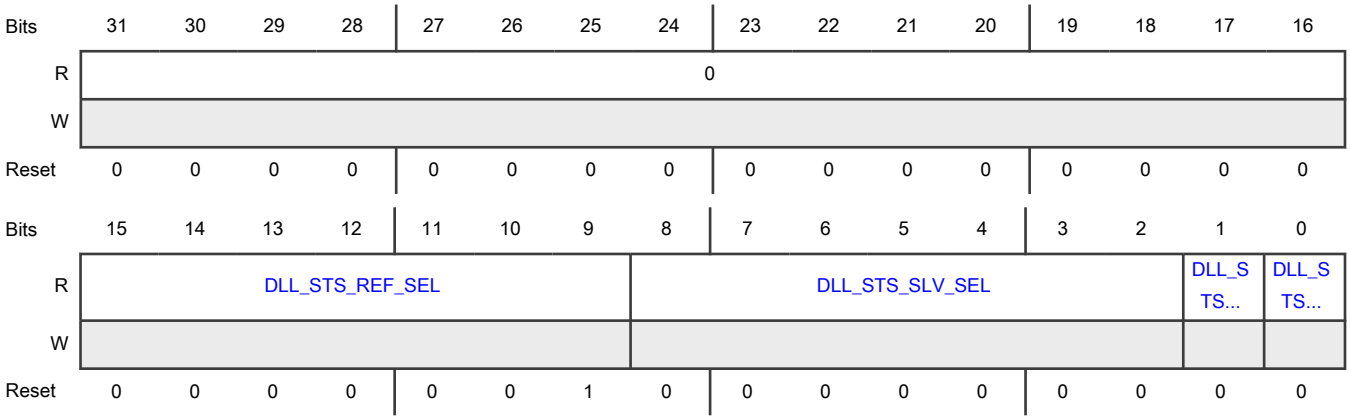
Offset

Register	Offset
DLL_STATUS	64h

Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

78.7.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

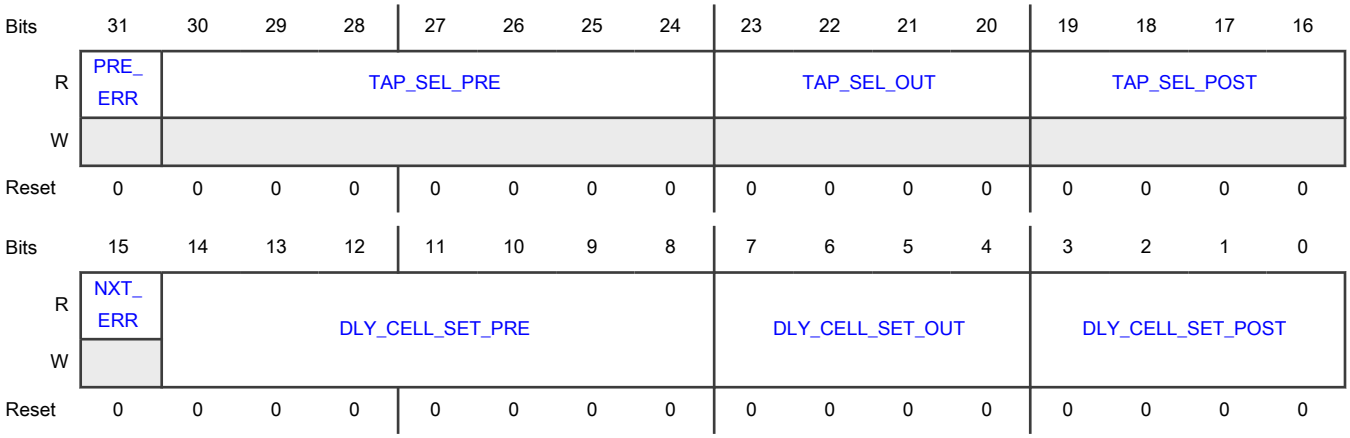
Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Function

This register contains the Clock Tuning Control status information. This register is added to support SD3.0 UHS-I SDR104 mode.

Diagram



Fields

Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.

Table continues on the next page...

Table continued from the previous page...

Field	Function
TAP_SEL_POST	
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

78.7.1.27 Vendor Specific Register (VEND_SPEC)

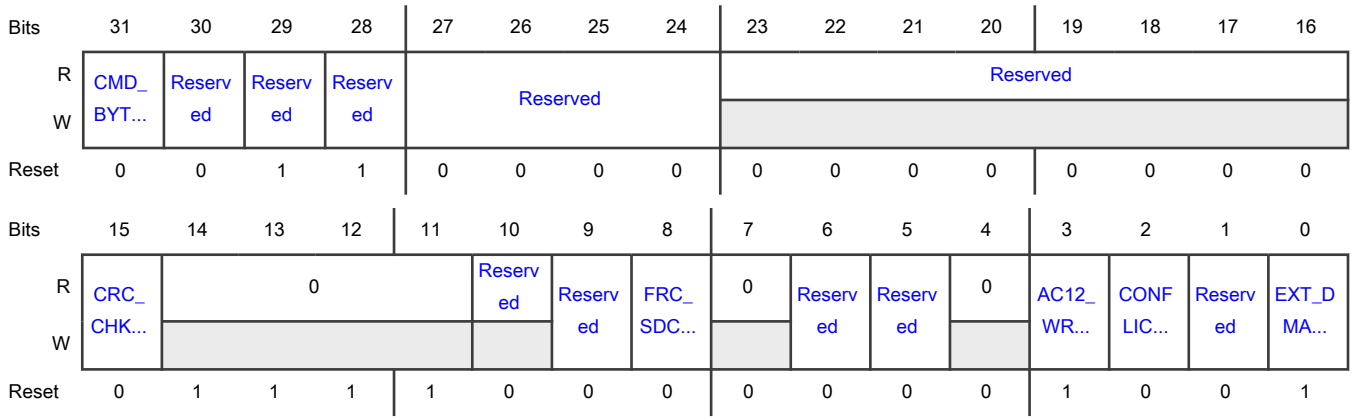
Offset

Register	Offset
VEND_SPEC	C0h

Function

This register contains the vendor specific control/status register.

Diagram



Fields

Field	Function
31 CMD_BYTE_EN	Register byte access for CMD_XFR_TYP This field controls the register byte access for Command Transfer Type (CMD_XFR_TYP). If this field is enabled, the register can be configured through byte write enable. IPS_bus can write only one byte once for one write operation. 0b - Disable. MIX_CTRL[7:0] is read/write and CMD_XFR_TYP[7:0] is read-only. 1b - Enable. MIX_CTRL[7:0] is read-only and CMD_XFR_TYP[7:0] is read/write.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0b - Check CRC16 for every read data packet and check CRC fields for every write data packet 1b - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet
14-11 —	Reserved Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active Do not set this bit to 1 unless it is necessary. Also, make sure that this bit is cleared when uSDHC's clock is about to be changed (frequency change, clock source change, or delay chain tuning). 0b - CLK active or inactive is fully controlled by the hardware. 1b - Force CLK active

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 AC12_WR_CHKBUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0b - Do not check busy after auto CMD12 for write data packet 1b - Check busy after auto CMD12 for write data packet
2 CONFLICT_CHK_EN	Conflict check enable It is not implemented in uSDHC IP. 0b - Conflict check disable 1b - Conflict check enable
1 —	Reserved
0 EXT_DMA_EN	External DMA request enable Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this field is set, uSDHC sends out DMA request when the internal buffer is ready. This field is particularly useful when transferring data by Arm platform polling mode, and it is not allowed to send out the external DMA request. By default, this field is set. 0b - In any scenario, uSDHC does not send out external DMA request. 1b - When internal DMA is not active, the external DMA request is sent out.

78.7.1.28 eMMC Boot (MMC_BOOT)

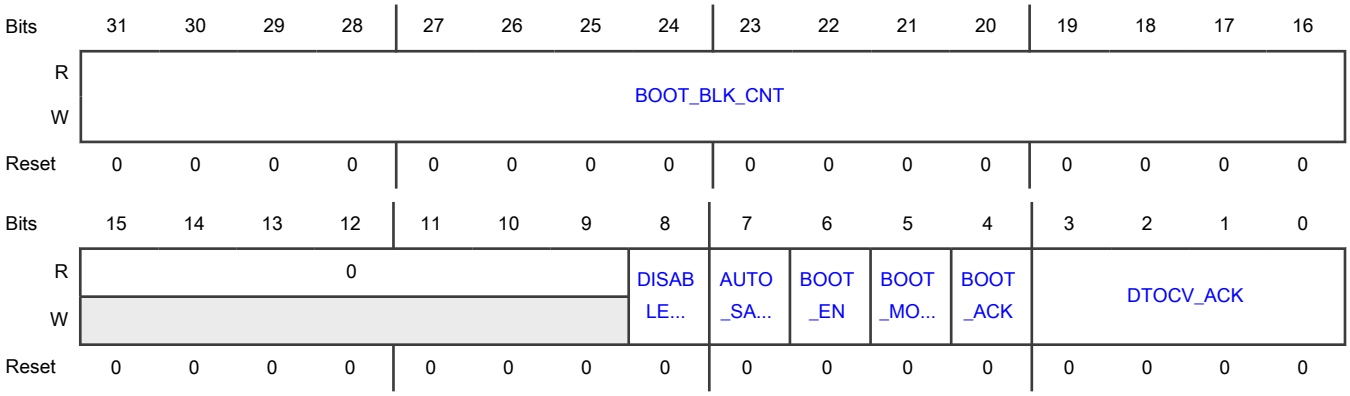
Offset

Register	Offset
MMC_BOOT	C4h

Function

This register contains the eMMC Fast Boot control register.

Diagram



Fields

Field	Function
31-16 BOOT_BLK_CNT	Stop At Block Gap value of automatic mode The value defines the Stop At Block Gap value of automatic mode. When received, card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, field 31 - 16 of 0x04.
15-9 —	Reserved
8 DISABLE_TIME_OUT	Time out **NOTE** When this field is set, there is no timeout check no matter whether BOOT_EN is set or not. 0b - Enable time out 1b - Disable time out
7 AUTO_SABG_EN	Auto stop at block gap During boot, enable auto stop at block gap function. This function is triggered, and host stops at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot enable Boot mode enable 0b - Fast boot disable 1b - Fast boot enable
5 BOOT_MODE	Boot mode Boot mode select

Table continues on the next page...

Table continued from the previous page...

8-7 —	Reserved
6 TUNING_CMD_EN	Tuning command enable Enable the auto tuning circuit to check the CMD line. 0b - Auto tuning circuit does not check the CMD line. 1b - Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Tuning 1bit enable Enables the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 TUNING_8bit_EN	Tuning 8bit enable Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together. 0b00 - Tuning circuit only checks the DATA[3:0] 0b01 - Tuning circuit only checks the DATA0 0b10 - Tuning circuit checks the whole DATA[7:0] 0b11 - Invalid **NOTE** The format of these two fields are [TUNNING_8bit_EN:TUNNING_1bit_EN]. **NOTE** In SDIO mode, auto-tuning only supports 1-bit [DATA(0)] tuning and the 4-bit [DATA(3:0)] autotuning in not supported for SDIO mode. SD mode supports 1-bit/4-bit [DATA(0)] and [DATA(3:0)] auto tuning. SD mode supports 1-bit/4-bit/8-bit [DATA(0)], [DATA(3:0)], and [DATA(7:0)] auto tuning.
3 CARD_INT_D3_TEST	Card interrupt detection test This field is used only for debugging. 0b - Check the card interrupt only when DATA3 is high. 1b - Check the card interrupt by ignoring the status of DATA3.
2-0 —	Reserved

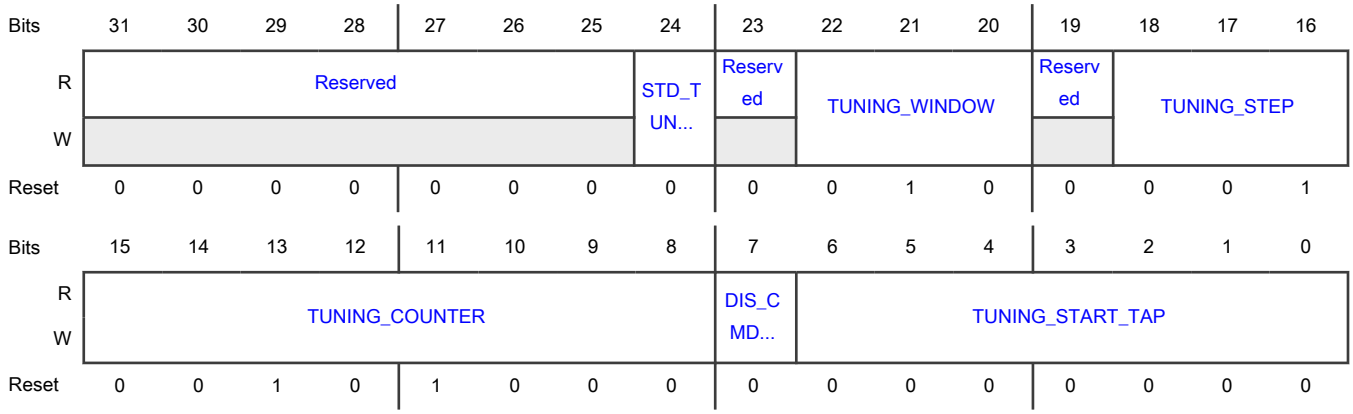
78.7.1.30 Tuning Control (TUNING_CTRL)

Offset

Register	Offset
TUNING_CTRL	CCh

Function
The register contains configuration of tuning circuit.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 STD_TUNING_EN	Standard tuning circuit and procedure enable This field is used to enable standard tuning circuit and procedure.
23 —	Reserved
22-20 TUNING_WINDOW	Data window Select data window value for auto tuning
19 —	Reserved
18-16 TUNING_STEP	TUNING_STEP The increasing delay cell steps in tuning procedure.
15-8 TUNING_COUNTER	Tuning counter The MAX repeat CMD19 times in tuning procedure.
7 DIS_CMD_CHK_FOR_STD_TUNING	Disable command check for standard tuning Writing 1 to this field disables command check (command CRC, CMD end bit error, and CMD index error or CMD timeout error) for standard tuning flow after each tuning command is sent.
6-0	Tuning start

Table continues on the next page...

Table continued from the previous page...

Field	Function
TUNING_START_TAP	The start delay cell point when send first CMD19 in tuning procedure.

Chapter 79
Debug Subsystem

79.1 Introduction

This chapter discusses the debug and trace architecture of the chip that is based on the specifications provided in the *Arm® CoreSight™ SoC-400 Technical Reference Manual*. See References for a link to this document and to other related documentation available on the Arm website.

The chip architecture includes debug and trace modules. See Features for details on the debug and trace features that Cortex-M7 core clusters support.

The debug components that the Cortex-M7 core supports are accessible via the Arm DAP controller-based architecture. The DAP controller works in parallel with the system JTAGC. Both these controllers share the JTAG port and JTAG instruction set.

The system components are similar for different chips in the same family and include the primary core debug interfaces, the chip-level debug interfaces, and chip-level trace interfaces. The accelerator components include debug and trace circuits. These circuits are necessary for any application-specific accelerators required for the different application spaces that a chip supports. They vary from one chip to another and could include only trace components.

79.2 Interfaces supported in S32K3 family

79.3 Block diagram

This figure illustrates the DAP architecture of the S32K3xx family.

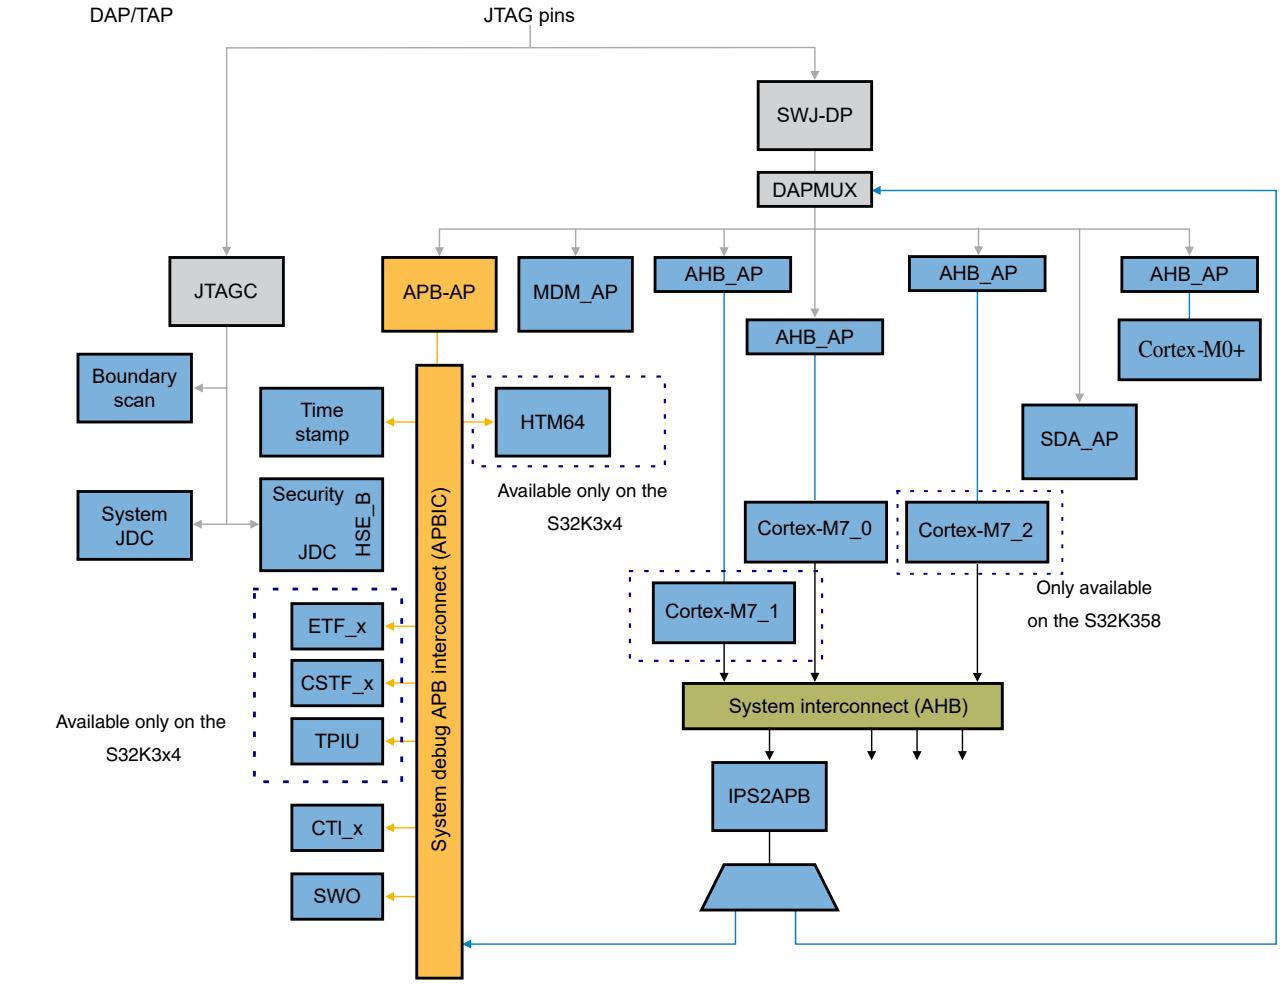

Figure 504. DAP architecture

NOTE

Debug components other than the Cortex-M0+ core are accessible through software path (CORE > AXBS > AIPS > DAPMUX > APs), that is, by directly specifying the memory mapped addresses without doing challenge response.

79.4 Features

This chip includes these features that support the functions listed under each feature type:

- Debug control
  - Is implemented via IEEE 1149.1-compliant JTAG
- Test control
  - Is implemented via IEEE 1149.1-compliant JTAG
  - Uses IEEE 1149.6 extension to IEEE 1149.1
- Trace interface
  - Includes four high-speed data pads and one clock pad @120 MHz (120 MB/s throughput per pad)
  - Includes 16 low-speed data pads and one clock pad @25 MHz (100 MB/s throughput per pad)
- Debug security

  - Includes a DAP/TAP interface that controls all debug features and is gated by Cortex M0+ JDC module
  - Includes security modes as described in the "Security" chapter
- Debugging and run control
  - Is implemeted through stopping points, starting points, breakpoints, and watchpoints
  - Each Cortex-M7 core supports eight instruction comparators and a watchpoint unit having four watchpoints
- Trace source
  - Includes Cortex-M7:
    - ETM that provides instruction and data trace
    - ITM that provides DWT, time-stamping, and diagnostic information
- Cross-triggering support
  - Controls run-control options of cores based on other cores
  - Provides a matrix having connections to:
    - HTM via system CTI
    - All Cortex-M7 CPUs
- Ability to view and modify all memory-mapped areas that are not otherwise blocked—includes a system bus debug access port
- Performance monitoring of cores—implements a performance monitoring unit (PMU) on each Cortex core
- Safety
  - Supports monitoring of debug signals to avoid common mode faults
  - Allows checking of erroneous activation of debugging, especially if intrusive (for example, a CPU entering Debug state)
- Timestamps
  - Generates a timestamp bus for distribution to the trace sources
  - Includes a 48-bit binary timestamp bus
  - Clocks timestamp generator by a frequency of 160 MHz

79.5 Debug

79.5.1 TAP connectivity

This figure shows a detailed view of TAP connectivity. JTAG select, SWJ-DP, and JTAG-DP are parts of DAP.

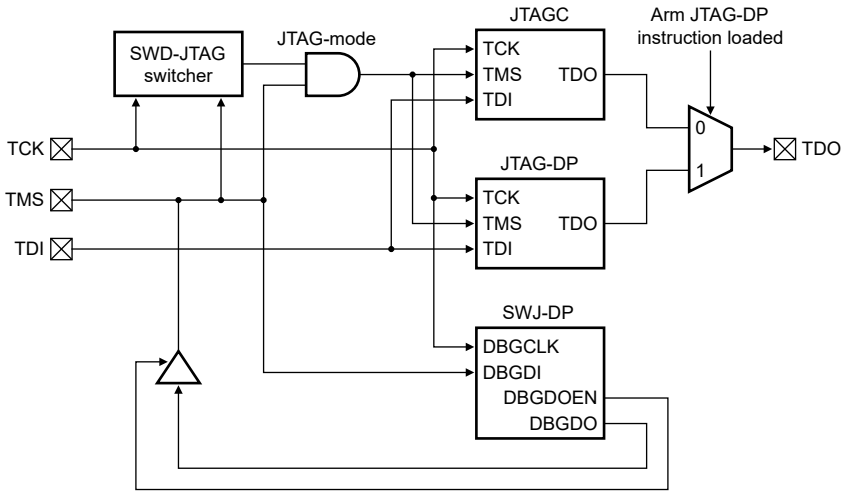

Figure 505. TAP connectivity

The debug port comes out of reset in a standard JTAG mode. It switches to another mode by using the change sequences. After the mode changes, unused debug pins can be reassigned to any of their alternative muxed functions.

JTAG-DP and JTAGC are connected in an overlay scheme and both have an Instruction Register (IR) length of 8 bits.

79.5.2 DAP TAP

DAP is an Arm component that provides multiple-master driving ports. A single external interface port accesses and controls these ports to provide system-wide debug.

The DAP Instruction Register (DAP IR) overlays with the system JTAG Instruction Register (JTAGC IR). Table 692 presents DAP instructions. In addition to the four codes listed in the table, DAP uses BYPASS, which is identical to JTAGC BYPASS and is therefore not shown in the table.

Table 692. DAP IR codes

Code	DAP IR
1111_1000b	ABORT
1111_1010b	DPACC
1111_1011b	APACC
1111_1110b	IDCODE

DAP offers an AHB master interface to access system buses. It also exports the internal DAP bus to extend the access ports. For more information on DAP TAP, see the *Arm Debug Interface Architecture Specification* document available in References.

In this chip:

- The AHB slave ports of all Cortex-M*x* cores provide debugger access to all memory units and registers in the system.
- The new pass-through approach allows the debugger to see a cache coherent view of the memory map for that core.
- The debugger must access the corresponding AHB_AP port to access the AHB-S port of that subsystem.
- XRDC controls system access.
- A core can access the debug components of another core through a DAPMUX to the bus interconnect.
- The exported DAP bus hosts AHB_AP and MDM_AP.

— MDM_AP hosts system-level JTAG status and control registers. These registers can be used for cross triggering, synchronized debug, and other miscellaneous control and status functions.

— APB_AP uses an APSEL value of 1h to access any APB-mapped debug modules.

Table 696 describes the access addresses of APB-mapped debug modules. The value of the DAP select signal in the APSEL field of SWJ-DP's Select register selects the access ports in the DAP. Table 693 shows APSEL decoding.

Table 693. DAP master address mapping

DAP master #	DAP component	DAPBUS base address (access from debugger) [1]	System memory map address (access from cores)		Selected port or master	Applicability
			Page number	Base address		
0h	Reserved	0000_0000h	0	4025_0000h	Reserved	-
1h	APB_AP to all APB-mapped debug modules (for example, ETFs, HTM, and trace funnels)	0100_0000h	0	4025_0100h	APB_AP to all APB-mapped debug modules (for example, ETFs, HTM, CSTF, and so on)	S32K3x4 (for ETF, HTM, and CSTF see Table 691)
2h	Reserved	0200_0000h	0	4025_0200h	Reserved	-
3h	AHB_AP to Cortex-M7_2 debug modules and chip system memory map	0300_0000h	0	4025_0300h	AHB_AP to Cortex-M7_2 debug modules and chip system memory map	S32K358, S32K338
4h	AHB_AP to Cortex-M7_0 debug modules and chip system memory map	0400_0000h	0	4025_0400h	AHB_AP to Cortex-M7_0 debug modules and chip system memory map	All
5h	AHB_AP to Cortex-M7_1 debug modules and chip system memory map	0500_0000h	0	4025_0500h	AHB_AP to Cortex-M7_1 debug modules and chip system memory map	S32K344, S32K324, S32K3x2, S32K358
6h	MDM_AP	0600_0000h	0	4025_0600h	MDM_AP	All
7h	SDA_AP	0700_0000h	0	4025_4700h	SDA_AP used for challenge-response (CR) in SWJ-DP mode	All
8h—FFh	Reserved (default AP response)	—	—	—	—	-

1. For example, 4000_XXYYh address is provided when accessing access ports (APs) via the debugger. Here, XX shows the AP select number and YY shows the address to be accessed. If you access SDA_AP via the debugger on 80h, you must provide the address 4000_0780h.

NOTE

Accessing SDA_AP simultaneously from the core and the debugger is prohibited. If you try to do so, you may receive unpredictable responses to core-initiated transactions (for example, incorrect data read, a failed attempt to write to the register, or a transfer error). Debugger-initiated transactions proceed correctly.

79.5.3 System JTAGC

JTAGC connects in parallel with the TAP controller (JTAG-DP of DAP), which has an IR length of 8 bits. The JTAGC IR codes overlay the ones of the DAP controller. DAP uses four instructions and JTAGC uses the remaining ones. The TAP outputs (TPOs) are multiplexed based on the selected IR code. This chip is fully JTAG-compliant and appears as a single TAP to the JTAG chain.

This table shows the JTAGC IR codes. The instructions that are used by Arm DAP TAP are shown in Table 692.

Table 694. JTAG instructions for JTAGC

Code	JTAGC IR
0000_0000b	IDCODE

79.5.3.1 Chip JTAG/Target ID

Each chip in the S32K3xx family includes a unique JTAG ID, which must be changed when instantiated with a different die in an SiP. The next table shows the JTAGC ID for this chip.

Table 695. JTAG/Target ID

Chip	PRN	DC	PIN	MIC	IDCODE ID	JTAG ID	Target ID
S32K344	0	26h (38d)	160h (352d)	Eh (14d)	1	0996_001Dh	0995_C01Dh

Table continues on the next page...

79.5.3.2 JDC

JDC allows you to access two 32-bit data registers by using the JTAG interface and by software running on one of the CPUs in the chip. These registers exchange data between an internal CPU and an external debug tool.

79.5.4 Peripheral IPG debug implementation

S32K344 is a multi-core chip. Any core can control a peripheral instance individually. You define the core's control over a peripheral during application development.

For peripheral halt, all individual cores have the same capability and are gated by a dedicated MDM_AP core halt register field. For more information, see the configurations defined in MDM_AP register descriptions.

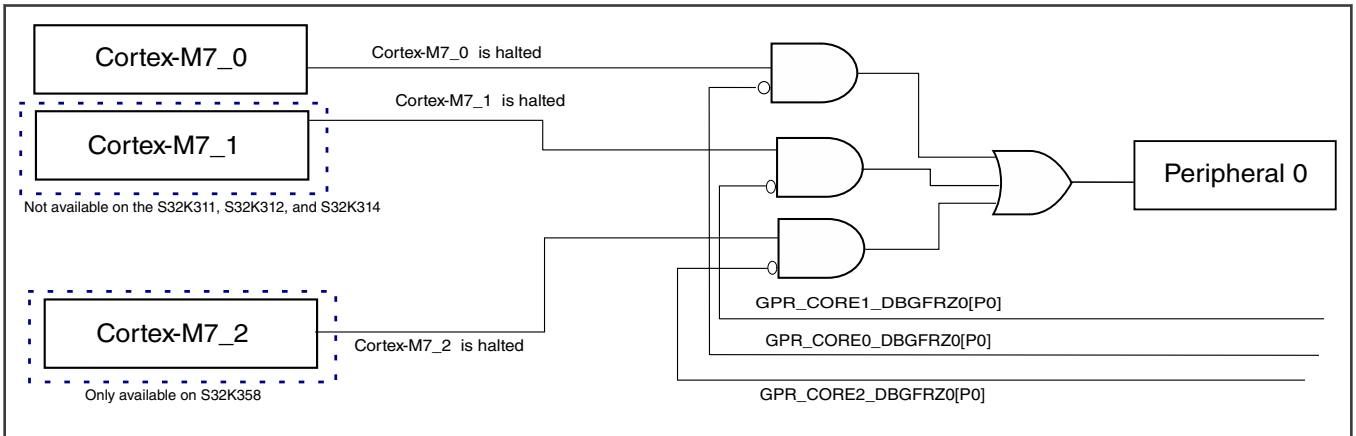

Figure 506. Peripheral IPG debug implementation

79.5.5 Application debugging

This section covers the following two cases:

- Case 1: Debugger connected—application debugging from the first instruction
- Case 2: Debugger not connected

79.5.5.1 Application debugging from first instruction

This chip supports debugging from the first instruction on system power-up, destructive reset, functional reset, and standby exit. However, by default, debugging from the first instruction is disabled.

The next figure shows the timing diagram of application debug implementation from first instruction on system power-up or destructive reset.

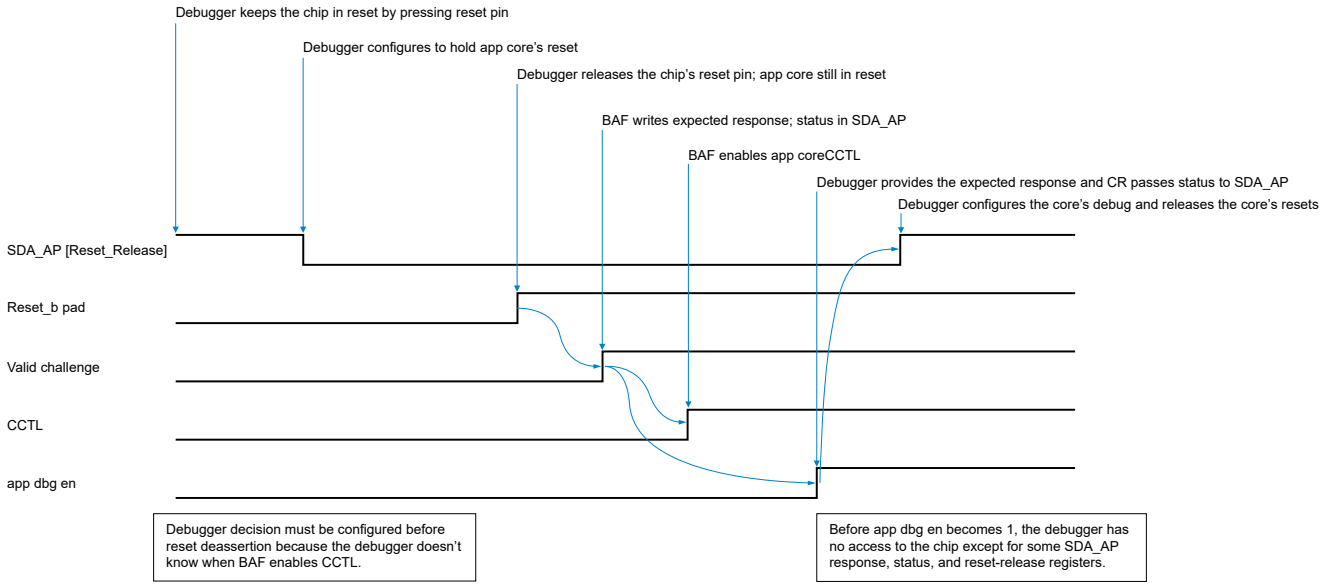

Figure 507. Application debug implementation from first instruction

These are the steps involved in enabling application debug from the first instruction on system power-up or destructive reset:

1. After the reset is applied, the debugger provides an option to debug from the first instruction. To do this:
   a. Write 1 to SDAAPRSTCTRL[RSTRELTLCM70] and SDAAPRSTCTRL[RSTRELTLCM71].
   b. Set the reset value of Reset Control (SDAAPRSTCTRL).
2. Cortex M0+ starts after the reset pin is released.
3. Debugger challenge-response (CR) starts.
4. Cortex-M7_0 and Cortex-M7_1 remain in reset until MC_ME's PRTN0_CORE0_PCONF[CCE] field becomes 1 for Cortex-M7_0 and PRTN0_CORE1_PCONF[CCE] field becomes 1 for Cortex-M7_1.
5. When BAF or FW writes 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0 and to PRTN0_CORE1_PCONF[CCE] field for Cortex-M7_1, and the debugger CR has passed:
   - If the value of SDAAPRSTCTRL[RSTRELTLCM71] and SDAAPRSTCTRL[RSTRELTLCM70] is 0 for their respective cores, the debugger configures the core debug registers and then enables these fields that start the code execution.
   - If the value of SDAAPRSTCTRL[RSTRELTLCM71] and SDAAPRSTCTRL[RSTRELTLCM70] is 1 for their respective cores, the debugger configures the core debug registers and then enables these fields that start the code execution.

To debug from the first instruction during the low-power debug protocol, the debugger:

1. Writes 0 to SDAAPRSTCTRL[RSTRELTLCM71] and SDAAPRSTCTRL[RSTRELTLCM70] for their respective cores.
2. Writes 1 to MDMAPWIRREL[WTRSTRGM].

79.5.5.2 Debugger not connected

If the debugger is not connected, the value of the DBGPWRUP_ACK signal is 0 as there is no DBGPWRUP_REQ. This results in the following scenario:

1. The booting core writes 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0 and to PRTN0_CORE1_PCONF[CCE] field for Cortex-M7_1.
2. The application core starts running. In case of Lock-step mode, the checker core executes the same code after a delay of two cycles.

79.5.6 Debugger considerations while flash program/erase

The flash programming can be done by application cores as well as debugger. The debugger can program/erase flash using either of the following two options:

1. Loading the program/erase code to SRAM from the debugger and then executing the program/erase sequence by application code from SRAM.
   - Debugger is connected and authenticated.
   - The debugger loads the code in the form of application binary image into the on-chip SRAM.
   - The debugger then initiates the application core to execute the binary from SRAM.
2. Debugger executing the program/erase sequence.
   - Debugger is connected and authenticated.
   - The debugger then initiates the flash programming by reading/writing the registers involved and following the program/erase sequence.

First option is the recommended because of less execution time. In second option, the debugger is the master and since the debug interface is serial, the execution takes more time.

In some cases, you might experience flash program/erase failure due to flash watchdog timeout when debugger executes the flash program/erase sequence due to the serial interface. Therefore, it is recommended to use the first option. In case second option is required, it should be performed in reduced clocking options (Option E and E2 only. For details, refer to the **Clocking details** section in the **Clocking** chapter).

79.5.7 SWJ-DP sequence for debug authentication

To perform the SWJ-DP sequence for debug authentication, the debugger:

1. Polls the AUTHSTTS[CHALRDY] field until it indicates the challenge status.
2. Reads Key Challenge (KEYCHAL0 - KEYCHAL7) if the challenge is valid and creates an authenticated 256-bit response key.
3. Writes a 256-bit response key to Key Response (KEYRESP0 - KEYRESP7).
4. Indicates that the response is ready by configuring AUTHCTL[HSEAUTHREQ].
5. Checks the status of Authentication Status (AUTHSTTS) to evaluate if the operation is successful.

   If the authentication process is successful and the debugger has write access to Debug Enable Control (DBGENCTRL), the challenge or response is considered successful too.

NOTE

SDA_AP supports challenge and response based on both JTAG and SWJ-DP modes. See SDAAPGENCTRL0[JTAG_CR_EN] for details.

79.6 APB memory map

You can access the debug registers via the APB_AP bus. The next table shows all the addresses for the CoreSight APB components and the addressing used for accessing the DAP components via the memory interface. You can also access all APB registers from the processing cores.

Table 696. APB components mapping

Debug APB component	APBIC base address (access from debugger)	System memory map address (access from cores)		Memory allocation (KB)	APB-AP0 slot number	Applicability
		Page number	Base address

79.7 Trace

79.7.1 Trace modules and connectivity

The Trace subsystem:

- Combines trace data from all internal clients that generate trace information
- Includes a 32-bit TPIU
- Includes these components:
  - ATB
  - ATBR
  - CSTF
  - Debug APB
  - ETF
  - TPIU

Multiple options for trace output allow parallel tracing. Trace information can be read from the trace interface or the DAP interface, and traces can be alternatively read out from ETF at a slow speed via APB_AP. Table 697 shows EFT sizes.

Table 697. ETF sizes

FIFO	Memory interface data width (in bits)	Size (KB)
Cortex-M7 ETM/ITM cluster ETF	64	1
Cortex-M7 ETMD cluster ETF	128	2
HTM ETF	64	1
Shared system ETF	64	2

NOTE

- The DMA-HTM trace supports four words at 80 MHz. For HTM trace, both DBGENCTRL[GSPNIDEN] and DBGENCTRL[GSPIDEN] must be 1.
- Enabling any one of data trace causes overflow inside ETM and trace packets get dropped. Enabling instruction trace of both the core simultaneously does not cause any overflow.

Control (MDMAPCTL) provides fields to override the speed control (see Table 698 for details) from some of the trace sinks (and TPIU). The complete trace pipeline bandwidth is limited by the slowest sink component. The default settings of these fields allow maximum bandwidth for the TPIU to trace. When tracing to memory (if supported), the fields may need to be changed.

Table 698. Trace output overrides

Trace destination	SWO_override	TPIU_override
TPIU	1	0

The trace sources of the chip are the cores and their related modules. Trace funnels exist for all possible trace clients. For more information on the various components in the trace bus connectivity, see the *CoreSight Components Technical Reference Manual* (available in References). See Table 699 for details on funnel assignments.

The ATBR is integrated to send a shared funnel output across TPIU. This figure illustrates the chip's detailed trace architecture.

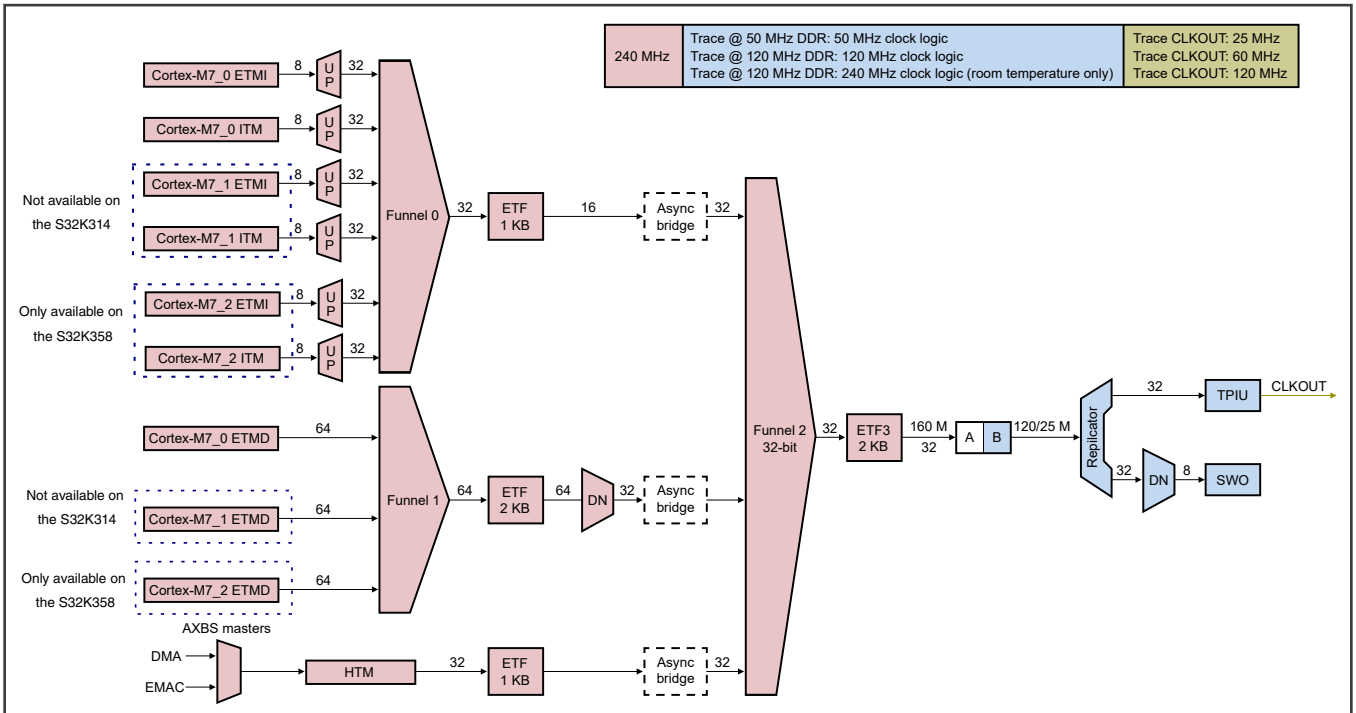

Figure 508. S32K358 and S32K3x4 detailed trace architecture

79.7.1.1 Chip's bus trace client

Chips in the S32K3xx family include a bus trace client.

HTM provides the address and data trace information about AXBS buses. The information from an HTM can be used with the debugger to enable easy, accurate debugging on AXBS-based embedded systems. The chip implements an HTM64 configuration to trace 64-bit AXBS masters in the system. To simplify the implementation, instead of tracing the individual ports of various AXBS masters and slaves, which may be running at different frequencies, HTM64 snoops the AXBS crossbar master ports that are all synchronous with a 160 MHz system clock. This table provides details related to the HTM input connectivity.

Table 700. HTM connections

HTM64 port	AHB crossbar port
HTMBUSSELECT0	M0 AXBS_Lite XBIC (DMA)
HTMBUSSELECT1	M3 AXBS (Ethernet)

79.7.1.2 TPIU interface

A standard 16-bit parallel TPIU is integrated into the debug subsystem. Chips in the S32K3xx family generate the trace via the trace port.

To prevent instruction trace from being dropped in a multi-core environment, a TPIU throughput of 55.2 MB/s or higher must be maintained. You could use these pin and frequency combinations:

- Four high-speed data + one clock pads @120 MHz (240 Mbit/s throughput per pad) totaling 120 MB/s
- 16 low-speed data + one clock pads @25 MHz (50 Mbit/s throughput per pad) totaling 100 MB/s

High-end chips from the S32K3xx family support at least 56 MB/s of trace throughput on the TPIU interface.

Table 701. Throughput

Core	Throughput value	Applicability
Cortex-M7_0	27.6 MB/s	All
Cortex-M7_1	27.6 MB/s	S32K338, S32K328 S32K324, S32K314 S32K322
Cortex-M7_2	27.6 MB/s	S32K358, S32K338
Total	82.8 MB/s	

79.7.1.3 TPIU flush

To allow the chip to enter Standby mode, software executes an WFI instruction indicating Standby entry. When the chip enters this mode, MC_RGM asserts a trace flush request to the TPIU and waits for a trace flush done signal from the TPIU before requesting MC_PCU to proceed. The TPIU and debug infrastructure clocks can be gated after this. Because the TPIU is sourced from system clock, the clock must not be gated until this point.

79.7.2 Trace assignments

ETF combines trace information from multiple clients into a single stream of trace data. This table shows the CoreSight funnel input assignments.

Table 702. CoreSight funnel assignments

Instance name	Port assignment	Applicability
Funnel 0 (CSTF0)	Cortex-M7_0 ETMI	S32K3x4
	Cortex-M7_0 ITM	All
	Cortex-M7_1 ETMI	S32K3x4
	Cortex-M7_1 ITM	S32K324, S32K322, S32K312
	Cortex-M7_2 ITM	S32K358, S32K338

Table continues on the next page...

Table 702. CoreSight funnel assignments (continued)

	Cortex-M7_2 ETMD	S32K358,S32K338
Funnel 2 (CSTF2)	Funnel 0	S32K3x4
	Funnel 1	S32K3x4
	HTM	S32K3x4

79.8 Embedded cross trigger (ECT)

ECT allows multi-core run control and trace cross-triggering, such as synchronous stop-start for all cores or trigger trace on a trigger event from another core or module. See the *CoreSight Components Technical Reference Manual* (available in References) for detailed information on ECT.

ECT architecture involves CTMs and CTIs. The CTIs provide a cross-triggering interface between the cores and other debug and trace modules. The channels of these CTIs are interconnected using CTMs, as shown in this figure.

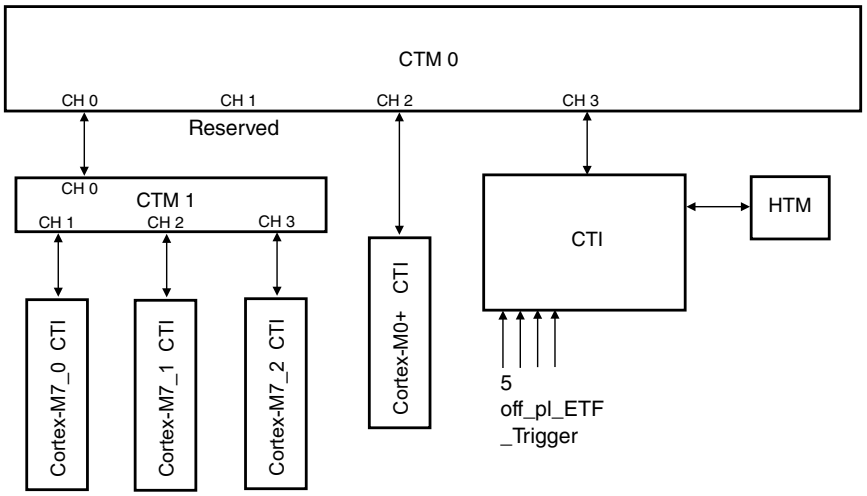

Figure 511. ECT

79.8.1 CTI assignments

Table 703. CTI assignments

CTI instance	Trigger number	Trigger in	Trigger out

79.9 Low-power debug handshake protocol

The debugger must perform this sequence to enter or exit Standby mode, if the debugger handshake is enabled:

1. Power on DAP.

   The debugger connection is established.

2. Configure the Debug subsystem for the relevant operations.

3. Write 1 to to gate entry into Standby mode with the debugger handshake.
4. Disable POR_WDG for monitoring the entry to or exit from Standby mode by writing 1 to DCM's DCMRWP1[8] field. This is required for low-power debug handshake because debugger configurations can be more time consuming than the POR_WDG threshold levels and can raise a false POR_WDG event.
5. Write 1 to DCMRWF1[STANDBY_IO_CONFIG] in the Device Configuration Module (DCM). This causes padkeeping to be disabled on standby entry itself without any software dependency. This is needed in case of low-power debug since otherwise the padkeeping on TDO would result in no debugger communication. In other cases, DCMRWF1[STANDBY_IO_CONFIG] should be configured as 0 before standby entry.
6. Initiate entry into Standby mode. See the "Power Management" chapter for the Standby mode entry sequence and configurations.
7. Identify whether the low-power debug is enabled on the low-power entry by reading MC_RGM's LPDEBUG[LP_DBG_EN] field.
   - If low-power debug is enabled and TPIU is enabled too, trace flush starts, and the debugger acknowledges the following:
     — Low-power debug traces
     — DAP-related configuration reception and context saving

     After this, the chip enters Standby mode.
   - If TPIU is disabled:
     — The debugger acknowledges DAP-related configuration reception and context saving by writing 1 to MDMAPWIRREL[PRVNTRSTRGM].

     After this, the chip enters Standby mode.
   - If low-power debug is disabled, the chip enters Standby mode without waiting for debugger acknowledgment.

   On any wakeup event, the chip starts the Standby mode exit sequence described in the "Power Management" chapter. After the chip exits Standby mode, the debugger connection is restored. By this time, the debugger is already aware that it has enabled the low-power debug handshake. In this case, the debugger must poll MDMAPSTTS[DESTRST] to check whether:
   - The debug infrastructure is out of reset.
   - The DAP connection can be established.

   After DAP is powered on (the debugger connection is established), the debugger:
   a. Reconfigures the debug and trace attributes using the fields in DBGENCTRL
   b. Writes 1 to MDMAPWIRREL[WTRSTRGM] after the debugger trace context is restored

      The chip exits Standby mode.

      If low-power debug is not configured, the chip exits Standby mode without waiting for the debugger to write to MDMAPWIRREL[WTRSTRGM].
8. Reconfigure the debug and trace configuration in SDA_AP register descriptions after the chip exits Standby mode.

NOTE

If the chip wakes up from Standby mode through pad reset, the debugger must perform a CR again.

79.10 Debug resets

The debug subsystem follows this sequence on the source of reset:

1. POR resets the complete debug logic.
2. The destructive reset resets all types of debug logic except JTAGC.

Conversely, the debug subsystem can generate a system reset using these mechanisms:

- System destructive reset defined in Control (MDMAPCTL) that allows the debugger to provide the destructive reset to the system. The debugger loses connection to the system with this reset.
- System functional reset defined in Control (MDMAPCTL) that allows the debugger to hold the system in functional reset.

To program various debug registers, the functional clocks must be enabled. All debug and trace components must be on destructive reset.

79.11 Debug across device LifeCycles

The debug access to the system is available in early lifecycles and subsequently based on NVM configuration settings.

After the debug is set to 'Trusted', the system access is allowed after a successful authorization step between the debugger and the system.

The authorization provides provisions to allow debug for Cortex M0+ core and Cortex M7 cores.

Following table shows the debug access based on various configuration bits.

Table 704. Debug access based on LifeCycle and bit configurations

LifeCycle	Configuration bits				Debug access
	DBG_EN_OEM	APP_DIS_OEM	DBG_EN_FLD	APP_DIS_FLD	Appl Core Debug
MCU_PROD	-	-	-	-	Open
	-	-	-	-	Open
CUST_DEL	-	-	-	-	Open
	-	-	-	-	Open
OEM_PROD	0	-	-	-	Closed
	1	0	-	-	Trusted
	1	0	-	-	Trusted
	1	1	-	-	Disabled
IN_FIELD	-	-	0	-	Closed
	-	-	1	0	Trusted
	-	-	1	0	Trusted
	-	-	1	1	Disabled
PRE_FA	-	-	-	-	Trusted
	-	-	-	-	Trusted
FA	-	-	-	-	Open

NOTE

1. **Closed:** Debug is not possible in this state (not even if keys are known - no authentication is possible)
2. **Open:** Debug is always possible
3. **Trusted:** Debug is possible after successful authentication (Challenge/Response handshake with correct credentials)
4. **Disabled:** Debug has been explicitly disabled via burning of a fuse in that LC, otherwise behaves as Closed
5. During functional reset, the debug-enable will retain its last status, while DCM scans NVM for lifecycle and DCF values. Debug status will be re-evaluated once dcm_done gets 1.
6. During temporary advancement of lifecycle, debug-en will immediately reflect the status based on updated lifecycle/DCF bits.

79.12 Pin interface

This table presents a summary of functional and power pins that are used for debugging purposes.

Table 705. Pin interface

Pin type	Pins	Number of pins (balls)[1]	Nominal voltage
Functional JTAG	JCOMP, TCK, TMS, TDI, TDO	Five (only TDI and TDO can be multiplexed with GPIO or other functions)	3.3 V, 5 V
Functional trace pins (parallel trace)	TRACE_CLK	One	3.3 V, 5 V
	TRACE_D[15:0]	16	3.3 V, 5 V
Ground	VSS	See the IOMUX file attached to this document for information on the number of VSS pins in various packages.	0 V

1. The terms pins and balls are used interchangeably. Some chip packages include pins and others include balls.

NOTE

Fast Trace pad TRACE_D[15:0] is available only in S32K344.

79.12.1 Debug port and pin descriptions

The pads to which the debug signals are mapped operate using the JTAG functionality out of reset but can later be reassigned to their alternate functionalities. TDI and TDO can operate as alternate GPIO functions. See this table for pin assignments in different modes.

Table 706. Debug port pins

Pin name	JTAG debug port		Internal pullup or pulldown logic
	Type	Description	
TMS	I/O	JTAG test mode selection (TMS)	Pullup
TCK/SWCLK	I	JTAG test clock (TCK)	Pulldown
TDI	I	JTAG test data input (TDI)	Pullup
TDO/TRACESWO	O	JTAG test data output (TDO)	Not connected

79.12.2 Trace port pin descriptions

This chip generates trace via TPIU that transmits the trace data out of the chip over a parallel trace port. The trace port consists of an ETM trace clock and 16 parallel trace data outputs. The Arm optional trace port control (TRACECTRL), debug request (DBGRQ), and debug acknowledge (DBGACK) signals are not implemented.

Table 707. Trace output port pins

Pin name	Description
TRACE_DATA00	ETM parallel trace data output 01
TRACE_DATA01	ETM parallel trace data output 01
TRACE_DATA02	ETM parallel trace data output 02
TRACE_DATA03	ETM parallel trace data output 03
TRACE_DATA04	ETM parallel trace data output 04
TRACE_DATA05	ETM parallel trace data output 05
TRACE_DATA06	ETM parallel trace data output 06
TRACE_DATA07	ETM parallel trace data output 07
TRACE_DATA08	ETM parallel trace data output 08
TRACE_DATA09	ETM parallel trace data output 09
TRACE_DATA10	ETM parallel trace data output 10
TRACE_DATA11	ETM parallel trace data output 11
TRACE_DATA12	ETM parallel trace data output 12
TRACE_DATA13	ETM parallel trace data output 13
TRACE_DATA14	ETM parallel trace data output 14
TRACE_DATA15	ETM parallel trace data output 15
TRACE_CLK	ETM parallel trace clock output

NOTE

ETM is supported in S32K344 only

NOTE

By default, Rx pins float and are not pulled inside. An internal active pulldown logic exists only when you enable Rx via software (IBE).

79.13 Timestamp distribution network

The timestamp distribution network uses CoreSight timestamp components to generate a 48-bit timestamp value for the trace sources, as shown in the next figure. The CoreSight timestamp generator generates a 64-bit counter value, but only the least significant 48 bits are distributed to the trace sources. A 7-bit narrow timestamp is derived from the 48-bit timestamp and distributed to the trace client, where a decoder regenerates the 48-bit timestamp. The generator must be programmed, and you could find the related programming information in the *CoreSight Components Technical Reference Manual* (available in References).

This chip supports 48-bit timestamping. The generator operates at a frequency of 160 MHz and gives a 64-bit timestamp value. The Cortex-M7_0 and Cortex-M7_1 cores operate at a frequency of 160 MHz.

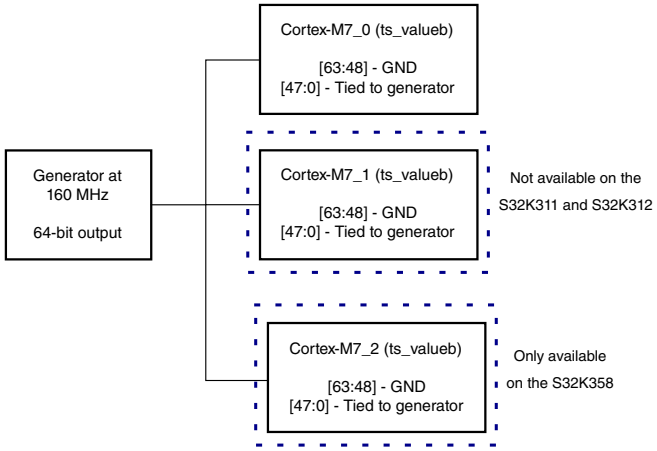

Figure 512. Timestamp distribution network

79.14 Peripheral debug freeze register descriptions

Implement the logic provided in this section for each peripheral instance supporting the debug operation.

NOTE

Debug freeze is enabled for all the peripherals so that as soon as the core halts, peripherals can be frozen to support debugging from the first instruction.

For register details, refer to the following registers in the Device Configuration Module (DCM):

- Read Write GPR On Destructive Reset Register (DCMRWD6)
- Read Write GPR On Destructive Reset Register (DCMRWD7)
- Read Write GPR On Destructive Reset Register (DCMRWD8)
- Read Write GPR On Destructive Reset Register (DCMRWD9)

79.15 MDM_AP register descriptions

The debugger has access to the status and control elements implemented as registers in MDM_AP, which is selected by APSEL (6h) on the DAP bus. These registers provide additional control and status information for typical debug, cross-triggering, and run-control scenarios. Also, the register fields provide a way for the debugger to get the updated status of the core without initiating a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

MDM_AP is accessible as DAP (see DAP TAP for details).

79.15.1 MDM_AP memory map

MDM_AP base address: 4025_0600h

Offset	Register	Width (In bits)	Access	Reset value

0 —	Reserved

79.15.3 Control (MDMAPCTL)

Offset

Register	Offset
MDMAPCTL	4h

Function

Allows the debugger:

- To give the destructive reset to the system. A system destructive reset enables this. The debugger also loses connection to the system with this reset.
- To hold the system in functional reset. A system functional reset enables this.

NOTE

The trace functionality on trace pins is selected with this register and is retained across the functional reset.

Offset

Register	Offset
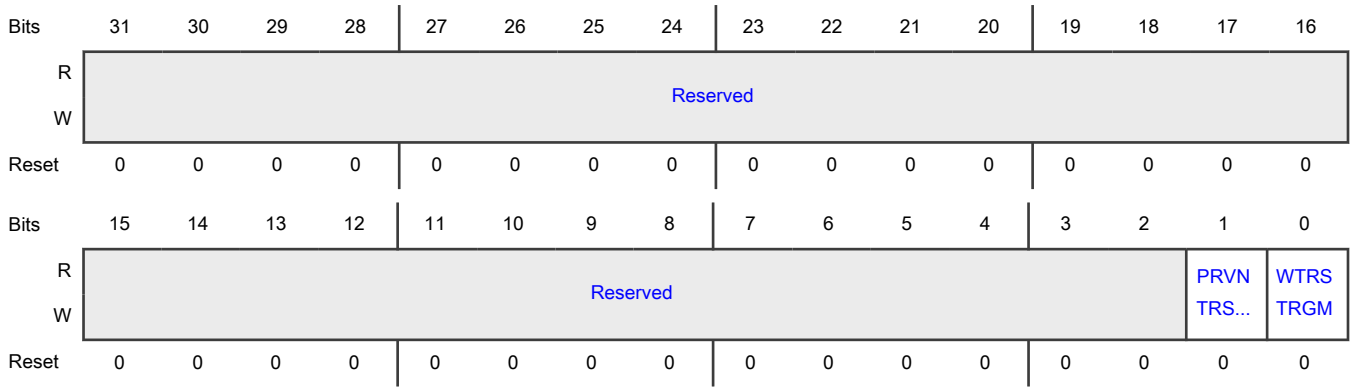
MDMAPWIRREL	38h

Diagram



Fields

Field	Function
31-2 —	Reserved
1 PRVNTRSTRGM	Prevent Reset Indicates if MC_RGM is prevented from generating reset. After TPIU flush, this field prevents MC_RGM from generating reset even if MC_RGM receives an acknowledge response from TPIU. This is valid for low-power entry. 0b - Normal operation 1b - MC_RGM prevented
0 WTRSTRGM	Wait In Reset B Indicates if waiting of MC_RGM from generating reset is supported. On exiting Standby mode, MC_RGM waits until the debugger writes to another field in the MDM_AP register to allow it to exit reset. 0b - Normal operation 1b - Wait supported

79.16 SDA_AP register descriptions

The debugger and system have access to secure authentication control and status, implemented as registers in SDA_AP on the DAP bus. These registers provide authentication control, authentication status, key exchange information, and debug enable controls.

79.16.1 SDA_AP memory map

SDA_AP base address: 4025_4700h

Offset	Register	Width (In bits)	Access	Reset value
0h	Authentication Status (AUTHSTTS)	32	RO	6000_0004h
4h	Authentication Control (AUTHCTL)	32	RW	0000_0000h
10h - 2Ch	Key Challenge (KEYCHAL0 - KEYCHAL7)	32	RO	0000_0000h
40h - 5Ch	Key Response (KEYRESP0 - KEYRESP7)	32	RW	0000_0000h

Chapter 80
JTAG Controller (JTAGC)

80.1 Chip-specific JTAGC information

The following figure shows the detailed TAP connectivity. SWD/JTAG SELECT, SWDP and JTAG-DP are part of ARM DAP

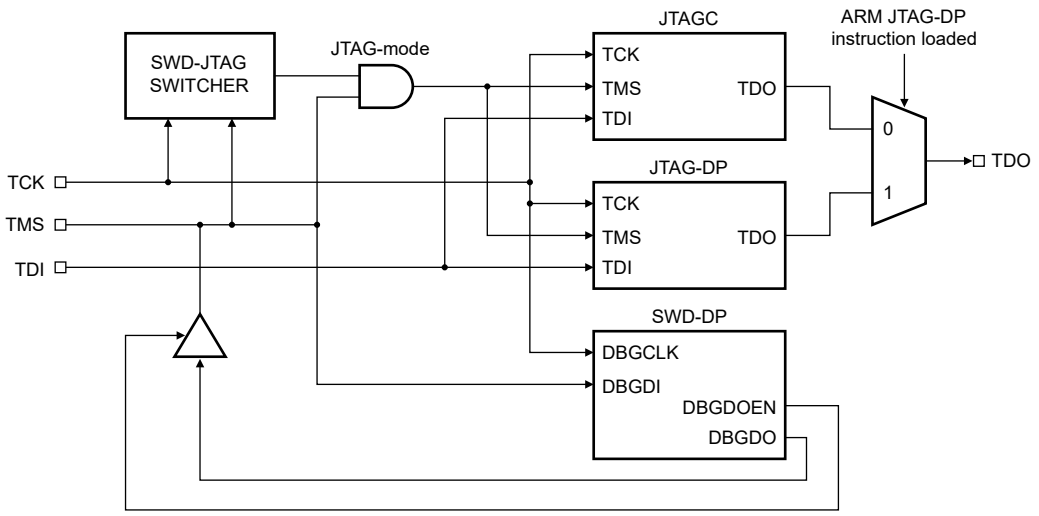

Figure 513. Test and Debug Access Port (TAP) connectivity

The debug port comes out of reset in a standard JTAG mode. It is switched to SWD mode by the change sequences described in JTAG to SWD change sequence . Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions

JTAG-to-SWD change sequence:

1. Send more than 50 TCK cycles with TMS (SWDIO) =1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111_1001_1110_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) =1

NOTE

In case of any reset event, JTAGC is moved to Test Logic Reset (TLR) state first and then JTAGC should be used.

NOTE

If JTAG pins are used for alternative functionality and reset event arrives, then these pins need to be reconfigured to required functionality before using it, in order to avoid unintentional entry in JTAG mode.

80.2 Overview

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

80.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

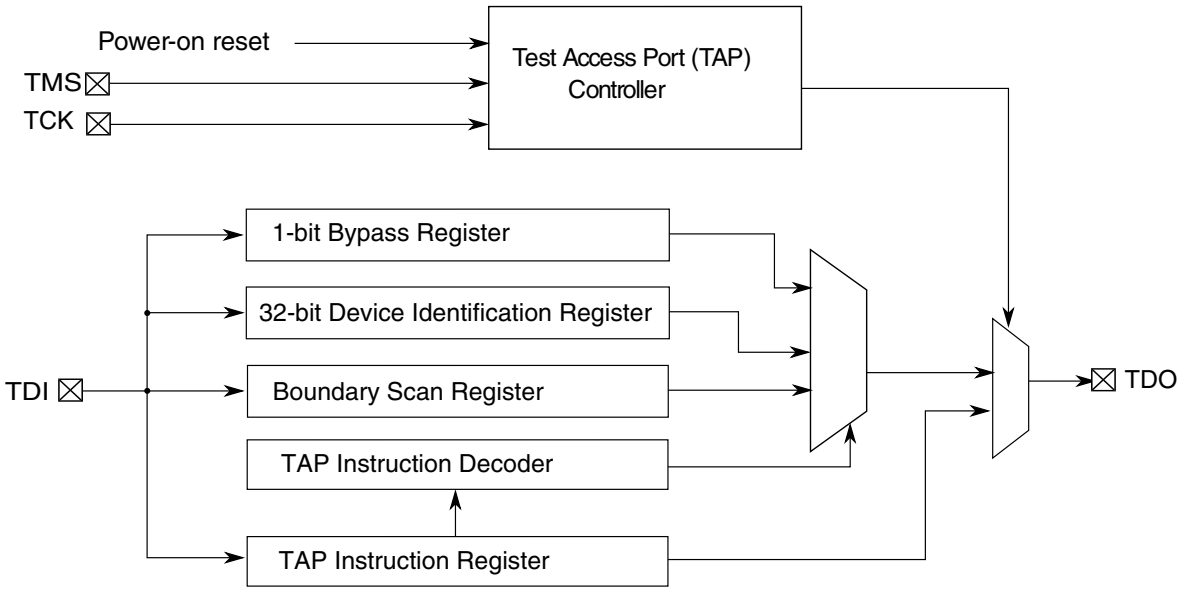

Figure 514. JTAG (IEEE 1149.1) block diagram

80.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

80.3 Functional description

This section explains the JTAGC functional description.

80.3.1 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

80.3.1.1 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

80.3.1.2 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE, and SAMPLE/PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

80.3.1.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

80.3.2 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

80.3.3 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions, see ACCESS_AUX_x instructions .

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

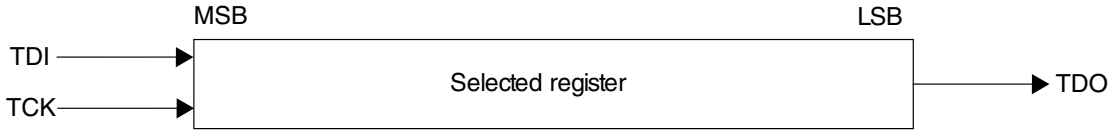

Figure 515. Shifting data through a register

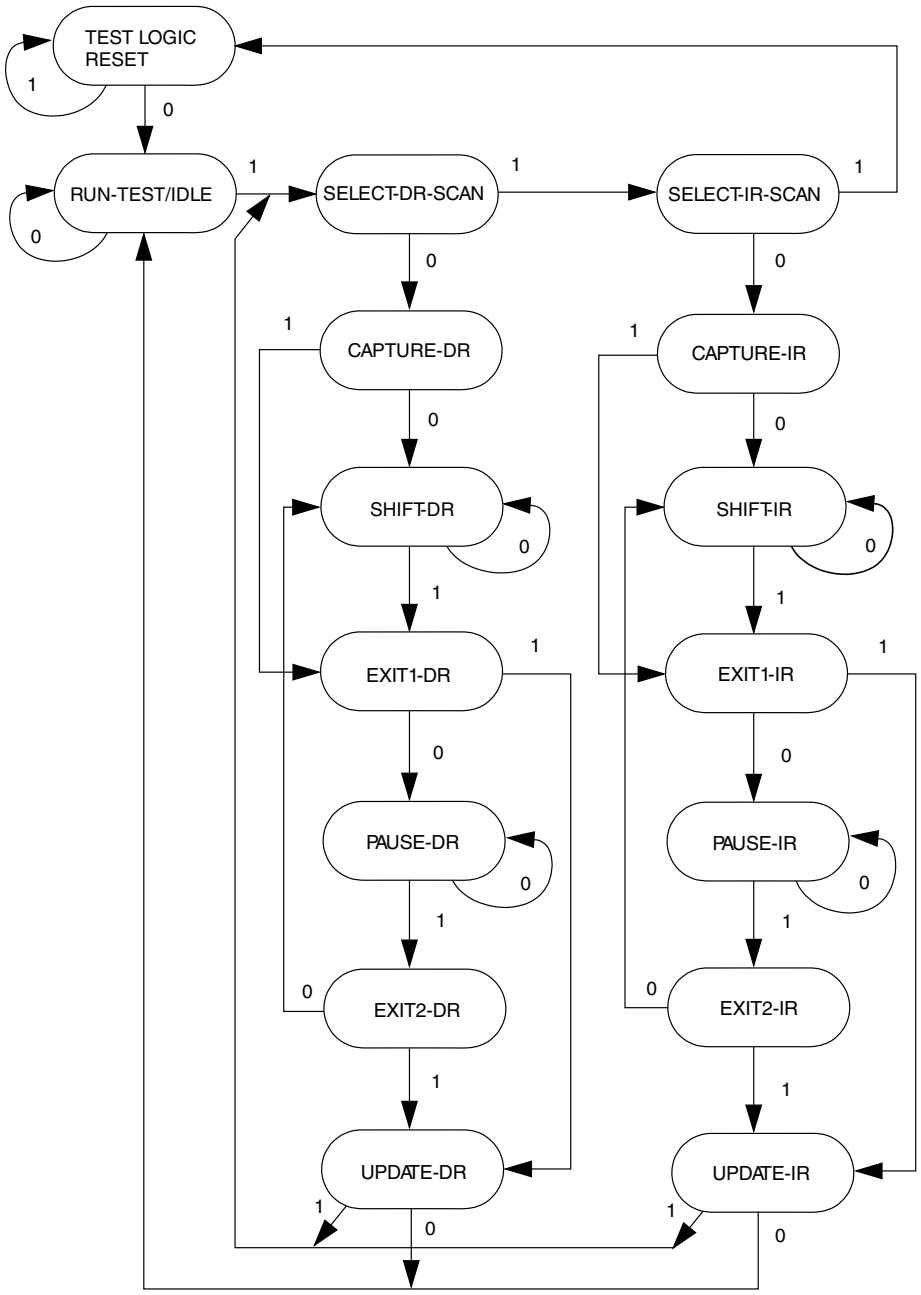
80.3.4 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 516. IEEE 1149.1-2001 TAP controller finite state machine

80.3.4.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

80.3.4.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

80.3.5 JTAGC block instructions

The JTAGC implements instructions defined in IEEE 1149.1-2001. See the chip-specific JTAGC information for the JTAGC instructions implemented on this chip. See the IEEE 1149.1-2001 standard for additional information. All undefined opcodes are reserved.

80.3.5.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

80.3.5.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

80.3.5.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

80.3.5.4 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

80.3.5.5 TEST_LEAKAGE instruction

The TEST_LEAKAGE instruction forces the jtag_leakage output signal to high. It is intended to tristate all output pad buffers and disable all of the part's pad input buffers except JCOMP and TEST. The jtag_leakage signal is asserted at the falling edge of TCK following the TAP controller state machine transition from the Update-IR state to the Run-Test-Idle state. When asserted, the part disables TCK, TMS, and TDI inputs and forces them to a logic 1. The TAP controller state machine remains in the Run-Test-Idle state until the JCOMP input is set to a value other than the JTAGC enable encoding. TEST_LEAKAGE also asserts the internal system reset for the MCU to force a predictable internal state.

80.3.5.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

80.3.5.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

80.3.5.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers.

When this instruction is loaded, control of the JTAG pins is transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins.

The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE when they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

80.3.5.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

80.3.6 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

80.4 External signal description

The JTAGC consists of a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 708. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

80.4.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

80.4.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

80.4.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

80.4.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

80.5 Initialization/application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS.
2. Load the appropriate instruction for the test or action to be performed.

80.6 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

80.6.1 Instruction register

The JTAGC block uses a 8-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

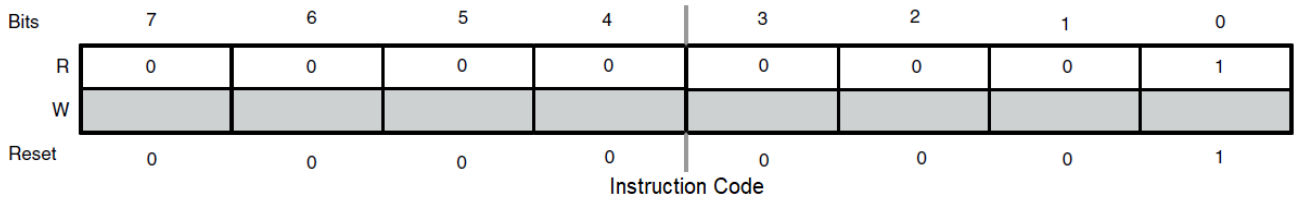


Figure 517. Instruction register

80.6.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

80.6.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

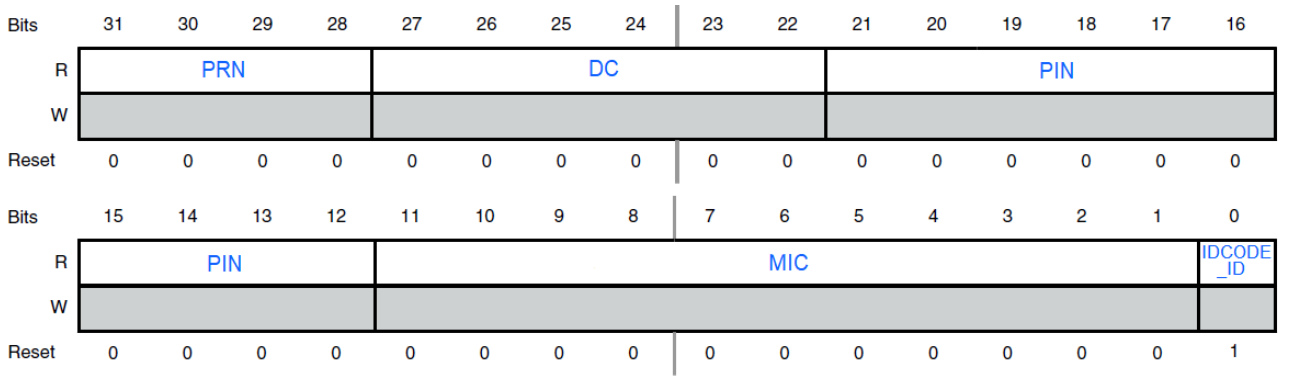

Figure 518. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 709. Device identification register field descriptions

Field	Function
PRN	Part revision number

Table continues on the next page...

Table 709. Device identification register field descriptions (continued)

Field	Function
	Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

80.6.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

80.7 Glossary

TAP	Test access port
TCK	Test clock
TDI	Test data in
TDO	Test data out
TMS	Test mode select
JCOMP	JTAG compliancy

Chapter 81
JTAG Data Communication (JDC)

81.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory-mapped register space and an external tool that accesses the JTAG port.

81.2 Overview

The JDC module consists of:

- IPS-accessible registers
- JTAG-accessible registers
- Associated logic to coordinate movement of data from one register domain to another

The JDC implements the following IPS data registers, occupying separate memory space:

- 1 32-bit memory mapped register that can be read or written via IPS (JTAG Output Data Register (JOUT_IPS)), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 1 32-bit memory mapped register that can only be read via IPS (JTAG Input Data Register (JIN_IPS)), and whose contents are loaded from a JTAG register (JIN).

JDC indicates when:

- New data has been shifted in via the JTAG port and is ready to be read from the JTAG Input Data Register (JIN_IPS) register
- New data has been written to the JTAG Output Data Register (JOUT_IPS) register and is ready to be read via the JTAG port

A Module Status Register (MSR) captures the state of these flags and also provides the flags to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

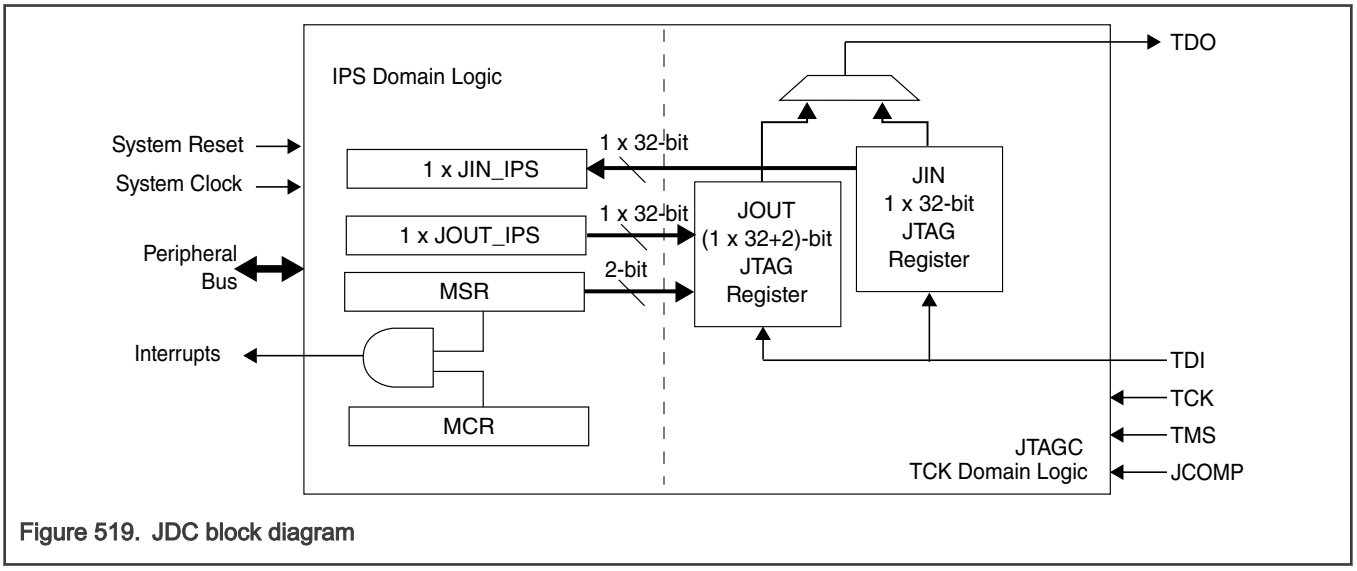

Figure 519. JDC block diagram

81.3 Signal description

JDC signals are listed in the following table.

Table 710. Signal properties

Name	Function	I/O	Reset
TCK	Test clock input	I	—
TMS	Test mode select	I	0
TDI	Test data in	I	0
JCOMP	JTAG compliance pin	I	0
TDO	Test data out	O	HiZ

81.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data in memory-mapped register that can be accessed via IPS. It also provides the ability to capture data written to memory-mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described here.

- Software write to the JOUT_IPS register:
  1. The JDC sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port.
  2. The MSR reflects the state of the JOUT_RDY bit.
  3. The JDC also captures the state of the JOUT_RDY bit in the JOUT register.
  4. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data.
  5. The JDC clears the JOUT_RDY flag bit upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction.
  6. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- JTAG write to the JIN register via execution of the JIN_WRITE JTAG instruction:
  1. The JDC updates the contents of the JIN_IPS register upon exit of the Update-DR state.
  2. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS.
  3. The MSR register reflects the state of the JIN_RDY bit.
  4. The JDC also captures the state of the JIN_RDY bit in the JOUT register.
  5. The JDC clears the JIN_RDY flag bit upon software read of the JIN_IPS register.
  6. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

81.4.1 JTAG register access

See the JTAGC documentation for information on how to access the JTAG registers.

81.4.1.1 JDC block instructions

The JDC block implements the instructions listed in Table 711. This section gives an overview of each instruction. All undefined opcodes are reserved.

Table 711. JTAG instructions

Instruction	Code[4:0]	Instruction summary
Reserved	00001	Factory debug reserved.
JOUT_READ	00010	Selects JOUT data register. The JDC captures data from JOUT_IPS into JOUT data register upon entry to Capture-DR state when JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. The JDC captures data from JIN into JIN_IPS upon exit of Update-DR state when JIN_WRITE is active.
BYPASS[1]	11111	Selects bypass register for data operations.
Reserved	All other opcodes	Decoded to select bypass register.

1. This is an IEEE 1149.1-2001 defined instruction. See the IEEE 1149.1-2001 standard for more details.

81.5 Secure challenge/response connection procedure

A summary of how the JDC can be used to interact with a security module to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.
7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The security module can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

For details related to the lifecycle stage at which this process is performed, see the "Hardware Security Engine" chapter.

81.6 JDC register descriptions

The following sections describe the implemented 32-bit registers. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

81.6.1 JDC memory map

JDC base address: 4039_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	0000_0000h
4h	Module Status Register (MSR)	32	W1C	0000_0000h
8h	JTAG Output Data Register (JOUT_IPS)	32	RW	0000_0000h
Ch	JTAG Input Data Register (JIN_IPS)	32	RO	0000_0000h

81.6.2 Module Configuration Register (MCR)

Offset

Register	Offset
MCR	0h

Function

The MCR enables the interrupt outputs of the JDC. This register is reset by system destructive reset.

81.6.4 JTAG Output Data Register (JOUT_IPS)

Offset

Register	Offset
JOUT_IPS	8h

Function

The JOUT_IPS register holds data written via IPS. The JDC captures the JOUT_IPS contents into the JOUT register to be read via the JTAG port. This register is reset by system destructive reset.

81.6.5 JTAG Input Data Register (JIN_IPS)

Offset

Register	Offset
JIN_IPS	Ch

Function

The JIN_IPS register holds data written to the JTAG input data register (JIN) via the JTAG port, where the data can be read via IPS. Any IPS write to the JIN_IPS register returns a transfer error. This register is reset by system destructive reset.

Diagram

81.7 Non-memory-mapped register definition

The JDC also implements two JTAG accessible registers that are not memory-mapped. One JTAG register shifts in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register plus ready status from the MSR, to be shifted out via the JTAG port.

81.7.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system destructive reset and JTAG reset. The reset value of the JOUT register is 0. The following figure shows the format of the JOUT register.

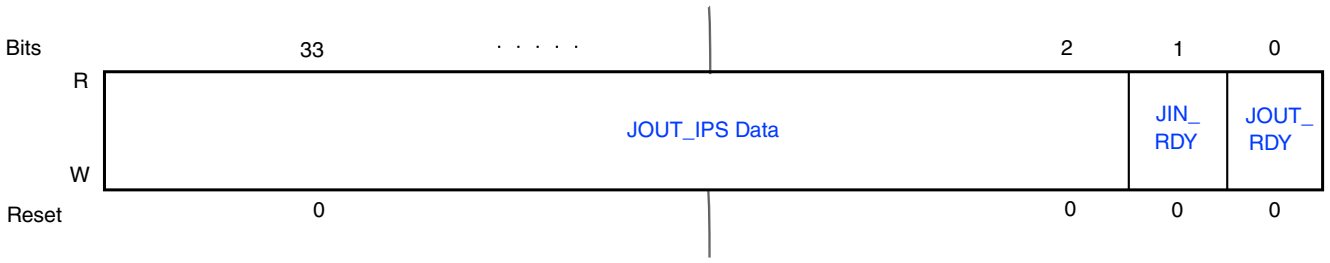

Figure 520. JOUT

The JOUT register is described in the following table.

Table 712. JOUT JTAG register field descriptions

Field	Function
JOUT_IPS Data	JOUT_IPS Data Data value from JOUT_IPS register
JIN_RDY	JIN_RDY State of JIN_RDY bit from MSR
JOUT_RDY	JOUT_RDY State of JOUT_RDY bit from MSR

81.7.2 JTAG input data register (JIN)

The external tool writes data to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JDC later captures JIN data in the JIN_IPS register to be read via IPS. This register is reset by system destructive reset and JTAG reset. The reset value of the JIN register is 0. The following figure shows the format of the JIN register.

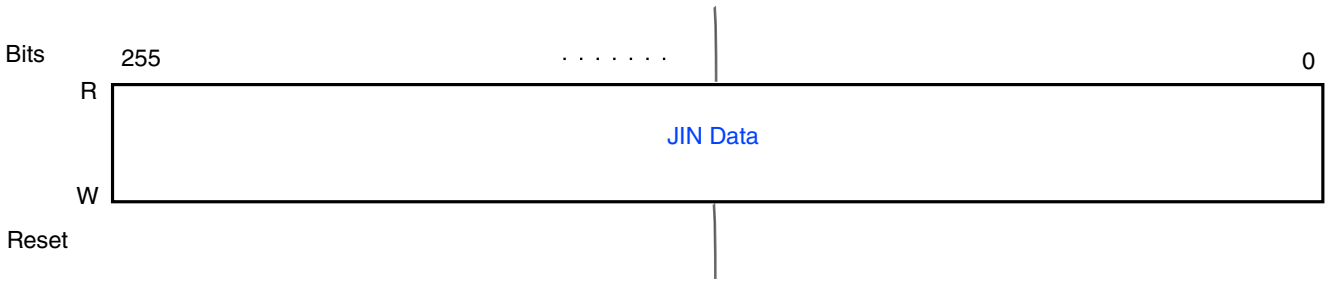

Figure 521. JIN

The JIN register is described in the following table.

Table 713. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

IPS	Internal peripheral system
XBAR	Crossbar bus interface

Chapter 82
Temperature Sensor (TempSense)

82.1 Introduction

The TEMPSENSE module contains control registers for use with the Temperature Sensor hard block. These registers use a peripheral bus interface to communicate with the chip.

82.1.1 Overview

TEMPSENSE is used to measure the temperature on the chip through an ADC.

82.1.2 Block diagram

The functional structure of the TEMPSENSE can be seen in the block diagram in Figure 522.

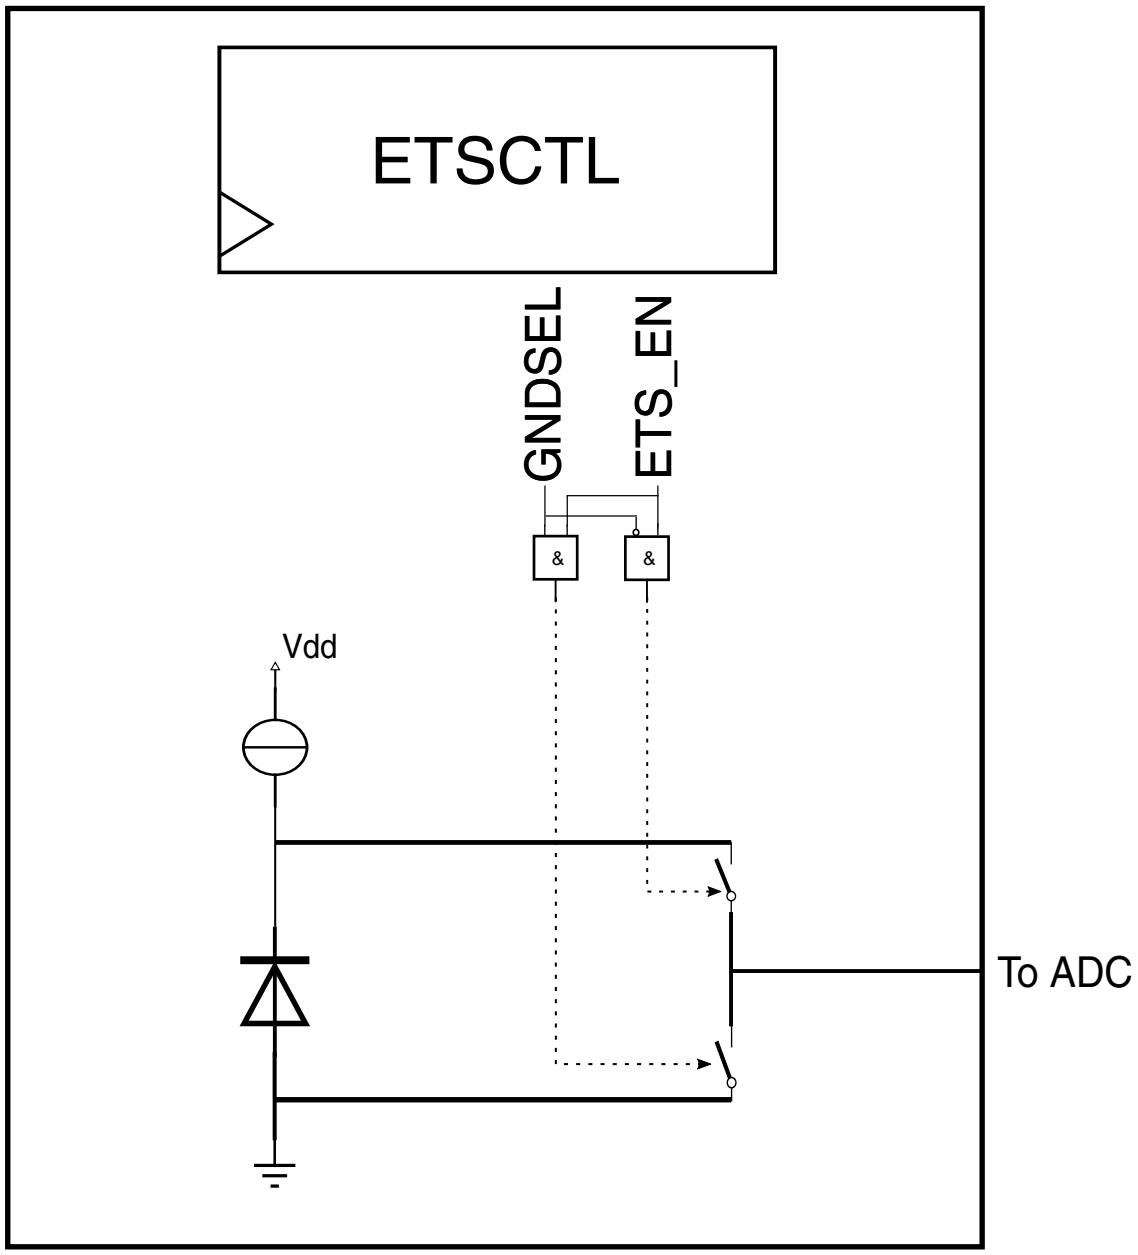

Figure 522. TEMPSENSE block diagram

82.1.3 Features

The TEMPSENSE includes the following features:

- Provide a voltage proportional to the temperature which will be read out by ADC
- Ground selection for improved precision in the ETS. The ETS ground could be different from the ADC ground. By exposing it to the ADC, the temperature calculation could be improved as the voltage value will be more precise.

82.2 Functional description

82.2.1 General

The TEMPSENSE module is designed to measure the temperature on the chip. The TEMPSENSE output can be read by an ADC on demand so that the software can determine the current die temperature. The software should enable the TEMPSENSE by setting ETSCTL[ETS_EN].

Coefficients are used to allow a simple and accurate calculation of linearized temperature directly from the ADC. The increase of the sampling time of the ADC from the minimum sampling value is increasing the temperature accuracy.

82.2.2 Conversion voltage Temperature

Solve the equation for the conversion from voltage to temperature. where V_{ETS} is the difference of V_{be} and V_{GND}. V_{GND} is expose on the ADC output when ETSCTL[GNDSEL] is set.

$$T_{ETS} = TCA_0 + TCA_1 \cdot V_{ETS} + TCA_2 \cdot V_{ETS}^2$$

The coefficients TCA0, TCA1 and TCA2 are read from the corresponding registers. They are stored in a signed fixed-point format as the folowing TCAx(11,4) (1 bit for the sign, 11 bits for the integer part and 4 bits for the decimal part).

The calculation of the temperature should be done with the actual coefficient values provided in the TCAx fields. See the example below for an ambient temperature of 25C, and an ADC reference voltage of 5V.

$$TCA0 = (000110100100.1110)_2 = (000110100100)_2 + (1110)_2 \times \frac{1}{2^4} = +((420)_{10} + (14)_{10} \times \frac{1}{2^4}) = +420.8750\ C$$

$$TCA1 = (100010101111.1110)_2 = (100010101111)_2 + (1110)_2 \times \frac{1}{2^4} = -((175)_{10} + (14)_{10} \times \frac{1}{2^4}) = -175.8750\ C/V$$

$$TCA2 = (100000011101.1110)_2 = (100000011101)_2 + (1110)_2 \times \frac{1}{2^4} = -((29)_{10} + (14)_{10} \times \frac{1}{2^4}) = -29.8750\ C^2/V^2$$

$$V_{ETS} = (010110001011)_2 = (1419)_{10} \times \frac{Vref}{2^{12}} = 1.7322\ V$$

By using the formula the junction temperature calculated is 26.5838 C.

The maximal calculation error is 0.0313 Degrees

If the supply of the ETS module is 3.3V, a conversion is necessary to calculate the accurate temperature.

$$V_{ETS} = (100001100110)_2 = (2150)_{10} \times \frac{Vrefadc}{2^{12}} \times \frac{Vsupply}{Vrefadc} = (2150)_{10} \times \frac{Vsupply}{2^{12}} = 1.7322\ V$$

82.3 Memory map and register definition

82.3.1 Transfer error description

The following actions will cause a transfer error and will not change the register content:

- Any access to an unused register address
- Write access to a read-only register (TCAx)

82.3.2 TempSense register descriptions

82.3.2.1 TempSense memory map

TEMPSENSE base address: 4037_C000h

V_{GND}	Ground voltage

Appendix A
General Changes

A.1 General changes

General changes

- Editorial changes
  - Each new release of this document includes editorial improvements such as:
    - Spelling
    - Grammar
    - Punctuation
    - Voice
    - Tense
    - Capitalization
    - Formatting
    - Presentation
    - Navigation
- Updated reference manual for S32K3xx family.

Appendix B
Release notes

B.1 About This Manual changes

No substantial content changes.

B.2 Introduction changes

No substantial content changes.

B.3 Memory map module changes

No substantial content changes.

B.4 Signal Multiplexing module changes

No substantial content changes.

B.5 Cortex-M7 changes

No substantial content changes.

B.6 Miscellaneous Control Module (MCM)

B.6.1 Chip-specific MCM information changes

No substantial content changes.

B.6.2 MCM module changes

- In MCM register descriptions, updated the reset values for LMEM_DESC_3 (0x85264000) and LMEM_DESC_4 (0x85446000).

- In MCM register descriptions, updated the reset values for LMEM_DESC_0 (0x87060000h), LMEM_DESC_1 (0x87042000h) and LMEM_DESC_2 (0x87042000h).
- In Local Memory Descriptor 0 (LMEM_DESC_0), updated the note to "The reserved bits can be read and written (instead of read as zero and write ignored). Setting any of these bits does not have any functional impact".

B.7 Miscellaneous System Control Module (MSCM)

B.7.1 Chip-specific MSCM information changes

No substantial content changes.

B.7.2 MSCM module changes

• Added registers ENEDC1 and IAHBCFGREG
• Made changes to the CPXTYPE, CPXNUM, CP2TYPE, CP2NUM, CP2REV, CP2CFG0, CP2CFG1, CP2CFG2, CP2CFG3, IRCP0ISR0, IRCP0IGR0, ENEDC, ENEDC1, IAHBCFGREG, IRSPRC0, and XN_CTRL registers. • Changed the reset values of these registers: CPXCFG0 to 0602_0604h, CP0CFG0 to 0602_0604h, CP1CFG0 to 0602_0604h, and XN_CTRL to 4000_0000h. • Marked bit positions 30 and 31 of the ENEDC register as "reserved." • Added fields "Soft lock" and "Hard lock" to the XN_CTRL register.

B.8 Virtualization Wrapper (VIRT_WRAPPER)

B.8.1 Chip-specific VIRT WRAPPER information changes

No substantial content changes.

B.8.2 Virt_Wrapper changes

• Updated the note from "Access to reserved spaces outside the register bank generates the transfer error. However, access to the reserved spaces within the register bank does not have any effect" to "Access to reserved spaces outside the register bank and holes (unimplemented registers) within register bank generates the transfer error.". • Added the note "Any master can access holes (unimplemented registers) of SIUL2 through PDAC0." for REG_A and REG_B. • Corrected the syntax to show the reserve RW Implemented hole bits within the registers REG_A and REG_B using MSCR_MAPPED parameter for REG_A and REG_B.
• Changed from PDAC to PDAC slot as applicable throughout the document. • Added a note, "PDAC and PDAC slot are interchangeable terms." in Glossary.
• Updated "10 - Reserved" as "10 - SIUL2_VIRTWRAPPER_PDAC4" throughout the document.

B.9 System Integration Unit Lite2 (SIUL2)

B.9.1 Chip-specific SIUL2 information changes

No substantial content changes.

B.9.2 SIUL2 module changes

• In the note "For the array of 16-bit registers PGPDO*n* and PGPDI*n*": rephrased the second bullet-item.
• Added field values 'Low' and 'High' for PGPDOn and PGPDIn registers.
• In External interrupt initialization added a new step 1 and added a note "When you chose external interrupt inputs for ...".
• Changed access type of reserved field from ROZ to RO in IFCPR and IFMCR*n* registers.

B.10 Touch Sensing Pin Coupling (TSPC)

B.10.1 Chip-specific TSPC information changes

No substantial content changes.

B.10.2 TSPC module changes

No substantial content changes.

B.11 Crossbar Switch (AXBS)

B.11.1 Chip-specific AXBS information changes

No substantial content changes.

B.11.2 AXBS module changes

No substantial content changes.

B.12 Peripheral Bridge (AIPS_Lite)

B.12.1 Chip-specific AIPS_Lite information changes

No substantial content changes.

B.12.2 AIPS_Lite module changes

No substantial content changes.

B.13 Direct Memory Access Multiplexer (DMAMUX)

B.13.1 Chip-specific DMAMUX information changes

No substantial content changes.

B.13.2 DMAMUX module changes

• Split the memory map within the DMAMUX register descriptions section into 2 sets of registers: one for channels having triggering capability (having TRIG bit) and the other for channels that don't have triggering capability (and hence no TRIG bit).
• Split the memory map within the DMAMUX register descriptions section into 2 sets of registers: one for channels having triggering capability (having TRIG bit) and the other for channels that don't have triggering capability (and hence no TRIG bit). • Added the footnote within the memory map as follows: "In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description."

Table continues on the next page...

- Added the section Glossary and cross-referenced the first-time usage of the terms.
- Updated DMAMUX register descriptions.
- Updated Glossary.

B.14 Chip-specific eDMA information changes

No substantial content changes.

B.15 INTM module changes

No substantial content changes.

B.16 Semaphores2 (SEMA42)

B.16.1 Chip-specific SEMA42 information changes

No substantial content changes.

B.16.2 SEMA42 module changes

No substantial content changes.

B.17 Crossbar Integrity Checker (XBIC)

B.17.1 Chip-specific XBIC information changes

No substantial content changes.

B.17.2 XBIC module changes

- EIR.EIE: Added note "This field is auto-cleared, once error is generated and acknowledged by FCCU"
- ESR.VLD: Updated the access to W1C

B.18 Extended Resource Domain Controller (XRDC)

B.18.1 Chip-specific XRDC information changes

No substantial content changes.

B.18.2 XRDC module changes

- Updated description of MRGD_W3_x[VLD]
- Overview:
  - Added 'If the value of MDACFG*m*[NMDAR] is 1 ... rights granted for this DID.'

B.19 Memories and Memory Interfaces changes

No substantial content changes.

B.20 Embedded Flash Memory (c40asf)

B.20.1 Chip-specific C40asf information changes

No substantial content changes.

B.20.2 Embedded Flash Memory (c40asf)

No substantial content changes.

B.21 Flash Memory Controller (PFLASH)

B.21.1 Chip-specific PFLASH information changes

No substantial content changes.

B.21.2 PFLASH controller module changes

No substantial content changes.

B.22 RAM Controller (PRAMC)

B.22.1 Chip-specific PRAMC information changes

No substantial content changes.

B.22.2 PRAMC module changes

No substantial content changes.

B.23 Clocking module changes

- In Figure 62, added details for FCLK.

B.24 Clock Generation Module (MC_CGM)

B.24.1 Chip-specific MC_CGM information changes

No substantial content changes.

B.24.2 MC_CGM module changes

No substantial content changes.

B.25 FIRC module changes

No substantial content changes.

B.26 SIRC module changes

No substantial content changes.

B.27 Fast Crystal Oscillator Digital Controller (FXOSC)

B.27.1 Chip-specific FXOSC information changes

No substantial content changes.

B.27.2 FXOSC module changes

- Added the CTRL[ALC_D] field.

B.28 SXOSC module changes

No substantial content changes.

B.29 PLL Digital Interface (PLLDIG)

B.29.1 Chip-specific PLLDIG information changes

No substantial content changes.

B.29.2 PLLDIG module changes

- Note "The value of this field is 0b when the module is under reset." added in PLLSR[CGE_OUT2 and CGE_OUT1] register.
- Maximum possible modulation depth formula added in "Frequency modulation programming" topic.
- Maximum possible modulation depth formula added for "When PLL[RDIV] is 0" in "Frequency modulation programming" topic.
- LOL abbreviation added in LOL topic.

B.30 Reset module changes

- Updated the chapter for S32K3xx variants.

B.31 Boot Overview changes

No substantial content changes.

B.32 Reset Generation Module (MC_RGM)

B.32.1 Chip-specific MC_RGM information changes

No substantial content changes.

B.32.2 MC_RGM module changes

• Added following note in sectionReset state machine: See chip-specific MC_RGM information for chip-specific reset sequence details.
• Added following note in DES[F_POR] field: All reset status in the FES and DES registers must be ignored at power up if this field is set.
• Removed the following content fromFunctional reset entry timer: See the chip-specific section for the default value of timeout value and the details on the chip behavior in case of functional reset entry timer timeout. • Added section: Alternate event generation.
• Removed the following statement from RESET_B pin assertion and pin safe state control: See STCU2 chapter for more details on its usage. • Added following note in Functional reset escalation: Functional counter increments for each reset source for which escalation is enabled. For details, see "Reset sources" table in the Reset chapter. • Added following note in Destructive reset escalation: Desctructive counter increments for each reset source for which escalation is enabled. For details, see "Reset sources" table in the Reset chapter.

B.33 POR_WDG module changes

No substantial content changes.

B.34 Security overview changes

No substantial content changes.

B.35 HSE_B module changes

No substantial content changes.

B.36 DCF module changes

• Remove the sections *Spreaded triple voting* and *Second write check*. • Remove a row UTEST DCF start record from the table *Integration of DCF information*.

B.37 Chip-specific DCM information changes

• Added Read Only GPR On Destructive Reset Register (DCMROD8).

Table continues on the next page...

• In Read Write GPR On Functional Reset 3 (DCMRWF3), added bitfields MAC_RX_CLK_MUX_BYPASS and MAC_TX_CLK_MUX_BYPASS. • Added Read Write GPR On Destructive Reset 16 (DCMRWD16) • In Read Write GPR On Functional Reset 1 (DCMRWF1), updated bitfield value of I3C0_CLK_MUX_SEL. • Editorial fixes throughout the chapter.
• In Read Only GPR On PMCPOR Reset 2 (DCMROPP2), removed the POR_WDG_STAT33, POR_WDG_STAT34, POR_WDG_STAT37, POR_WDG_STAT42, POR_WDG_STAT43, POR_WDG_STAT44, POR_WDG_STAT45, POR_WDG_STAT46, POR_WDG_STAT47, POR_WDG_STAT49, POR_WDG_STAT50, POR_WDG_STAT51, POR_WDG_STAT53, POR_WDG_STAT54, POR_WDG_STAT55, POR_WDG_STAT56, POR_WDG_STAT57, POR_WDG_STAT58, POR_WDG_STAT59, POR_WDG_STAT60, and POR_WDG_STAT63 fields (their bit positions are now reserved). • In Read Only GPR On PMCPOR Reset 3 (DCMROPP3), removed the POR_WDG_STAT65, POR_WDG_STAT66, POR_WDG_STAT69, POR_WDG_STAT71, POR_WDG_STAT75, POR_WDG_STAT77, POR_WDG_STAT83, POR_WDG_STAT84, POR_WDG_STAT85, POR_WDG_STAT86, POR_WDG_STAT87, POR_WDG_STAT88, POR_WDG_STAT89, POR_WDG_STAT90, POR_WDG_STAT91, POR_WDG_STAT92, and POR_WDG_STAT95 fields (their bit positions are now reserved).

B.38 DCM module changes

No substantial content changes.

B.39 Messaging Unit (MU)

B.39.1 Chip-specific MU information changes

No substantial content changes.

B.39.2 MU changes

No substantial content changes.

B.40 Power management changes

No substantial content changes.

B.41 PMC changes

No substantial content changes.

B.42 PMC changes

No substantial content changes.

B.43 PMC changes

No substantial content changes.

B.44 Mode Entry Module (MC_ME)

B.44.1 Chip-specific MC_ME information changes

No substantial content changes.

B.44.2 MC_ME module changes

No substantial content changes.

B.45 MC_PCU changes

No substantial content changes.

B.46 Wakeup Unit (WKPU)

B.46.1 Chip-specific WKPU information changes

- Updated this section for S32K3xx family.

B.46.2 WKPU module changes

- Replaced the content in Non-maskable interrupts with If the IBE of NMI is tied off to 1, no false interrupt is expected.

B.47 Safety overview changes

No substantial content changes.

B.48 Error Injection Module (EIM)

B.48.1 Chip-specific EIM information changes

No substantial content changes.

B.48.2 EIM changes

- In Functional description, added information about enabling/disabling error injection.

B.49 Error Reporting Module (ERM)

B.49.1 Chip-specific ERM information changes

No substantial content changes.

B.49.2 ERM module changes

• Updated the description of the SR registers.
• Added following note in the "ERM register descriptions" section: To access the channel registers, corresponding channel clocks must be enabled.

B.50 Fault Collection and Control Unit (FCCU)

B.50.1 Chip-specific FCCU information changes

No substantial content changes.

B.50.2 FCCU module changes

• Note "Software reset of FCCU by MC_RGM_PRST5[FCCU_RST] bit is optional since FCCU registers are not initialized during functional reset. MC_RGM_PRST5[FCCU_RST] has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default." removed from topic "Use cases and limitations".
• Reset interface topic moved into chip specific section.
• The equation changed from "Tmin = 250 µs + DELTA_T to "Tmin = (250us + DELTA_T) * (SAFE_CLK_FREQ/CLKSAFE freq).

B.51 SELFTEST_GPR module changes

• Information added for different K3xx variants (K342, K312 and K311).
• Added note in Introduction section.

B.52 Self-Test Control Unit (STCU2)

B.52.1 Chip-specific STCU2 information changes

No substantial content changes.

B.52.2 STCU2 module changes

• In Example: Multi-phase BIST sequence, changed the BIST number from 38 to 30 for phase 0.
• Removed MTR from the function of "MBIST interface" in Table 258.

B.53 Register Protection (REG_PROT)

B.53.1 Chip-specific REGPROT information changes

No substantial content changes.

B.53.2 REG_PROT module changes

- In Change lock settings via area #2 section, changed from "To do so, you can use area # 2." to "To do so, you must use area # 2.".
- In Memory map and register definition section, changed from "The proper register slot size for each module is mentioned in the Memory Map file attached to this document." to "The proper register slot size for each protected module is mentioned in the REG_PROT_details file attached to this document.".
- Moved the section, "Memory map and register definition" under "Functional description".

B.54 Clock Monitoring Unit – Frequency Check (CMU_FC)

B.54.1 Chip-specific CMU_FC information changes

No substantial content changes.

B.54.2 CMU_FC module changes

No substantial content changes.

B.55 Clock Monitoring Unit – Frequency Meter (CMU_FM)

B.55.1 Chip-specific CMU_FM information changes

No substantial content changes.

B.55.2 CMU_FM module changes

No substantial content changes.

B.56 Cyclic Redundancy Check (CRC)

B.56.1 Chip-specific CRC information changes

No substantial content changes.

B.56.2 CRC module changes

- Renamed the section "Introduction" to Overview
- Added the section External signals.
- Moved the section Modes of operation within the Functional description section.
- Moved the section CRC initialization/reinitialization after the Functional description section.

B.57 PCMC changes

No substantial content changes.

B.58 Analog-to-Digital Converter (ADC)

B.58.1 Chip-specific ADC information changes

No substantial content changes.

B.58.2 ADC module changes

No substantial content changes.

B.59 Low Power Comparator (LPCMP)

B.59.1 Chip-specific LPCMP information changes

No substantial content changes.

B.59.2 LPCMP module changes

- In LPCMP register descriptions, edited register descriptions throughout.

- Added Glossary of terms.

- Changed the name of the "Clocks" section to Clocking.
- Changed the name of the "Trigger Mode" section to Round Robin Trigger mode and clarified the full name of the Round Robin Trigger mode.
- Clarified Latency issues.
- Added register links to Initialization.

B.60 Logic Control Unit (LCU)

B.60.1 Chip-specific LCU information changes

No substantial content changes.

B.60.2 LCU module

No substantial content changes.

B.61 Enhanced Modular IO Subsystem (eMIOS)

B.61.1 Chip-specific eMIOS information changes

No substantial content changes.

B.61.2 eMIOS module changes

No substantial content changes.

B.62 Body Cross-triggering Unit (BCTU)

B.62.1 Chip-specific BCTU information changes

No substantial content changes.

B.62.2 BCTU module changes

No substantial content changes.

B.63 Trigger MUX (TRGMUX)

B.63.1 Chip-specific TRGMUX information changes

No substantial content changes.

B.63.2 TRGMUX module changes

No substantial content changes.

B.64 Software Watchdog Timer (SWT)

B.64.1 Chip-specific SWT information changes

No substantial content changes.

B.64.2 SWT module changes

- In CR[FRZ], replaced "chip" with "core."
- In Behavior in different chip and core modes, replaced "chip" with "core."

B.65 System Timer Module (STM)

B.65.1 Chip-specific STM information changes

No substantial content changes.

B.65.2 STM module changes

- Renamed "Introduction" to Overview.
- Restructured to conform to BGAC outline.
- Added the Clocking topic.
- Added the Interrupts topic.
- Restored the External signals topic.
- Added the Initialization topic.

B.66 Periodic Interrupt Timer (PIT)

B.66.1 Chip-specific PIT information changes

No substantial content changes.

B.66.2 PIT_RTI module changes

- Updated description of MCR[MDIS]. Changed the sentence “You must write 1 to this field before setting up anything” to “You must ensure that the clock is disabled (MDIS = 1) before configuring PIT. After configuration, user must enable clock (MDIS=0).”
- Updated Modes of operation to include Debug mode.

B.67 Real Time Clock (RTC)

B.67.1 Chip-specific RTC information changes

No substantial content changes.

B.67.2 RTC module changes

No substantial content changes.

B.68 Low Power Serial Peripheral Interface (LPSPI)

B.68.1 Chip-specific LPSPI information changes

No substantial content changes.

B.68.2 LPSPI module changes

- In Master mode, Transmit and command FIFO commands, and Transmit Command (TCR), clarified that LPSPI must be enabled to update command word.
- Updated Features.

- Updated Low-power modes

- Updated Timing parameters.
- Added a warning on writing data to Clock Configuration (CCR).

- Moved "SPI bus transfers" content from Transmit and command FIFO commands to subtopic
- Moved "Circular FIFO" content from Transmit and command FIFO commands to subtopic

B.69 Low Power Inter-Integrated Circuit (LPI2C)

B.69.1 Chip-specific LPI2C information changes

No substantial content changes.

B.69.2 LPI2C module changes

• Changed MCFGR0[1] to reserved.
• Added MCFGR0[HRPOL].
• Updated Low power modes, Interrupts and DMA requests, Master Mode, and Slave Mode. • Added cross references to LPI2C register descriptions.
• Updated MCFGR1[IGNACK].
• Changed title of External signals

B.70 Improved Inter-Integrated Circuit (I3C)

B.70.1 Chip-specific I3C information changes

• In I3C instances and configuration, added notes.

B.70.2 I3C module changes

• Updated Reading and writing I2C messages using the normal method. • Updated Reading/writing I3C messages using the normal methods (SDR and HDR-DDR). • Reformatted Slave data write to Master. • Updated DMA (for internal FIFO use only). • Updated MWMSG_DDR_CONTROL[LEN].
• Added Interrupt service flow. • Updated Configuration initialization.
• Updated MCTRL[TYPE].
• Updated Configuration initialization description in ODBAUD, ODHPP, and I2CBAUD. • In Master Control (MCTRL), updated MCTRL[TYPE], MCTRL[IBIRESP].
• Updated Reading/writing I3C messages using the normal methods (SDR and HDR-DDR). • Updated Slave Maximum Limits (SMAXLIMITS) description. • Updated MCTRL[REQUEST].
• Updated register references throughout. • Updated Overview. • Updated Features. • Updated Master vs. slave roles for I3C.
• Added note to SDATACTRL[UNLOCK] and MDATACTRL[UNLOCK].
• Added note to Slave DMA Control (SDMACTRL) and DMA (for internal FIFO use only).

B.71 Flexible I/O (FlexIO)

B.71.1 Chip-specific FlexIO information changes

No substantial content changes.

B.71.2 FLEXIO module changes

No substantial content changes.

B.72 CAN (FlexCAN)

B.72.1 Chip-specific FlexCAN information changes

- In FlexCAN instances and configuration, added note "The availability of 'Interrupt Masks 3 Register (IMASK3)' and 'Interrupt Flags 3 Register (IFLAG3)' registers for an instance depends upon the number of message buffers..".

B.72.2 FlexCAN module changes

- In Overview, removed the text "See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip".

- In Features, Overview and , updated the ISO 11898-1 to ISO 11898-1:2015.
- In Protocol timing, added text "It is the smallest time unit for all configuration values".

- Updated the ISO 11898-1 to ISO 11898-1:2015 throughout the chapter.

- In Bus interface added the following registers:
  - EPRS
  - ENCBT
  - EDCBT
  - ETDC

B.73 Synchronous Audio Interface (SAI)

B.73.1 Chip-specific SAI information changes

- Updated Table 485.

B.73.2 SAI module changes

- Updated TCR2[BCI] and RCR2[BCI] with note about enabling buffers.

- Updated field descriptions: TCSR[FR], TCSR[SR], TCSR[FWDE], TCR1[TFW], TCR5[WNW], TCR5[W0W], TCR5[FBT]. RCSR[FR], RCSR[SR], RCSR[FWDE], RCR1[RFW], RCR3[WDFL], RCR4[FRSZ], RCR4[SYWD], RCR5[WNW], RCR5[W0W], and RCR5[FBT].
- In Receive Configuration 5 (RCR5), updated description.

B.74 Ethernet Media Access Controller (EMAC)

B.74.1 Chip-specific EMAC information changes

No substantial content changes.

B.74.2 ENET_Controller module changes

- MAC_VLAN_HASH_TABLE register: Updated description as 'The upper four bits of the calculated CRC value are used to index the contents of the VLAN hash table'
- MAC_VLAN_Tag.DOVLTC: Added 'The VLAN filter is bypassed when VLAN type ... VLAN type in the VLAN filter'

B.75 Gigabit Ethernet Media Access Controller (GMAC)

B.75.1 Chip-specific GMAC information changes

No substantial content changes.

B.75.2 GMAC module changes

- Added new chapter for S32K358 variant.

B.76 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

B.76.1 Chip-specific LPUART information changes

No substantial content changes.

B.76.2 LPUART module changes

No substantial content changes.

B.77 Quad Serial Peripheral Interface (QuadSPI)

B.77.1 Chip-specific QuadSPI information changes

No substantial content changes.

B.77.2 QuadSPI module changes

- Removed the phrase ",and this depends on the configuration of RBCT[RXBRD]" in Flash memory read section

- Changed the figure title to "Data strobe functionality in SDR mode for read operation" in Figure 478.
- Added a Note in the Figure 471.
- Added a Note:The IOs are driven from QuadSPI as per the number of pads configured for ongoing phase for the Figure 471

Table continues on the next page...

- Removed 2nd and 3rd Note in the Figure 471
- Updated Figure 471 with Note1.
- Changed "DLLCRL"to "DLLCRB" in the section Dummy Pad loopback
- Changed the content for high and low frequency delay chain manual programming with additional content with "DLLCR[FREQEN]" and "or DLLCRB[SLV_DLY_COARSE]" in the section Dummy Pad loopback

- Changed the variable "tDel,total" to "ttotal_delay" in the section Basic description under the topic "Sampling of serial flash memory input data"

- Updated the description of the Master Read Command (MRC)
- Updated the description of the Master Timeout (MTO)
- Updated the description of the Master Global Configuration (MGC)

- Updated Figure 470
- Added the parameterised phrase "or using AHB (64-bit width interface)" in the section Features
- Updated the Register file for SR register description in the section SR[RXFULL]
- Updated the Register file for MCR register description for 0b in the section MCR[SWRSTSD]
- Updated the Register file for MCR register description of 0b bit in the section MCR[SWRSTHD]

- Added new image for the Figure 470

- Updated the Register file for SR register description in the section SR[TXWA]

- Updated the Register file for RSER register description in the section RSER[CRCAIE]
- Updated the Register file for FR register description in the section FR[CRCAEF]

- Updated the Instruction set entry for the CMD instruction in the Programmable sequence engine section
- Updated the Instruction set entry for the DATA_LEARN instruction in the Programmable sequence engine section for Operand[6:0]
- Updated the LUT section statement for Reset Sequence Table for more clarity in LUT
- Updated the description for Flash Programming memory section for better clarity in Flash memory programming
- Added the description for Flash memory read section in 2nd bullet point of "A read access to the external serial flash memory device can be triggered in two different ways:" in Flash memory read
- Added the description for "Byte ordering of serial flash memory read data" topic in the section Byte ordering of serial flash memory read data
- Updated the description for 2nd Note in the topic "DQS sampling method" in DQS sampling method

- Removed the sentence "Master should ensure that it completes the programming sequence for flash access request (write SFAR and IPCR with SEQID) so that target queue is not left after writing SFAR or IPCR without the SEQID." from the section MDAD. and placed it after "If IPCR is written before SFAR then it will result in IPS transfer error." in the section MDAD checks
- Changed the description of the "Data masking during write list" from the section HyperRAM support. and replaced it with new descrition as per SMEs inputs with the list "Programming considerations for HyperRAM support".
- Tagged the "CK2_DCARS_FB" with new expression in MCR register description section

B.78 Ultra Secured Digital Host Controller (uSDHC)

B.78.1 Chip-specific uSDHC information changes

No substantial content changes.

B.78.2 uSDHC module changes

- Added new chapter for S32K358 variant.

B.79 Debug changes

- Removed the following columns from the Table 704: hse_dis_oem, hse_dis_fld, hse_dis_cus, and HSE_DIS_PRE_FA.
- Updated the reset value of Status (MDMAPSTTS).
- Added SDAAPRSTCTRL[RSTRELTLCM72].

- Removed the information about "HSE_DIS_CR_MCU_PROD" and "HSE Debug" from the Debug across device LifeCycles.

B.80 JTAG Controller (JTAGC)

B.80.1 Chip-specific JTAGC information changes

No substantial content changes.

B.80.2 JTAGC module changes

No substantial content changes.

B.81 JDC module changes

No substantial content changes.

B.82 TEMPSENSE module changes

No substantial content changes.

Legal information

Definitions

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at http://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Translations — A non-English (translated) version of a document is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

Suitability for use in automotive applications — This NXP product has been qualified for use in automotive applications. It has been developed in accordance with ISO 26262 and has been ASIL classified. If this product is used by customer in the development of, or for incorporation into, products or services (a) used in safety critical applications or (b) in which failure could lead to death, personal injury, or severe physical or environmental damage (such products and services hereinafter referred to as "Critical Applications"), then customer makes the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, safety, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP. As such, customer assumes all risk related to use of any products in Critical Applications and NXP and its suppliers shall not be liable for any such use by customer. Accordingly, customer will indemnify and hold NXP harmless from any claims, liabilities, damages and associated costs and expenses (including attorneys' fees) that NXP may incur related to customer's incorporation of any product in a Critical Application.
