Chapter 40
Power Management

40.1 Introduction

The power management system generates, monitors, and controls power supplies and related resets. This chapter describes the system's interaction with other peripherals.

The power management system includes the following modules:

Table 215. Power management system modules and their functions

Part	Function
MC_ME	Initiates entry into Low-Power mode
MC_PCU	Controls entry into and exit from Low-Power mode
PMC	Regulates and monitors power supplies of the Run and the Standby domains
MC_RGM	Ensures a clean state and Run domain sanity by controlling the reset sequence
FIRC, WKPU, and other chip peripherals	Controls Standby mode wake-up and operations in Run and Standby modes

Power management system for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322 and Power management system for S32K312 and S32K311 represent block diagrams of the power management system for the S32K3xx family.

40.1.1 Power management system for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322

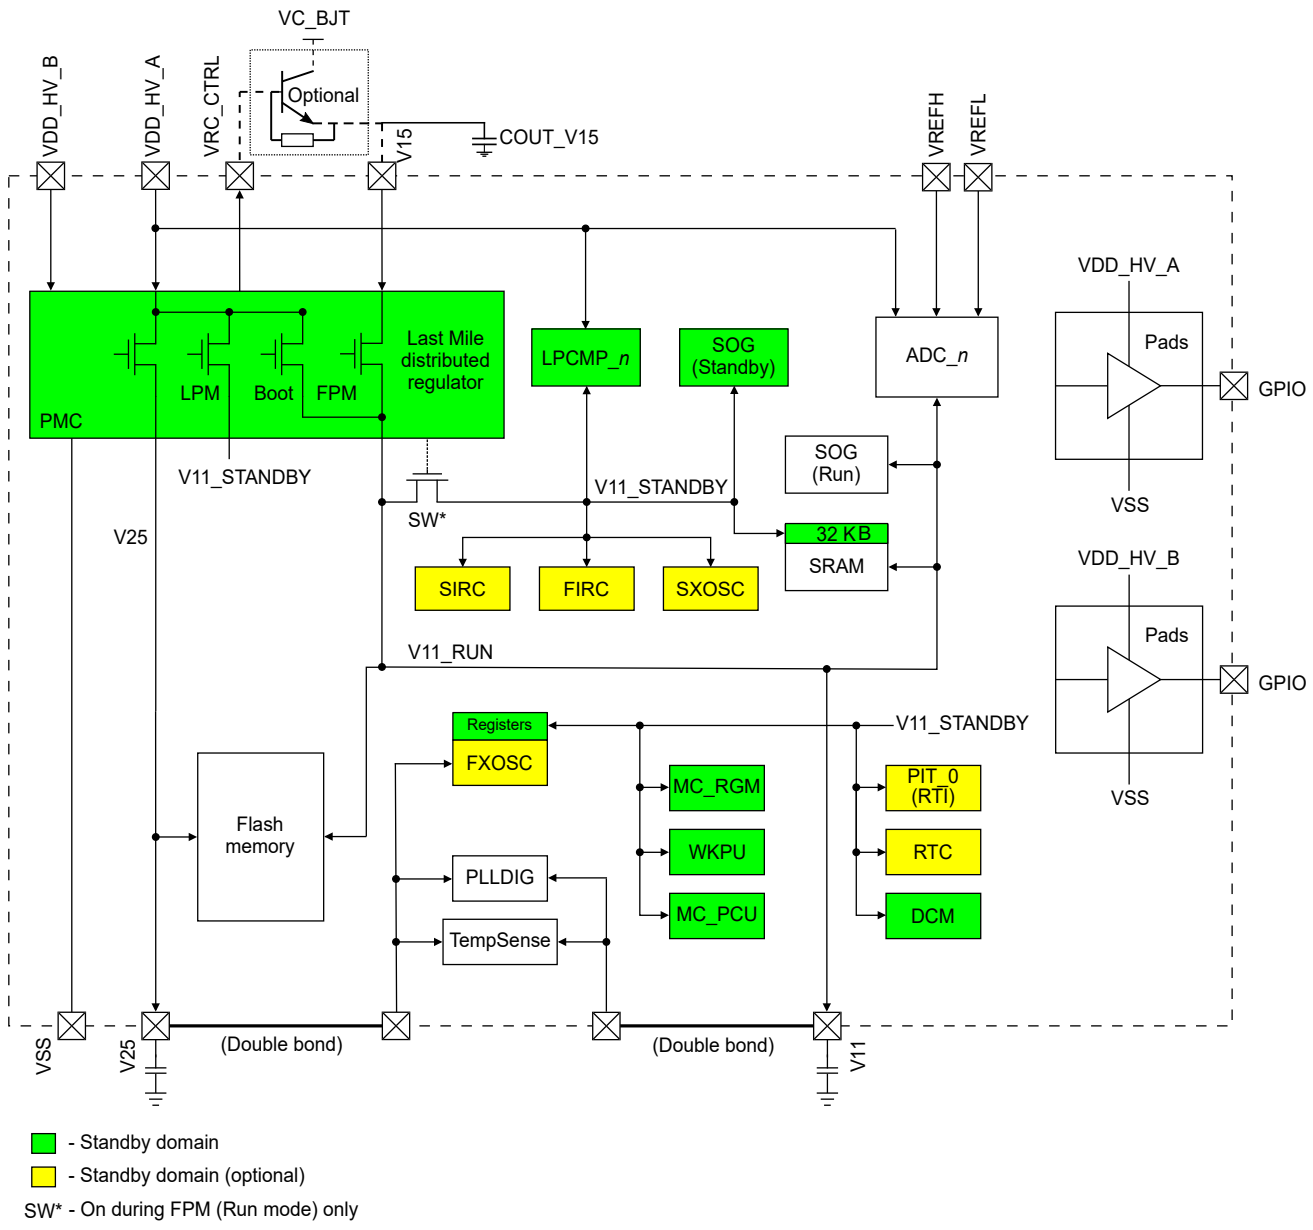

Figure 150. Power management system for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322

40.1.2 Power management system for S32K312 and S32K311

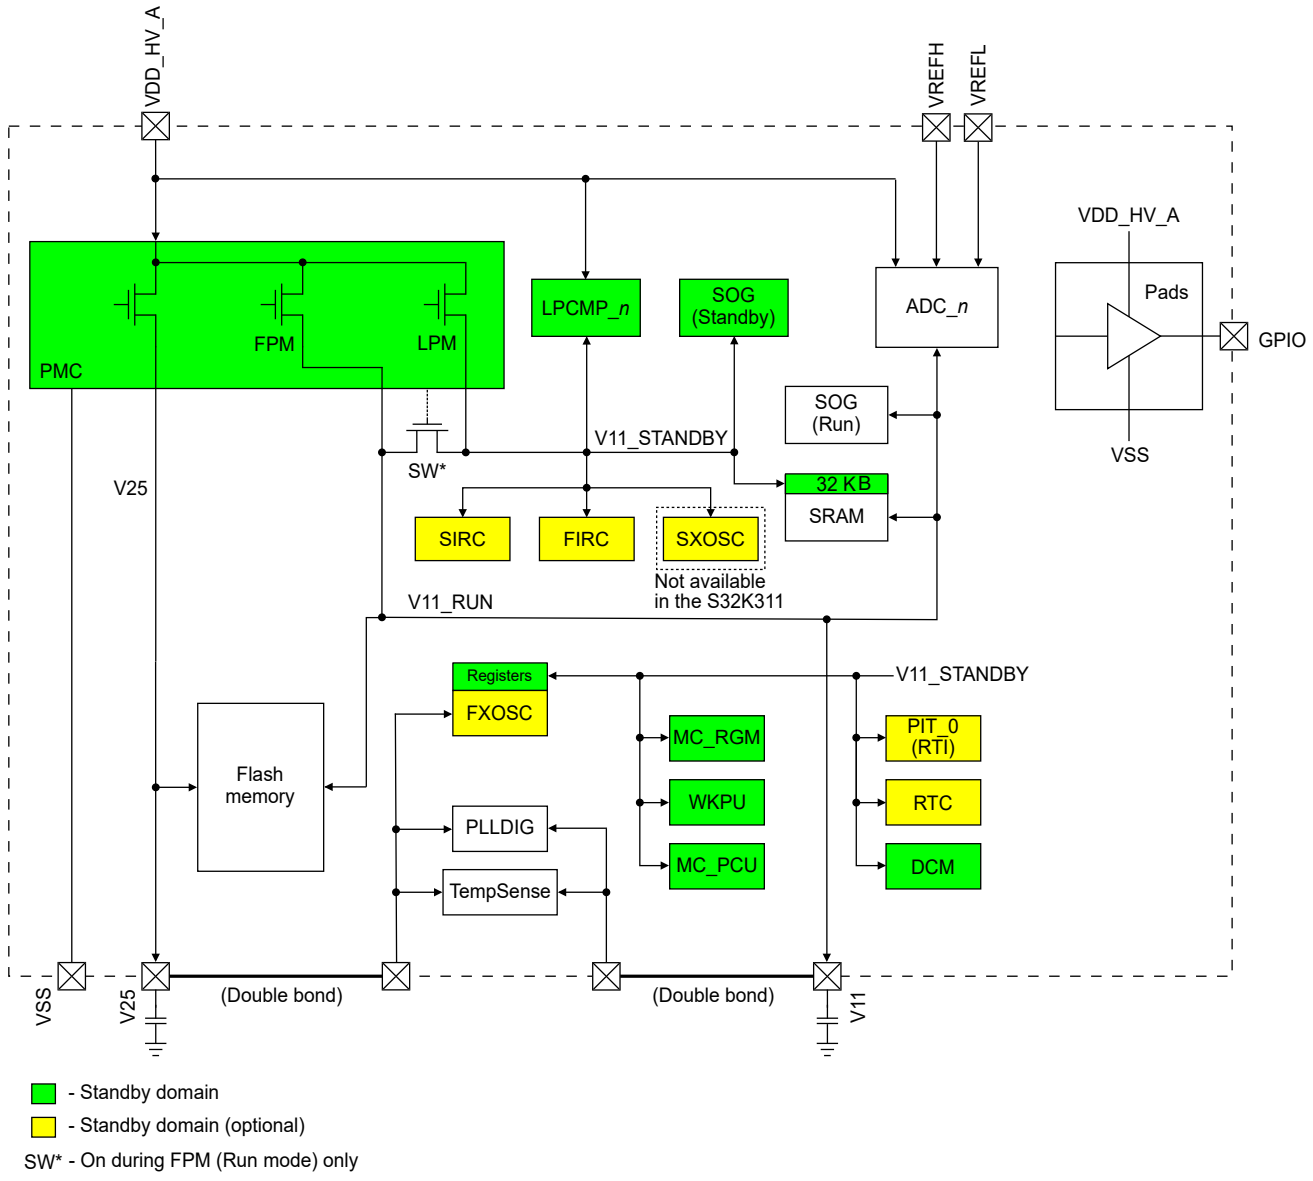

Figure 151. Power management system for S32K312 and S32K311

40.1.3 Power management system for S32K358

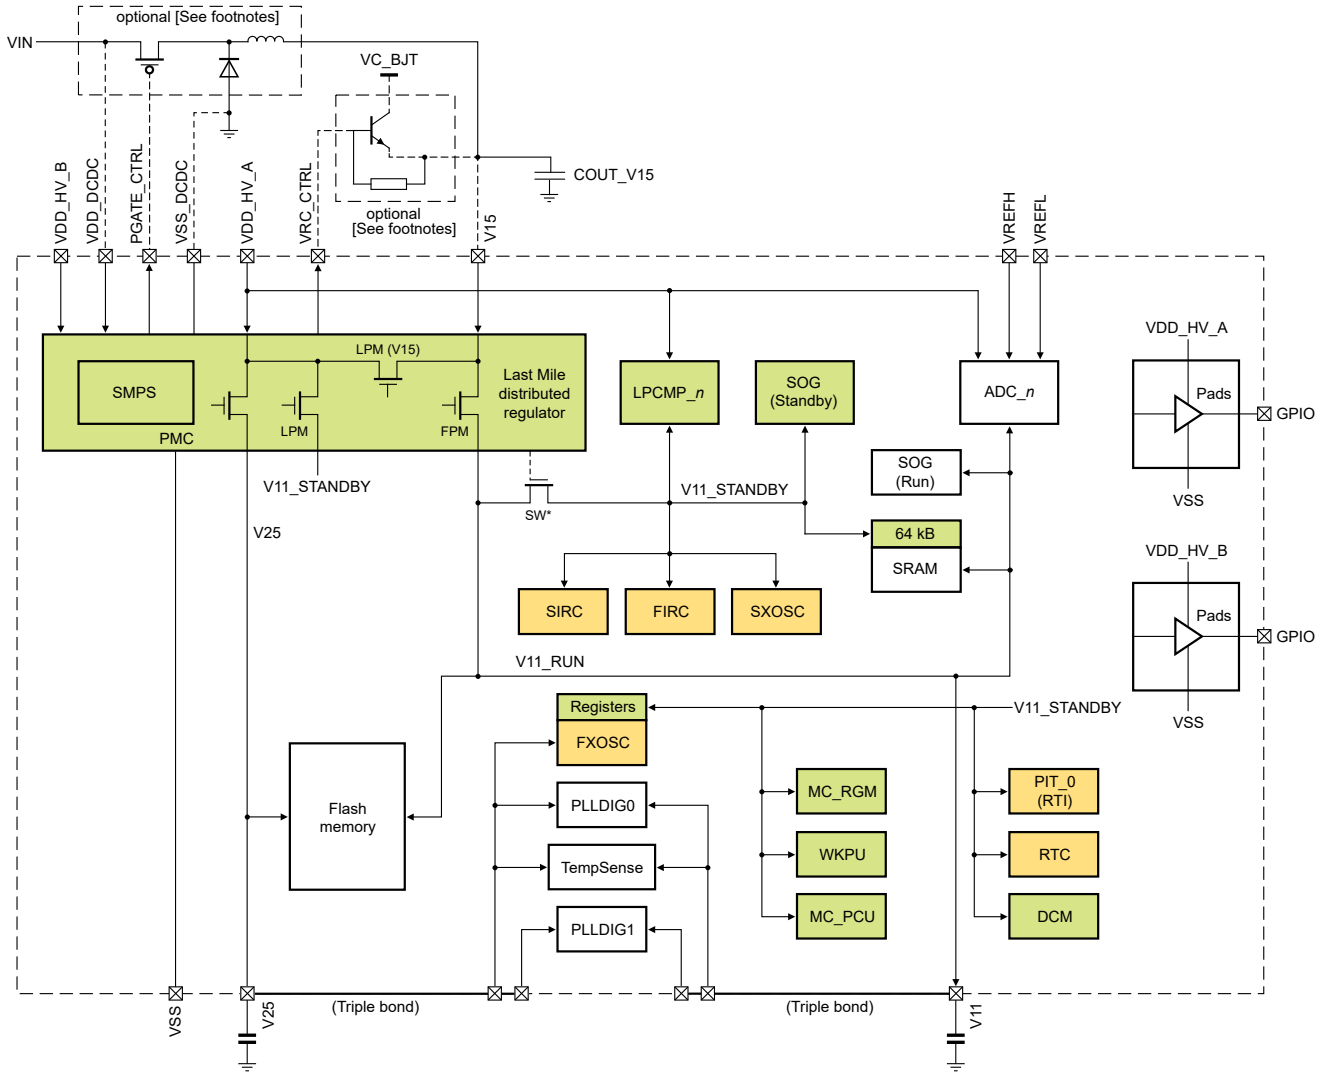

Figure 152. Power management system for S32K358

40.1.4 Features

- Includes a linear regulator to use an optional external ballast (BJT) and VRC_CTRL output for 1.5 V generation. PMC uses 1.5 V supply and an internal regulator to generate 1.1 V (nominal) supply (V11_RUN) for the core logic
- Supports a low-power regulator (LPM) supplying core logic during Standby mode (V11_STANDBY)
- Includes two regulators for driving the logic in Run mode (both can be software-controlled):
  - Boot (Applicable for S32K3x4 and S32K3x2)

  - Last-mile (FPM)
  - SMPS regulator to generate 1.5V (Applicable for S32K3x8 only)
- Supports power switches to isolate voltage islands and configure the chip in Standby mode
- S32K358 supports a DC-DC buck converter stage, with a dedicated pin to control an external Power MOSFET in the range from 1.4V to 1.5V.
- In S32K358, a high voltage detection (HVD) monitor monitors the 1.5V supply, including a status bit, a flag and an interrupt option.
- Includes a linear regulator that generates a 2.5 V supply (V25) from VDD_HV_A
- Supports voltage monitors ensuring transitions to a safe state (POR) when a supply is out of a valid range
- Controls power-mode transitions through an interaction with the digital interface
- Offers a padkeeping feature that retains I/O configuration after exiting Standby mode
- Separates ADC reference supplies (VREFH and VREFL)

40.1.5 Operational power modes

This chip uses two modes:

- Run mode (FPM): Main operation mode having full-chip performance and a higher current consumption as compared to Standby mode.
- Standby mode (LPM): Low-performance mode of the chip in which the Run domain is turned off. Most of the cores and peripherals turn off in this mode.

The boot regulator manages the chip during the booting process.

The last-mile regulator is the full-performance regulator, which you enable for running applications. The upcoming sections discuss the sequence to enable or disable the regulator.

The LPM regulator manages the chip in Standby mode.

40.1.6 External 1.5 V source

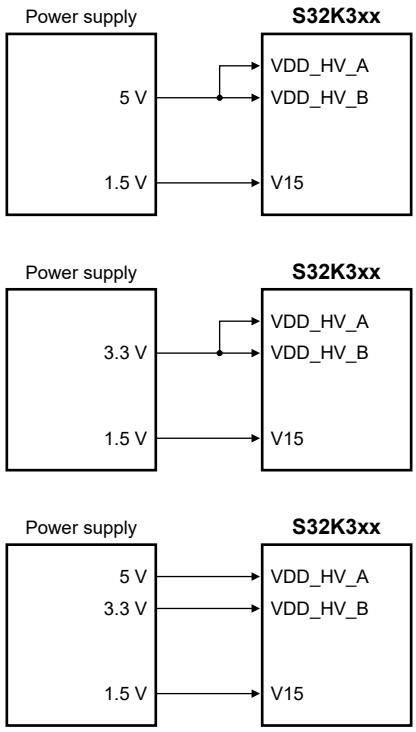

Figure 153. External 1.5 V source

40.1.7 Using a BJT for 1.5 V generation

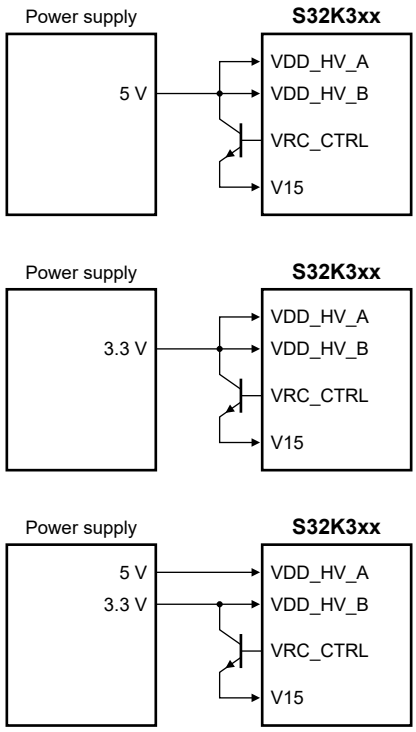

Figure 154. Using a BJT for 1.5 V generation

40.2 Power-up sequence

Figure 155 shows the reset sequence for a power-up or Standby mode event. This sequence starts from the POR phase. For the Run domain logic, Standby mode exit operation is same as power-up.

See the Reset Overview chapter for more information about the chip reset sequence.

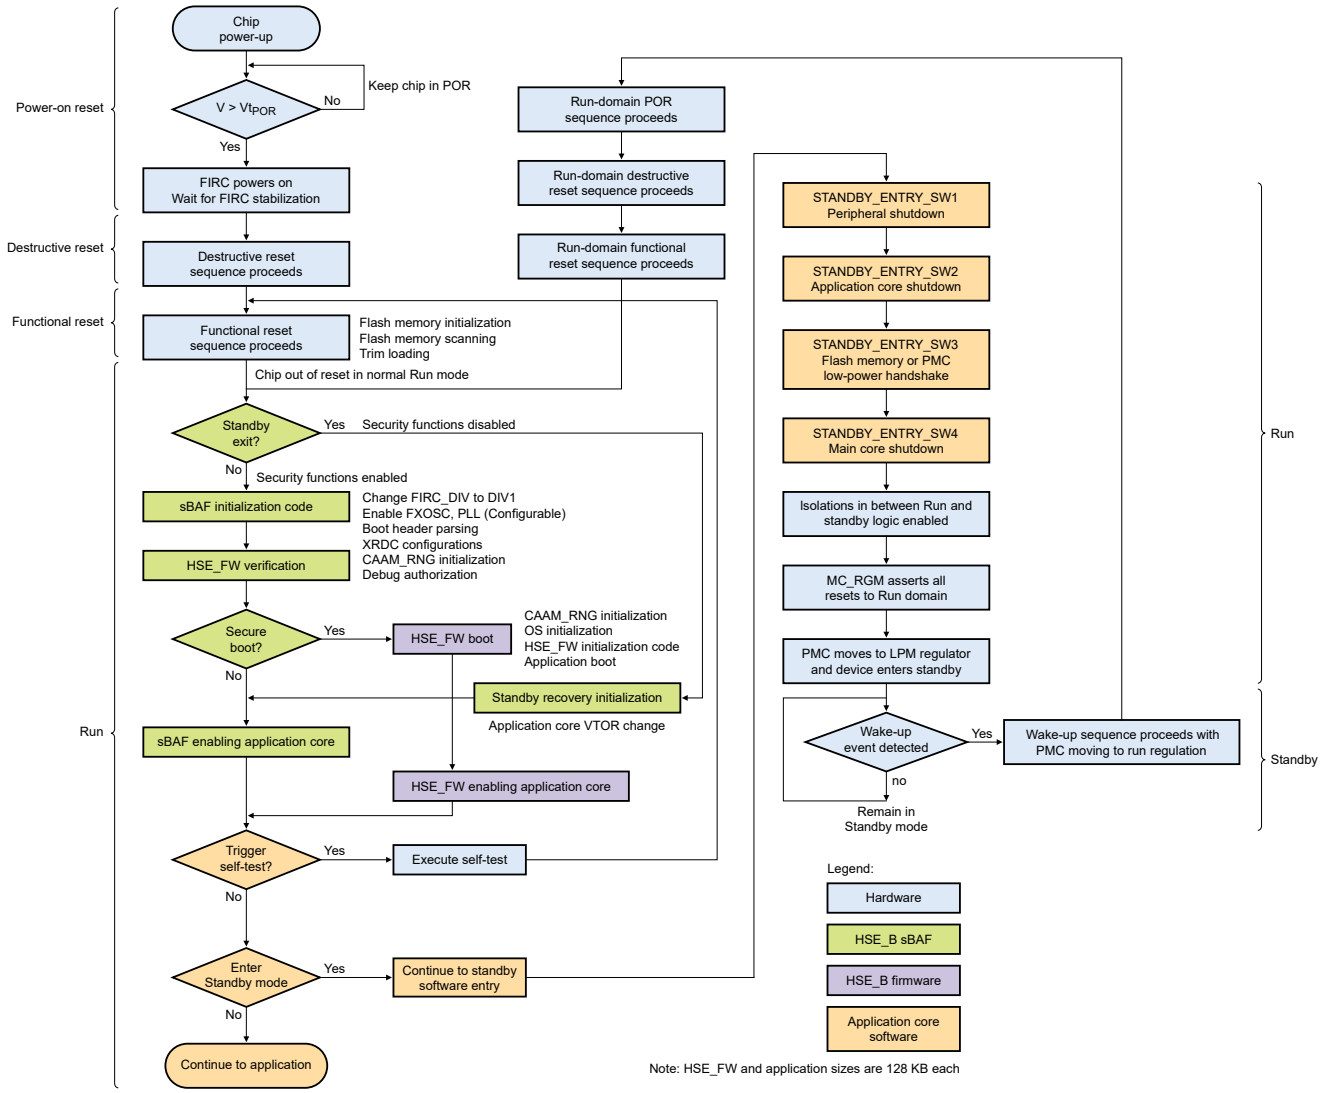

Figure 155. Power-up sequence

40.3 PMC last-mile regulator auto-enable feature

PMC includes an automatic last-mile auto-enable feature. After starting on boot regulator, this feature allows automatic switch over to last-mile regulator if 1.5 V is present during:

- Chip startup
- Standby mode recovery

You can control the PMC last-mile regulator by appropriately configuring:

- PMC's CONFIG[LMAUTOEN] field
- PMC's CONFIG[LM_EN] field

  For more information, see the descriptions of these fields in PMC's CONFIG register.

NOTE

You must write 1 to PMC's CONFIG[LM_EN] field before transtioning to faster clock frequencies irrespective of the setting of PMC's CONFIG[LMAUTOEN] field. This is because of the reduced clock speed when using the boot regulator.

40.3.1 Last-mile regulator with 1.5 V from an external source

Table 216. Last-mile regulator with 1.5 V from an external source

Operating condition	Last-mile regulator operation
After POR	Boots on boot regulator and then automatically switches to the last-mile regulator
After destructive reset	Remains on last-mile regulator **NOTE** If the destructive reset source is low voltage reset on 1.1 V then switchback happens from last-mile to boot regulator for boot.
After functional reset	Remains on last-mile regulator
After PMC's LVSC[LVD15S] field becomes 1	Switches, automatically, to the boot regulator to configure clocks for slow speed

40.3.2 Last-mile regulator using a BJT

Table 217. Last-mile regulator using a BJT

Operating condition	Last-mile regulator operation
After POR	Boots on boot regulator; switches to the last-mile regulator post reset when the Cortex-M7 core configures the software (post-secure boot) on FIRC (100 ms)
After destructive reset	Switches to boot regulator to check reset propagation delay
After functional reset	Remains on last-mile regulator
After PMC's LVSC[LVD15S] field becomes 1	Switches, automatically, to boot regulator to configure clocks for slow speed

40.4 Standby mode entry sequence

The Standby mode entry sequence includes three phases of operation:

- Standby mode entry configuration phase or software Standby mode entry sequence
- Standby mode entry handshake phase or hardware Standby mode entry sequence
- Standby mode entry or PMC Standby mode entry

NOTE

The Standby mode entry sequence described in this section is the only supported sequence. Contact NXP support if you require an alternate Standby mode entry sequence.

40.4.1 Software Standby mode entry sequence

The Standby mode entry sequence discusses chip configuration described in the sections that follow.

Before entering the software Standby mode sequence, the system clock source must be changed to FIRC because PLLDIG is not available in Standby mode. In this mode, all clock sources can be optionally disabled (including FIRC, which results in a no-clock,

low-power consumption mode). You could use FXOSC, if enabled, when the 2.5 V supply is available by appropriate configuration of PMC's CONFIG[LPM25EN].

The software Standby mode entry sequence consists of four steps:

1. SW1: Module shutdown process
2. SW2: Application core shutdown process
3. SW3: Flash memory low-power handshake and PMC last-mile regulator control
4. SW4: Main core shutdown process

These processes are described in detail in the sections that follow. See Figure 155 that shows the relationship between these four steps in a flow diagram.

40.4.1.1 SW1: Module shutdown process

I/O and module configuration for Standby mode discusses the procedure to configure I/O and the chip modules for Standby mode.

The entry sequence for this mode includes module clock disabling steps (see the "Clocking" chapter for module clock turn on and turn off processes). You must use MC_ME's PRTN*n*_COFB*m*_CLKEN[REQ*p*] fields to enable or disable module clocks.

40.4.1.1.1 Disabling modules

Disable modules by configuring the appropriate fields in their registers for Standby mode operation. See specific module chapters for more information.

The Standby mode entry sequence includes the module clock disabling step, with which you can disable the modules that you do not need for Standby mode operation.

The sequence of disabling modules is shown in I/O and module configuration for Standby mode.

NOTE

While enabling or disabling the modules, you must verify that the module is disabled when you read MC_ME's PRTNn_COFBm_STAT register and the module disable field, if applicable. In case of a discrepancy, you must perform proper diagnostic steps.

You must clear the I/O controls for the pads that you do not require in Standby mode (OBE, IBE, and so on). This avoids any unwanted pad keeping settings. See Pad keeping for more information on the chip pad keeping process.

For any standby wake source, if an interrupt occurs it must be disabled before entering into standby and only the wake up event of that source must be enabled. This is to avoid any SW conflict in the interrupt handling for multi application core cases.

The MC_ME's PRTN*n*_COFB*m*_STAT register indicates the status of peripheral clock enable or disable. It may take up to three clock cycles for MC_ME's PRTN*n*_COFB*m*_STAT register to update after MC_ME's PRTN*n*_COFB*m*_CLKEN register is updated.

40.4.1.1.2 I/O and module configuration for Standby mode

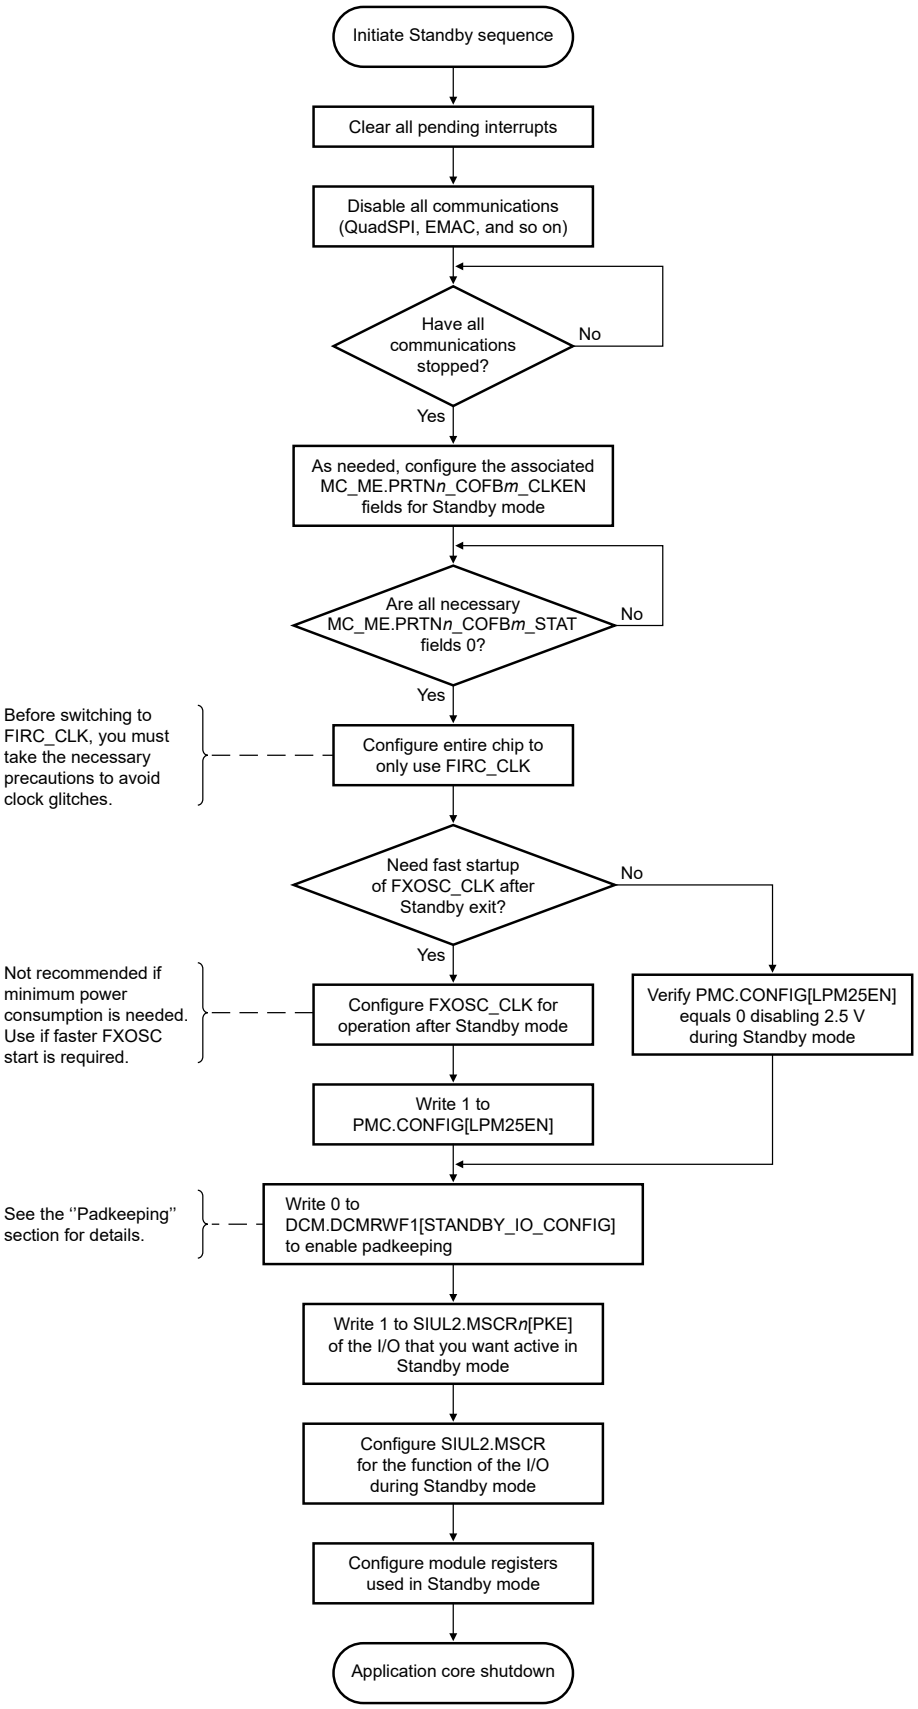

Figure 156. I/O and module configuration for Standby mode

40.4.1.2 SW2: Application core shutdown process

The application cores(s) execute a WFI (as opposed to the main core running the Standby mode entry sequence). See the section "Application core shutdown" in the MC_ME chapter for more information.

The main core configuration (programming valid core ID and enabling standby entry process) and wake-up source configuration must also be set in SW2, so that SW4 contains only the main core WFI execution.

40.4.1.3 SW3: Flash memory low-power handshake and PMC last-mile regulator

In this process, you execute a flash memory low-power handshake and disable the PMC last-mile regulator by executing the procedures indicated in Figure 157 and Figure 158 .

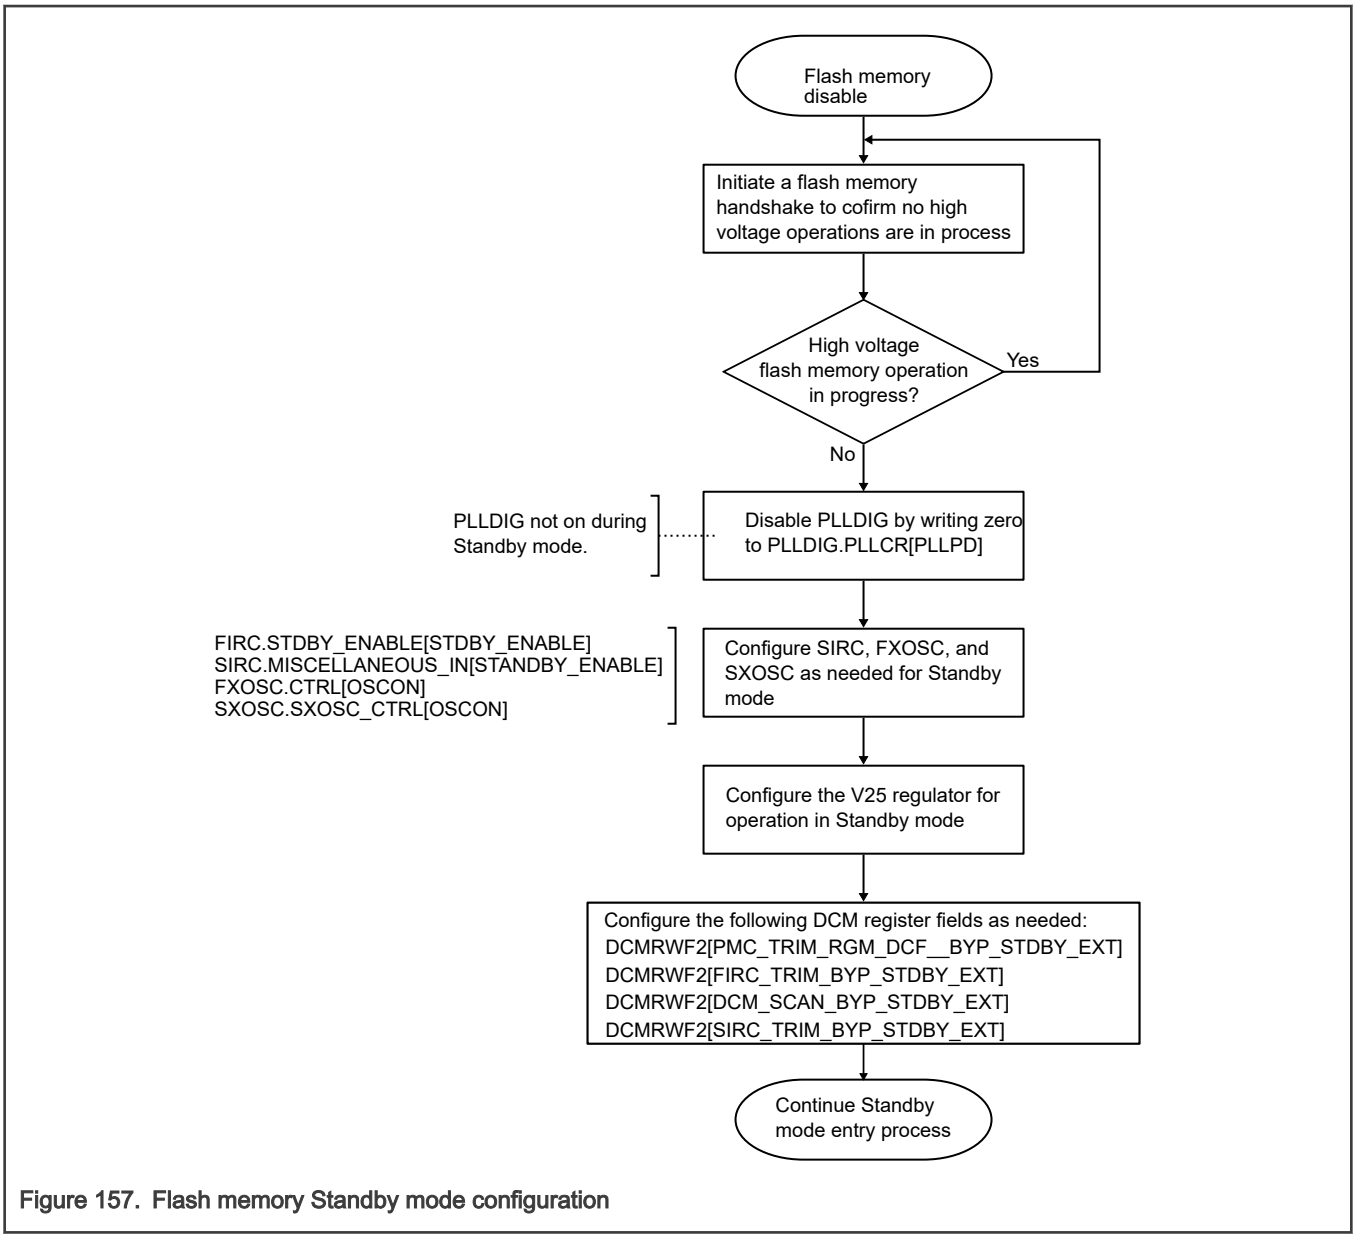

Figure 157. Flash memory Standby mode configuration

NOTE

Disable the last-mile regulator according to the Last-mile regulator disable sequence.

40.4.1.3.1 Last-mile regulator disable sequence

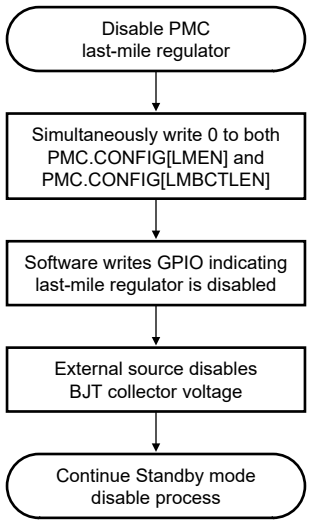

Figure 158. Last-mile regulator disable sequence

When exiting Standby mode, the 1.1 V capacitor is charging. You can charge the 1.5 V capacitor during or after the 1.1 V capacitor is charged. If you charge the 1.5 V capacitor sequentially after the 1.1 V capacitor, you will need additional time to complete the overall charging process.

Leaving PMCs CTRL[LMBCTLEN] = 1 saves time when exiting Standby mode and does not draw any additional current during this mode.

40.4.1.4 SW4: Main core shutdown process

For information on this process, see these in the "Mode Entry Module (MC_ME)" chapter:

- Figure "Standby entry sequence along with main core shutdown"
- Section "Main core shutdown and Standby mode entry"

You must configure WKPU before disabling interrupts to avoid missing any events as shown in the Standby entry sequence along with main core shutdown flowchart in the MC_ME chapter. You must program WKPU, disable interrupts, and configure MC_ME's Standby mode entry in SW1 (see SW1: Module shutdown process for more information). In SW4, you must perform only the main-core WFI execution.

40.4.2 Hardware Standby mode entry sequence

The hardware Standby mode entry sequence consists of handshaking between MC_PCU and MC_ME occuring after Software Standby mode entry sequence completes. The FSM in MC_PCU performs these steps automatically and does not require your intervention (see Power sequence FSM in the Power Control Unit (MC_PCU) chapter for more information).

40.4.2.1 PMC Standby mode entry

The PMC Standby mode entry sequence starts after Hardware Standby mode entry sequence completes, and consists of these phases:

1. Standby mode entry acknowledgment and initiation of an internal low-power process on receiving Standby mode entry request
2. Disabling of the boot regulator within the PMC low-power process. This point is only applicable for S32K3x4 and S32K3x2.
3. Disabling of the V25 regulator and the FPM LVR monitors

4. Disabling of the V25 regulator (oscillator and flash memory supply) and the LPM monitor, unless it is enabled during Standby mode (see PMC's CONFIG[LPM25EN] field in the PMC chapter for more information)
5. Disabling of the VDD_HV_B LPM monitors

40.5 Chip status at the end of Standby mode entry sequence

After PMC Standby mode entry completes, the chip completes Standby mode entry as follows:

1. Configures Standby domain peripherals according to SW1 (see SW1: Module shutdown process).
2. Enables pad keeping on pins as described in SW1 (see SW1: Module shutdown process). See Pad keeping for other details.
3. Powers down all memory types except Standby RAM (in SRAM0).
   - The V25 regulator can remain on during Standby mode. However, for maximum power savings, it must remain off in this mode.
4. Isolates Standby and Run domains from each other:
   - Standby domain is functional.
   - Run domain is held in reset.
5. Configures the system clock (FIRC_CLK or PLL_PHI*n*_CLK, depending on their configuration) and other clock sources according to SW3 (see Figure 157 for the procedure details).

   The cores are off and in the Standby domain.
6. Turns off the boot and FPM regulators.
7. Waits for a wake-up event to initiate recovery from Standby mode.

40.6 Chip operation in Standby mode

This chip supports the following functionalities in Standby mode:

- STANDBY_RAM content retention during Standby mode.
- Wake-up from up to 60 digital inputs (for details, see the signals WKUP[*n*] functions of WKPU module in the IOMUX file attached to this document). The section WKPU configuration on the chip in the "Wakeup Unit (WKPU)" chapter shows mapping of the wake-up sources.
- Wake-up from up to 16 analog inputs through the Trigger mode functionality (see the signals CMP*n*_IN*m* functions of CMP*n* modules in the IOMUX file attached to this document).
- Wake-up from on-chip timers:
  - RTI (function of PIT[0])
  - SWT0
  - RTC
- Ability to configure the chip clocking modules to optionally enable or disable in Standby mode (FIRC, SXOSC, FXOSC, and SIRC).

40.7 Standby mode exit

This chip supports Standby mode exit from a wake-up, functional reset, or destructive reset event. The sources that cause chip Standby mode exit are:

- MC_RGM functional reset event
- MC_RGM destructive reset event

- WKPU wake-up events, WKPU[0]–WKPU[63]. See the WKPU chapter for more information.

After Standby mode exit, the following events occur (for more information, see "Power sequence FSM" in the MC_PCU chapter for MC_PCU FSM transitions during entry into and exit from Standby mode):

1. A wake-up event arrives.
2. FIRC starts powering up (if disabled in Standby mode).
3. PMC starts the transition process to FPM (for example, enables the last-mile regulator and provides V11_RUN supply to the chip).
4. MC_PCU removes the isolation between Run and Standby domains.
5. Run domain reset deasserts (asserts on Standby mode entry) and the chip undergoes a functional reset exit sequence for this domain.
6. The chip enters Run mode of operation.

40.7.1 Faster Standby mode exit

The chip supports an optional configuration for faster recovery from Standby mode on the expense of a higher capacitor recharging current. See the CONFIG[FASTREC] field description in the PMC chapter for more information on faster PMC recovery from Standby mode.

This chip supports an optional feature that bypasses SIRC trimming, FIRC trimming, PMC trimming and DCM scanning phases in case of Standby mode exit sequence by writing 1 to DCM's DCMRWF2[6], DCMRWF2[5], DCMRWF2[4], and DCMRWF2[3] fields respectively before Standby mode entry for bypass operation. This results in a considerable reduction in Standby mode exit duration. The trim values are retained across Standby mode and bypassing these values does not cause any impact.

40.7.2 Last-mile regulator enable sequence

After Standby mode exit, you must re-enable the PMC last-mile regulator before transitioning to faster clock frequencies. Figure 159 shows the last-mile regulator enable sequence part of the Standby mode exit process.

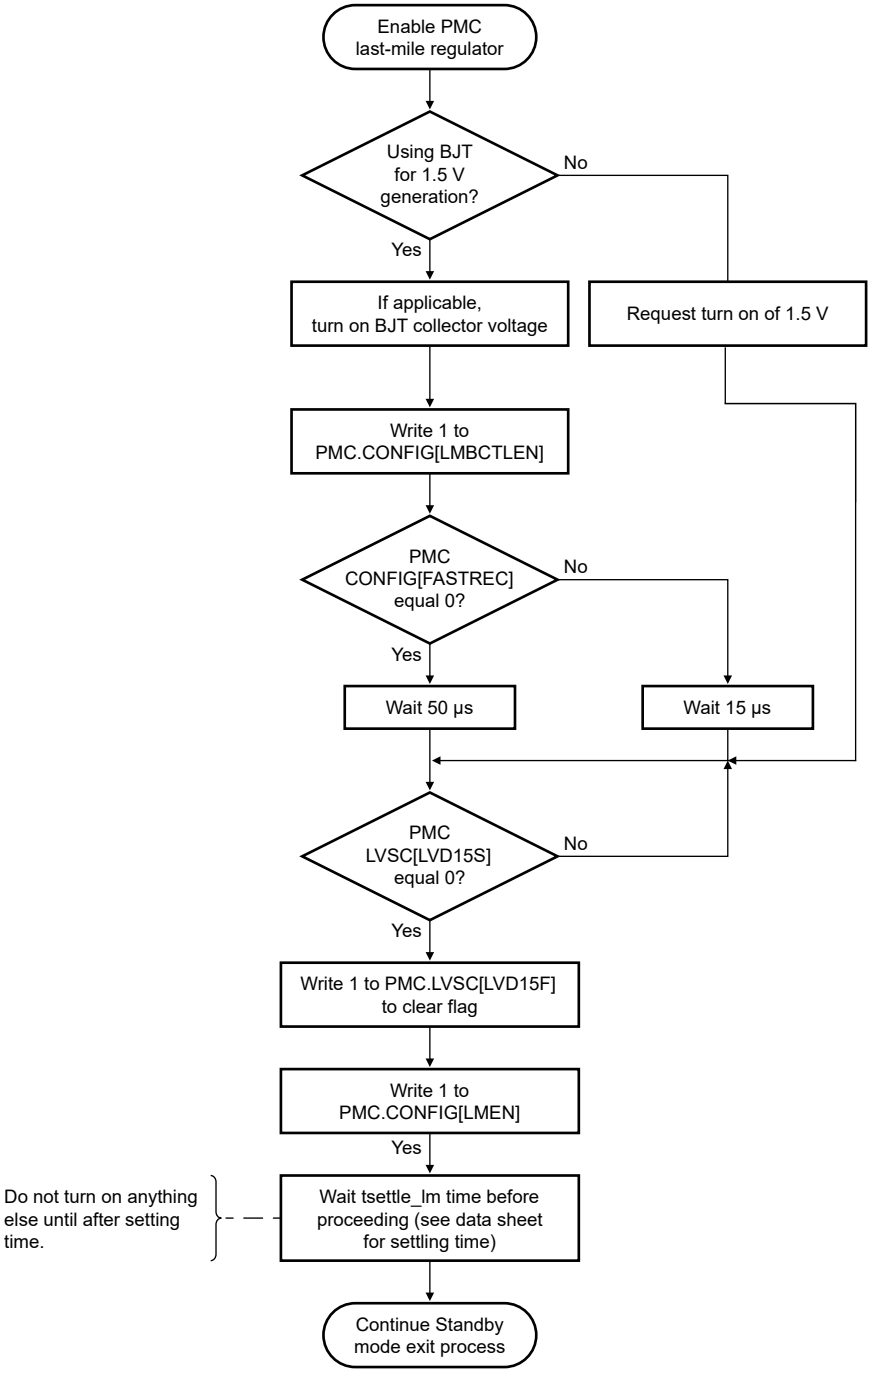

Figure 159. Last-mile regulator enable sequence

40.8 Chip power domain partitioning

These are the modules in the Standby domain. For more information, see "Peripheral reset status" in the "Reset Overview" chapter.

DCM and DCF records	Yes	Yes	Yes	Yes	Yes
DCM Flash Interface	Yes	Yes	Yes	Yes	Yes

SWT0 (Cortex-M7_0) resides in the Standby domain and supports a configurable hardware-based timer operation during Standby mode depending on the configuration of SWTs.

All clock sources (excpet PLLDIG) are available in Standby mode. SIRC is present in the Standby domain for low-power wake-up, but can be enabled.

NOTE

This chip does not support Stop and Wait modes. The only low-power mode it supports is Standby.

40.9 Pad keeping

Pad keeping allows you to return to I/O Run mode configuration settings after using I/O during Standby mode. It eliminates I/O reconfiguration in Run mode.

40.9.1 Pad keeping on Run domain pins

The process of entering Standby mode ensures that the chip maintains the Run domain configuration settings. Software Standby mode entry sequence specifies that you must write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG] before configuring I/O pad keeping. You could consider DCM's DCMRWF1[STANDBY_IO_CONFIG] field as a global enable for all pad keeping purposes during Standby mode. If you are unable to write to this field as described, pad keeping works as explained in this chapter, during Standby mode.

After the chip exits Standby mode, you must write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field (see "Chip specific register descriptions" in the DCM chapter). Writing 1 to this field disables pad keeping and places chip I/O according to its Run mode configuration.

40.9.2 Pad keeping on Standby domain pins

The Standby domain pads can have pad keeping enabled or disabled based on pad availability in Standby mode. Writing to SIUL2's MSCR*n*[PKE] field configures Standby mode pad keeping on a selected I/O.

Ensure that DCM's DCMRWF1[STANDBY_IO_CONFIG] = 0 before Standby mode entry for pad keeping on Standby domain pads. Write 0 to the field in case its value is not 0 already.

If a pad is not required during Standby mode, the corresponding MSCR*n*[PKE] field in SIUL2 must be 0.

40.9.3 Pad keeping configuration procedure

This procedure specifies how to enable an I/O for pad keeping:

1. Configure SIUL2's MSCR*n* register to control the pad state prior to Standby mode entry (for example, writing 0 to SIUL2's MSCR*n*[OBE], MSCR*n*[IBE], and MSCR[PUE] fields tristates the corresponding I/O).
2. Configure SIUL2's MSCR*n*[PKE] field as needed for an I/O pad keeping state during Standby mode.
3. Write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG].

   The application core executes WFI, and Standby mode sequence starts.
4. Write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field on Standby mode exit to disable pad keeping. This configures SIUL2 according to its previous settings.

If you write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field before entering Standby mode, the isolation removal hardware removes pad keeping on Standby mode exit. This (writing 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field before Standby mode entry) is useful in case of low-power debug because enabling pad keeping does not allow low-power debug protocol to work properly (because the TDO pad is padkept). For low-power debug, you must write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field prior to Standby mode entry.

In case of Standby mode exit by reset, the pad keeping of the reset pin is removed when the chip is reset on Standby mode wake up. See the "GPIO padkeeping enable" signal in Figure 161. The signal corresponds to wake-up via reset event case.

40.9.4 Pad keeping waveforms

40.9.4.1 Pad keeping when the chip wakes up from Standby mode via an interrupt event

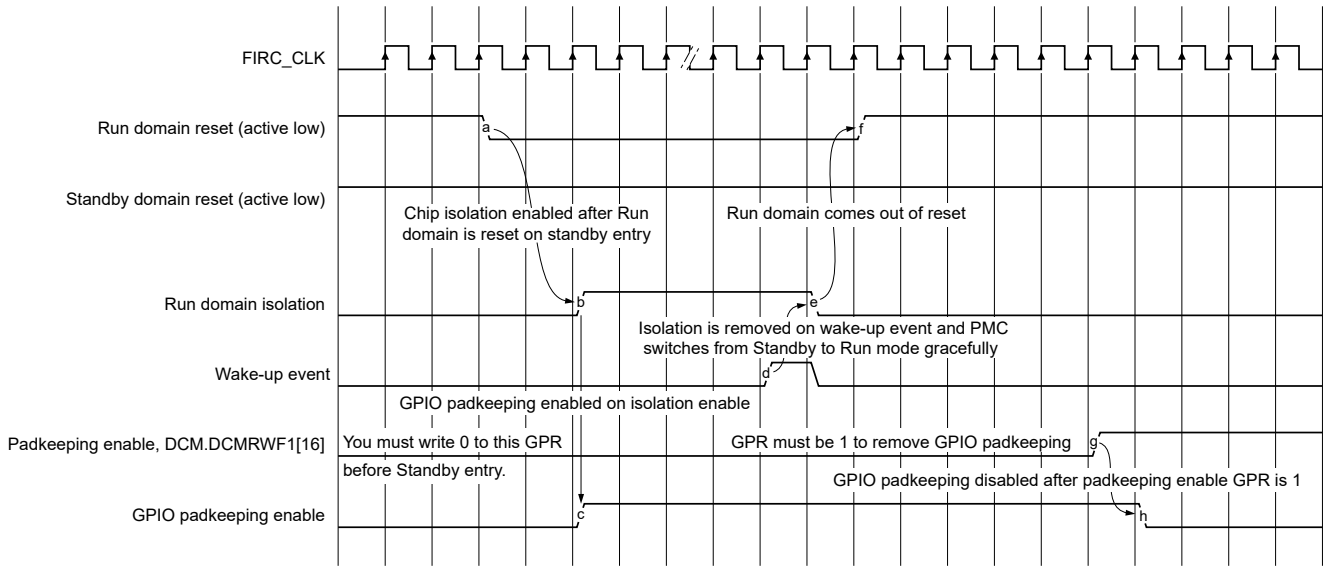

Figure 160. Pad keeping when the chip wakes up from Standby mode via an interrupt event

40.9.4.2 Pad keeping when the chip wakes up from Standby mode via reset

If the chip exits Standby mode via reset, the reset pad keeping is removed when the chip resets after Standby-mode wake-up. See the figure's "GPIO padkeeping enable" waveform corresponding to wake-up via a reset event.

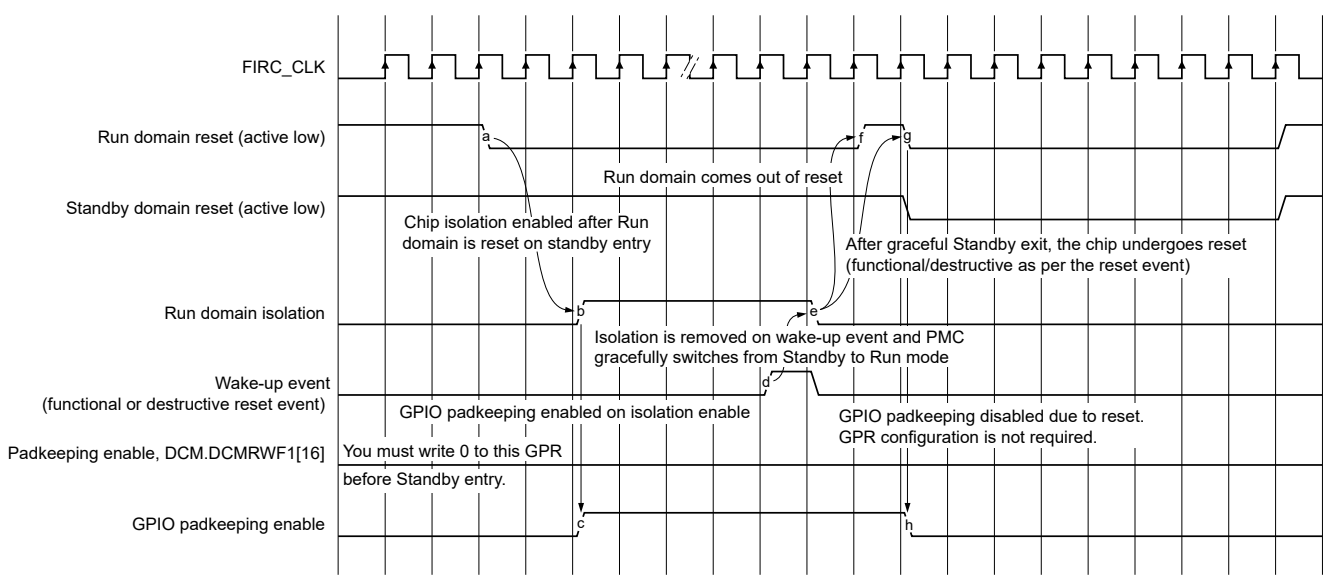

Figure 161. Pad keeping when the chip wakes up from Standby mode via reset

40.9.5 SIUL2's fields for actively-driven pins in Standby mode

If you use a WKPU pin as a wake-up input, perform these operations on SIUL2's fields:

1. Write 1 to MSCR*x*[IBE].
2. Program MSCR*x*[PUE] and MSCR*x*[PUS] according to the use case.
3. Write 0 to MSCR*x*[PKE].

For the GPIO pins that are driven to high impedance during Standby mode:

1. Write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field.
2. Write 0 to SIUL2's MSCR*x*[SSS] field (GPIO mode).
3. Write 0 to SIUL2's MSCR*x*[IBE] and MSCR*x*[OBE] fields.

Some of the pins are, by default, actively driven in Standby mode. If these pins retain a static value throughout the mode, program the corresponding MSCR*x*[PKE] bits individually.

This table shows the list of pins available in Standby mode along with the functions they perform.

Table 219. Active pins in Standby mode

Pin[1]	Function
GPIO_4	CMP0_OUT
GPIO_5	RESET_b
GPIO_9	CMP2_OUT
GPIO_11	CMP0_RRT
GPIO_12	CLKOUT_STANDBY; CMP1_OUT
GPIO_69	CMP2_RRT

GPIO_131	CMP0_OUT
GPIO_138	CLKOUT_STANDBY
GPIO_143	CMP1_RRT
GPIO_158	CMP1_OUT
GPIO_159	CMP1_RRT
GPIO_174	CMP0_OUT
GPIO_175	CMP0_RRT
GPIO_196	CMP2_OUT
GPIO_197	CMP2_RRT

1. See the IOMUX sheet attached to this document for details on pins configuration in different chips.

40.10 Glossary

Application core Core apart from the main core

Boot regulator The on chip 1.1 V regulator that is active during startup and entry and exit from Standby mode

FSM Finite state machine

FPM Full-power mode (Run mode)—uses the last-mile regulator and 1.5 V source to generate the 1.1 V core logic supply during a full-power operation (V11_RUN)

LPM	Low-power mode (Standby mode)—uses the low-power regulator to generate the 1.1 V core logic supply during low-power operation (V11_STANDBY)
LVR	Low voltage reset
Main core	Core initiating the chip Standby mode request (for example, the core corresponding to the "core index" in MC_ME's MAIN_COREID register)
Pad keeping	Maintains I/O pad configuration during Standby mode, if enabled
V11_STANDBY	Core logic and clock sources, low-voltage supply to Standby domain
V11_RUN	Low-voltage supply to Run domain
V15	High-current input for core or logic supply from either an external BJT or from direct 1.5 V external supply
V25	Flash memory, FXOSC, and PLLDIG high-voltage supply
VDDA_ADC	ADC supply voltage
VREFH	ADC high-voltage reference supply
VREFL	ADC low-voltage reference supply
VSS	Core logic ground supply
VDD_HV_A	Main I/O voltage supply (5 V or 3.3 V)
VDD_HV_B	Other I/O domain voltage supply (5 V or 3.3 V)
VRC_CTRL	PMC voltage regulator control output using the BJT option to generate a 1.5 V supply
WFI	Wait for interrupt software instruction

Chapter 41
Power Management Controller (PMC for S32K34x, S32K32x and S32K314)

41.1 Introduction

PMC is the power management controller for the S32K3 family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detect system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

41.2 Features

PMC includes the following features:

- Combination of internal and external voltage regulator options, offering RUN and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software

41.3 Modes of operation

PMC provides two basic modes of operation for the voltage regualtors and monitors:

- FPM, which is used on chip-level in RUN modes: For high-current consumption
- LPM, which is used on chip-level for Standby modes: For low-current consumption

41.4 Block diagram

The following figure shows the block diagram for this module.

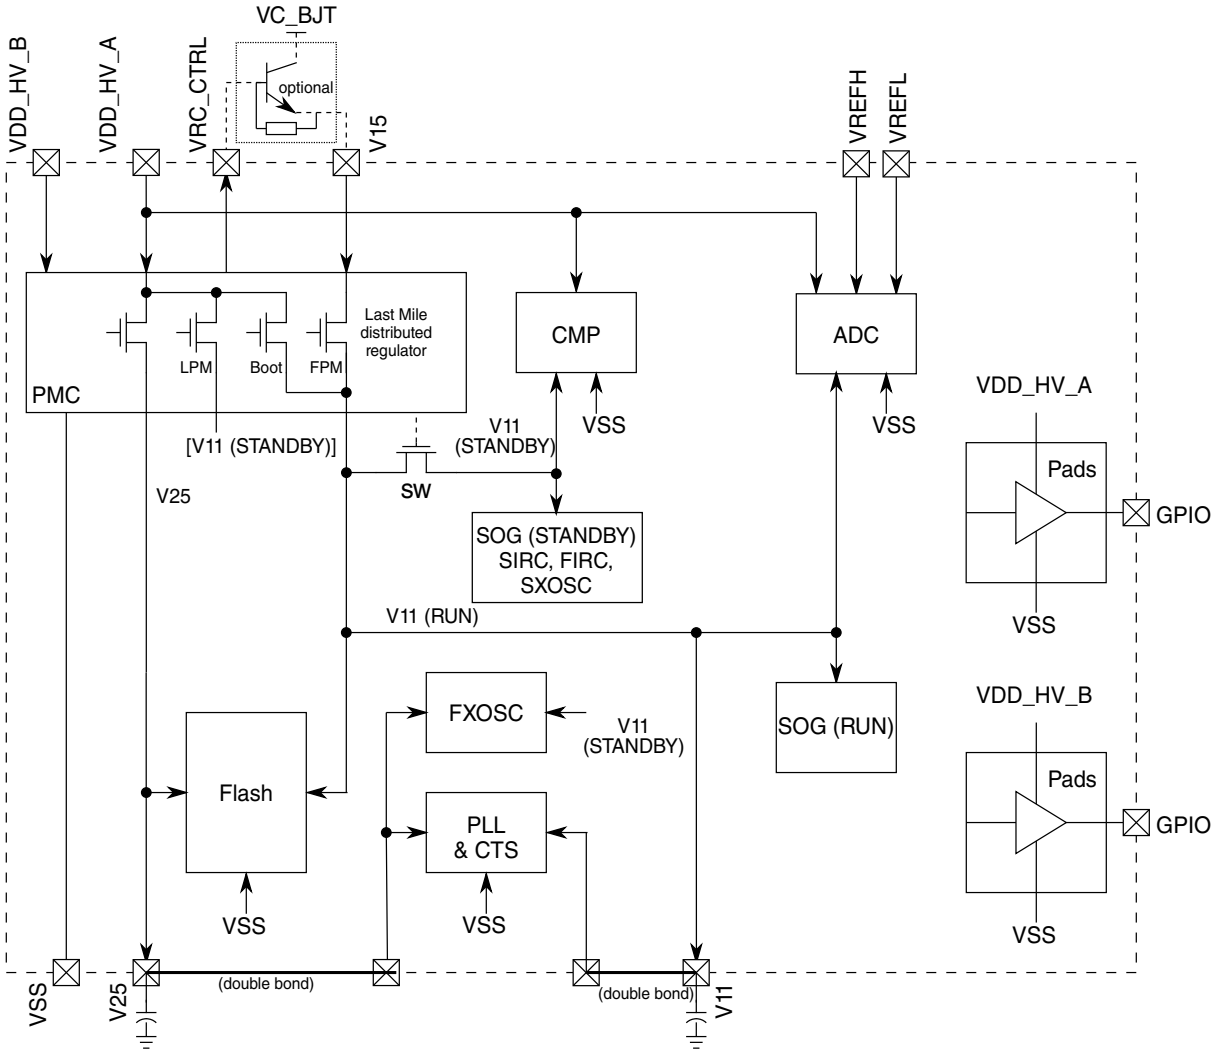

Figure 162. PMC block diagram

41.5 Signals

This table describes the PMC module signals.

Table 220. Signal Description

Signal	I/O	Description
VDD_HV_A	Supply input	This is the primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, it must be kept powered at all times of operation (FPM and LPM).
VDD_HV_B[1]	Supply input	This is the secondary high-voltage supply input supervised by the PMC. After the VDD_HV_B domain is powered up, it must be kept powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 220. Signal Description (continued)

Signal	I/O	Description
V25	Supply output	V25 power supply domain is driven by a fully integrated low-dropout linear voltage regulator. It supplies the Flash memory and (via a double bond) the clock modules.
V15[1]	Supply input	This is the high-current input for core/logic supply that can be fed by an external BJT or another source.
VRC_CTRL	Output	VRC_CTRL connects to the base of external BJT, if this option is used to generate V15.
V11	Supply output	V11 is the core/logic supply. It is driven by a fully integrated low-dropout linear voltage regulator.
VSS	Ground	VSS must be grounded. All VSS Pins need to be externally connected to the same ground node.

1. VDD_HV_B and V15 not present in S32K312 and S32K311.

41.6 Functional description

The following sections describe functional details of the PMC.

41.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, it can be determined which power domain caused it, by reading in the PMC_LVSC register, the POR flag, and LVR flags.

After an initial power ramp up of the MCU in the PMC_LVSC register, the POR flag and the LVR flags are all set to 1. The Go/Nogo flags have an arbitrary value.

NOTE

After an initial power ramp up, all flags in the LVSC register must be cleared (by writing 0xFFFFFFFF to the LVSC register).

Because the flags are sticky bits, it is required to clear them before usage. So, in case of an unxepected MCU POR, the source of the problem can be tracked and debugged by reading the flags in the LVSC register.

41.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: It combines all HVD monitors into one interrupt source. Interrupt enable is the HVDIE field in the CONFIG register. See the PMC Configuration Register (CONFIG) and Low Voltage Status and Control Register (LVSC) registers for details.
- LVD interrupt: It combines the LVD15 and LVD5A monitors into one interrupt source. Interrupt enable is the LVDIE field in the CONFIG register. See the CONFIG and LVSC registers for details.

41.7 PMC register descriptions

41.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers.

PMC base address: 402E_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control Register (LVSC)	32	W1C	See description
4h	PMC Configuration Register (CONFIG)	32	RW	See description
Ch	Version ID register (VERID)	32	RO	0200_0001h

41.7.2 Low Voltage Status and Control Register (LVSC)

Offset

Register	Offset
LVSC	0h

Function

This register contains status and control bits to support the low-voltage reset and low- or high-voltage detect function. When the PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), in case a reset occurs at the same time while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

Fields

Field	Function
31	POR flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
PORF	Indicates that a power-on reset event has occurred. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No power-on reset event has occurred 1b - Power-on reset event has occurred
30-26 —	Reserved
25 GNG11OSCF	Go/NoGo detect flag on Osc part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 1.1V clocking modules (for example, PLL). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
24 GNG25OSCF	GO/NoGo detect flag on Osc part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2.5V clocking modules (for example, XOSC and IRC). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
23 LVR11LPF	LVR11LP flag on V11 domain Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain (FPM or LPM). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
22 LVR11F	LVR11 flag on V11 domain in FPM Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain in the FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
21 LVR25LPF	LVR25LP flag on V25 domain Indicates that a low-voltage reset event has occurred on the V25 power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
20	LVR25 flag on V25 domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVR25F	Indicates that a low-voltage reset event has occurred on the V25 power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
19 LVRBLPF	LVRBLP flag on VDD_HV_B domain Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
18 LVRBF	LVRB flag on VDD_HV_B domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
17 LVRALPF	LVRALP flag on VDD_HV_A domain Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
16 LVRAF	LVRA flag on VDD_HV_A domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
15-14 —	Reserved
13 LVD15S	LVD15 status on V15 domain in FPM Shows the status of the 1.5V low-voltage detect, LVD15, on the V15 power domain. This monitor indicates when the V15 voltage level generated from external is on target. This feature is available only in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD15F flag and check the status bit LVD15S to determine voltage level on V15 supply. 0b - Voltage on V15 is above low-voltage detect threshold or LPM. 1b - Voltage on V15 is below low-voltage detect threshold and FPM.
12	LVD5A status on VDD_HV_A domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD5AS	Shows the status of the 5V low-voltage detect, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5V (see Datasheet for exact value). The feature is only available in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD5AF flag and check the status bit LVD5AS to determine voltage level on VDD_HV_A supply. 0b - Voltage on VDD_HV_A is above low-voltage detect threshold 1b - Voltage on VDD_HV_A is below low-voltage detect threshold
11 HVD11S	HVD11 status on V11 domain in FPM Shows the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V11 is below high-voltage detect threshold or LPM. 1b - Voltage on V11 is above high-voltage detect threshold and FPM.
10 HVD25S	HVD25 status on V25 domain in FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on V25 is below high-voltage detect threshold or LPM. 1b - Voltage on V25 is above high-voltage detect threshold and FPM.
9 HVDBS	HVDB status on VDD_HV_B domain in FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_B is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_B is above high-voltage detect threshold and FPM.
8 HVDAS	HVDA status on VDD_HV_A domain in FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_A is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_A is above high-voltage detect threshold and FPM.
7-6 —	Reserved
5 LVD15F	LVD15 flag on V15 domain in FPM PMC writes 1 to the LVD15F field when the LVD15S status field changes. To clear LVD15F, write 1 to it. If enabled, LVD15F causes an interrupt request. 0b - LVD15S has not changed. 1b - LVD15S has changed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 LVD5AF	LVD5A flag on VDD_HV_A domain in FPM PMC writes 1 to this field when LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - LVD5AS has not changed. 1b - LVD5AS has changed.
3 HVD11F	HVD11 flag on V11 domain in FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - HVD11S has not changed. 1b - HVD11S has changed.
2 HVD25F	HVD25 flag on V25 domain in FPM PMC writes 1 to the HVD25F field when HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - HVD25S has not changed. 1b - HVD25S has changed.
1 HVDBF	HVDB flag on VDD_HV_B domain in FPM PMC writes 1 to the HVDBF field when HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - HVDBS has not changed. 1b - HVDBS has changed.
0 HVDAF	HVDA flag on VDD_HV_A domain in FPM PMC writes 1 to the HVDAF field when HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - HVDAS has not changed. 1b - HVDAS has changed.

41.7.3 PMC Configuration Register (CONFIG)

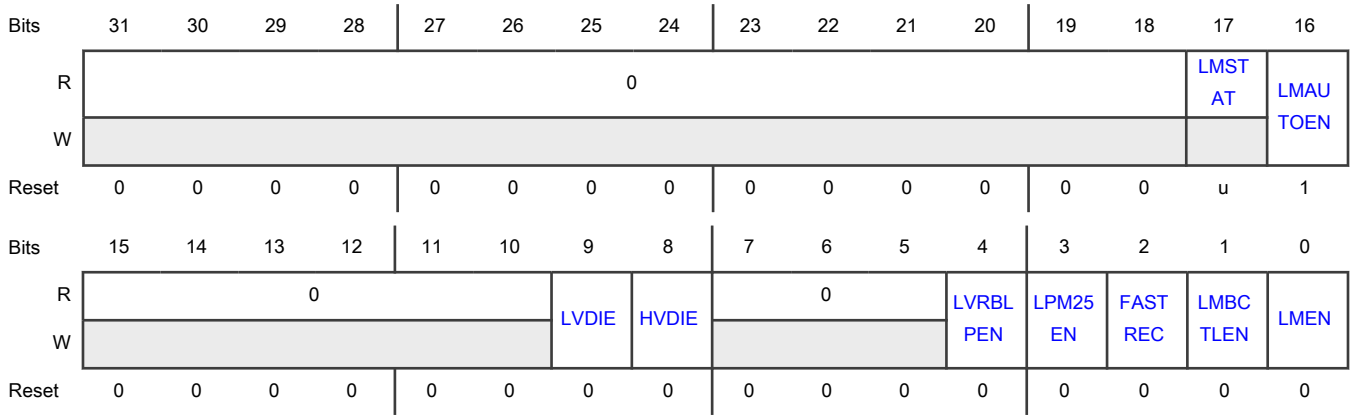
Offset

Register	Offset
CONFIG	4h

Function

If the Last Mile Regulator option is not available on your device (Version ID register (VERID) register: LMFEAT=0), then the bits LMEN, LMBCTLEN, LMAUTOEN and LMSTAT fields can not be written and read always 0.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 LMSTAT	Last Mile regulator status bit This bits reflects the current status of the Last Mile regulator. This information is required as when auto turn over feature is enabled (LMAUTOEN=1) the PMC will switch automatically between Boot regulator and Last Mile regulator debending on the V15 status (LVD15S). 0b - Last Mile Regulator is off 1b - Last Mile Regulator is on
16 LMAUTOEN	Last Mile regulator auto turn over bit Enables to turn over automatically from Boot Regulator Mode to Last Mile regulator mode and vice versa depending on the V15 voltage status (LVD15S). As long as LMEN=0 software must make sure that the system clock is on FIRC clock or slower. To use higher clock speed software must set LMEN=1. 0b - Auto turnover disabled 1b - Auto turnover enabled
15-10 —	Reserved
9 LVDIE	Low voltage detect interrupt enable Enables hardware interrupt requests if any of the following flags is set: LVD5AF, LVD15F. LVD interrupt must be disabled before going into LPM. 0b - LVD hardware interrupt is disabled (use polling). 1b - Request an LVD hardware interrupt when LVDA5F=1 or LVD15F=1.
8 HVDIE	High voltage detect interrupt enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables hardware interrupt requests if any of the following flags is set: HVDAF, HVDBF, HVD25F, HVD11F. 0b - HVD hardware interrupt is disabled (use polling). 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1.
7-5 —	Reserved
4 LVRBLPEN	LVRBLP enable bit during LPM Controls whether the low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain is active or inactive in LPM 0b - Low-voltage reset detection is disabled in LPM. 1b - Low-voltage reset detection is enabled in LPM.
3 LPM25EN	V25 domain enable bit during LPM Controls whether the V25 regulator and low-voltage reset detection (LVR25LP) are active or inactive in LPM 0b - V25 regulator and LVR25LP are disabled in LPM. 1b - V25 regulator and LVR25LP are enabled in LPM.
2 FASTREC	Fast recovery from LPM enable bit Controls the recovery time from LPM to FPM. At recovery from LPM, all the tank capacitors from the secondary supplies have to be recharged. This causes a high-current demand, which might not be met by the supply driving the VDD_HV_A primary domain. When selecting the fast recovery time, the current for recharging is approximately three times higher than that for FASTREC=0. The application must determine from the drive capability of the external VDD_HV_A regulator, the size of tank caps on the secondary supply pins and the selected recovery time if this is sufficient to start up from LPM in time. 0b - Normal recovery time from LPM 1b - Fast recovery time from LPM
1 LMBCTLEN	Last Mile regulator base control enable bit This field must be set to 1 if external BJT between VDD_HV_A and V15 is used on the PCB. The base of this BJT must be connected to the VRC_CTRL pin and is controlled by the PMC to regulate a voltage of 1.5V on V15 pin. After setting LMBCTLEN=1 the software has to wait for 15us (FASTREC=1) respectively 50us (FASTREC=0) before polling LVD15S=0 and then setting LMEN=1. This respects the softstart time of the V15 regulator. If LMAUTOEN=1 then LMBCTLEN can be left enabled when going into LPM, the hardware will turn the regulator off and back on automatically after recovery from LPM. 0b - External BCTL regulator for V15 disabled 1b - External BCTL regulator for V15 enabled
0 LMEN	Last Mile regulator enable bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the Last Mile regulator, which regulates an external 1.5V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1V. Setting LMEN=1 hands over the V11 voltage generation from the Boot regulator to the Last Mile regulator. The software must ensure that before enabling the Last Mile regulator, the voltage on V15 is sufficiently high as indicated by the LVD15S status field (LVD15S=0). To use external BJT between VDD_HV_A and V15, the LMBCTLEN field must be set before the LMEN field, and the software must wait until 1.5V is up (LVD15S=0). If LMAUTOEN=0 then to disable the Last Mile regulator, LMEN and LMBCTLEN must be cleared simultaneously (single register write). The software must disable (LMEN=0) the Last Mile regulator before going into LPM. After setting LMEN=1, software must wait a minimum time of 1.5us before changing clock rate. 0b - Last Mile regulator is disabled. 1b - Last Mile regulator is enabled.

41.7.4 Version ID register (VERID)

IRC	Internal RC oscillator
LM	Last mile regulator
LPM	Low Performance mode
LVD	Low voltage detect
LVR	Low voltage reset
NVM	Nonvolatile memory
POR	Power on reset
XOSC	External crystal oscillator

Chapter 42
Power Management Controller (PMC for S32K312)

42.1 Introduction

PMC provides multiple power options to allow you to optimize power consumption for the appropriate level of functionality. It includes:

- Internal voltage regulators
- POR
- Integrated low and high voltage detection system with reset (brownout) capability

The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

42.2 Features

- A combination of internal and external voltage regulator options, offering Run and Standby modes
- Active POR, providing brownout detect
- LVR for all system-relevant power domains
- Software-readable Low Voltage Status and Control register that contains flags that indicate low- or high-voltage conditions

42.3 Modes of operation

PMC provides two basic modes of operation for voltage regulators and monitors:

- FPM supports chip run modes that have high current consumption.
- LPM supports chip standby modes that have low current consumption.

42.4 Block diagram

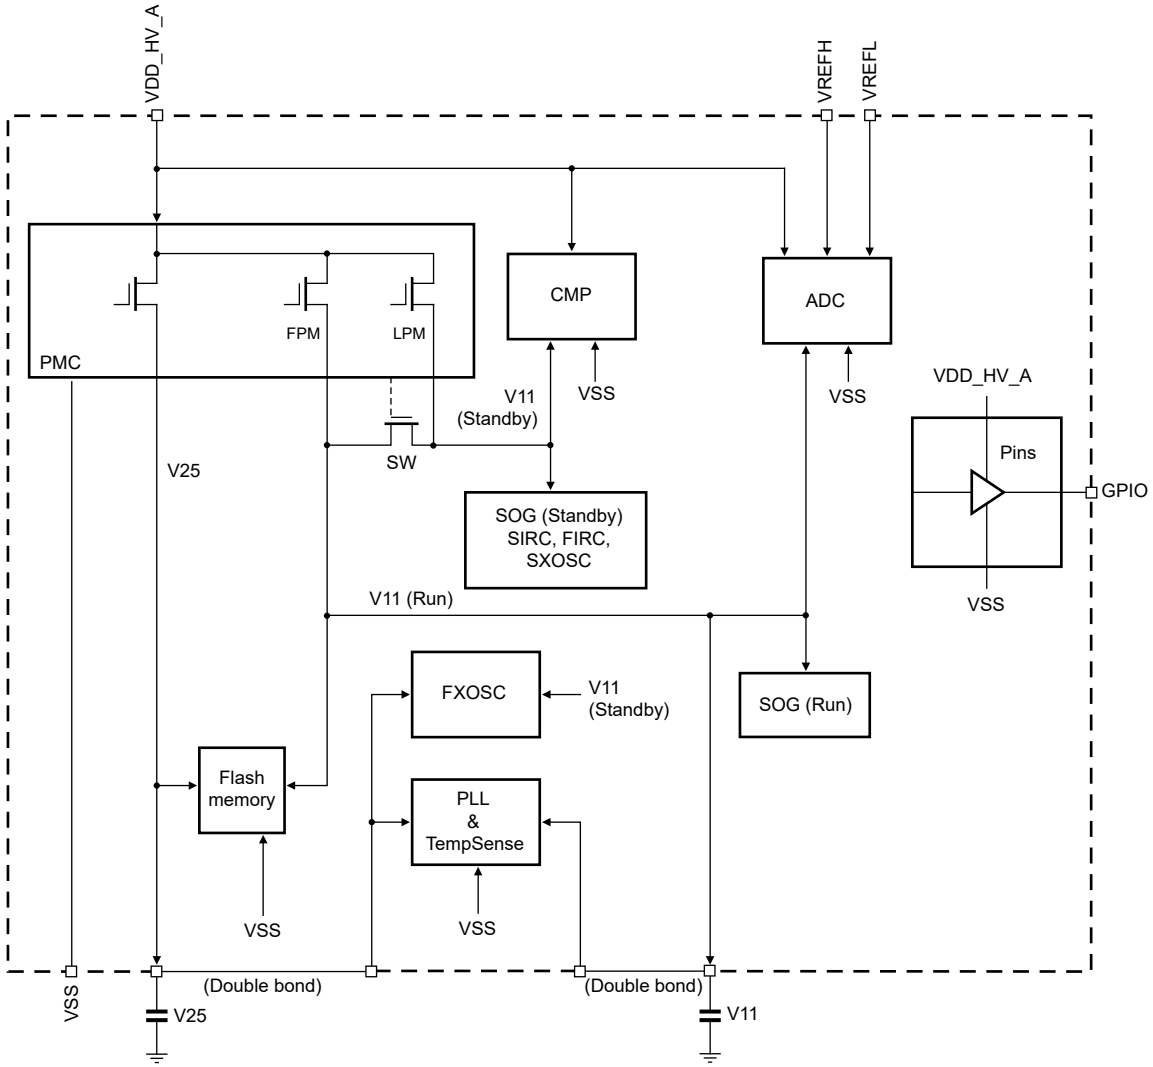

Figure 163. Block diagram

42.5 Signals

Table 221. Signals

Signal	Type	Description
VDD_HV_A	Supply input	The primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A power domain is powered up, it must always be kept powered for both FPM and LPM.
V25	Supply output	A fully integrated low-dropout linear voltage regulator drives the V25 power supply domain. V25 supplies the flash memory and (via a double bond) the clock modules.

Table continues on the next page...

Table 221. Signals (continued)

Signal	Type	Description
V11	Supply output	V11 is the core and logic supply. A fully integrated low-dropout linear voltage regulator drives V11.
VSS	Ground	VSS must be grounded. You must connect all VSS pins externally to the same ground node.

42.6 Functional description

42.6.1 Reset

The POR and all LVRs combine into one single chip POR.

After a chip POR event, you can determine which power domain caused it by reading the PORF and LVR*x* flags in Low Voltage Status And Control (LVSC).

After an initial power ramp-up of the chip in LVSC, PMC sets the POR and LVR*x* flags. The go/no go flags have an arbitrary value.

NOTE

After an initial power ramp-up, you must clear all flags in LVSC by writing FFFF_FFFFh to that register.

Because the flags are sticky bits, you must clear them before using them. That way, if an unexpected chip POR occurs you can track and debug the source of the problem by reading the flags in LVSC.

42.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: Combines all HVD monitors into one interrupt source. CONFIG[HVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.
- LVD interrupt: The LVD5A monitor is the only interrupt source. CONFIG[LVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.

42.7 PMC register descriptions

42.7.1 PMC memory map

PMC base address: 402E_8000h

Ch	Version ID (VERID)	32	RO	0300_0000h

42.7.2 Low Voltage Status And Control (LVSC)

Offset

Register	Offset
LVSC	0h

Function

Contains status and control fields that support the low-voltage reset and low- or high-voltage detect functions. When PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), if a reset occurs while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you must clear the flag again after exiting from reset.

Field	Function
	1b - Clear the flag
30-26 —	Reserved
25 GNG11OSCF	Go/No Go Detect Flag On OSC Part Of V11 Power Domain Indicates that the go/no go sensor has detected a low voltage in the V11 power domain in FPM. This applies only to the part of the power domain that supplies the 1.1 V clocking modules (for example, PLL). Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
24 GNG25OSCF	Go/No Go Detect Flag On OSC Part of V25 Power Domain Indicates that the go/no go sensor has detected a low voltage in the V25 power domain in FPM. This applies only to the part of the power domain that supplies the 2.5 V clocking modules (for example, XOSC and IRC). Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
23 LVR11LPF	LVR11LP Flag On V11 Power Domain Indicates that a low-voltage reset event has occurred in the 1.1 V V11 power domain (FPM or LPM).Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading

22 LVR11F	LVR11 Flag On V11 Power Domain In FPM Indicates that a low-voltage reset event has occurred in the 1.1 V V11 power domain in FPM. Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
21 LVR25LPF	LVR25LP Flag On V25 Power Domain Indicates that a low-voltage reset event has occurred in the V25 power domain (FPM or LPM). Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
20 LVR25F	LVR25 Flag On V25 Power Domain In FPM Indicates that a low-voltage reset event has occurred in the V25 power domain in FPM. Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
19-18 —	Reserved
17 LVRALPF	LVRALP Flag On VDD_HV_A Power Domain Indicates that a low-voltage reset event has occurred in the VDD_HV_A power domain (FPM or LPM). Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
16 LVRAF	LVRA Flag On VDD_HV_A Power Domain In FPM Indicates that a low-voltage reset event has occurred in the VDD_HV_A power domain in FPM. Other reset sources have no effect. **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
15-13 —	Reserved
12	LVD5A Status On VDD_HV_A Power Domain In FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD5AS	Indicates whether the voltage on VDD_HV_A is above or below the low-voltage detect threshold. This monitor reflects the status of the 5 V low-voltage detect, LVD5A, and indicates if the voltage is below a certain threshold, which is set slightly below 4.5 V (see the chip data sheet for the exact value). The feature is only available in FPM and is disabled in LPM. After a reset or wake-up from LPM, you must clear the LVD5AF flag and check LVD5AS to determine the voltage level on the VDD_HV_A supply. 0b - Above 1b - Below
11 HVD11S	HVD11 Status On V11 Power Domain In FPM Indicates whether the voltage on V11 is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and is disabled in LPM. 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
10 HVD25S	HVD25 Status On V25 Power Domain In FPM Indicates whether the voltage on V25 is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and is disabled in LPM. 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
9 —	Reserved
8 HVDAS	HVDA Status On VDD_HV_A Power Domain In FPM Indicates whether the voltage on VDD_HV_A is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVDA, on the V25 power domain. The feature is only available in FPM and is disabled in LPM. 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
7-5 —	Reserved
4 LVD5AF	LVD5A Flag On VDD_HV_A Power Domain In FPM Indicates whether LVD5AS has changed. When LVD5AS changes, PMC changes LVD5AF to 1. **NOTE** This field behaves differently for read and write operations. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
3 HVD11F	HVD11 Flag On V11 Power Domain In FPM Indicates whether HVD11S has changed. When HVD11S changes, PMC changes HVD11F to 1. **NOTE** This field behaves differently for read and write operations. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
2 HVD25F	HVD25 Flag On V25 Power Domain In FPM Indicates whether HVD25S has changed. When HVD25S changes, PMC changes HVD25F to 1. **NOTE** This field behaves differently for read and write operations. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
1 —	Reserved
0 HVDAF	HVDA Flag On VDD_HV_A Power Domain In FPM Indicates whether HVDAS has changed. When HVDAS changes, PMC changes HVDAF to 1. **NOTE** This field behaves differently for read and write operations. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag

42.7.3 PMC Configuration (CONFIG)

Offset

Register	Offset
CONFIG	4h

Function
Configures PMC.

Fields

Field	Function
31-10 —	Reserved
9 LVDIE	Low Voltage Detect Interrupt Enable Enables hardware interrupt requests if LVSC[LVD5AF] = 1. You must disable the LVD interrupt before entering LPM.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - LVD hardware interrupt is disabled (use polling) 1b - Request an LVD hardware interrupt when LVDA5F = 1
8 HVDIE	High Voltage Detect Interrupt Enable Enables hardware interrupt requests if any of the following flags in Low Voltage Status And Control (LVSC) are set: • HVDAF • HVDBF • HVD25F • HVD11F 0b - HVD hardware interrupt is disabled (use polling) 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1
7-4 —	Reserved
3 LPM25EN	V25 Power Domain Enable During LPM Controls whether the V25 regulator and low-voltage reset detection (LVR25LP) are enabled or disabled in LPM 0b - Disabled 1b - Enabled
2 FASTREC	Fast Recovery From LPM Enable Controls the recovery time from LPM to FPM. At recovery from LPM, all the tank capacitors from the secondary supplies must be recharged. This causes a high-current demand, which the supply driving the VDD_HV_A primary power domain might not meet. When you select the fast recovery time, the current for recharging is approximately three times higher than that for normal recovery time. You must determine whether this current is sufficient to start up from LPM in time, using these criteria: • Drive capability of the external VDD_HV_A regulator • Size of the tank caps on the secondary supply pin • Selected recovery time 0b - Normal 1b - Fast
1-0 —	Reserved

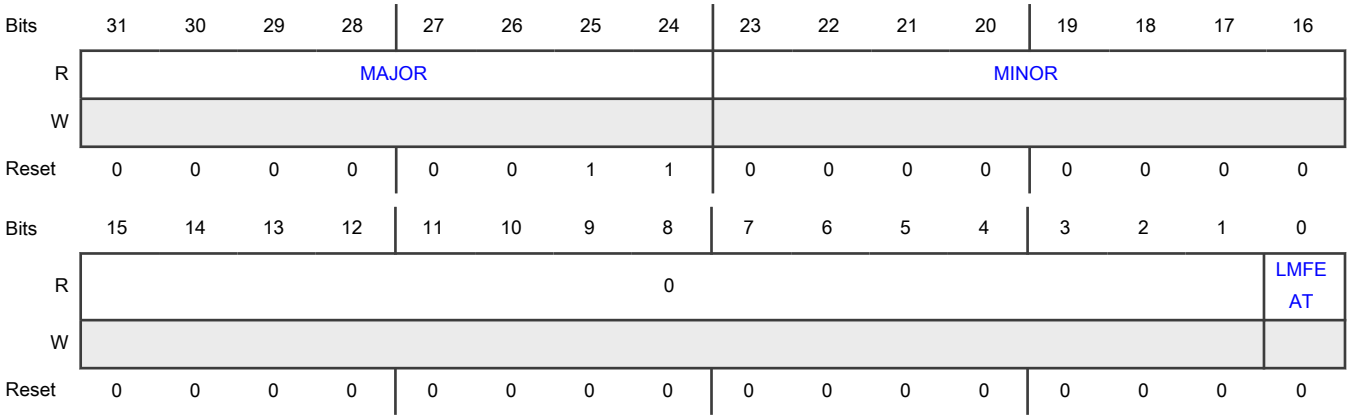
42.7.4 Version ID (VERID)

Offset

Register	Offset
VERID	Ch

Function
Records the specific PMC version in the chip.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number of the PMC design.
23-16 MINOR	Minor Version Number Indicates the minor version number of the PMC design.
15-1 —	Reserved
0 LMFEAT	Last-Mile Regulator Feature Indicates whether the last-mile regulator (1.5 V to 1.1 V) is available. 0b - Not available 1b - Available

42.8 Glossary

FPM	Full Performance mode
HVD	High voltage detect

LPM	Low Power mode
LVD	Low voltage detect
LVR	Low voltage reset
POR	Power-on reset

Chapter 43
Power Management Controller (PMC for S32K358)

43.1 Introduction

PMC is the power management controller for the S32K3 family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detect system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

43.2 Features

PMC includes the following features:

- Combination of internal and external voltage regulator options, offering RUN and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software

43.3 Modes of operation

PMC provides two basic modes of operation for the voltage regualtors and monitors:

- FPM, which is used on chip-level in RUN modes: For high-current consumption
- LPM, which is used on chip-level for Standby modes: For low-current consumption

43.4 Block diagram

The following figure shows the block diagram for this module.

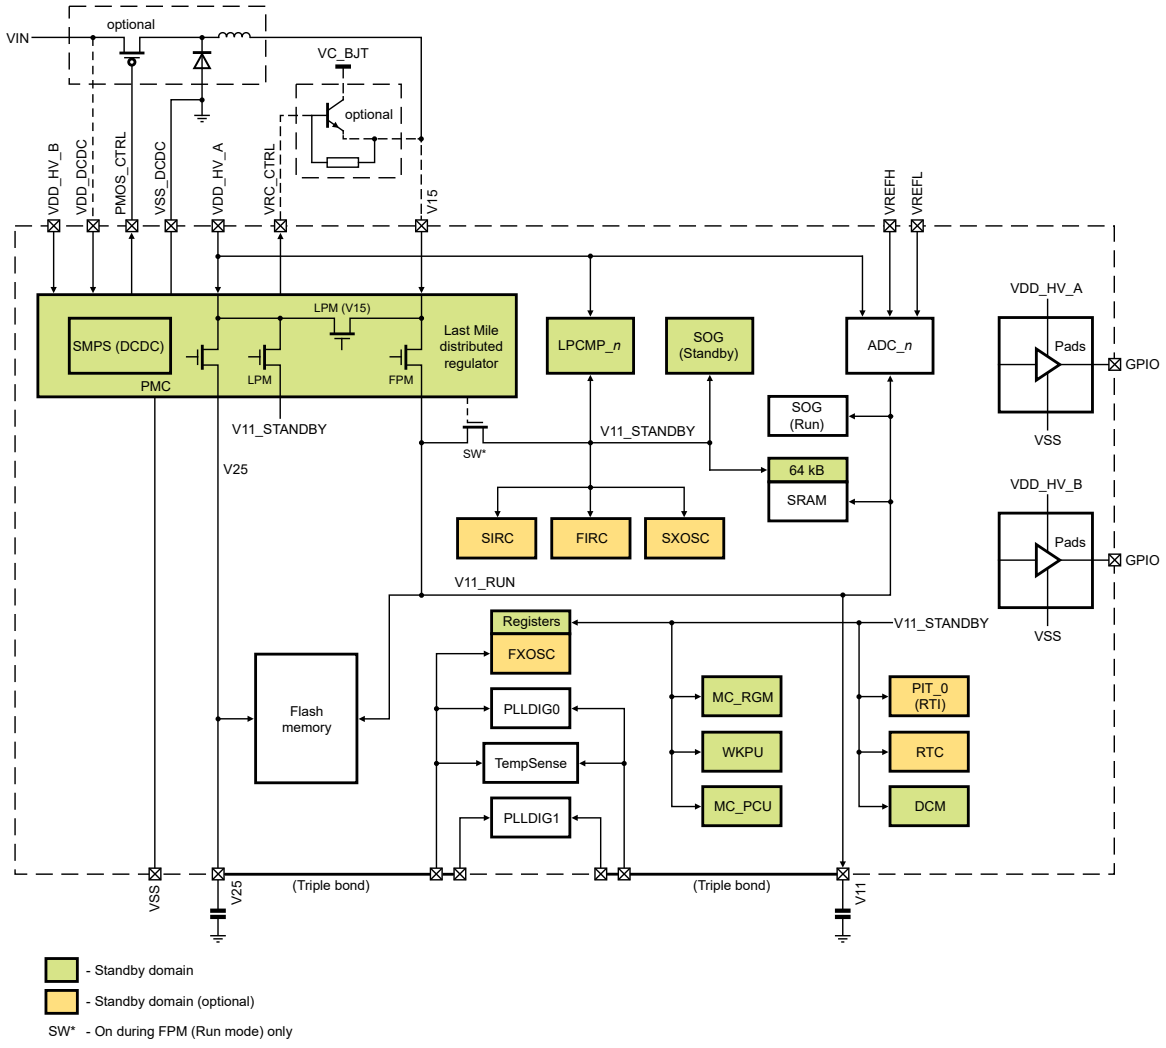


Figure 164. PMC block diagram

43.5 Signals

This table describes the PMC module signals.

Table 222. Signal Description

Signal	I/O	Description
VDD_HV_A	Supply input	This is the primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, it must be kept powered at all times of operation (FPM and LPM).
VDD_HV_B	Supply input	This is the secondary high-voltage supply input supervised by the PMC. After the VDD_HV_B domain is powered up, it must be kept powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 222. Signal Description (continued)

Signal	I/O	Description
V25	Supply output	V25 power supply domain is driven by a fully integrated low-dropout linear voltage regulator. It supplies the Flash memory and (via a double bond) the clock modules.
V15	Supply input	This is the high-current input for core/logic supply that can be fed by an external BJT or the SMPS or an external source.
VRC_CTRL	Output	VRC_CTRL connects to the base of external BJT, if this option is used to generate V15.
V11	Supply output	V11 is the core/logic supply. It is driven by a fully integrated low-dropout linear voltage regulator.
VSS	Ground	VSS must be grounded. All VSS Pins need to be externally connected to the same ground node.
VDD_DCDC	SMPS supply input	This is the power supply domain for the SMPS gate driver and must be shorted with the source voltage of the external power FET. Off-chip decoupling capacitor (10uF or larger) between VDD_DCDC and ground is required.
VSS_DCDC	SMPS ground	This is the power ground for the SMPS gate driver and must be shorted with the main ground node and the ground node of the external Schottky diode.
PMOS_CTRL	PMOS Control, SMPS Gate Drive output	This is the gate driver output for the external power FET. In case Switched-mode power supply feature is not used (software can clear CONFIG register: LMSPMSEN=0) this pin can be used as general purpose output. If used as general purpose output the following must be considered: • As SMPS is enabled by default (LMSMPSEN=1) the pin can behave randomly during startup phase. • If LMSMPSEN=0 then during low power mode the PMOS_CTRL is forced to VDD_DCDC voltage level, regardless of the output data value that the software has programmed.

43.6 Functional description

The following sections describe functional details of the PMC.

43.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, it can be determined which power domain caused it, by reading in the PMC_LVSC register, the POR flag, and LVR flags.

After an initial power ramp up of the MCU in the PMC_LVSC register, the POR flag and the LVR flags are all set to 1. The Go/Nogo flags have an arbitrary value.

NOTE

After an initial power ramp up, all flags in the LVSC register must be cleared (by writing 0xFFFFFFFF to the LVSC register).

Because the flags are sticky bits, it is required to clear them before usage. So, in case of an unxepected MCU POR, the source of the problem can be tracked and debugged by reading the flags in the LVSC register.

43.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: It combines all HVD monitors into one interrupt source. Interrupt enable is the HVDIE field in the CONFIG register.
- LVD interrupt: This is the interrupt for the LVD5A monitor. Interrupt enable is the LVDIE field in the CONFIG register.

See the PMC Configuration Register (CONFIG) and Low Voltage Status and Control Register (LVSC) registers for details.

43.7 PMC register descriptions

43.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers.

PMC base address: 402E_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control Register (LVSC)	32	W1C	See description
4h	PMC Configuration Register (CONFIG)	32	RW	0000_0083h
8h	SMPS Configuration Register (SMPSCONFIG)	32	RW	See description
Ch	Version ID register (VERID)	32	RO	0400_0001h

43.7.2 Low Voltage Status and Control Register (LVSC)

Offset

Register	Offset
LVSC	0h

Function

This register contains status and control bits to support the low-voltage reset and low- or high-voltage detect function. When the PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), in case a reset occurs at the same time while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

NOTE

For the GNG flags, in case a GNG event occurs at the same time as the GNG flag is read, the flag value might not be defined appropriately. In such case, you need to read the flag twice and consider the value only if it both read values match.

Fields

Field	Function
31 PORF	POR flag Indicates that a power-on reset event has occurred. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No power-on reset event has occurred 1b - Power-on reset event has occurred
30-28 —	Reserved
27 GNG11OSC2F	Go/NoGo detect flag on 2nd PLL part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 2nd PLL. Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
26 GNG25OSC2F	GO/NoGo detect flag on 2nd PLL part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2nd PLL. Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 GNG11OSCF	Go/NoGo detect flag on Osc part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 1.1V clocking modules (e.g. PLL, IRC). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
24 GNG25OSCF	GO/NoGo detect flag on Osc part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2.5V clocking modules (e.g. PLL, XOSC and IRC). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
23 LVR11LPF	LVR11LP flag on V11 domain Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain (FPM or LPM). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
22 LVR11F	LVR11 flag on V11 domain in FPM Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain in the FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
21 LVR25LPF	LVR25LP flag on V25 domain Indicates that a low-voltage reset event has occurred on the V25 power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
20 LVR25F	LVR25 flag on V25 domain in FPM Indicates that a low-voltage reset event has occurred on the V25 power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
19 LVRBLPF	LVRBLP flag on VDD_HV_B domain

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
18 LVRBF	LVRB flag on VDD_HV_B domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
17 LVRALPF	LVRALP flag on VDD_HV_A domain Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
16 LVRAF	LVRA flag on VDD_HV_A domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
15 —	Reserved
14 HVD15S	HVD15 status on V15 domain in FPM Shows the status of the high-voltage detect, HVD15, on the V15 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V15 is below high-voltage detect threshold or LPM. 1b - Voltage on V15 is above high-voltage detect threshold and FPM.
13 —	Reserved, ignore value Reserved, ignore value
12 LVD5AS	LVD5A status on VDD_HV_A domain in FPM Shows the status of the 5V low-voltage detect, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5V (see Datasheet for exact value). The feature is only available in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD5AF flag and check the status bit LVD5AS to determine voltage level on VDD_HV_A supply.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Voltage on VDD_HV_A is above low-voltage detect threshold 1b - Voltage on VDD_HV_A is below low-voltage detect threshold
11 HVD11S	HVD11 status on V11 domain in FPM Shows the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V11 is below high-voltage detect threshold or LPM. 1b - Voltage on V11 is above high-voltage detect threshold and FPM.
10 HVD25S	HVD25 status on V25 domain in FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on V25 is below high-voltage detect threshold or LPM. 1b - Voltage on V25 is above high-voltage detect threshold and FPM.
9 HVDBS	HVDB status on VDD_HV_B domain in FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_B is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_B is above high-voltage detect threshold and FPM.
8 HVDAS	HVDA status on VDD_HV_A domain in FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_A is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_A is above high-voltage detect threshold and FPM.
7 —	Reserved
6 HVD15F	HVD15 flag on V15 domain in FPM PMC writes 1 to this field when the HVD15S status field changes. To clear HVD15F, write 1 to it. If enabled, HVD15F causes an interrupt request. 0b - HVD15S has not changed. 1b - HVD15S has changed.
5 —	Reserved
4	LVD5A flag on VDD_HV_A domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD5AF	PMC writes 1 to this field when LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - LVD5AS has not changed. 1b - LVD5AS has changed.
3 HVD11F	HVD11 flag on V11 domain in FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - HVD11S has not changed. 1b - HVD11S has changed.
2 HVD25F	HVD25 flag on V25 domain in FPM PMC writes 1 to the HVD25F field when HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - HVD25S has not changed. 1b - HVD25S has changed.
1 HVDBF	HVDB flag on VDD_HV_B domain in FPM PMC writes 1 to the HVDBF field when HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - HVDBS has not changed. 1b - HVDBS has changed.
0 HVDAF	HVDA flag on VDD_HV_A domain in FPM PMC writes 1 to the HVDAF field when HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - HVDAS has not changed. 1b - HVDAS has changed.

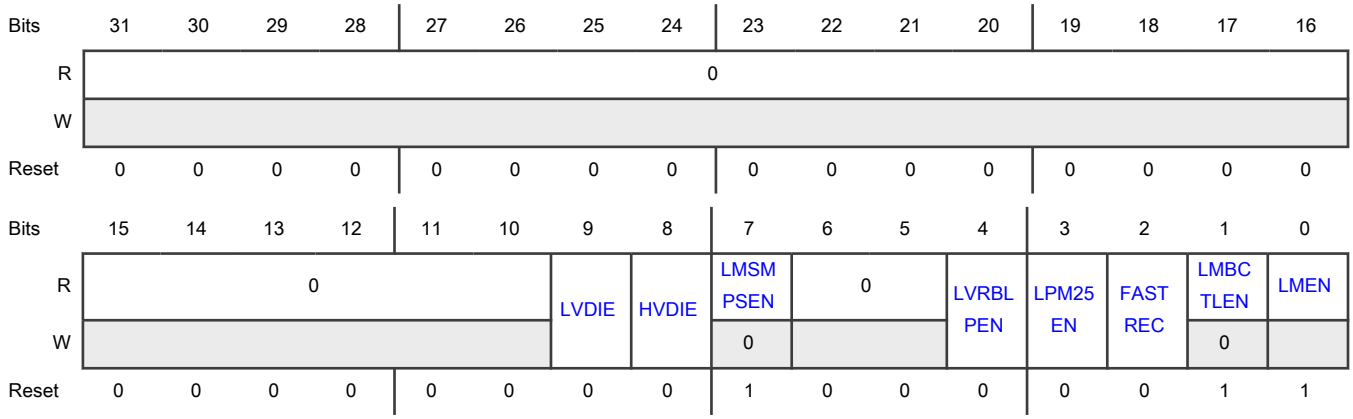
43.7.3 PMC Configuration Register (CONFIG)

Offset

Register	Offset
CONFIG	4h

Function
This register configures the various PMC options.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 LVDIE	Low voltage detect interrupt enable Enables hardware interrupt requests if any of the following flags is set: LVD5AF, LVD15F. LVD interrupt must be disabled before going into LPM. 0b - LVD hardware interrupt is disabled (use polling). 1b - Request an LVD hardware interrupt when LVDA5F=1 or LVD15F=1.
8 HVDIE	High voltage detect interrupt enable Enables hardware interrupt requests if any of the following flags is set: HVDAF, HVDBF, HVD25F, HVD11F. 0b - HVD hardware interrupt is disabled (use polling). 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1.
7 LMSMPSEN	V15 Switched-mode power supply enable bit Enables the SMPS regulator (Switched-mode power supply), which regulates from VDD_DCDC down to 1.5V on V15 pin to supply the Last Mile regulator. As LMSMPSEN=1 after startup or reset, in case SMPS is not used, software must write LMBSMPSEN=0 after each reset to turn the feature off. Once LMSMPSEN=0 it can no longer be written 1 until next reset. 0b - Switched-mode power supply (SMPS) for V15 disabled 1b - Switched-mode power supply (SMPS) for V15 enabled
6-5 —	Reserved
4 LVRBLPEN	LVRBLP enable bit during LPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Controls whether the low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain is active or inactive in LPM 0b - Low-voltage reset detection is disabled in LPM. 1b - Low-voltage reset detection is enabled in LPM.
3 LPM25EN	V25 domain enable bit during LPM Enables a low power V25 regulator and the low-voltage reset detection (LVR25LP) in LPM. In FPM this low power regulator is always off. 0b - V25 regulator and LVR25LP are disabled in LPM. 1b - V25 regulator and LVR25LP are enabled in LPM.
2 FASTREC	Fast recovery from LPM enable bit Controls the recovery time from LPM to FPM. This causes a higher current demand on V15, and this translates to a higher current demand on the primary side of the V15 supply. 0b - Normal recovery time from LPM 1b - Fast recovery time from LPM
1 LMBCTLEN	V15 external BJT enable bit This field must be set to 1 if external BJT between VDD_HV_A and V15 is used on the PCB. The base of this BJT must be connected to the VRC_CTRL pin and is controlled by the PMC to regulate a voltage of 1.5V on V15 pin to supply the Last Mile Regulator. As LMBCTLEN=1 after startup or reset, in case BJT is not used, software must write LMBCTLEN=0 after each reset to turn the feature off. Once LMBCTLEN=0 it can no longer be written 1 until next reset. 0b - External BCTL regulator for V15 disabled 1b - External BCTL regulator for V15 enabled
0 LMEN	Last Mile regulator enable bit Enables the Last Mile regulator, which regulates an external 1.5V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1V. As the Last Mile regulator is always enabled on this device, LMEN bit is read-only and always reads 1.

43.7.4 SMPS Configuration Register (SMPSCONFIG)

Offset

Register	Offset
SMPSCONFIG	8h

Function

This register configures the various options of the Switched-mode power supply (SMPS) generating the V15 (1.5V input supply to the last mile regulator).

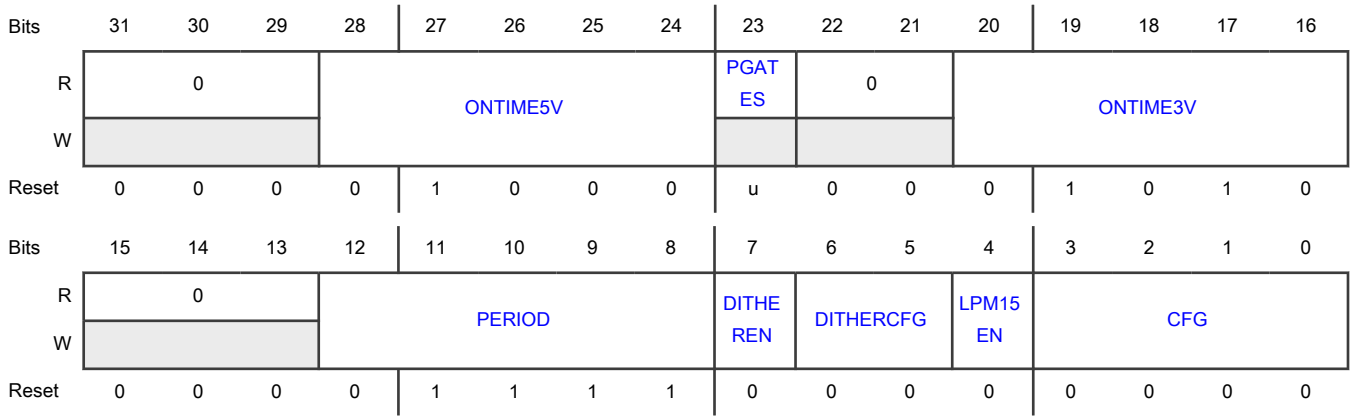
Table 223. SMPS configurations for driving PMOS_CTRL pin

CFG[3:0] bits	PMOS_CTRL Frequency	PMOS_CTRL Duty cycle 3V	PMOS_CTRL Duty cycle 5V
0000	470 kHz	58.8%	47.1%
0001	470 kHz	64.7%	52.9%
0010	470 kHz	52.9%	41.2%
0011	533 kHz	60%	46.7%
0100	533 kHz	66.7%	53.3%
0101	533 kHz	53.3%	40%
0110	421 kHz	57.9%	47.4%
0111	421 kHz	63.2%	52.6%
1000	421 kHz	52.6%	42.1%
1001 to 1110	Reserved	Reserved	Reserved
1111	8 MHz / (PERIOD[4:0]+1)	ONTIME3V[4:0] / (PERIOD[4:0]+1)	ONTIME5V[4:0] / (PERIOD[4:0]+1)

Table 224. 8 MHz IRC Dither configurations

DITHERCFG[1:0] bits	Dither Amplitude	Dither Frequency
00	+/- 0.4 MHz	400 kHz
01	+/- 0.6 MHz	286 kHz
10	+/- 0.8 MHz	222 kHz
11	+/- 1 MHz	182 kHz

Diagram



Fields

Field	Function
31-29	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
28-24 ONTIME5V	SMPS Duty cycle for 5V range These bits determine the duty cycle of the output signal at PMOS_CTRL pin. This duty cycle is applied while VDD_DCDC is greater or equal than 4V. It calculates as follows: Duty_pmos_ctrl = ONTIME3V[4:0] / (PERIOD[4:0] + 1)
23 PGATES	PMOS_CTRL Status Bit This read-only bit reflects the status of the PMOS_CTRL pin. 0b - PMOS_CTRL pin driven to VSS_DCDC (which is connect to GND) 1b - PMOS_CTRL pin driven to VDD_DCDC voltage
22-21 —	Reserved
20-16 ONTIME3V	SMPS Duty cycle for 3V range These bits determine the duty cycle of the output signal at PMOS_CTRL pin. This duty cycle is applied while VDD_DCDC is smaller than 4V. It calculates as follows: Duty_pmos_ctrl = ONTIME3V[4:0] / (PERIOD[4:0] + 1)
15-13 —	Reserved
12-8 PERIOD	SMPS Period These bits determine the period and frequency of the output signal at PMOS_CTRL pin. It calculates as follows: Freq_pmos_ctrl = 8 MHz / (PERIOD[4:0] + 1)
7 DITHEREN	IRC Dither Enable This bit enables dithering of the 8MHz IRC. The amplitude and period of the frequency modulation is determined by the DITHERCFG[1:0] bits. 0b - 8MHz IRC dithering disabled 1b - 8MHz IRC dithering enabled
6-5 DITHERCFG	IRC Dither Configuration Configuration bits to select IRC dithering amplitude and frequency. This feature is to spread the spectrum of driving PMOS_CTRL pin to reduce radiated emission. To change the value: Write DITHEN=0, then write desired dither configuration (DITHERCFG[1:0]), finally write DITHEN=1 again. See Table 224 for configuration options.
4 LPM15EN	V15 domain enable bit during LPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the V15 in LPM. This is useful for fast recovery to FPM when using the SMPS mode to generate the V15. This feature is only active in LPM, in FPM it is turned off. For this purpose there is a small LDO inside the PMC that regulates the V15 to target value during LPM. **NOTE** LPM15EN bit is only allowed to use, when using the SMPS to generate the V15. For other options to generate the V15 it is forbidden and software should always write 0 to LPM15EN. 0b - V15 not kept on target in LPM 1b - V15 kept on target in LPM
3-0 CFG	SMPS configuration select These bits select a configuration for period and duty cycle (ontime) of the Switched-mode power supply driving via PMOS_CTRL the external power FET according to Table 223. **NOTE** As seen in the table CFG[3:0] = 1111 allows for free customization of the PERIOD[4:0], ONTIME5V[4:0] and ONTIME3V[3:0] bits. If choosing this option consider carefully the value of these bits. To ensure the proper function of the SMPS, and to keep the EMI in check, the switching frequency and duty cycle must be programmed within a reasonable range.

43.7.5 Version ID register (VERID)

Offset

Register	Offset
VERID	Ch

Function

This register returns the major and minor version numbers of hardware implementation.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MAJOR								MINOR

Fields

Field	Function
31-24 MAJOR	Major version number Returns the version number for the specification
23-16 MINOR	Minor version number Returns the version number for the hardware implementation
15-1 —	Reserved
0 LMFEAT	Last Mile Regulator Feature This read-only field shows if the Last Mile regulator feature is available. 0b - No Last Mile regulator 1b - Last Mile regulator (1.5V to 1.1V) is available

43.8 Glossary

FPM	Full Performance mode
HVD	High voltage detect
IRC	Internal RC oscillator
LM	Last mile regulator
LPM	Low Performance mode
LVD	Low voltage detect
LVR	Low voltage reset
NVM	Nonvolatile memory
POR	Power on reset
XOSC	External crystal oscillator
SMPS	Switched-mode power supply

Chapter 44
Mode Entry Module (MC_ME)

44.1 Chip-specific MC_ME information

44.1.1 MC_ME modes

This chip implements these modes:

- Reset
- Run
- Standby

The chip always enters Run mode after exiting Reset mode wherein you can configure the chip to perform its computational and communication functions. In Run mode:

- The chip remains fully powered. The boot core is the only core enabled on Run entry.
- You can enable and disable application cores and peripherals as needed, based on functional and power requirements.
- You can configure the pins and self-test as needed. See "Self-Test programming sequence" section in the STCU2 chapter for the self-test programming sequence to be followed before initiating self-test, in which:
  - Pins are safe-stated.
  - No computational or communication activities are possible.
- The chip automatically enters Reset mode after self-test (BIST) is complete.

44.1.2 Core operation modes

The Cortex-M7 cores in the chip support these two modes of operation:

- Decoupled/independent operation
- Coupled/lockstep operation

The device configuration clients (utest_misc DCF client) control these modes of operation. See the DCF clients file attached to this document for details.

44.1.3 MC_ME partition mapping of cores and peripherals

MC_ME provides registers and interface signals to support multiple partitions. These MC_ME partitions are different from the chip's LBIST partitions described in the "Safety Overview" chapter. This chip has three MC_ME partitions:

- Partition 0: Contains application cores and the on/off-platform slots on AIPS_0 bridge
- Partition 1: Contains the on/off-platform slots on AIPS_1 bridge
- Partition 2: Contains the on/off-platform slots on AIPS_2 bridge

Table 225 and Table 226 specify the core and peripheral mapping on MC_ME partitions and their associated clock gating possiblities.

MC_ME also provides provisions to control the booting address for application cores, which can be configured to start from a nondefault address location by appropriately configuring PRTN*x*_CORE*n*_ADDR[ADDR].

44.1.4 Core clock gating

MC_ME has individual core-clock enable fields that gate the application core clocks, which can also be clock gated by executing Waiting for Interrupt (WFI).

You can enable the application cores by configuring the respective CCE fields. See Application core initialization process and Application core shutdown process for proper initialization and shutdown of application cores. There is no clock control for the HSE_B core. It needs to be only put into WFI if required to be shutdown (for example, in Standby mode).

Table 225. MC_ME partition core mapping

Core	MC_ME partition	MC_ME clock enable register field
Cortex-M7_0	0	MC_ME.PRTN0_CORE0_PCONF[CCE]
Cortex-M7_1 (not present on S32K312 and S32K311)	0	MC_ME.PRTN0_CORE1_PCONF[CCE]
Cortex-M7_2 (Present on S32K358 only)	0	MC_ME.PRTN0_CORE2_PCONF[CCE]

44.1.5 Peripheral clock gating

See Peripheral initialization process and Peripheral shutdown process for proper initialization and shutdown of peripherals. See Table 226 for peripheral clock gating possibilities.

The application core can program the reserved configurations.

NOTE

Before accessing the registers of a peripheral to start using it, its clock must be turned on, otherwise, a Hard-Fault event will occur.

Table 226. MC_ME partition peripheral mapping and clock control

1. See the memory-map sheet attached to this document for details on available peripherals in different chips.
2. While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled. i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

44.1.6 Application core initialization process

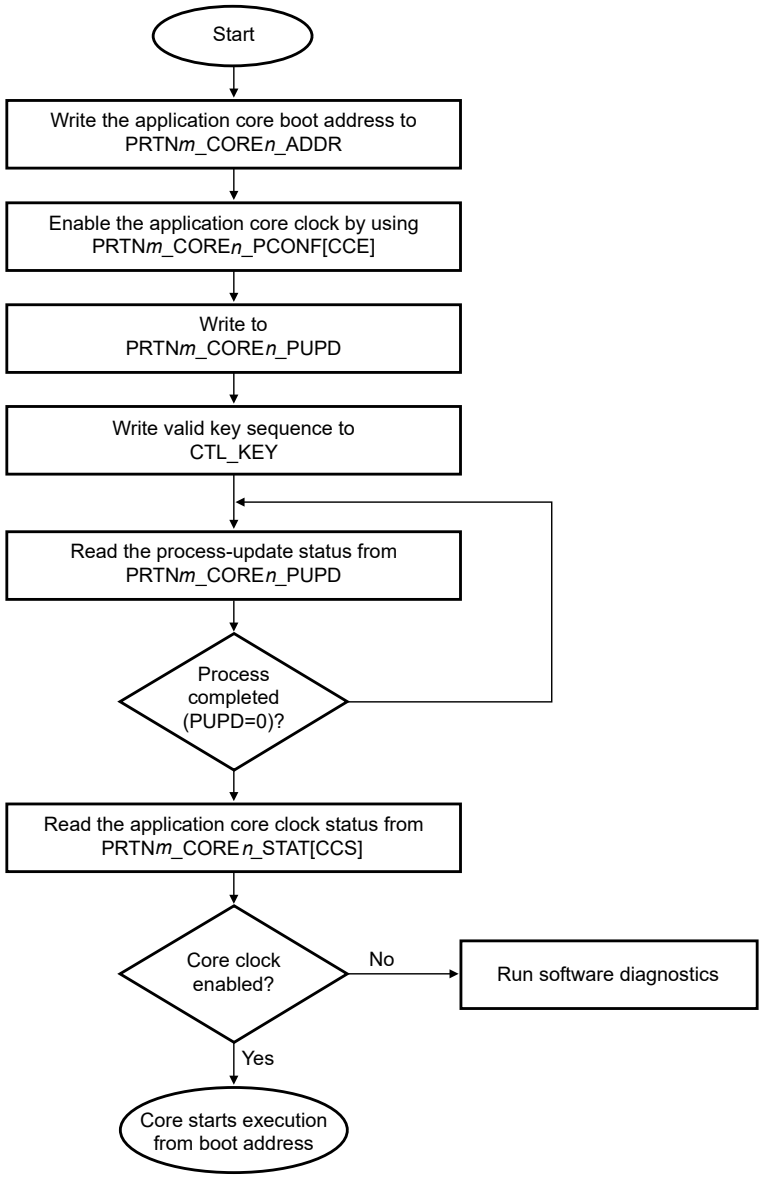

Figure 165. Application core initialization process

44.1.7 Application core shutdown process

If a debugger is attached to the chip and application debug is enabled, the application core continues running if you write 0 to MDM_AP.MDMAPCT[CM7_*n*_CORE_ACCESS].

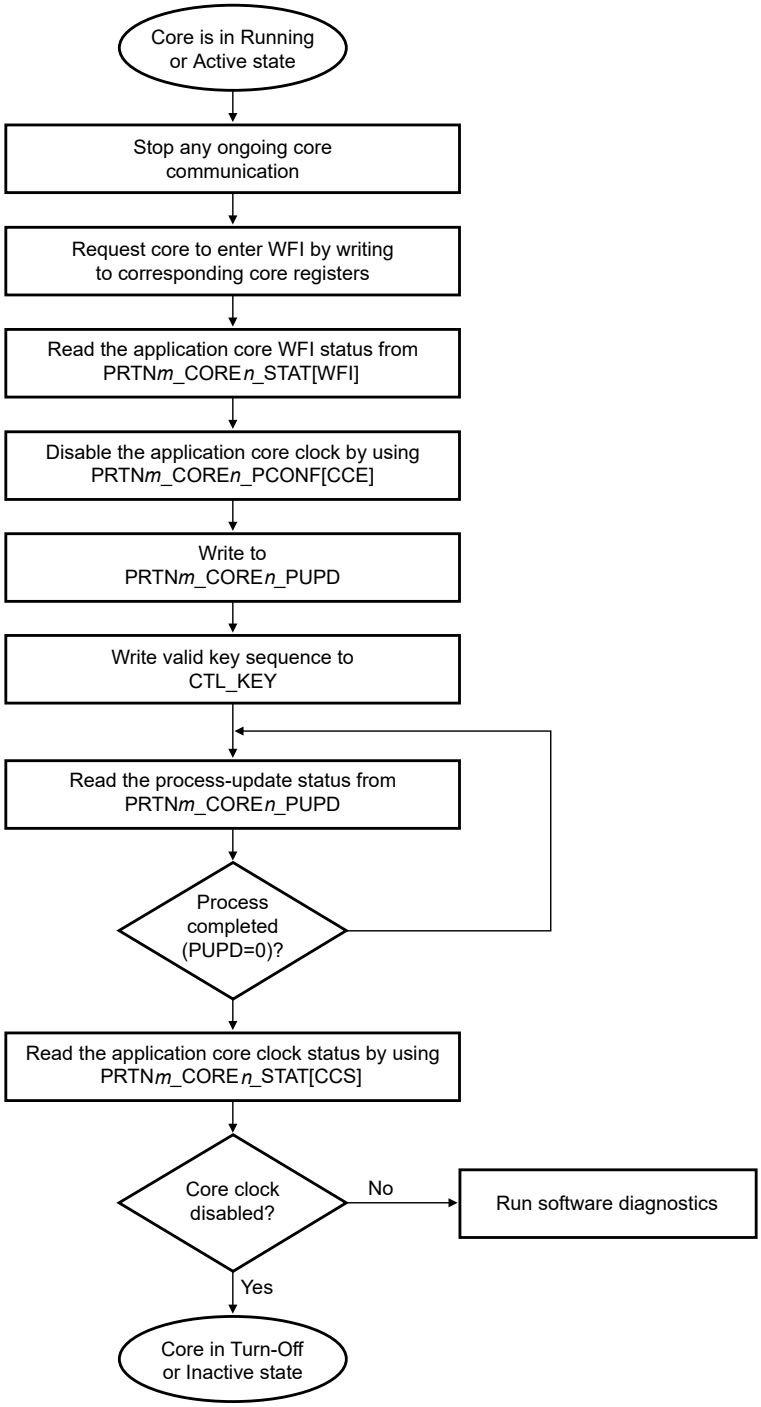

Figure 166. Application core shutdown process

44.1.8 Peripheral initialization process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

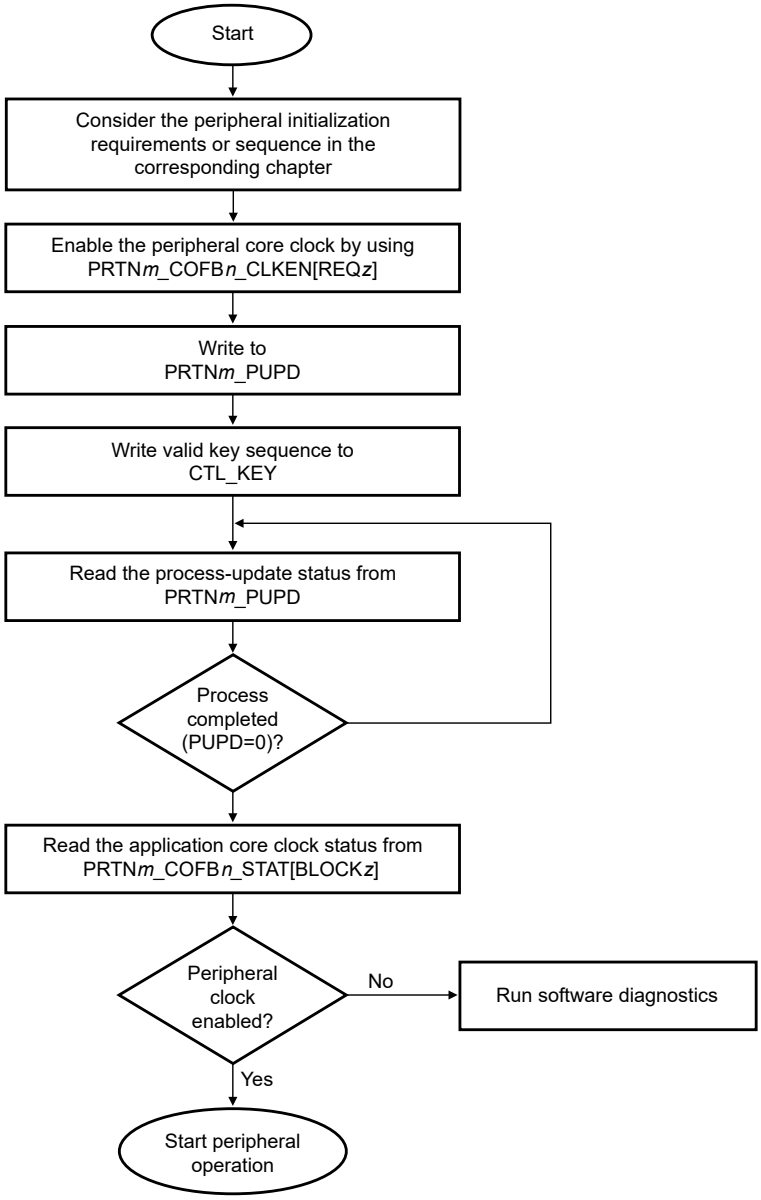

Figure 167. Peripheral initialization process

44.1.9 Peripheral shutdown process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

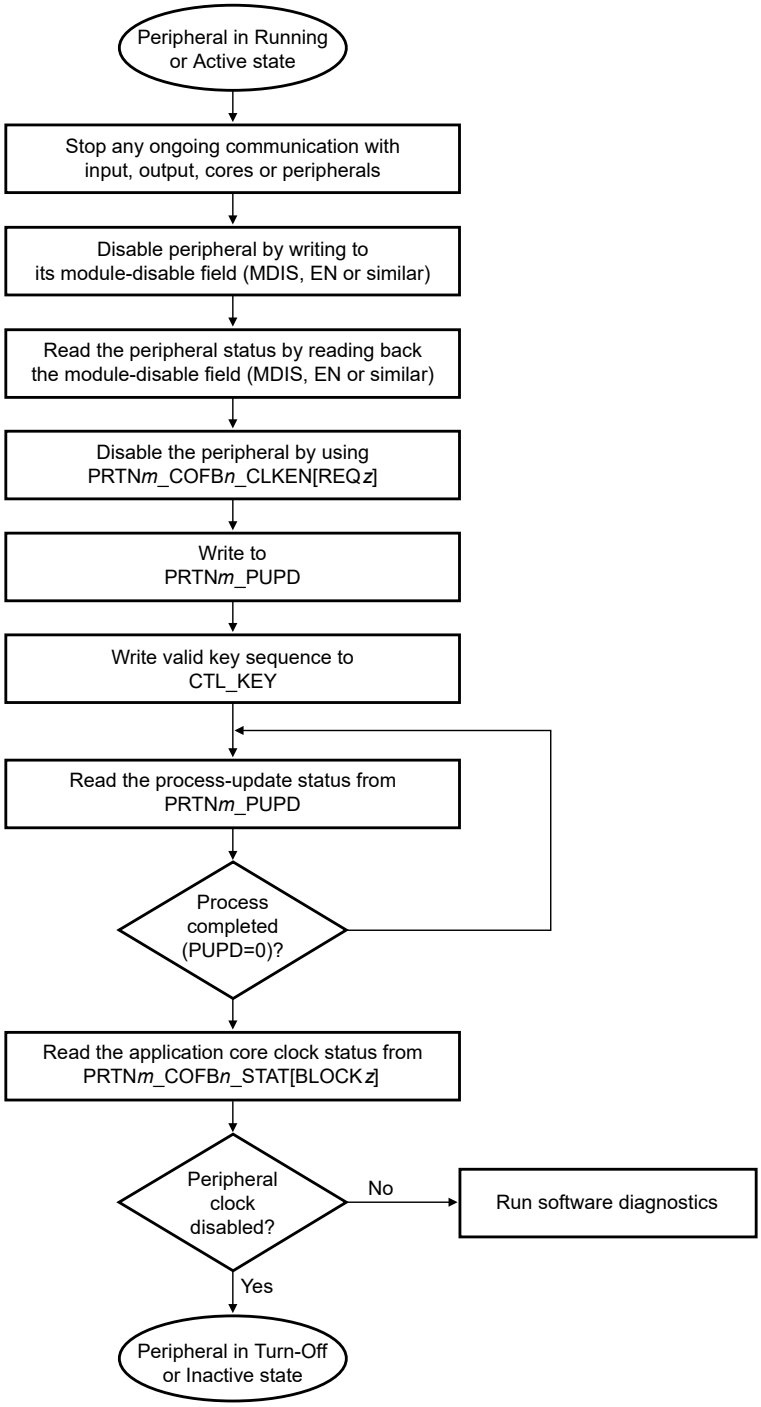

Figure 168. Peripheral shutdown process

44.2 Introduction

The MC_ME module generates control signals for a set of modules of the SoC. The set of signals are defined in corresponding 'Partition Configuration Registers'. It also implements a software-based mechanism for initiating a functional and destructive reset sequence and standby entry handshake with power management of SoC. See Figure 169 for the MC_ME block diagram.

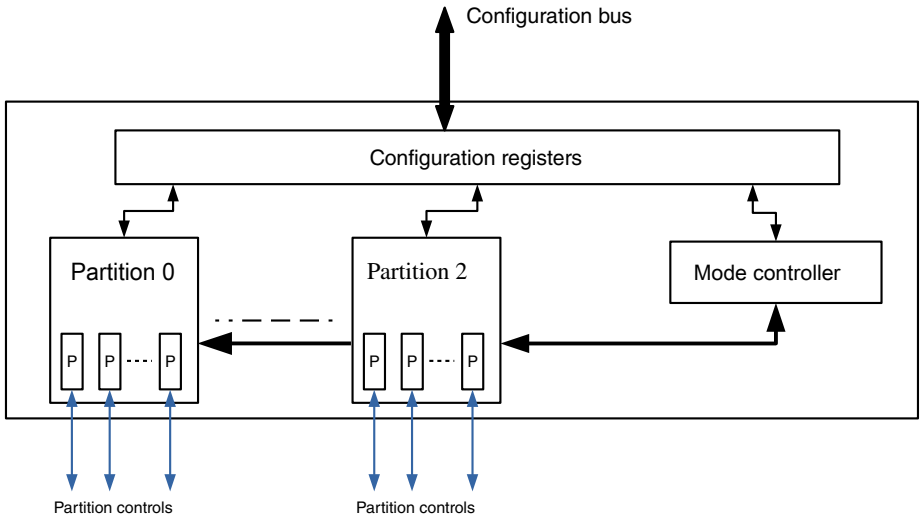

Figure 169. MC_ME block diagram

44.3 Features

MC_ME includes the following features:

- 3 logic partitions implementation and their controls
- Core clock controls
- Partition clock control
- Control mechanism for initiating a destructive or functional reset sequence to MC_RGM
- Control mechanism for initiating standby mode entry for SoC

The logic partition inside MC_ME refers to a certain group of on-chip resources (or IP blocks) that are clubbed together to represent a single 'Partition' inside MC_ME. The MC_ME partition can be the same or different than an LBIST partition. Each of the MC_ME partitions implements a certain number of hardware processes. These hardware processes provide a mechanism to regulate various control signals provided to or received from the IP blocks. The corresponding status signals can also be monitored from MC_ME register(s). Each of the hardware processes is bound to finish in 512 cycles of the MC_ME register configuration clocks. Therefore, the hardware processes are non blocking in nature. Mismatch in the expected versus actual status of any hardware process is controlled by a pre-defined software.

44.4 Partition processes

Each of the processes inside the partition controls register space and corresponds to a control signal provided to that partition. A partition can include a core, or COFBs, or both. The MC_ME hardware processes provide control and status via signals provided to partitions. Each partition can be assigned a signal for control and a signal for status. Each of the control signals implements functionality for the partition. For example, clock gating and peripheral control.

The hardware process can be triggered and monitored using a set of three registers:

- Configuration register; for example, Partition n Process Configuration register
- Update register; for example, Partition n Process Update register
- Status register; for example, Partition n Status register

Similar registers exist for cores inside the partition.

The process setup and triggering procedure is shown in Figure 170. Each of the processes is independent of others and can be triggered or retriggered in parallel or sequential to other processes. The triggering or retriggering mechanism remains the same.

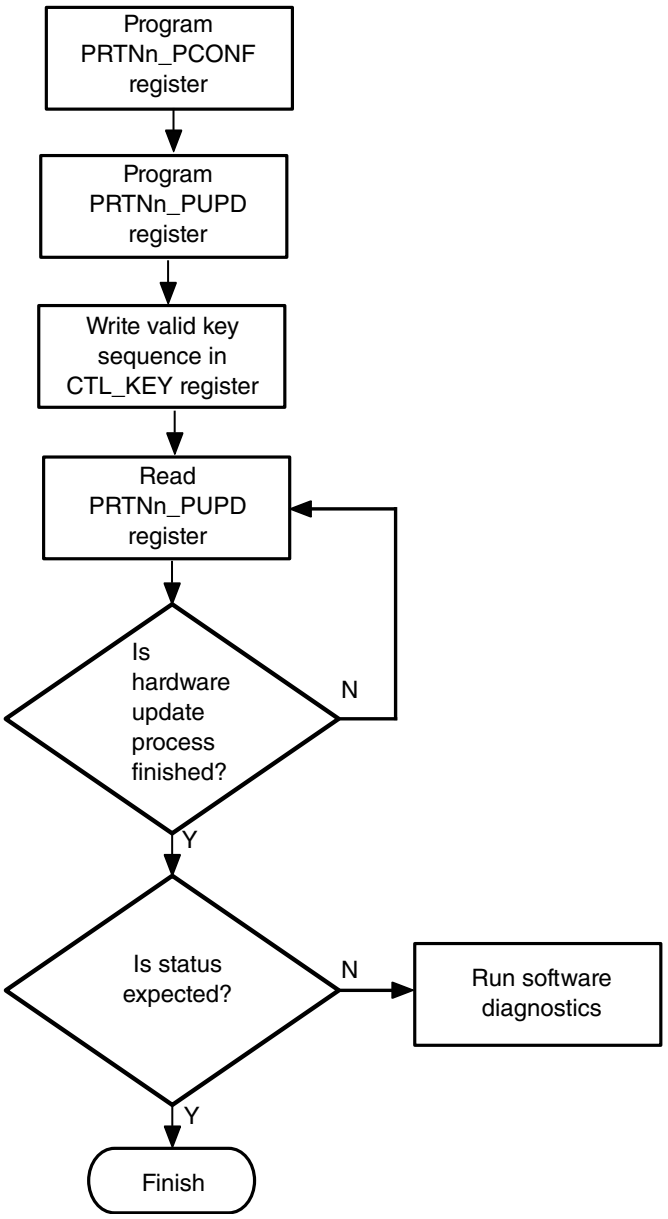

Figure 170. Partition process setup procedure

All the hardware processes are bound to finish in 512 cycles of the MC_ME configuration clock. If the actual and the expected status for a process does not match, then the diagnostics is left as a software responsibility. The software diagnostic can include further wait cycles for the status to match.

44.5 Mode transition

MC_ME implements a mode transition mechanism, whereby the mode of operation for SoC can be changed. Then module implements a mechanism that can lead to:

- Destructive reset
- Functional reset
- Standby mode entry

Destructive reset and functional reset requests from MC_ME are non-retractable transitions. After it is initiated, the other MC_ME functionality is rendered unusable and bus errors are provided for upcoming access to the MC_ME register until a reset sequence is executed by MC_RGM. Hence, it is vital that MC_RGM should never ignore or gate the reset requests from MC_ME.

For transition into the standby mode, the software should ensure that required IP blocks such as clock sources and I/O communication are in their respective inactive states before initiating a standby mode transition to MC_ME. After MC_ME initiates a power down sequence request, it cannot be retracted. The SoC enters a standby power down sequence and then reenter power-up sequence even for cases where the standby wakeup happens right at the time of initiating a power-down sequence request.

Steps for initiating the MC_ME mode transition:

1. Setup the MODE_CONF register with the corresponding target mode bit set to logic-1.
2. Perform the same update as done in the MODE_CONF register on the CONF_UPD register.
3. Write the valid control key (0x5AF0) on the CTL_KEY register.
4. Write the valid invert control key (0xA50F) on the CTL_KEY register.

Mode transition to MC_ME is initiated, after the sequence mentioned above is completed.

In step 1, if both FUNC_RST and DEST_RST in Mode Configuration Register (MODE_CONF) are 1:

- After step 4 is complete, MC_ME initiates a mode transition to a destructive (not functional) reset.
- After the chip exits reset, MC_RGM records that both MC_ME's destructive reset and MC_ME's functional reset were the reset source.

NOTE

Any hardware partition processes setup, along with mode transition, is executed in parallel to the mode transition of MC_ME.

44.6 Standby entry

MC_ME provides hardware processes that implement shutdown sequencing of on-chip resources, such as cores and COFBs. The standby entry sequencing can be achieved or implemented using these hardware processes. The order of the hardware process is determined by the software and MC_ME. It requires no restriction in sequencing of the operation. Following is an example sequence for initiating a power-down sequence for entering the standby mode for SoC. The standby entry sequence should include (but not limited to) the following steps:

1. Setting up wakeup lines
2. Shutting down cores and COFBs
3. Switching all MC_CGM muxes to FIRC with PCFS
4. Powering down all clock sources except FIRC
5. Setting up MC_ME using the main core and initiating a standby mode transition
6. Executing WFI instruction on the main core (per Arm specification)

44.6.1 Application core shutdown

This section describes a mechanism for shutting down an application core. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence, can be further integrated with an SoC-specific task.

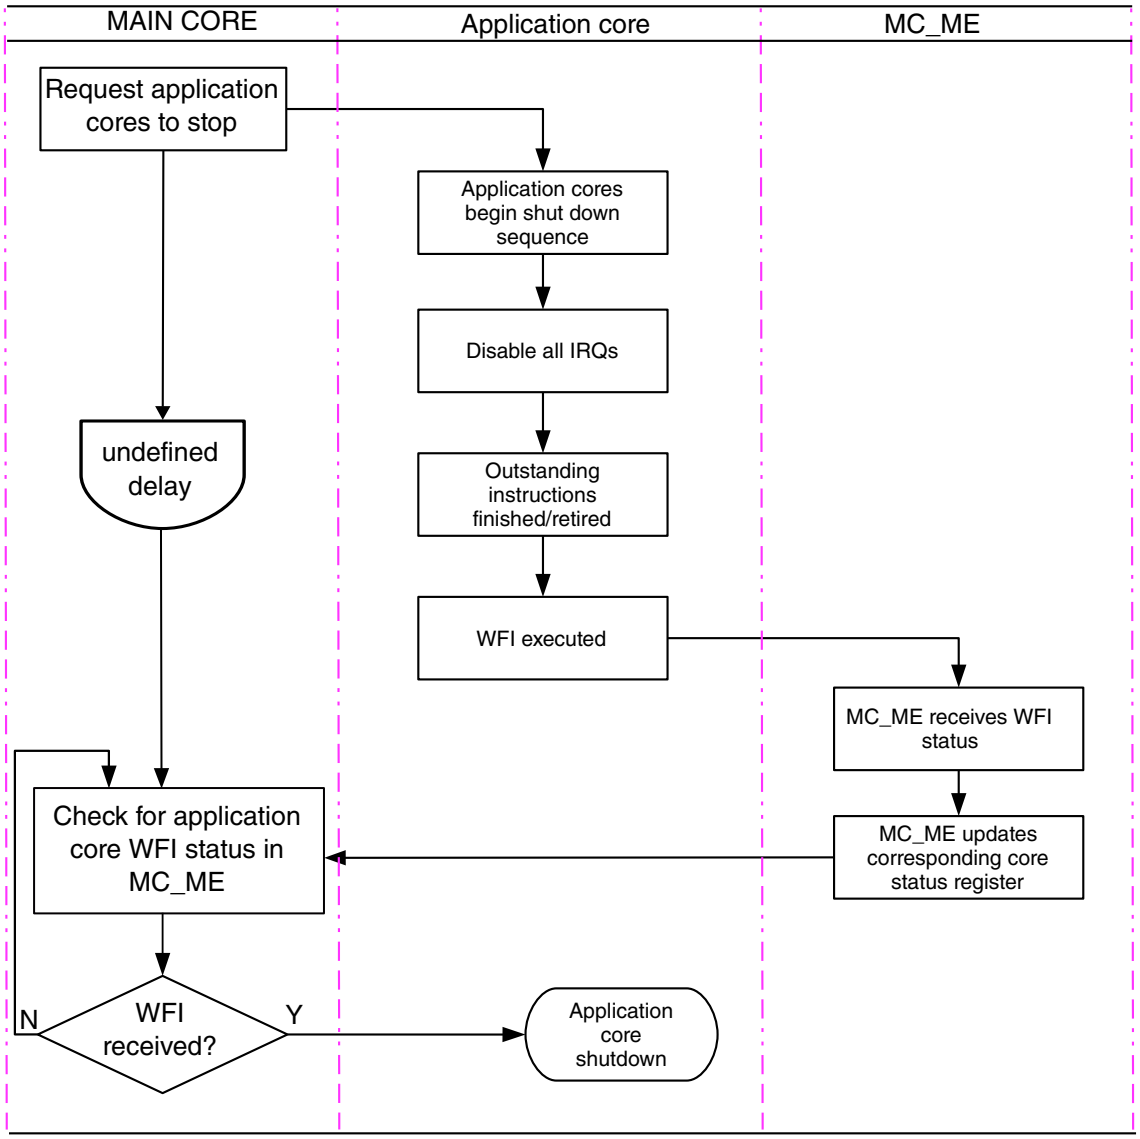

Figure 171. Application core shutdown

After the application core is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

44.6.2 Main core shutdown and standby entry

This section describes standby entry sequence along with the main core shutdown. This sequence should only be initiated after SoC is ready for entering standby and has completed all the housekeeping activities. It is necessary that the main core has completed all the operations pertaining to other (application cores) and is the last active core before initiating the standby entry sequence. See Figure 172.

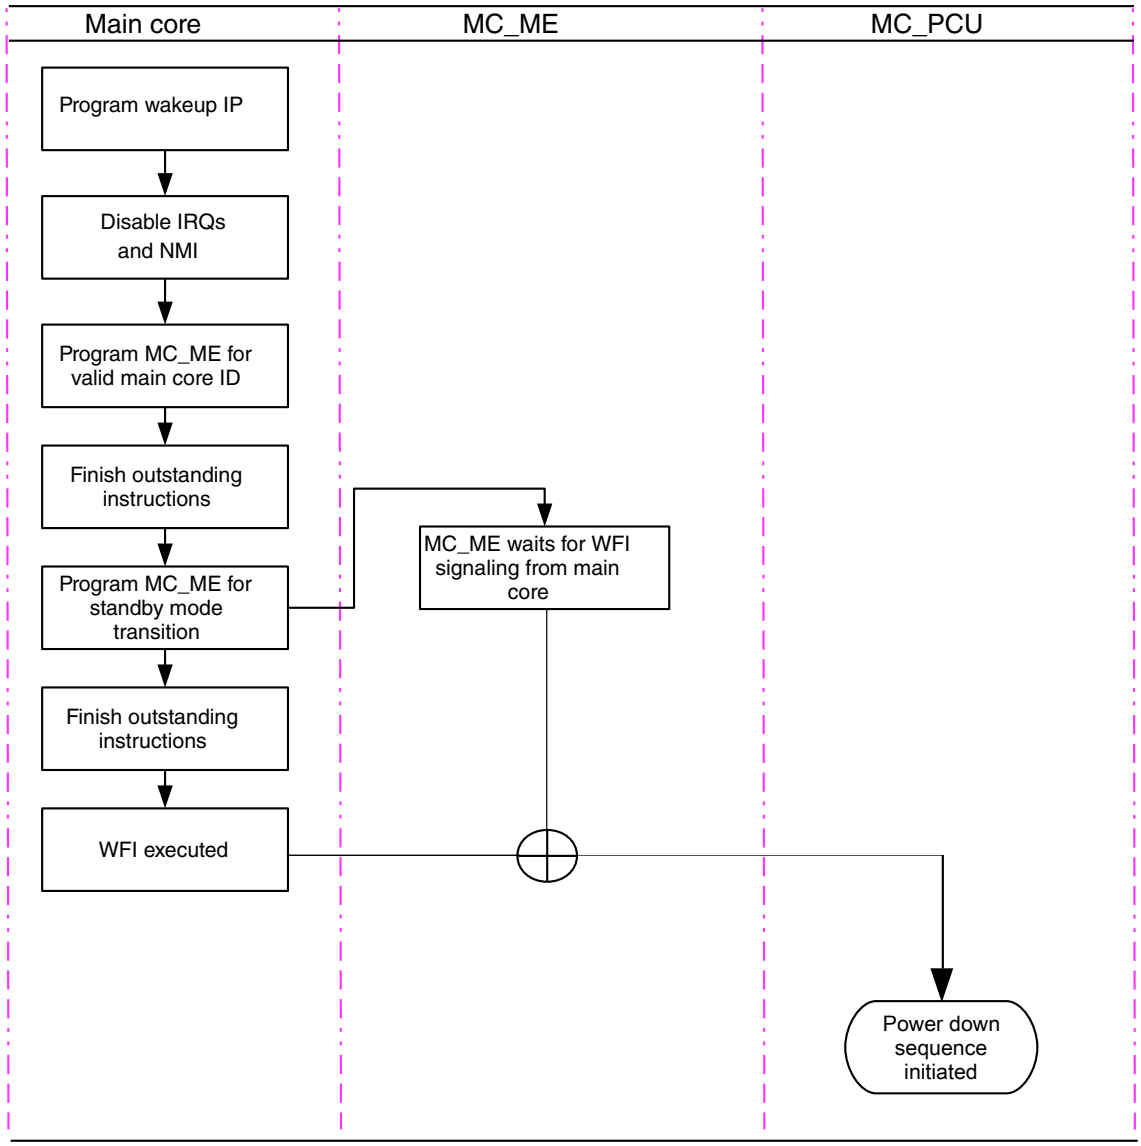

Figure 172. Standby entry sequence along with main core shutdown

NOTE

- MC_ME initiates the power sequence to MC_PCU. This enables the main core to remain inactive (WFI state) until it is reset and power-up again at standby exit.

44.7 MC_ME register descriptions

MC_ME implements set hardware processes that can be used by the software for changing the mode of operation for a partition. Following are the features of MC_ME registers:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error message.

- Writes to read-only registers are aborted with an error message.

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value

44.7.2 Control Key Register (CTL_KEY)

Offset

Register	Offset
CTL_KEY	0h

Function

This register provides the mechanism to MC_ME for starting the hardware processes for the partition(s) and standby entry sequence. The hardware processes for partitions are triggered through the corresponding PRTNn_PCONF register. The mechanism to trigger the hardware processes of the respective partitions require two write operations: first time with key and second time with inverted key. The hexadecimal value of key is 0x5AF0 whereas for inverted key is 0xA50F.

For initiating a standby entry sequence, the MODE_CONF register is used for providing a standby entry request along with a valid key combination.

NOTE

Reads from this register return a valid key value to be written next.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	KEY															
W																
Reset	0	1	0	1	1	0	1	0	1	1	1	1	0	0	0	0

Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15-0 KEY	Control key Key for starting the hardware processes. Writes with a value other than key or inverted key are ignored. Reads return bit inverted value corresponding to last write.

44.7.3 Mode Configuration Register (MODE_CONF)

Offset

Register	Offset
MODE_CONF	4h

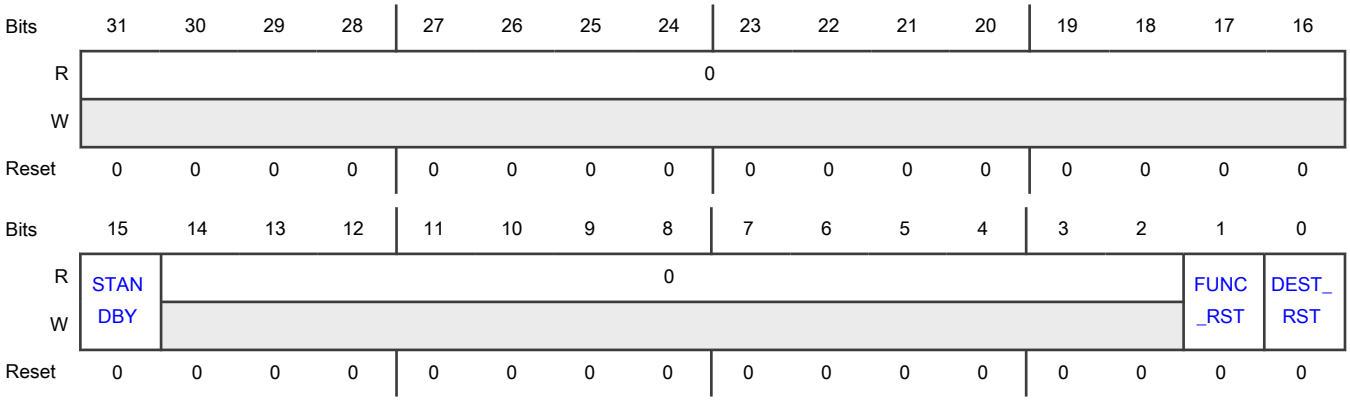
Function

This register is used for initiating a standby request or a reset event (destructive or functional) for the chip. The functional or destructive events are signaled to MC_RGM for further handling.

NOTE

Software must not enable mode entry if the value of multiple fields is 1 in the MODE_CONF register.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15 STANDBY	Standby request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a standby entry sequence request to MC_ME.
14-2 —	Reserved This field is reserved and read returns zeros.
1 FUNC_RST	Functional reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a functional reset event signaling to MC_RGM.
0	Destructive reset request

Table continues on the next page...

Table continued from the previous page...

Field	Function
DEST_RST	Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a destructive reset event signaling to MC_RGM.

44.7.4 Mode Update Register (MODE_UPD)

Offset

Register	Offset
MODE_UPD	8h

Function

This register is used for initiating a mode change. Mode change refers to initiating a standby request, or generating a destructive or functional reset event to MC_RGM. Setting mode update field to logic-1, along with programming MODE_CONF registers and then followed by a valid key combination will generate a mode transition request.

NOTE

The MODE_UPD register is implemented to make mode transition programming model the same as partition programming model. This is for future expansion inside MC_ME.

Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 MODE_UPD	Mode update Writing a logic-1 to this bit, followed by a valid key combination initiates a mode change as per the MODE_CONF register.

44.7.5 Mode Status Register (MODE_STAT)

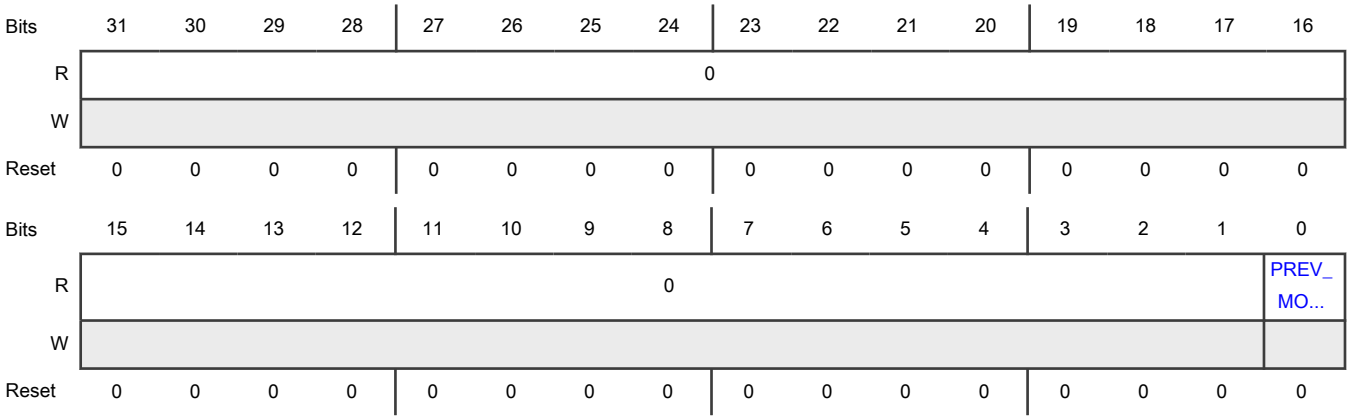
Offset

Register	Offset
MODE_STAT	Ch

Function

This register provides the status of the previous mode. In case of standby exit, if the reset event status register of MC_RGM are set, then contents of this register should be ignored.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 PREV_MODE	Previous mode This bit shows the status of the previous mode. 0b - The previous mode was reset (any reset). 1b - The previous mode was standby.

44.7.6 Main Core ID Register (MAIN_COREID)

Offset

Register	Offset
MAIN_COREID	10h

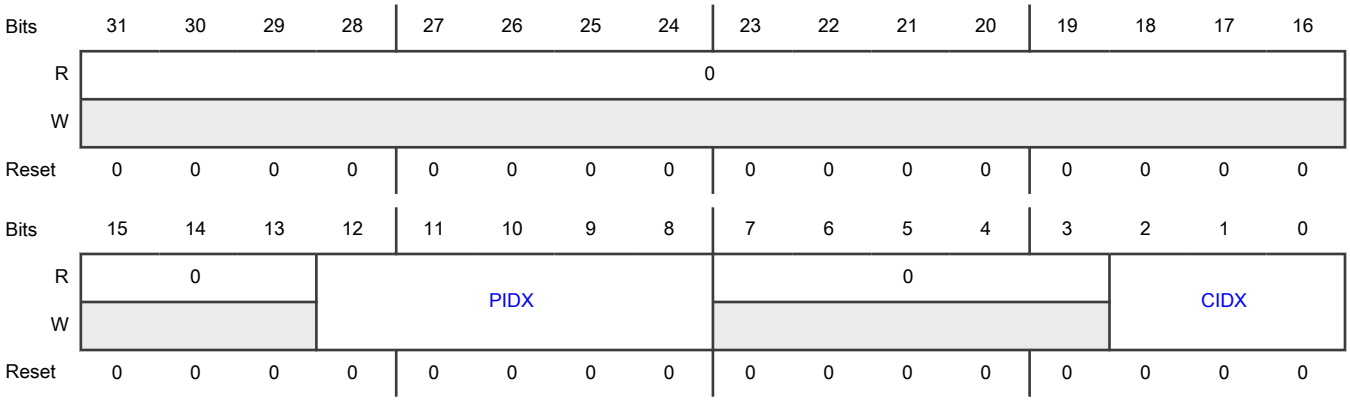
Function

This register provides the ID of the main core sequencing the operation for the standby sequence. Core ID is required for entering in the standby mode, and using this MC_ME locates the WFI instruction execution of the main core. The core ID in this register is specified by the partition index along with the core index.

NOTE

Before initiating a standby entry sequence, the contents of this register should point to the correct main core. Providing non-existing or incorrect core ID leads to unpredictable hardware behavior.

Diagram



Fields

Field	Function
31-13 —	Reserved This field is reserved and read returns zeros.
12-8 PIDX	Partition index Provides the partition index of the main core. Only values 0 - 2 can be written.
7-3 —	Reserved This field is reserved and read returns zeros.
2-0 CIDX	Core index Provides the core index of the main core inside the partition.

44.7.7 Partition 0 Process Configuration Register (PRTN0_PCONF)

Offset

Register	Offset
PRTN0_PCONF	100h

Function

This register provides a configuration for the hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_PCONF and PRTN0_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

Field	Function
1 —	Reserved This field is reserved and read returns zeros.
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

44.7.8 Partition 0 Process Update Register (PRTN0_PUPD)

Offset

Register	Offset
PRTN0_PUPD	104h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

44.7.12 Partition 0 COFB Set 0 Clock Enable Register (PRTN0_COFB0_CLKEN)

Offset

Register	Offset
PRTN0_COFB0_CLKEN	130h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 0. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

44.7.13 Partition 0 COFB Set 1 Clock Enable Register (PRTN0_COFB1_CLKEN)

Offset

Register	Offset
PRTN0_COFB1_CLKEN	134h

Function

This register provides clock control signaling to the individual COFBs in set 1 inside partition 0. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

44.7.14 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)

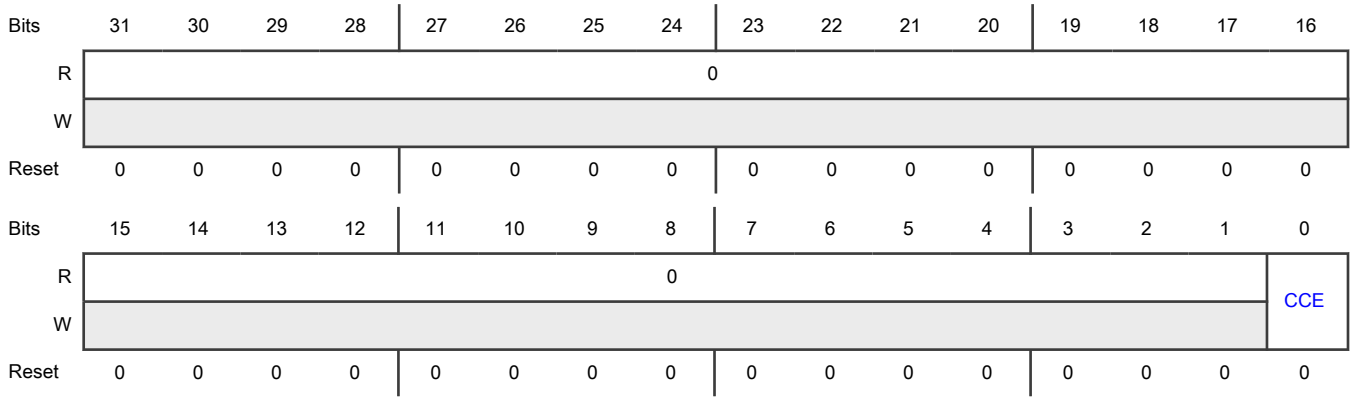
Offset

Register	Offset
PRTN0_CORE0_PCONF	140h

Function

This register provides configurations for the Core 0 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE0_PUPD and PRTN0_CORE0_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 0 clock enable This bit controls whether the clock to Core 0 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

44.7.15 Partition 0 Core 0 Process Update Register (PRTN0_CORE0_PUPD)

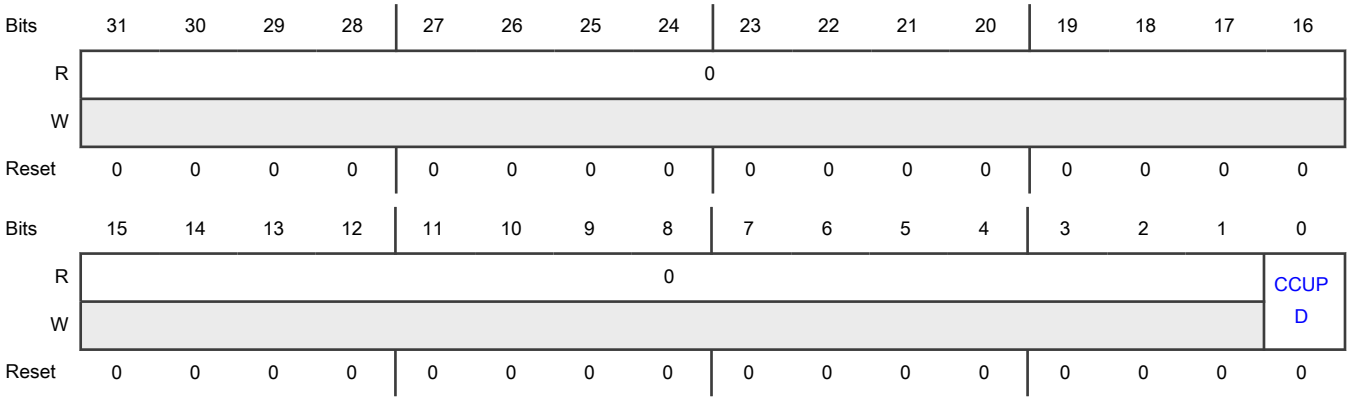
Offset

Register	Offset
PRTN0_CORE0_PUPD	144h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE0_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 0 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 0 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

44.7.16 Partition 0 Core 0 Status Register (PRTN0_CORE0_STAT)

Offset

Register	Offset
PRTN0_CORE0_STAT	148h

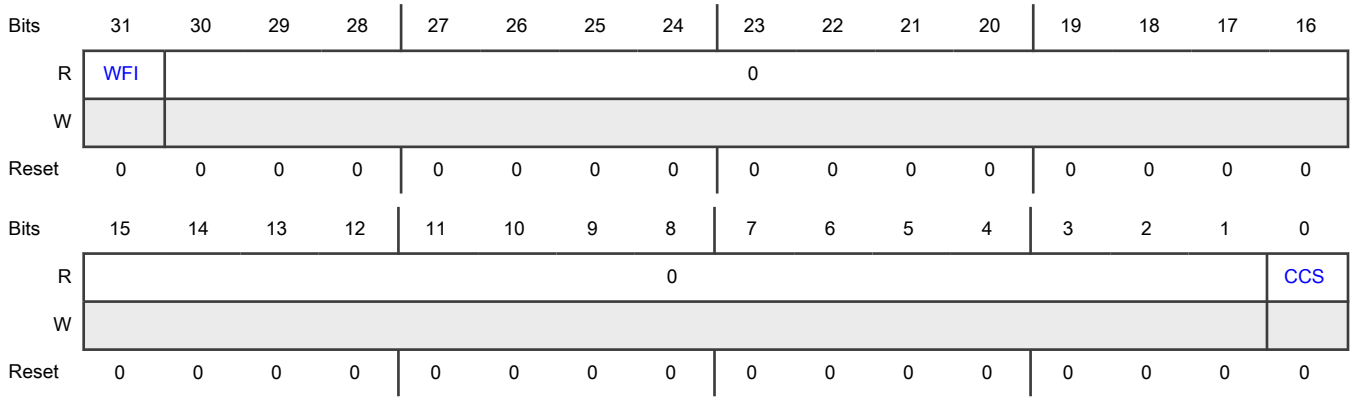
Function

This register provides the status corresponding to Core 0 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 0.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 0 in partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 0 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

44.7.17 Partition 0 Core 0 Address Register (PRTN0_CORE0_ADDR)

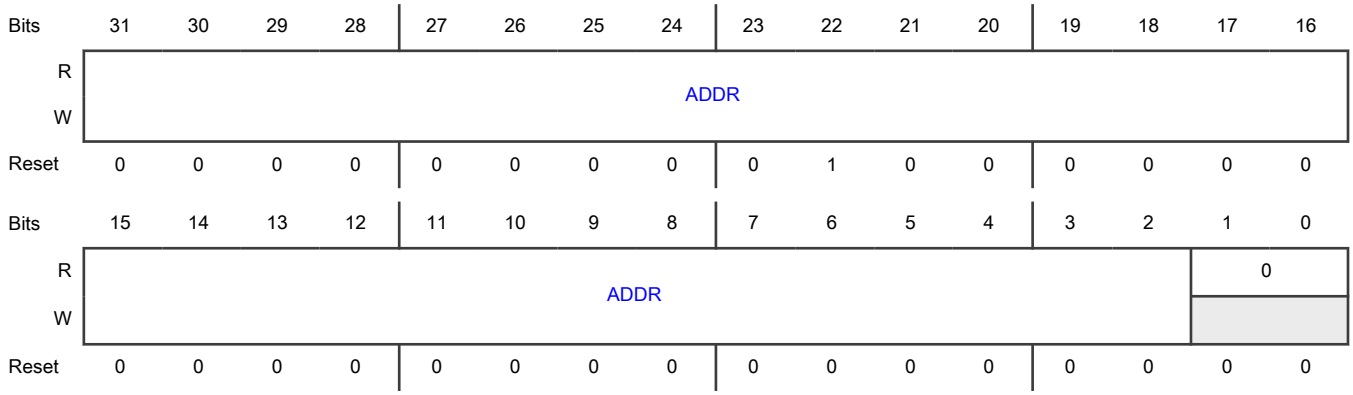
Offset

Register	Offset
PRTN0_CORE0_ADDR	14Ch

Function

This register contains the boot address for Core 0 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 0 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

44.7.18 Partition 0 Core 1 Process Configuration Register (PRTN0_CORE1_PCONF)

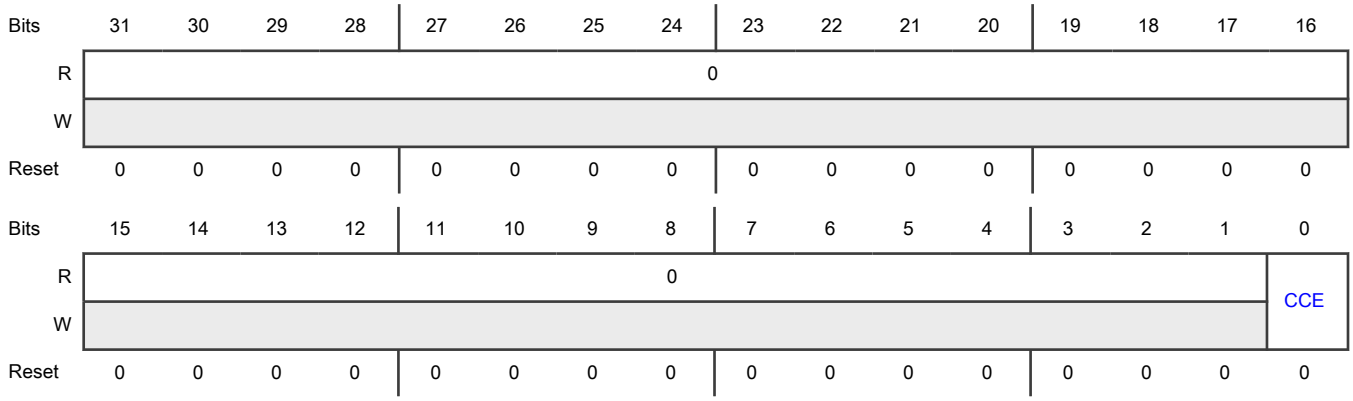
Offset

Register	Offset
PRTN0_CORE1_PCONF	160h

Function

This register provides configurations for the Core 1 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE1_PUPD and PRTN0_CORE1_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 1 clock enable This bit controls whether the clock to Core 1 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

44.7.19 Partition 0 Core 1 Process Update Register (PRTN0_CORE1_PUPD)

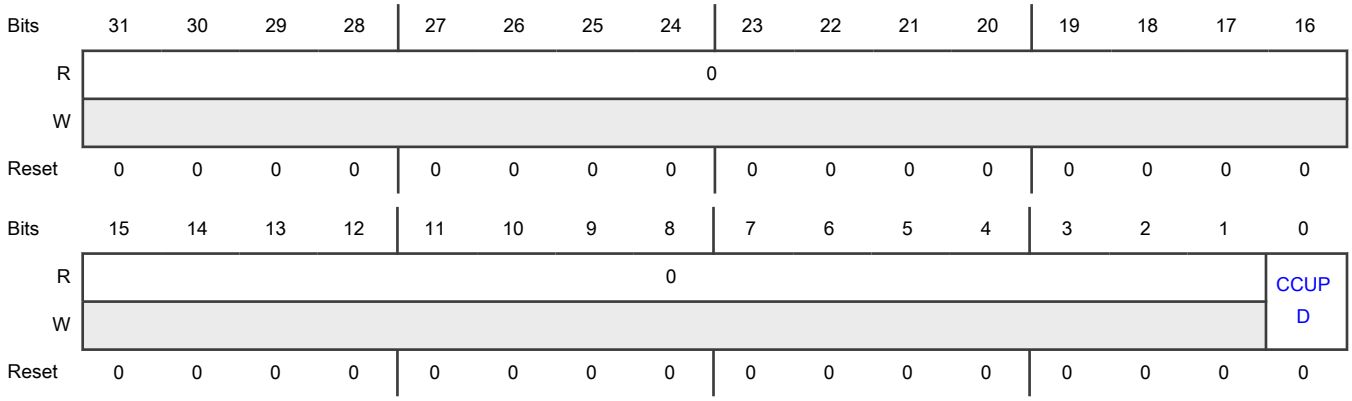
Offset

Register	Offset
PRTN0_CORE1_PUPD	164h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE1_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 1 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 1 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

44.7.20 Partition 0 Core 1 Status Register (PRTN0_CORE1_STAT)

Offset

Register	Offset
PRTN0_CORE1_STAT	168h

Function

This register provides the status corresponding to Core 1 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 1.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

44.7.21 Partition 0 Core 1 Address Register (PRTN0_CORE1_ADDR)

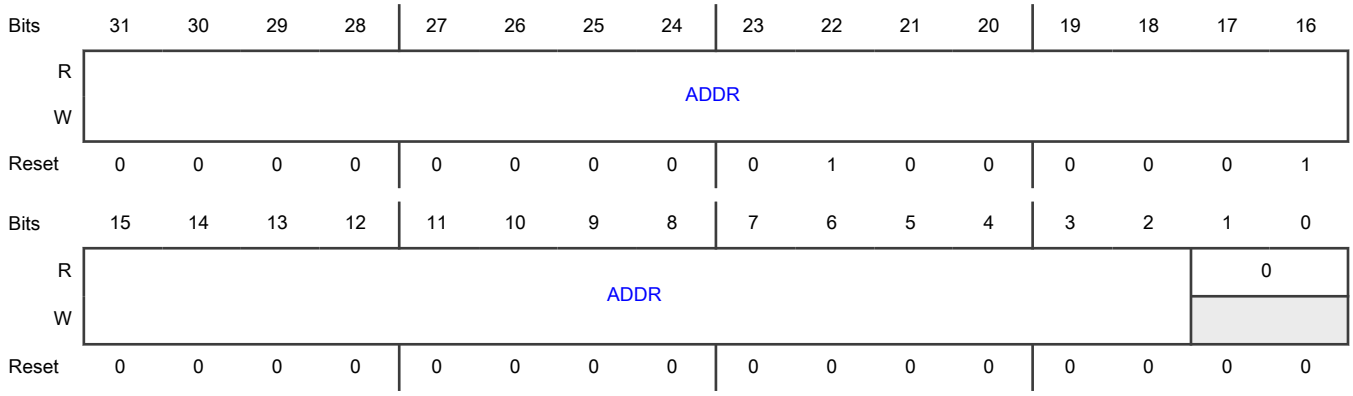
Offset

Register	Offset
PRTN0_CORE1_ADDR	16Ch

Function

This register contains the boot address for Core 1 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 1 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

44.7.22 Partition 0 Core 2 Status Register (PRTN0_CORE2_STAT)

Offset

Register	Offset
PRTN0_CORE2_STAT	188h

Function

This register provides the status corresponding to Core 2 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 2.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

1-0 —	Reserved This field is reserved and read returns zeros.

44.7.28 Partition 1 Process Configuration Register (PRTN1_PCONF)

Offset

Register	Offset
PRTN1_PCONF	300h

Function

This register provides a configuration for the hardware processes corresponding to partition 1. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN1_PCONF and PRTN1_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

44.7.33 Partition 1 COFB Set 2 Clock Status Register (PRTN1_COFB2_STAT)

Offset

Register	Offset
PRTN1_COFB2_STAT	318h

Function

This register provides the status of set 2 of COFBs inside partition 1.

NOTE

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

44.7.35 Partition 1 COFB Set 0 Clock Enable Register (PRTN1_COFB0_CLKEN)

Offset

Register	Offset
PRTN1_COFB0_CLKEN	330h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

44.7.36 Partition 1 COFB Set 1 Clock Enable Register (PRTN1_COFB1_CLKEN)

Offset

Register	Offset
PRTN1_COFB1_CLKEN	334h

Function

This register provides clock control signaling to the individual COFBs in set 1 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

0 —	Reserved This field is reserved and read returns zeros.

44.7.38 Partition 1 COFB Set 3 Clock Enable Register (PRTN1_COFB3_CLKEN)

Offset

Register	Offset
PRTN1_COFB3_CLKEN	33Ch

Function

This register provides clock control signaling to the individual COFBs in set 3 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

44.7.39 Partition 2 Process Configuration Register (PRTN2_PCONF)

Offset

Register	Offset
PRTN2_PCONF	500h

Function

This register provides a configuration for the hardware processes corresponding to partition 2. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN2_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN2_PCONF and PRTN2_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

1 —	Reserved This field is reserved and read returns zeros.
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

44.7.40 Partition 2 Process Update Register (PRTN2_PUPD)

Offset

Register	Offset
PRTN2_PUPD	504h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 2. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN2_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

44.7.45 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)

Offset

Register	Offset
PRTN2_COFB0_CLKEN	530h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

Chapter 45
Power Control Unit (MC_PCU)

45.1 Introduction

The power control unit (MC_PCU) is used for initiating a Standby mode entry that reduces the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply. The blocks inside the chip are grouped into multiple parts having this capability, which are called "power domains".

When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information, such as, power domain is lost. When you reconnect a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage. Maximum power saving is achieved by entering the Standby mode.

After the MC_ME asserts a standby entry request, MC_PCU initiates the power sequence, which is non-retractable and includes the handshake with the chip power management controller. The power-up/down sequences are handled by FSMs to ensure a smooth and safe transition into and out of the Standby mode. Exiting the Standby mode can only be done through a system wakeup event, power-on reset, destructive reset, or a functional reset.

45.2 Power sequence FSM

MC_PCU implements an FSM to initiate the power sequencing of the Standby mode entry/exit sequence for the chip.

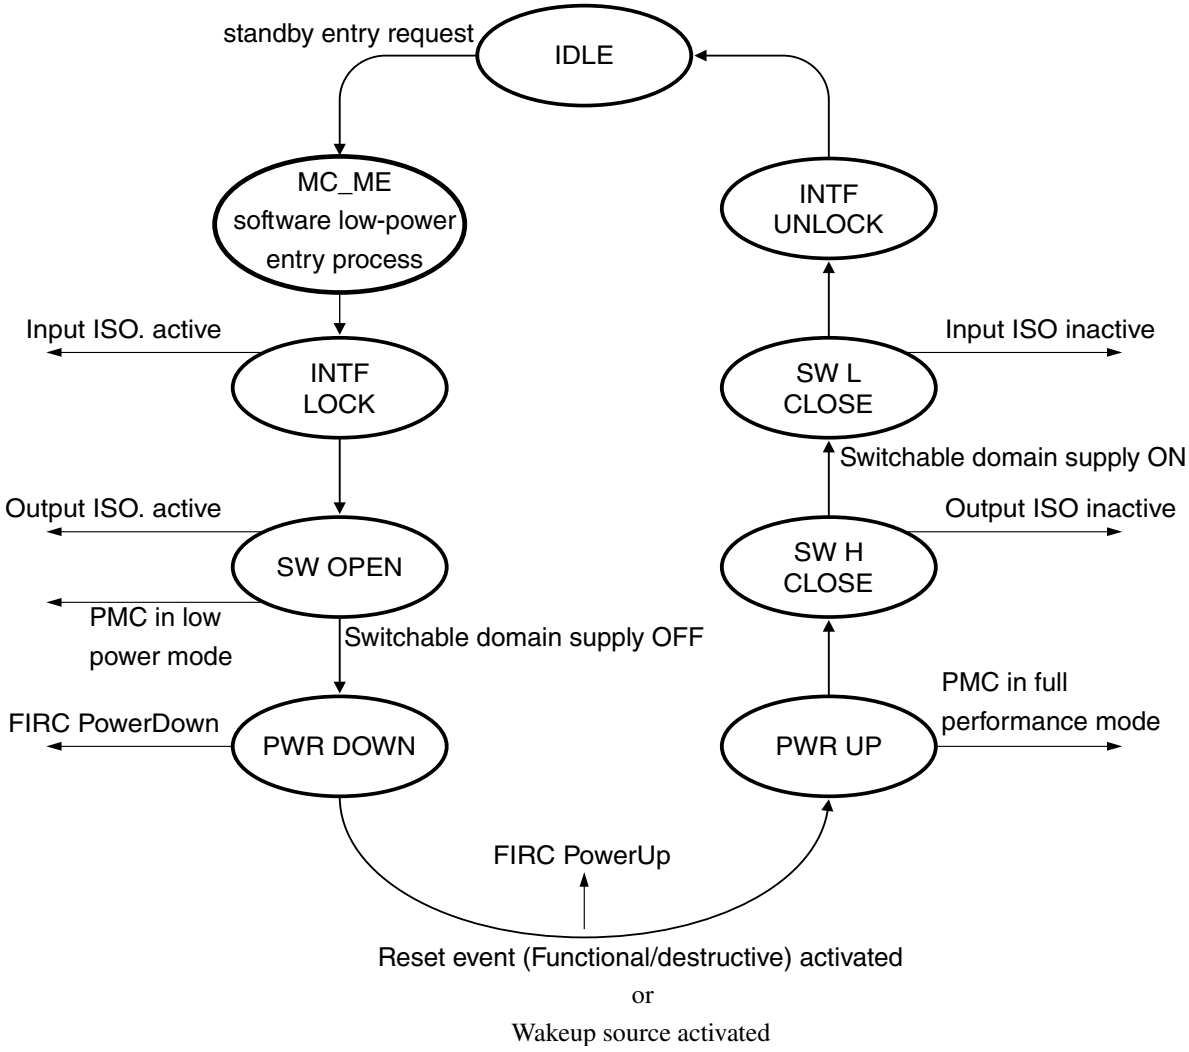

Figure 173. MC_PCU FSM

NOTE

When destructive reset is asserted from MC_RGM, MC_PCU FSM moves to the IDLE state immediately. Indication of this is not shown in the above figure.

Table 227. MC_PCU FSM transition description

State	Name	Exit condition	Signal controlled	Signal monitored

FSM Finite state machine

Chapter 46
Wakeup Unit (WKPU)

46.1 Chip-specific WKPU information

46.1.1 WKPU configuration on the chip

WKPU provides the following features:

- A configurable, low-power wake-up capability to the chip from multiple configurable asynchronous wake-up events.
- Support for four internal and minimum 59 external source depending on the chip, that can generate interrupts or wake-up events.
- Support for an NMI input.

Table 228. WKPU configuration on the chip

Number of sources, interrupts, and vectors	S32K3x4/ S32K3x2	S32K358	Description
NMI sources	1	1	Single NMI pin routed to all application cores
Internal wake-up sources	4	4	• SWT_0 wake-up, RTC-API wake-up • RTC timeout • Analog comparator round robin wake-up (from LPCMP_0, 1, and 2 round robin wake-up)[1] • RTI wake-up
External wake-up sources	60	67	Minimum 59 GPIO pins (WKPU[0]-WKPU[59])[2] support the wake-up functionality. See the IOMUX file attached to this document for details.
Glitch filters for external interrupts	60	67	Glitch filter on each external wake-up source
External interrupt vectors	8	8	—

1. Both wake-up sources 0 (RTC-API) and 2 (CMP_*x* trigger mode wake-up) use RTC-API wake-up, with Trigger mode having a higher priority. This means, if you configure LPCMP_*x*.RRCR0[ERR_EN] for either of the comparators, the RTC_API wake-up is used only for the CMP_*x* trigger mode operation. The RTC-API wake-up does not cause wake-up from Standby mode in this scenario.
2. For S32K312, WKPU[34] is reserved.

All of the aforementioned wake-up sources can be enabled or disabled. Also, you can configure these wake-up sources, by using WKPU configuration registers, to provide wake-up on rising or falling events. See the WKPU register memory map for details.

NOTE

You must use SIUL2 to perform WKPU pin configurations (PUE, PUS, and IBE). For this, you must first configure SIUL2.MSCR[IBE] for the corresponding pin. This chip does not support WKPU-provided pin configurations; it supports only bypass control.

46.1.2 WKPU register fields and their applicability

Table 229. WKPU register fields and applicability

Register	Field	Chips where applicable
NSR	NIF1	S32K324, S32K322
NSR	NOVF1	S32K324, S32K322
NCR	NLOCK1	S32K324, S32K322
NCR	NDSS1	S32K324, S32K322
NCR	NWRE1	S32K324, S32K322
NCR	NREE1	S32K324, S32K322
NCR	NFEE1	S32K324, S32K322
NCR	NFE1	S32K324, S32K322

46.1.3 WKPU NMI configuration

WKPU supports one external source that can cause non-maskable interrupts to on-chip cores and wake-up events to the system.

The following figure shows applicable cores, some family chips may not have cores Cortex-M7_1 or Cortex-M7_2. In case of a wake-up event (internal or external), WKPU initiates the recovery of the chip and feeds an interrupt to the core(s) depending on the configuration. The sections that follow provide details related to the associated configurations.

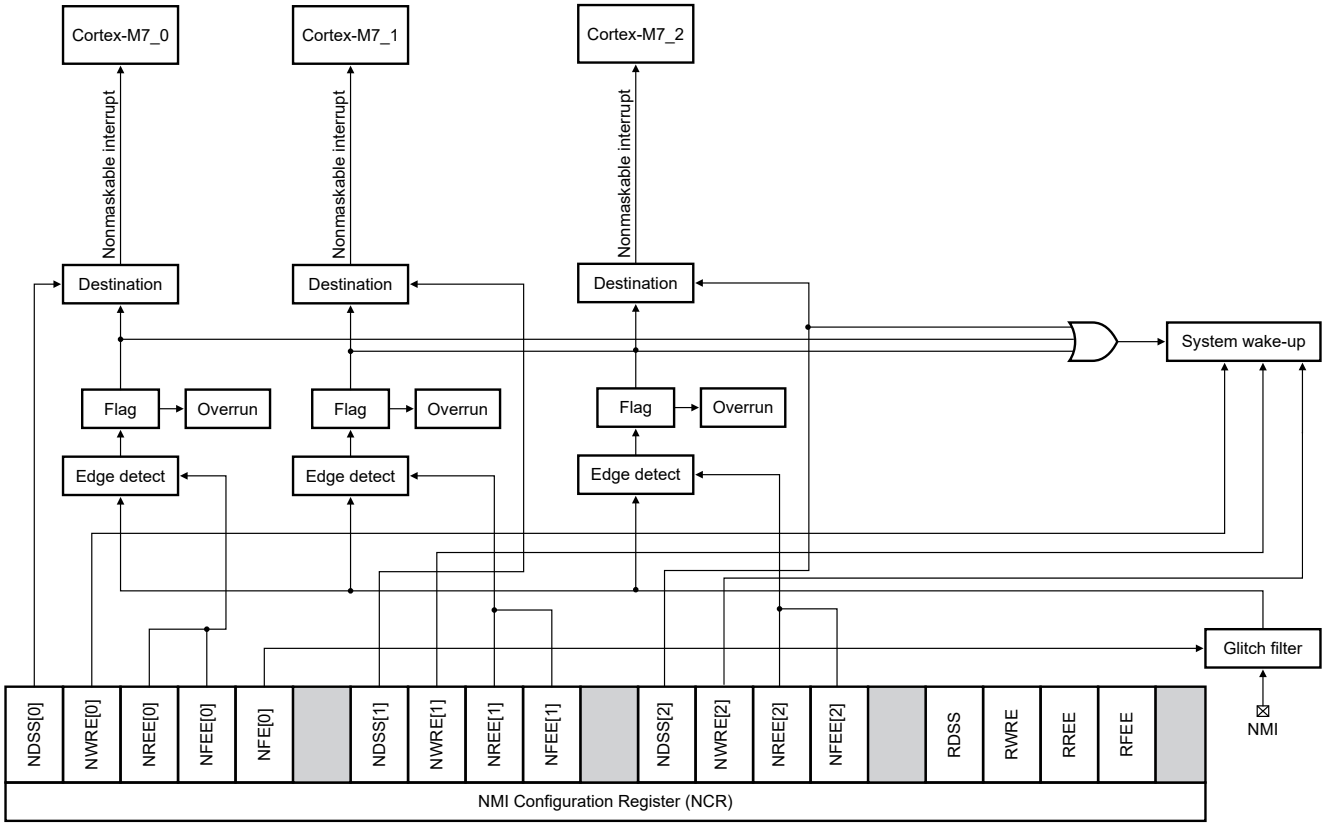

Figure 174. WKPU NMI configuration

46.1.4 WKPU wake-up source connectivity

WKPU allows the external NMI pin to assert the core NMIs on the chip. NMI supports NSR's status and overrun flags. This is what you could do using NCR:

- Control the NMI destination interrupt by configuring NCR[NDSS].
- Control the rising edge, falling edge, or either of the edge reactions to the NMI pin by using bits 2:0 of NCR[NFEE] and NCR[NREE]. The enabling of these edge reactions to the NMI pin is independent of each core.

WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The following figure shows routing of external wake-up events or interrupts with WKPU and the system interrupt controller.

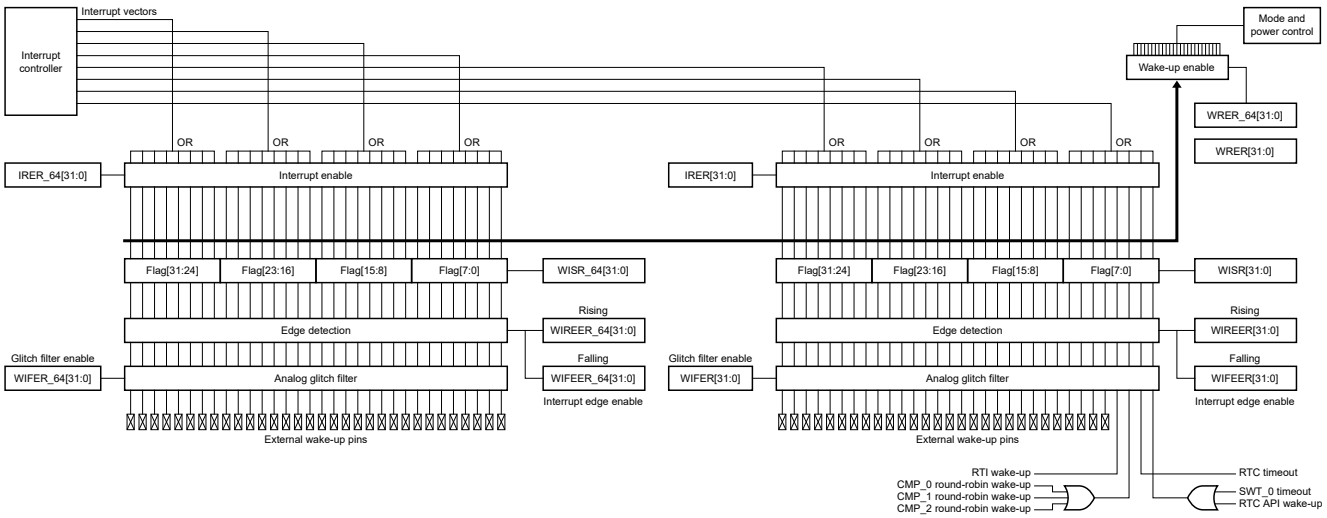

Figure 175. WKPU wake-up source connectivity

This is the wake-up source mapping to WKPU:

- Wake-up source 0 : SWT_0 timeout, RTC-API API wake-up
- Wake-up source 1 : RTC-API RTC timeout
- Wake-up source 2 : Round robin wake-up interrupt (Trigger mode interrupt) from LPCMP_0, LPCMP_1, or LPCMP_2
- Wake-up source 3 : RTI wake-up
- Wake-up source 4 : Wake-up source minimum 59-external pin wake-up sources, WKPU[0]-WKPU[59]

If you configure any or all of the LPCMP_*x*.RRCR0[RR_EN] fields to be active, the corresponding CMP_*x* pins must be dedicated for the CMP_*x* operation. In case you are not using any of the CMPs, you can use SIUL2.MSCR*x*[SSS] to configure the pins for digital functionalities.

NOTE

You must enable WKPU (by using MC_ME.PRTN*x*_COFB*y*_CLKEN) before entering any of the chip's low-power modes.

46.2 Introduction

The WKPU supports 64 external sources that can generate interrupts or wakeup events and 3 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from other wakeup sources to supply a single wakeup to the system. The block diagram of WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See chip-specific WKPU for more information.

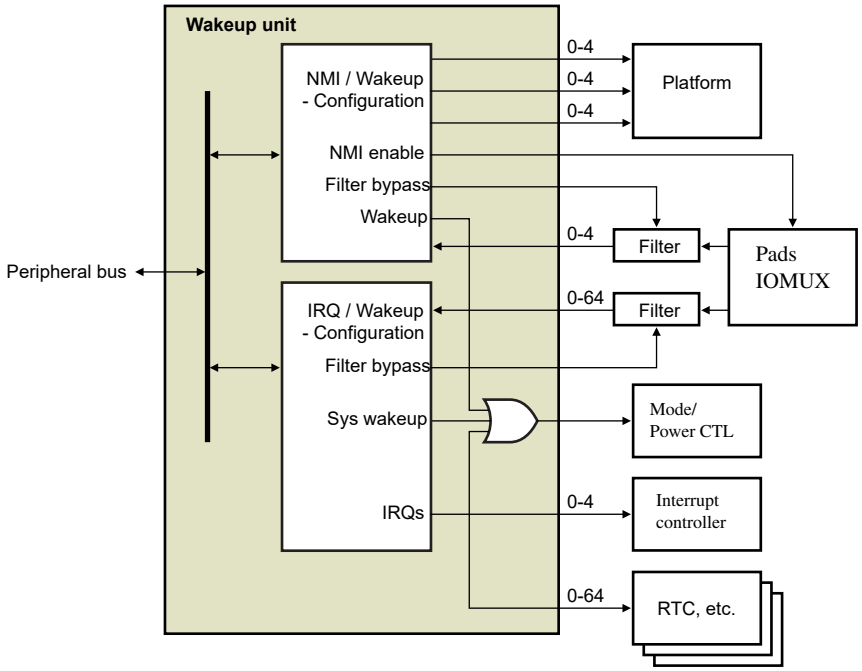

Figure 176. WKPU and connected system components

46.3 Features

The WKPU supports these features:

- Non-maskable interrupt support with:
  - 3 NMI sources
  - 3 analog glitch filters
  - Independent interrupt destination for each core:
    - Non-maskable interrupt
    - Critical interrupt
  - Active (rise/fall) edge selection control for events
  - Configurable system wakeup triggering from NMI sources
- External wakeup/interrupt support with:
  - One System interrupt vector for interrupt sources
  - 64 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources

46.4 Functional description

This section provides functional description of WKPU.

46.4.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, although it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be performed when NMI is disabled, to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

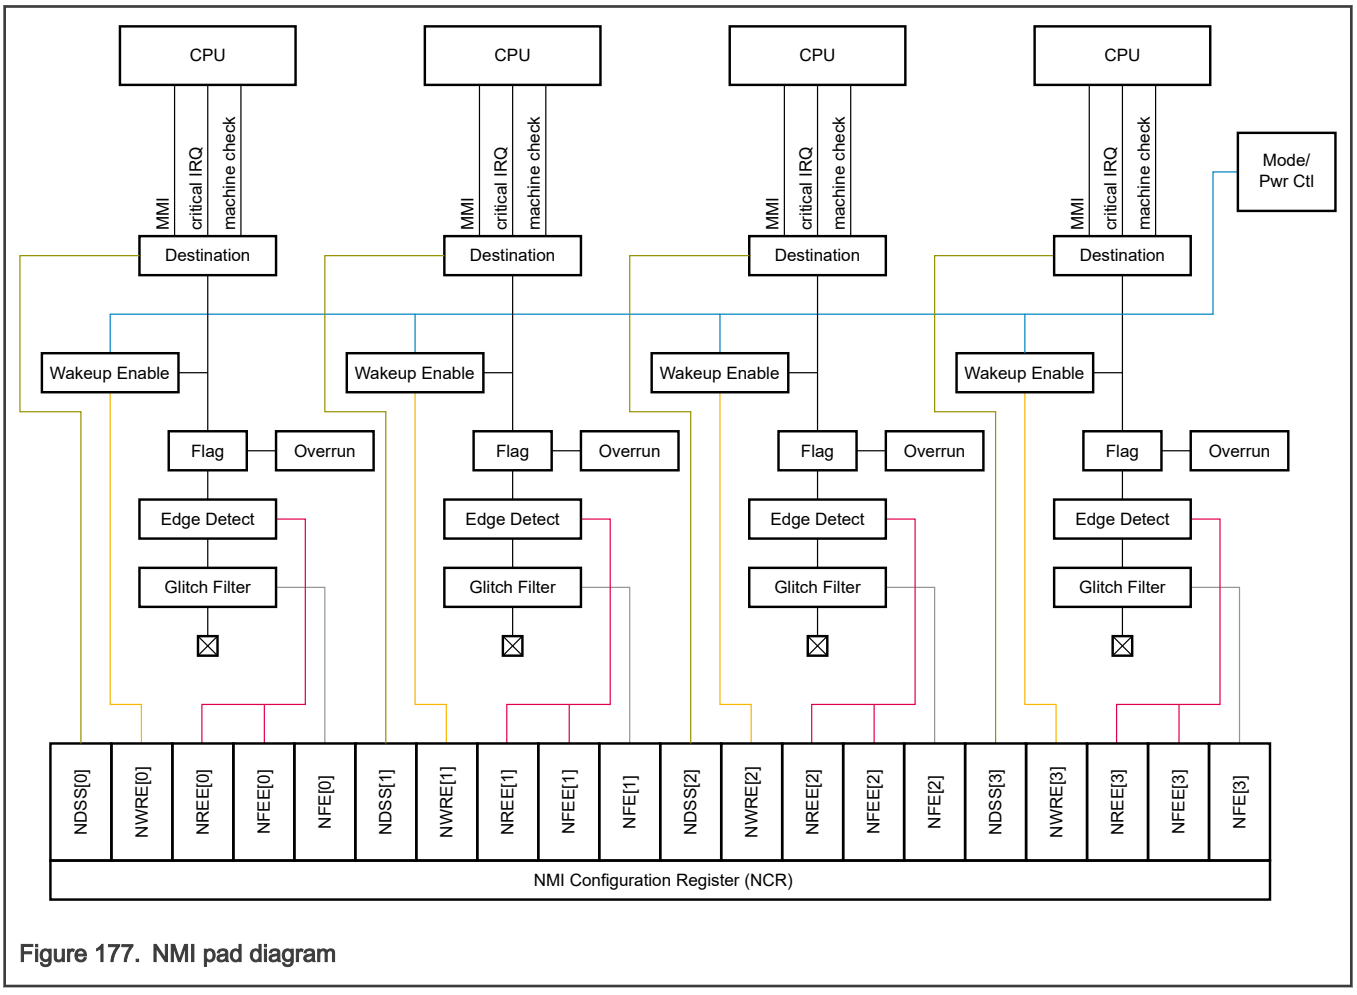

Figure 177. NMI pad diagram

46.4.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NCR[NREEn] and NCR[NFEEn] bits.

NOTE

After reset, NREE and NFEE are set to '0'; therefore, the NMI functionality is disabled after reset and must be enabled explicitly by software.

After a pad's NMI functionality is enabled, the pad cannot be reconfigured to override or disable the NMI. See the chip-specific WKPU information for details of NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NCR[NDSSn] bits. See NMI Configuration Register (NCR) for details.

Each NMI supports a status flag and an overrun flag, which are located in the NSR register (see NMI Status Flag Register (NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (that is, status flag has not been cleared).

NOTE

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt is not cleared.

During an NMI ISR, on wakeup of the chip from an NMI, any writes to the ECC-protected memory must have the correct ECC.

46.5 External wakeups/interrupts

The WKPU supports 3 interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support up to the number of external interrupt sources from the device pads, with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt source is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

See the following figure for an overview of the external interrupt implementation, showing an example of four interrupt vectors with eight external interrupt sources each.

NOTE

The figure below shows a generic representation of WKPU. See the chip-specific WKPU information for details on how this device's configuration might differ from this figure.

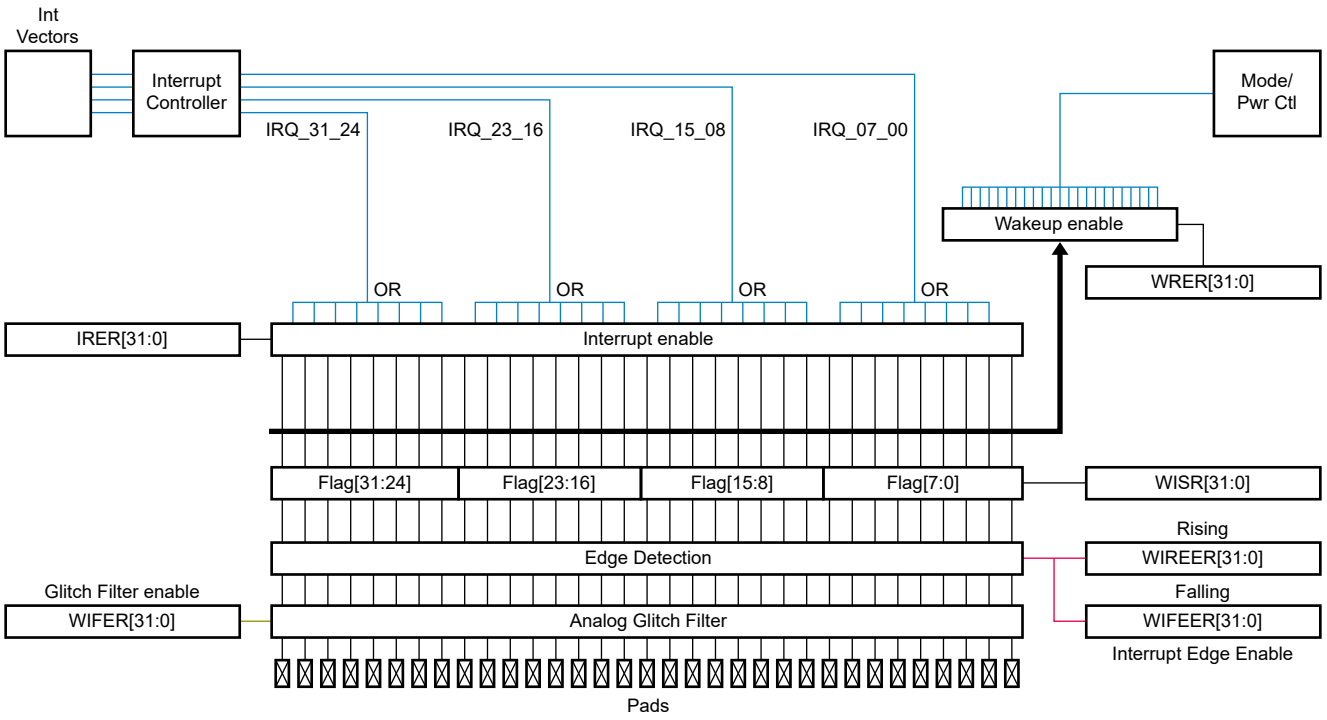

Figure 178. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is set based on the platform and the interrupt controller's priority levels, but the allocation of pads to each group of interrupts can be independently configured by the chip.

External interrupt lines have a digital glitch filter applied to them.

46.5.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled-up register (Interrupt Request Enable Register (IRER)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active.

NOTE

Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (that is, no system wakeup or interrupt is generated on any activity of that pad).

The active IRQ edge is controlled by users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag, which is held in the flag register, WISR. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

46.6 Initialization information

This section discusses initialization for the following features:

- Glitch filter and pad configuration
- Non-maskable interrupts

46.6.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed when the NMI is disabled. This is to avoid erroneous triggering by glitches caused by the configuration process.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NCR[NREE], NCR[NFEE], NCR[RREE], and NCR[RFEE] bits in the same register write.

46.6.2 Non-maskable interrupts

If the IBE of NMI is tied off to 1, no false interrupt is expected.

46.7 WKPU memory map and registers

46.7.1 WKPU register descriptions

This section provides a detailed description of all the registers accessible in the WKPU module.

NOTE

Reserved registers read as zero and writes have no effect. A transfer error is generated when trying to access a completely reserved register space. The field length of external pad control registers depends on the number of WKPU channels implemented in a chip.

46.7.1.1 WKPU memory map

WKPU base address: 402B_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	NMI Status Flag Register (NSR)	32	W1C	0000_0000h
8h	NMI Configuration Register (NCR)	32	RW	6060_6000h
14h	Wakeup/Interrupt Status Flag Register (WISR)	32	W1C	0000_0000h
18h	Interrupt Request Enable Register (IRER)	32	RW	0000_0000h
1Ch	Wakeup Request Enable Register (WRER)	32	RW	0000_0000h
28h	Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER)	32	RW	0000_0000h
2Ch	Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER)	32	RW	0000_0000h
30h	Wakeup/Interrupt Filter Enable Register (WIFER)	32	RW	0000_0000h
54h	Wakeup/Interrupt Status Flag Register (WISR_64)	32	W1C	0000_0000h
58h	Interrupt Request Enable Register (IRER_64)	32	RW	0000_0000h
5Ch	Wakeup Request Enable Register (WRER_64)	32	RW	0000_0000h
68h	Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER_64)	32	RW	0000_0000h
6Ch	Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER_64)	32	RW	0000_0000h
70h	Wakeup/Interrupt Filter Enable Register (WIFER_64)	32	RW	0000_0000h

46.7.1.2 NMI Status Flag Register (NSR)

Offset

Register	Offset
NSR	0h

Function

This register holds the non-maskable interrupt status flags.

NOTE

This register is accessible by 8-, 16-, and 32-bit read/write operations.

Access: User read/write

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 NIF0	NMI Status Flag 0 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an interrupt request. 0b - No event has occurred on the pad 1b - An event as defined by NREE0 and NFEE0 has occurred
30 NOVF0	NMI Overrun Status Flag 0 This flag can be cleared only by writing 1. Writing 0 has no effect. It will be a copy of the current NIF0 value whenever an NMI event occurs, thereby indicating to the software that the NMI occurred when the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 0b - No overrun has occurred on NMI input 0 1b - An overrun has occurred on NMI input 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-24 —	Reserved
23 NIF1	NMI Status Flag 1 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (NREE1 or NFEE1 set), NIF1 causes an interrupt request. 0b - No event has occurred on the pad 1b - An event as defined by NREE1 and NFEE1 has occurred
22 NOVF1	NMI Overrun Status Flag 1 This flag can be cleared only by writing 1. Writing 0 has no effect. It will be a copy of the current NIF1 value whenever an NMI event occurs, thereby indicating to the software that the NMI occurred when the last one was not yet serviced. If enabled (NREE1 or NFEE1 set), NOVF1 causes an interrupt request. 0b - No overrun has occurred on NMI input 1 1b - An overrun has occurred on NMI input 1
21-16 —	Reserved
15 NIF2	NMI Status Flag 2 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an interrupt request. 0b - No event has occurred on the pad 1b - An event as defined by NREE2 and NFEE2 has occurred
14 NOVF2	NMI Overrun Status Flag 2 This flag can be cleared only by writing 1. Writing 0 has no effect. It will be a copy of the current NIF2 value whenever an NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 0b - No overrun has occurred on NMI input 2 1b - An overrun has occurred on NMI input 2
13-8 —	Reserved
7-6 —	Reserved
5-0 —	Reserved

46.7.1.3 NMI Configuration Register (NCR)

Offset

Register	Offset
NCR	8h

Function

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing 0 to both NREE[*n*] and NFEE[*n*] disables the NMI functionality completely (that is, no non-maskable interrupt is generated on any pad activity).

Access: User read/write

46.7.1.4 Wakeup/Interrupt Status Flag Register (WISR)

Offset

Register	Offset
WISR	14h

Function

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located at the left of the external wakeup/interrupt status bits and are read-only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

Access: User read/write

46.8 Glossary

NMI Non-maskable interrupts

Chapter 47
Safety Overview

47.1 Introduction

This chip family is developed following the ISO 26262 standards, with derivatives targeting the chips that are operable in a system that fulfills the requirements of the ASIL D or ASIL B safety integrity levels.

Table 230. ASIL levels

Chip	ASIL level
S32K344	D
S32K342	
S32K358	
S32K312	B
S32K311	

The ASIL level targets the safety processing, which means the software functions are executed as intended:

1. Read instructions from memory.
2. Execute instructions.
3. Read data from memory.
4. Process data.
5. Write back the result data into memory.

Some elements of the safety concept are based on the assumption that the chip is connected to an external SBC or PMIC. The SBC or PMIC performs observations and control functionalities that are essential to fulfill some related functional safety requirements. If you do not use an SBC or PMIC, you must ensure that your S32K-family chip provides an equivalent functionality that properly manages the corresponding interface(s).

The following figure illustrates the safety interface between the chip and the SBC or PMIC.

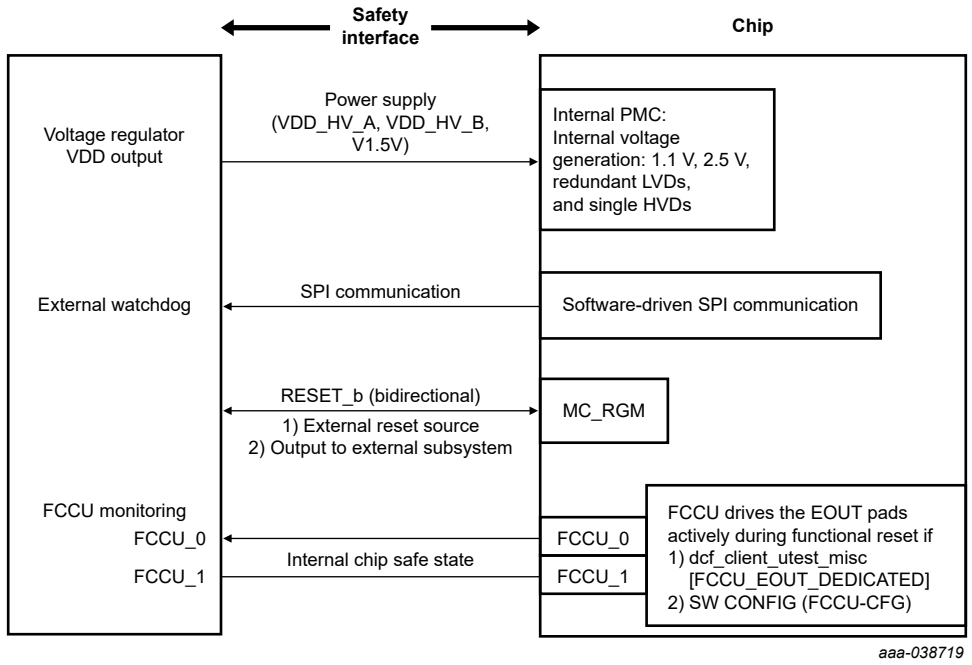

Figure 179. Safety interface between the chip and the SBC or PMIC

In the safety context, the chip interfaces can be classified into the groups shown in the table.

Table 231. Chip interface groups

Interface	Description
Power supply	This interface is between the SBC and the chip. It ensures that the supply to the chip is in the correct range. In case of any low-voltage event, the chip has POR, LVR, and LVD circuits in place and in case of any HVD event, the chip raises an interrupt. The SBC must ensure that the voltage regulator outputs never exceed the allowed range (more specifically for HVD range).
Communication	Responsible for communication between the SBC and the chip. Though the chip supports multiple communication protocols (UART, LIN, SPI, I2C, FlexCAN, and so on), SPI is the preferred communication with SBC. This is relevant to initialize an external watchdog when the chip is inoperative for a considerably long time (this is indicated by the pin states of the communication interface).
Reset	The chip consists of a reset bidirectional pin interfaced with SBC. The SBC can initiate a chip reset via this pin as a safety reaction in case of: • Extreme critical faults • An inoperative chip • Stuck cases based on the criticality and the application requirements

Table continues on the next page...

Table 231. Chip interface groups (continued)

Interface	Description
	The SBC also samples the reset pin state to identify the chip condition (whether in running state or in reset).
FCCU	The chip indicates the chip faults to the SBC via FCCU EOUT pins through this interface.

The interfaces in Table 231 ensure the chip's operational safety and integrity.

47.2 Safety architecture elements

The chip safety architecture consists of following elements that operate in an interconnected way to meet the ASIL requirements:

- Cortex-M7 core complex (including the cache controllers) operating in delayed lockstep (ASIL D only)
- eDMA controller
- Structural core self-test
- Internal windowed watchdogs with independent clock sources
- Power supply monitoring with redundant low-voltage detectors, single high-voltage detectors, and internal ADC connection to check the internal voltages during application
- Robust clock monitoring, including PLL loss of lock detection
- Embedded flash memory with ECC (single-bit data correction, double-bit data detection) and address encoding (parallel address path check)
- System RAM with ECC
  - Single-bit data correction
  - Double-bit data detection
  - Address detection
- Cortex-M7 cache memories with ECC (single-bit data correction, double-bit data detection)
- Peripherals memories (EMAC, FlexCAN) with ECC (single-bit data correction, double-bit data detection)
- End-to-End EDC (E2E EDC), with address encoding and monitoring of the control signals done by a dedicated module (XBIC). This ensures the safety of storage and of the data path to the internal storage (RAM, flash memory, core cache) and peripherals across the crossbar switch. See the XBIC chapter for details.
- Hardware CRC module that supports end-to-end data check integrity for any data transfer in the system (SRAM to peripherals via DMA transfer, external interfaces to SRAM/peripherals, and so on)
- Cortex-M7 MPUs
- XRDC for memory and peripheral protection
- AIPS_Lite peripheral protection with trusted master-slave connection
- Register protection mechanism for safety-critical registers
- On-chip temperature sensor for temperature monitoring
- Self-test:
  - LBIST to detect latent faults in functional logic as well as in safety integrity mechanisms

NOTE

LBIST is not supported in S32K312 and S32K311.

  - MBIST to ensure integrity of the memories in the chip (SRAM, ITCM, DTCM, peripheral memories, and so on)
  - Check-the-checker software library
  - ADC self-test
- FCCU for error collection and reaction, including reporting error status to system; FCCU supports these programmable reaction types:
  - Interrupt
  - Functional reset
- Error pads indicate the chip's internal state to the external chip interface or SBC.
- EIM to inject errors into the memories and interface gaskets to verify the error-detection features of the memory controllers and the interface gaskets
- ERM to collect diagnostic information from memory controllers in case of an error event

47.3 I/O peripherals

The arrangement of I/O peripherals across peripheral bridges allows redundant use of peripherals while limiting possible causes of CCF. Redundant use includes using equivalent peripherals in a replicated way as well as using functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism.

The peripherals are distributed evenly across the peripheral bridges (AIPS*n*), except for singular modules like EMAC, QuadSPI, and so on.

NOTE

EMAC and QuadSPI are not present in S32K312 and S32K311.

47.4 Self-test

The chip supports a self-test operation. Your safety software must initiate self-test by configuring STCU2; the chip does not initiate it. STCU2 then controls the self-test operation. Self-test supports both MBIST and LBIST. After the self-test operation completes, the chip enters a reset sequence. Self-test results are stored in STCU2 and your safety software can read the results after the reset sequence.

Figure 180 depicts the processing steps related to the self-test operation, and its linkage to the chip reset and an application start. You decide whether to run a self-test or to skip it before starting an application. You must also specify the self-test configuration before relinquishing control to STCU2 for performing the self-test operation. This processing finishes by reentering the chip reset sequence, depending on whether the chip encountered an unrecoverable fault during the self-test operation. When an unrecoverable fault is encountered during the self-test operation, the chip enters a reset sequence by performing a destructive reset. When no such fault is encountered, the self-test operation completes by entering the chip sequence with a functional reset sequence. You can prevent reset cycling by limiting the amount of resets permitted; the chip shuts down when this limit has been reached. See the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter.

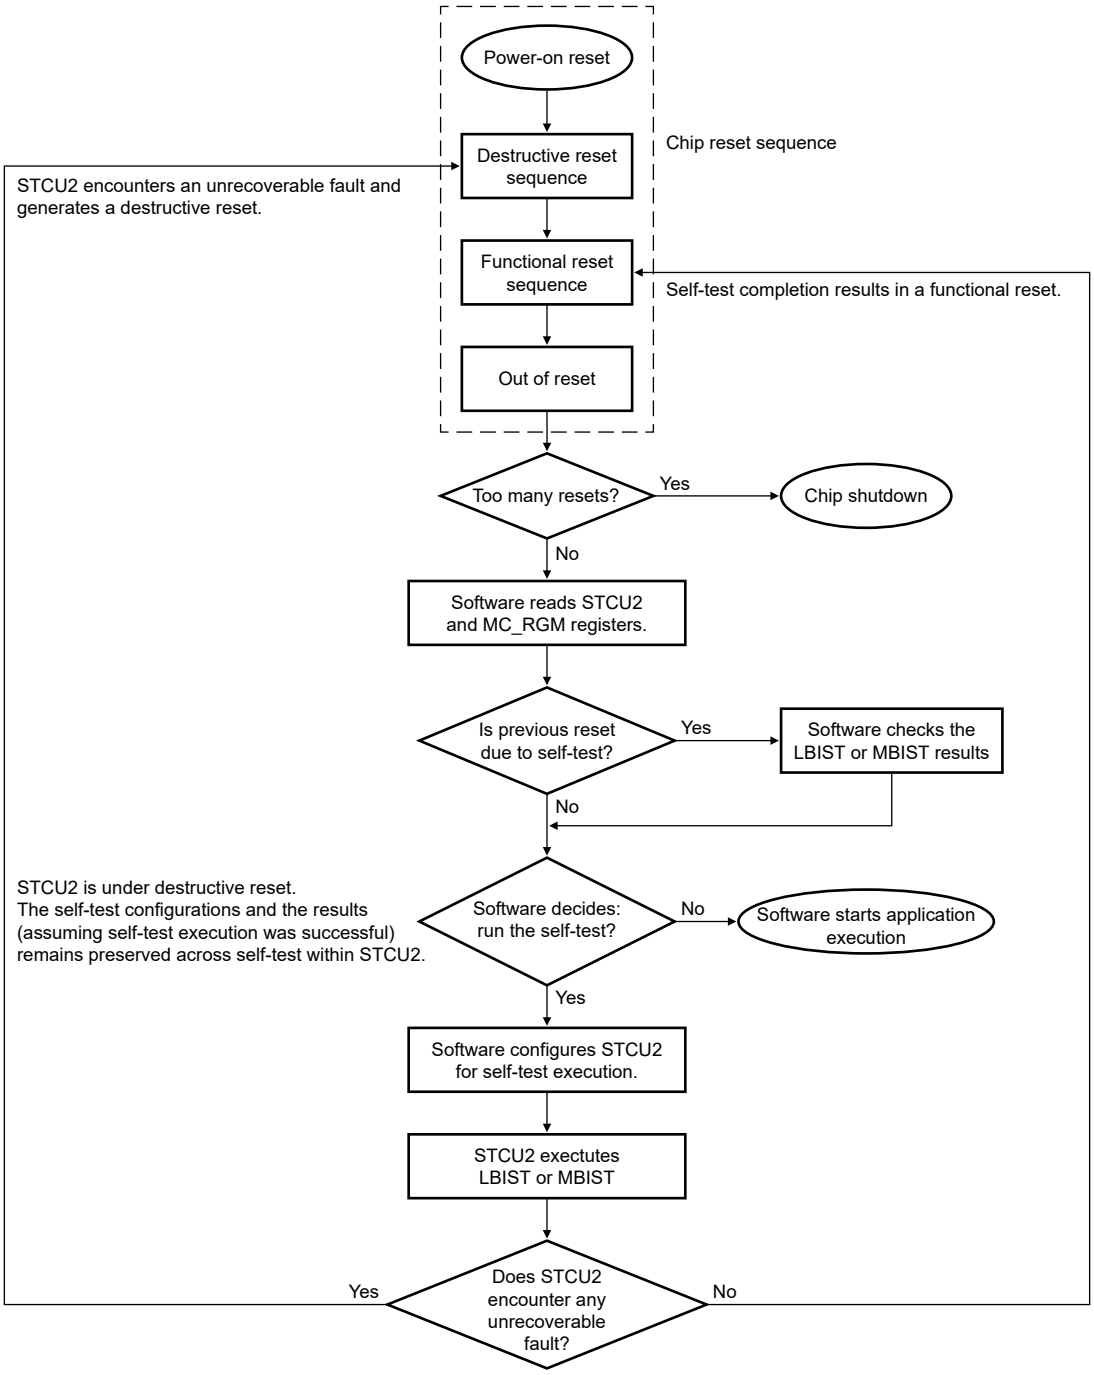

Figure 180. LBIST/MBIST execution

Figure 181 visualizes the top-level partitioning of the chip. The chip consists of two partitions, Run and Standby.

- Run: This partition consists of logic which is present in switchable domain and is shut off (has no supply) while the chip operates in low-power (Standby) mode.
- Standby: This partition consists of always-on logic which is functional even while the chip operates In low-power (Standby) mode.

The Run partition also contains the control logic that is essential for the chip self-test operation, as well as blocks that undergo self-test. The chip consists of a single LBIST partition, which is a subpartition within the Run partition. The LBIST subpartition

contains the logic over which self-test is executed. The logic outside the LBIST subpartition and within the Run partition consists of the LBIST control logic as well as logic which does not undergo LBIST.

The components within these different partitions are listed below the figure (they are not indicated in the figure for clarity).

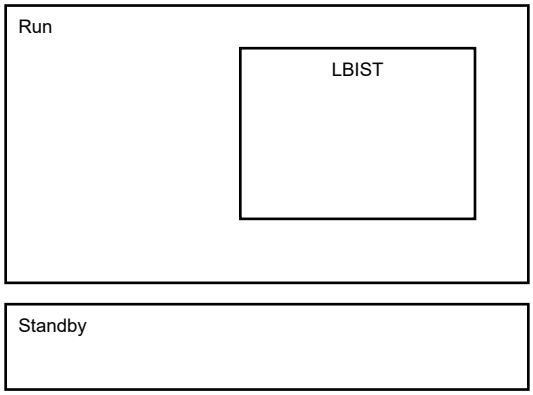

Figure 181. S32K314/S32K324/S32K344 chip top-level partition view

The following list specifies the content of the LBIST partition and both power domains related to their participation in the self-test operation:

- Modules participating in the LBIST operation:

  NOTE

  LBIST is not supported in S32K312 and S32K311. The modules participating in the LBIST operation are out of LBIST in S32K312 and S32K311.

  — eDMA
  — EIM
  — ERM
  — XRDC
    - MDAC0 (Cortex-M7_0)
    - MDAC1 (eDMA)
    - MDAC2 (reserved)
    - MDAC3 (HSE_B)
    - MDAC4 (Cortex-M7_1)
    - MDAC5 (EMAC)
    - MRC0 (flash memory)
    - MRC1 (PRAM)
    - MRC2 (QuadSPI)

      NOTE

      Cortex-M7, EMAC, and QuadSPI are not present in S32K312 and S32K311.

    - PDAC1
    - PDAC2
  — CRC
  — FCCU

- FOSU
- PFLASH_CTL
- PRAM_C0
- PRAM_C1
- SWT_1
- CMU
  - CMU_FC_0
  - CMU_FM_1
  - CMU_FM_2
  - CMU_FC_3
  - CMU_FC_4
  - CMU_FC_5
- IAHB gaskets

NOTE

An IAHB gasket is a frequency translation gasket in the system. These gaskets are used to add register walls and synchronize the timing domain across different operating frequencies. See the configurable gaskets in the 'Block diagram' in 'Introduction' chapter for the locations of the IAHB_GASKETs in the chip.

  - DMA_GSKT
  - HSE_GSKT
  - AIPS1_GSKT
  - AIPS2_GSKT
  - QSPI_GSKT

NOTE

AIPS2_GSKT and QSPI_GSKT are not present in S32K312 and S32K311.

  - TCM_GSKT
  - EMAC_GSKT
  - EDC master checker gaskets (See block diagram in Introduction chapter for details)
  - EDC slave checker gasket (See block diagram in Introduction chapter for details)
- Crossbar switches and bridges
  - AXBS_0 (main)
  - AXBS_1 (peripheral)
  - AXBS_2 (eDMA)
  - AXBS_3 (Cortex-M7 TCM)
  - AXBS_4 (HSE)
  - AIPS_Lite_1
  - AIPS_Lite_2

NOTE

AIPS2_Lite_ is not present in S32K312 and S32K311.

- Modules within the Standby domain (not participating in the LBIST operation):
  - 32 KB standby SRAM
  - LPCMP_0–LPCMP_2
  - Reset generation
    - MC_RGM
    - POR_WDG
  - Power management
    - PMC
    - MC_PCU
    - WKPU
    - Chip standby pins
  - Clock sources
    - FIRC
    - SIRC
    - FXOSC
    - SXOSC

NOTE

SXOSC is not present in S32K311.

  - Timers
    - PIT_0
    - RTC
    - SWT_0
- Modules not participating in the LBIST operation (in the Run domain):
  - HSE subsystem
    - Engine
    - Memories
  - Cortex-M7_0
    - Core
    - I-cache
    - D-cache
    - ITCM
    - DTCM
  - Cortex-M7_1

NOTE

Cortex-M7_1 is not present in S32K312 and S32K311.

    - Core
    - I-cache

- D-cache
- ITCM
- DTCM

— CMUs
- CMU0
- CMU3

— Analog blocks
- ADC_0–ADC_2
- TempSense

NOTE

ADC_2 is not present in S32K342, S32K312, and S32K311.

— Communication modules
- LPSPI_0–LPSPI_5
- LPI2C_0
- LPI2C_1
- LPUART_0–LPUART_15
- FlexCAN_0–FlexCAN_5
- SAI_0
- SAI_1

NOTE

SAI_0 and SAI_1 are not present in S32K312 and S32K311.

— Timers
- PIT_1
- PIT_2
- eMIOS
- BCTU
- STM_0
- STM_1

NOTE

PIT_2 and STM_1 are not present in S32K312 and S32K311.

— TRGMUX

— PLLDIG

— SIUL2

— LCU_0

— LCU_1

— STCU2

— DMAMUX

— MCM

— MCSM

— INTM

— SEMA42

— MU

NOTE

SEMA42 and chip MU are not present in S32K312 and S32K311.

— TSPC

NOTE

REG_PROT of an IP undergoes (or does not undergo) LBIST in conjunction with the protected module that undergoes (or does not undergo) LBIST.

The modules that are vital to the self-test operation are excluded from LBIST regions to allow LBIST to execute successfully.

You must run self-test with PLLDIG configured as the system clock. The LBIST clock controller controls the clock during serial shift, but returns clock control to the functional nodes during the self-test.

47.5 Glossary

ASIL Automotive safety integrity level. This is a risk classification scheme as defined by ISO 26262 for automotive standard.

CCF Common cause failure

DTCM Data tightly coupled memory

ECC Error correction code

ITCM Instruction tightly coupled memory

LBIST Logic built-in self-test

MBIST Memory built-in self-test

PLL Phase-locked loop oscillator

PMIC Power management integrated chip

SBC System basis chip

Chapter 48
Error Injection Module (EIM)

48.1 Chip-specific EIM information

48.1.1 EIM instances

This chip supports up to three instances of EIM:

- EIM_0
- EIM_1
- EIM_2

Table 232. EIM instances

Instances	S32K358	S32K322/S32K324/S32K344/S32K342/S32K312/S32K311/S32K314
EIM_0	Yes	Yes
EIM_1	Yes	No
EIM_2	Yes	No

48.1.2 EIM channel mapping

EIM integrates with the memory controller and memory array to enable error injection in a controlled way. Each memory controller has its own EIM channel.

Cortex-M7_1, EMAC, AIPS2 gasket, Cortex-M7 lockstep, and QuadSPI gasket are not available in the S32K312 and S32K311 product variants of the S32K3 family.

EIM channel mapping - S32K3x1, S32K3x2, S32K3x4

Table 233. EIM channel mapping - S32K3x1, S32K3x2, S32K3x4

Channel #	Target	Data bits [1]	Check bits[1]	# of data bits	# of check bits
0	SRAM0	Word1[31:0] – SRAM0 read data[63:32] Word2[31:0] – SRAM0 read data[31:0]	Word0[31:24] – SRAM0 read data ECC[7:0]	64	8

1. You must write to EICHDi_WORDj registers to inject errors in the desired data and check bits. For details, see tables "Error injection channel descriptor: DATA_MASK details" and "DATA_MASK bit: Channel-word mapping" in this chapter.
2. SRAM1 is not available for the S32K342, S32K312, and S32K311 variants.
3. Applicable for S32K342 and S32K322 only.

The two enables, GEIEN and EICHEN*n*, enable the error injection functionality. The former enables it globally and the latter does it for a particular channel. This double-layer enable provides protection against accidental enabling and reconfiguration of the error injection function for each channel.

EIM provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs through its data mask registers.

NOTE

For enabling error injection on EDC gaskets (corresponding to channel 28, channel 29, and channel 30), you must also enable the fields corresponding to the required EDC gasket in the MSCM_ENEDC register before enabling the EIM channel.

EIM_EICHD1_CH01, EIM_EICHD1_CH08, EIM_EICHD1_CH09, EIM_EICHD1_CH10, EIM_EICHD1_CH11, EIM_EICHD1_CH12, EIM_EICHD1_CH16, EIM_EICHD1_CH17, EIM_EICHD1_CH18, EIM_EICHD1_CH19, EIM_EICHD1_CH21, EIM_EICHD1_CH22, EIM_EICHD1_CH24, EIM_EICHD1_CH26, EIM_EICHD1_CH27 are not present in K312, hence the registers corresponding to these channels are also not present in K312.

48.1.3 Behavior of EIM error injection on gaskets

The error injection on gaskets don't impact the actual data flow. The gasket read data, write data and the monitor error don't get changed when EIM error injection is done. The gasket compares the actual data with the modified data (with error injection) and flags the gasket alarm. In case of single-bit error also, the alarm is flagged.

The channels which depict such behavior are the gasket channels listed below:

- Channel 19: EMAC gasket
- Channel 20: Cortex-M7 TCM gasket
- Channel 21: DMA AXBS S0 gasket
- Channel 22: DMA AXBS S1 gasket
- Channel 23: HSE gasket
- Channel 24: QuadSPI gasket
- Channel 25: AIPS1 gasket
- Channel 26: AIPS2 gasket

48.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of internal memories (for example, system RAM, cache RAMs, and peripheral memories). See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to induce artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

48.2.1 Features

The EIM includes these features:

- Supports 27 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

48.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

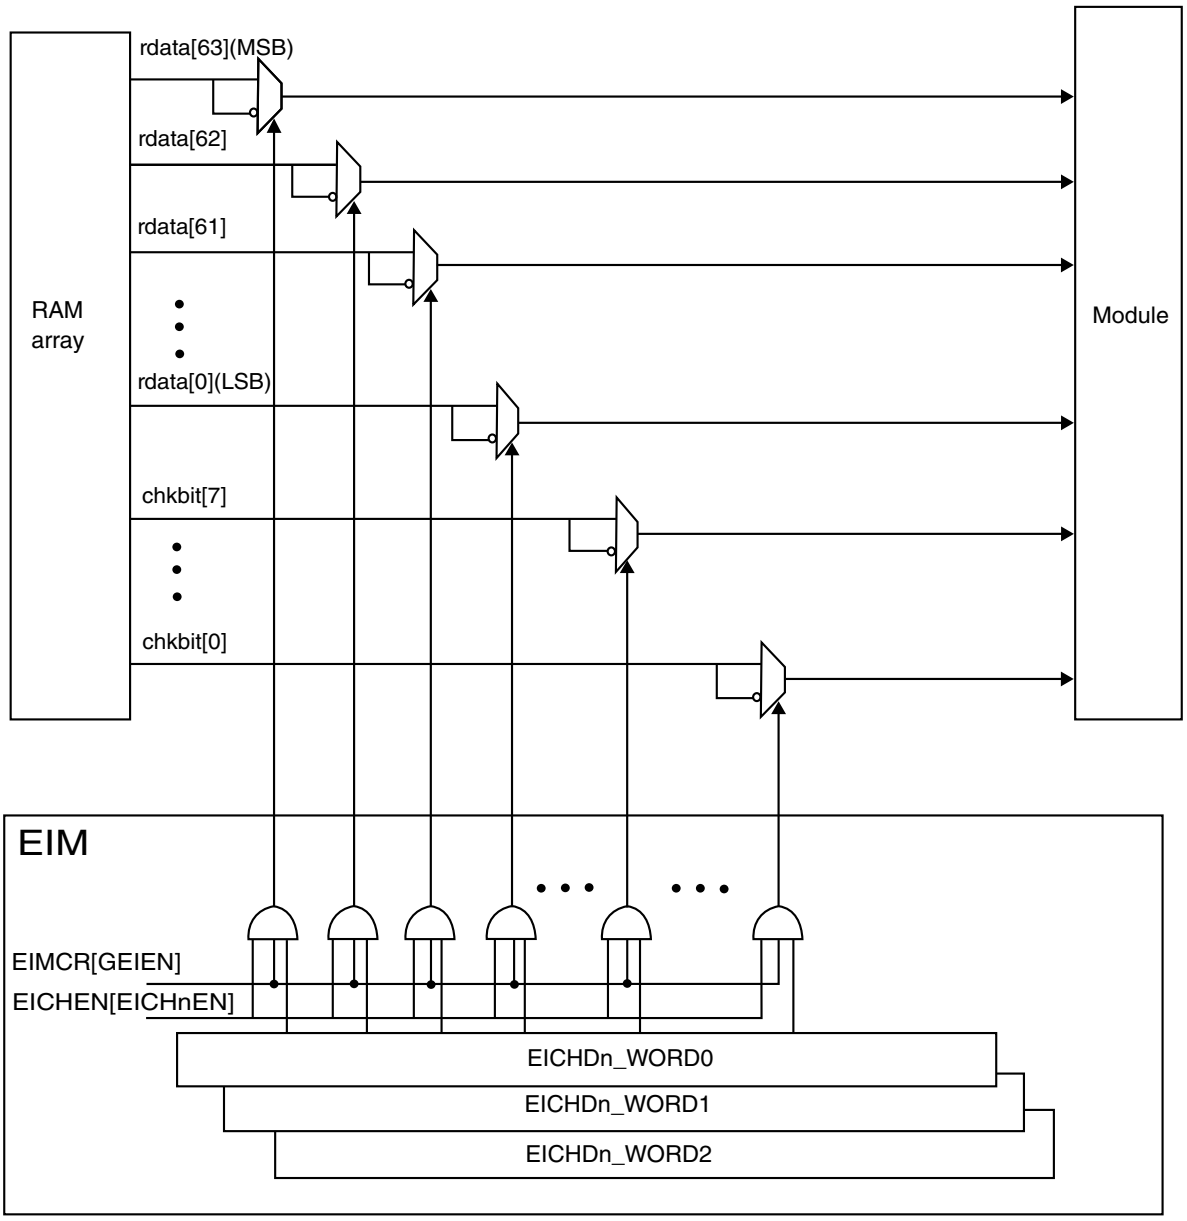

Figure 182. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

48.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.

- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 27 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 182 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

To enable error injection:

1. Set the EICHD*n*_WORD*m*[CHKBIT_MASK] and EICHD*n*_WORD*m*[B*a*_*b*DATA_MASK] fields for each channel that will be driving an injection.
2. Program the EICHEN register to enable the channels that will be injecting errors.
3. Set the EIMCR[GEIEN] field to globally allow all enabled channels to actively inject errors.

To disable error injection, either disable the EIMCR[GEIEN] field or disable the individual channel enable fields of the EICHEN register.

48.4 EIM register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 237. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3

48.4.2 Error Injection Module Configuration Register (EIMCR)

Offset

Register	Offset
EIMCR	0h

Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

Diagram

Fields

Field	Function
31-1 —	Reserved
0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

48.4.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Diagram

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 2 1b - Error injection is enabled on Error Injection Channel 2
28 EICH3EN	Error Injection Channel 3 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 3 1b - Error injection is enabled on Error Injection Channel 3
27 EICH4EN	Error Injection Channel 4 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. **NOTE** This field is not supported in every instance. The following table includes only supported registers. 0b - Error injection is disabled on Error Injection Channel 4 1b - Error injection is enabled on Error Injection Channel 4
26 EICH5EN	Error Injection Channel 5 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection.

EIM_1	EICHEN	—

0b - Error injection is disabled on Error Injection Channel 31

1b - Error injection is enabled on Error Injection Channel 31

48.4.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

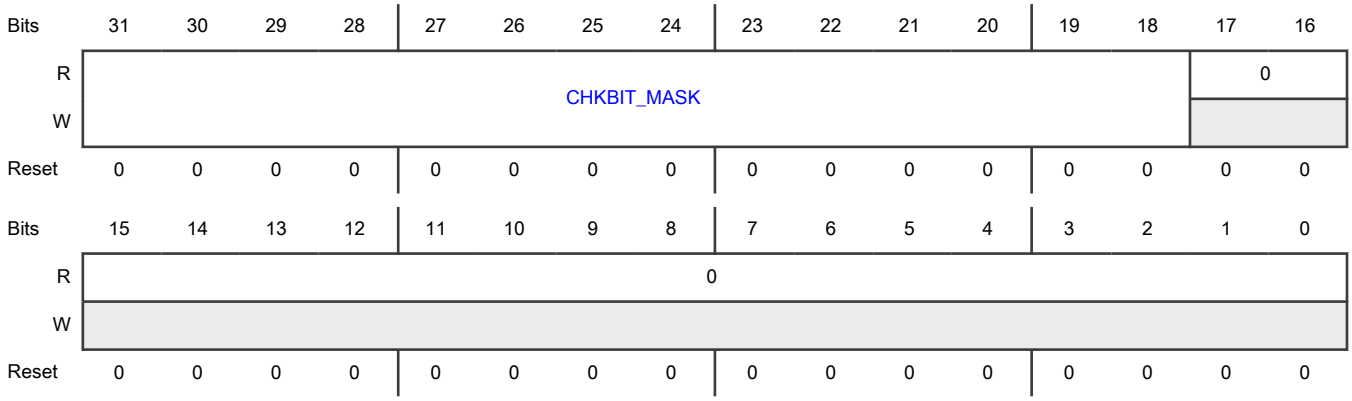
Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-18 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted. **NOTE** This field is not supported in every instance. The following table includes only supported registers.
17-0 —	Reserved

Fields

Field	Function
31-0 B12_15DATA_MASK	Data Mask Bytes 12-15 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B12_15DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 12-15 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 12-15 on the read data bus is inverted.

48.4.10 Error Injection Channel Descriptor n, Word0 (EICHD2_WORD0 - EICHD4_WORD0)

Offset

Register	Offset
EICHD2_WORD0	300h
EICHD3_WORD0	400h
EICHD4_WORD0	500h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

NOTE

Each module instance supports a different number of registers.

<tr><th>Field</th><th>Function</th></tr>
<tr><td>31-4
CHKBIT_MASK</td><td>Checkbit Mask
This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored.
For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information.
NOTE
Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit.
0b - The corresponding bit of the checkbit bus remains unmodified.
1b - The corresponding bit of the checkbit bus is inverted.
NOTE
This field is not supported in every instance. The following table includes only supported registers.

48.5 Glossary

SEC-DED	Single error correct – dual error detect
ECC	Error correction code

Chapter 49
Error Reporting Module (ERM)

49.1 Chip-specific ERM information

49.1.1 ERM instances

This chip supports up to two instances of ERM:

- ERM_0
- ERM_1

Table 239. ERM instances

Instances	S32K358	S32K322/S32K324/S32K344/S32K342/S32K312/S32K311/S32K314
ERM_0	Yes	Yes
ERM_1	Yes	No

49.1.2 ERM channel mapping

ERM provides information on memory events associated with ECC and parity. It also provides you an option to enable interrupt notification for these events.

Table 240. ERM_0 channel mapping

Channel #	Module	Captured status
00	SRAM0	Single-bit error, multi-bit error, syndrome, absolute error address aligned to double-word (64-bit) boundary
01	SRAM1 [1]	Single-bit error, multi-bit error, syndrome, absolute error address+18000h aligned to double-word (64-bit) boundary[2]
02	Cortex-M7_0 I-cache tag RAM	Single-bit error, multi-bit error[3]
03	Cortex-M7_0 I-cache data RAM	Single-bit error, multi-bit error[3]
04	Cortex-M7_0 D-cache tag RAM	Single-bit error, multi-bit error[3]
05	Cortex-M7_0 D-cache data RAM	Single-bit error, multi-bit error[3]
06	Cortex-M7_1 I-cache tag RAM [4]	Single-bit error, multi-bit error[3]
07	Cortex-M7_1 I-cache data RAM	Single-bit error, multi-bit error[3]
08	Cortex-M7_1 D-cache tag RAM	Single-bit error, multi-bit error[3]
09	Cortex-M7_1 D-cache data RAM	Single-bit error, multi-bit error[3]
10	Cortex-M7_0 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
11	Cortex-M7_0 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address
12	Cortex-M7_0 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[5]
13	Cortex-M7_1 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
14	Cortex-M7_1 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address

Table continues on the next page...

Table 240. ERM_0 channel mapping (continued)

Channel #	Module	Captured status
15	Cortex-M7_1 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[5]
16	DMA TCD	Single-bit error, multi-bit error, syndrome, offset error address[6]
17	Flash memory port p0	Single-bit error, multi-bit error, absolute error address
18	Flash memory port p1	Single-bit error, multi-bit error, absolute error address
19	Flash memory port p2 [7]	Single-bit error, multi-bit error, absolute error address

1. SRAM1 is not available for the S32K342, S32K312, and S32K311 product variants.
2. The size of SRAM0 is 160 KB, and therefore, to align addresses to the next power of 2, an address space of 256 KB is reserved for error reporting. However, SRAM0 and SRAM1 are in contiguous locations in the memory map. So, you must subtract 18000h (256 KB-160 KB = 96 KB that corresponds to 18000h) from the reported address to get an absolute address. See the "Memory and Memory Interfaces" chapter for SRAM details on different S32K3xx variants.
3. The cache controller does not report error addresses and syndrome.
4. Cortex-M7_1 and its associated RAM and caches are not available in the S32K312 and S32K311 product variants.
5. For address reporting, bit 2 of the address is masked because this bit decides whether the access (read or write) is for D0TCM or D1TCM. For example, if the offset address is 0h or 8h, it is routed to D0TCM, but if the offset address is 4h or Ch, it is routed to D1TCM. The errors that are latched for these offset addresses are as follows:
   - Offset 0h : Address 0h is latched into the ERM channel corresponding to D0TCM.
   - Offset 4h : Address 0h is latched into the ERM channel corresponding to D1TCM.
   - Offset 8h : Address 8h is latched into the ERM channel corresponding to D0TCM.
   - Offset Ch : Address 8h is latched into the ERM channel corresponding to D1TCM.
6. Bits [31:10] and [2:0] are always 0 because they are not connected.

   Bits [9:5] indicate the corresponding TCD out of all the 32 implemented TCDs.

   Bits [4:3] indicate an offset of TCDs with respect to a 64-bit aligned boundary.
   - If [4:3] is 00, it indicates that an error is on offset address 20h.
   - If [4:3] is 01, it indicates that an error is on offset address 28h.
   - If [4:3] is 10, it indicates that an error is on offset address 30h.
   - If [4:3] is 11, it indicates that an error is on offset address 38h.
7. Flash memory port p2 is not applicable for the S32K312 and S32K311 product variants.

NOTE

Table 241 is aplicable for S32K358 only.

Table 241. ERM_1 channel mapping

Channel #	Module	Captured status
0	SRAM2	single-bit error, multi-bit error, syndrome, absolute error address aligned to double, word (64-bit) boundary
1	-	-
2	CM7_2 I-cache tag RAM	single-bit error, multi-bit error
3	CM7_2 I-cache data RAM	single-bit error, multi-bit error
4	CM7_2 D-cache tag RAM	single-bit error, multi-bit error
5	CM7_2 D-cache data RAM	single-bit error, multi-bit error

21	-	-
22	-	-
23	-	-

NOTE

For S32K358, you have to enable both the ERM instance even if you are only using the one otherwise software might hang during interrupt subroutine.

49.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If memory supports ECC then ERM syndrome and error address information is captured along with error event. ERM does not receive this information in case of cache or memory with parity along with error event.

49.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

49.3 Functional description

49.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. This sequence describes how to use the option:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

49.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. This sequence describes how to use the option:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:

- Records the event and address and stores the ECC syndrome as usual.
- Additionally sends an interrupt notification corresponding to the event.

3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

49.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

49.5 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

NOTE

- See the chip-specific ERM information for details on Memory channel mapping.
- To access the channel registers, corresponding channel clocks must be enabled.

49.5.8 ERM Memory a Error Address Register (EAR0 - EAR19)

Offset

Register	Offset
EAR0	100h
EAR1	110h
EAR10	1A0h
EAR11	1B0h
EAR12	1C0h
EAR13	1D0h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
EAR14	1E0h
EAR15	1F0h
EAR16	200h
EAR17	210h
EAR18	220h
EAR19	230h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ERM_0	EAR0–EAR1 EAR10–EAR19	—
ERM_1	EAR0 EAR10–EAR12 EAR17	EAR1 EAR13–EAR16 EAR18–EAR19

EAR13–EAR16	0000_0000h
EAR17	ERM_0,ERM_1: 0000_0000h
EAR18–EAR19	0000_0000h

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

49.5.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

Register	Offset
SYN0	104h
SYN1	114h
SYN10	1A4h
SYN11	1B4h
SYN12	1C4h
SYN13	1D4h
SYN14	1E4h
SYN15	1F4h
SYN16	204h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

EOUT0	FCCU_ERR0
EOUT1	FCCU_ERR1

50.1.3 FCCU clocking

Table 244. FCCU clocking

FCCU clock signal	Chip clock signal
CLKSAFE	FIRC_CLK
CLKPRIM	AIPS_PLAT_CLK

50.1.4 FOSU timer interval

The FOSU_COUNT value determines the FOSU timer interval. On this chip, FOSU_COUNT is 69780h.

50.1.5 Supported internal chip reactions

The short functional reset discussed in this chapter is equivalent to the chip functional reset. See the interrupt map file attached to this document for interrupts from FCCU to NVIC.

NOTE

After STCU2 completes the self-testing procedure, the chip reboots and FCCU resets.

50.1.6 Supported FCCU EOUT fault output modes (protocols)

This chip supports only the Bistable protocol of FCCU EOUT, and does not support the other protocols discussed in this chapter, Dual-Rail and Time-Switching.

50.1.7 Recommended reaction programming for faults

You can upgrade or downgrade the reaction of the faults according to the recommended reaction discussed in the fault map file attached to this document.

In case you upgrade a reaction, no issues are expected in the behavior. If you downgrade the reaction, the functionality is not guaranteed.

This is the recommendation for faults caused by lockstep errors:

1. The recommended reaction for the lockstep error fault is a functional reset.
2. Program the core to perform the following steps after rebooting:
    a. Initialize TCM (because TCMs can become corrupted)
    b. Invalidate the cache (because caches can become corrupted)
3. Write 1 to the corresponding bit in FCCU.NCF_S0 register to clear the non-critical fault status.
4. If the FCCU fault gets cleared, you have nothing else to do for fault handling (this means, the FCCU lockstep error is recovered).
5. If the error persists, it indicates that the internal registers of the two cores have different values. To bring them to the same value, you could perform any of these steps:

a. Initialize destructive reset through software by using MC_ME.MODE_CONF[DEST_RST] to recover from lockstep. This initializes the FCCU with no pending faults.

b. Reconfigure the Cortex-M7 debug configurations (which would have been lost in previous step due to destructive reset in the system).

50.1.8 FCCU NCF handling architecture

This chip supports eight NCFs. Therefore, multiple faults of similar nature are ORed together and then connected as a single NCF to FCCU. To control individual fault, there are enable/disable controls provided within DCM in registers DCMRWD3, DCMRWD4 and DCMRWD5.

Similarly, the FCCU.NCF_S0 captures the status of fault within FCCU. This fault might have resulted due to any fault mapped on the corresponding FCCU NCF channel. The DCM status registers, DCMROD3, DCMROD4 and DCMROD5 capture the status of individual faults which are mapped onto FCCU NCFs. Figure 183 shows this arrangement.

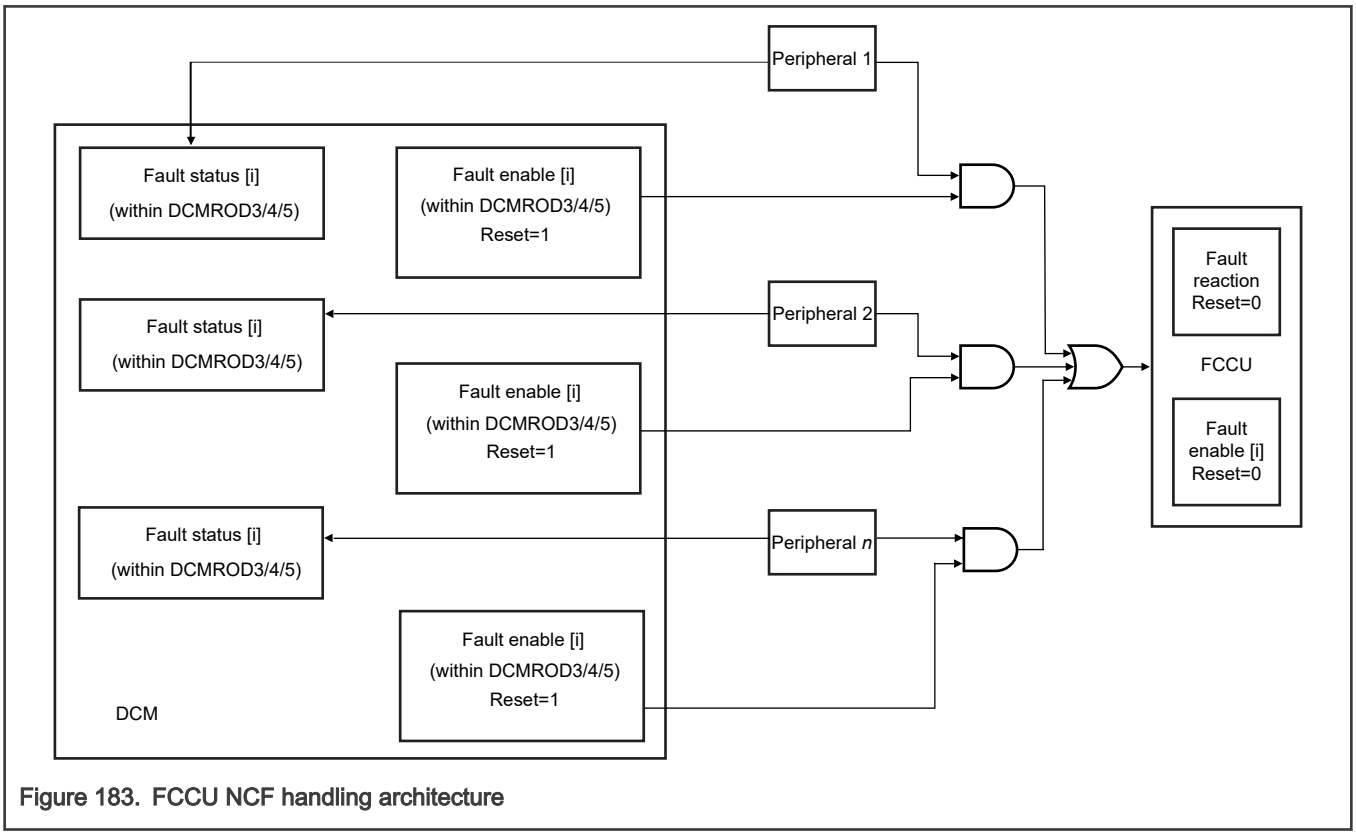

Figure 183. FCCU NCF handling architecture

50.2 Introduction

The FCCU provides a hardware interface to collect faults and to place the device into a safe state when a failure is detected in the device. No CPU intervention is requested for collection and control operations. FCCU offers a systematic approach to fault collection and control.

50.3 Features

The key features of the FCCU module are these:

- Management of non-critical faults
- HW or SW fault recovery management
- Fault collection from safety relevant modules on the device

- Fault injection (fake faults)
- Collection of test results
- Lockable configuration
  - Changes are only possible after entering the CONFIG state
  - Supports a transient and a permanent lock
  - Configuration changes observed by a watchdog timer
- Configurable fault control
- External reaction (FAULT state): EOUT signaling. Error indication via the pin(s) is controlled by FCCU.
- Internal chip reactions (ALARM state): interrupt request
- Configurable internal chip reactions for each NCF (FAULT state):
  - Short functional reset request pulse
  - NMI
  - No reaction
  - IRQ
- In Bi-Stable operational mode, one of the EOUT signals is high to indicate an OK operational state of FCCU.
- After power on, the EOUT signals have high impedance.[6] They indicate an operational state only after the software configures them.
- In case of a failure event or on software request for error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} (see DELTA_T[DELTA_T]), even if the software tries to release it before (for the case of error pin configured in Bi-Stable mode only).

The self-checking procedure checks the FCCU circuitry at the start up. The FCCU is operational with the default configuration immediately after the completion of the self-checking procedure. Internal (short functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the Configuration (CONFIG) state. FCCU is designed to function when CLKPRIM is faster than the CLKSAFE clocks.

50.4 Block diagram

The following figure represents a top-level diagram of the FCCU module.

[6] Actual value depends on device-specific setting at pad level.

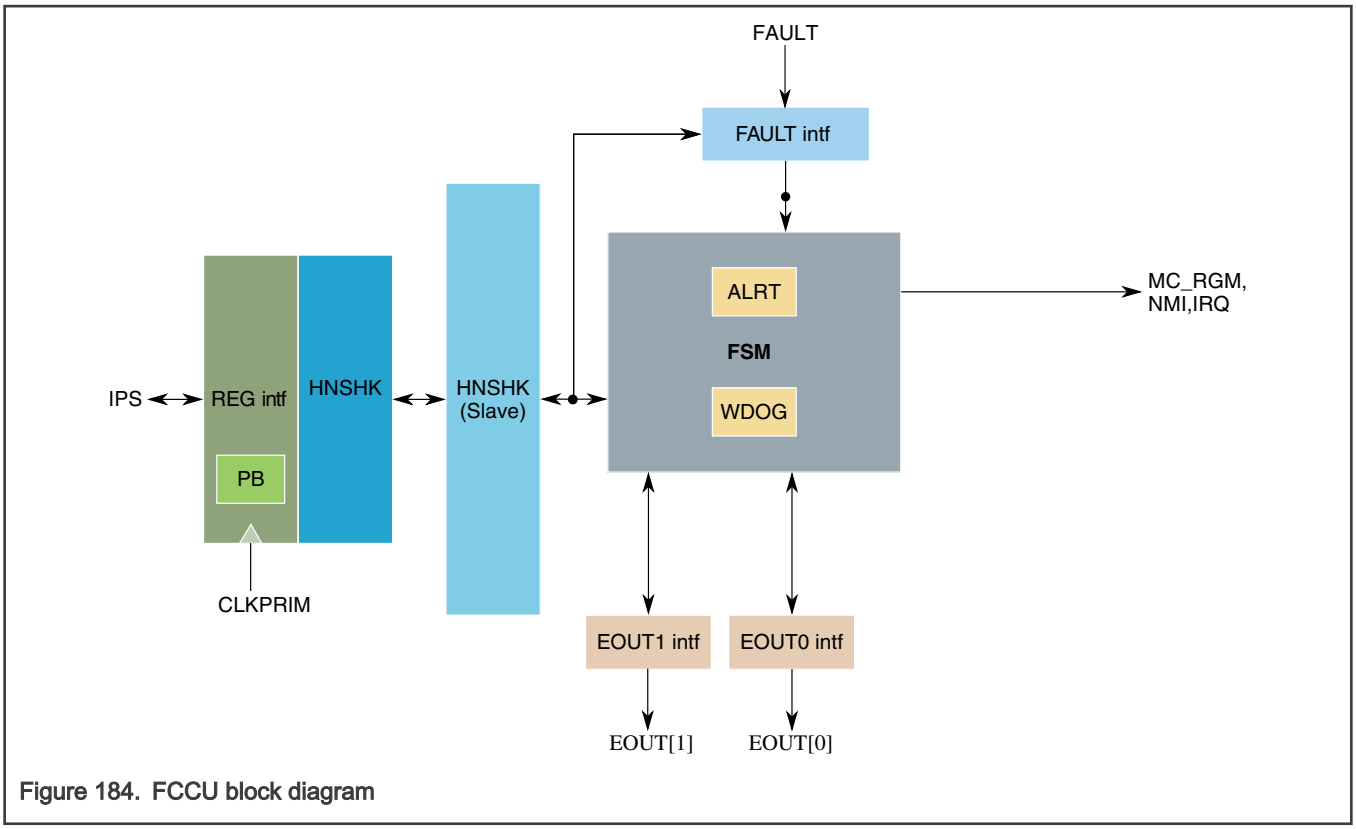

Figure 184. FCCU block diagram

This table describes the FCCU submodules.

Table 245. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM ability to support the handshake between the REG interface and the FSM unit because of the usage of two asynchronous clocks [CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)]
FSM unit	Implements the main functions of FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

50.5 Signal description

50.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Sensitivity	Clock
Clock and reset				
CLKPRIM	Input	Primary Clock—supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
Fault interface				
NCF[7:0]	Input	Non-critical Fault Channels—receive indications of non-critical faults from various sources. See the fault map file attached to this document.	Programmable	Asynchronous
EOUT interface				
EIN[1:0]	Input	Error Inputs—provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. FCCU captures the states in the EINOUT[EIN1] and EINOUT[EIN0] fields.	—	Asynchronous
EOUT[1:0]	Output	Error Outputs—indicate FCCU's condition (faulty, nonfaulty, or configuration) (or, for Fault-Toggle fault-output mode, faults only) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				
FIF	Output	FCCU In Fault—indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: *Case 1*	High	CLKSAFE0, CLKSAFE1

Table continues on the next page...

Table continued from the previous page...

Signal	Direction	Function	Sensitivity	Clock
		When the EOUT signals are programmed to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal until the EOUT signals are programmed not to be always low. *Case 2* When the EOUT signals are programmed not to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal when all of the following are true: • FCCU enters the FAULT state as the result of a fault. • If the fault is a non-critical fault, the associated EOUT_SIG_ENa[EOUTENn] field is set to enabled. FCCU deasserts this signal when FCCU leaves the FAULT state.		
Interrupt interface				
NMIOUT	Output	Non-maskable Interrupt Output—Sends a non-maskable interrupt request to the processor core or cores when FCCU enters the FAULT state as the result of a non-critical fault for which NMI is enabled as the reaction (NMI_ENa[NMIENn]).	Low	CLKPRIM

50.6 Functional description

50.6.1 Definitions

In general, the following definitions are applicable for fault management:

- HW recoverable fault: The fault indication is a level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: The fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition is corrected.

For details related to reset interface, see the reset interface section in the chip reference manual.

50.6.2 FSM description

The functionality of FCCU is depicted by the FSM state diagram (see Figure 185).

FCCU has four states that are identified with the following meaning:

- CONFIG: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, non-critical fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in the NORMAL state and if the configuration is not locked. A permanent configuration lock can be disabled by a reset that also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into TRANS_LOCK[TRANSKEY] (that is, other than BCh). To lock FCCU for configuration, write FFh to PERMNT_LOCK[PERMNTKEY].

  After the release of reset, the state of the transient lock is locked, and the state of the permanent lock is unlocked.

  The locking feature only restricts the FSM movement into CONFIG state. After the user enters the CONFIG state and then tries to lock the configuration, the locking of configuration is effective only after FCCU moves to the NORMAL state; it will not be effective in the current CONFIG state.

  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request for state change to NORMAL appears at the same time, watchdog timeout has the priority and hence the configuration registers (those that are writable only in the CONFIG state) are reset to their default values. The movement to the NORMAL state is made.

  The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when FCCU is moved to the NORMAL state, according to the new configuration.

  All pending faults that occur during the CONFIG state result in both of the following:

  — Highest-priority state transition

  — Interrupt generation (NMI or alarm IRQ)

  If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or non-pending faults) that occurred during the CONFIG state.

- NORMAL: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

  — Unmasked non-critical faults with the timeout disabled: FCCU moves to the FAULT state.

  — Unmasked non-critical faults with the timeout enabled: FCCU moves to the ALARM state.

  — Masked non-critical faults: FCCU stays in the NORMAL state.

- ALARM: FCCU moves into the ALARM state when an unmasked non-critical fault occurs and the timeout is enabled. Transition to the ALARM state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the FAULT state. The timeout is reinitialized if FCCU enters the NORMAL state. The timeout restarts following the recovery from the FAULT state.

- FAULT: FCCU moves into the FAULT state when one of the following condition occurs:

  — Timeout related to a non-critical fault when FCCU is in the ALARM state

  — Unmasked non-critical faults with the timeout disabled

The transition from the NORMAL or ALARM to the FAULT state goes along with the generation of:

- Internal chip reaction—NMI interrupt (optional)
- External reaction—EOUT signaling (optional)
- Internal chip reaction—SW option: Soft reaction (Short functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed to all cores.

After moving to the FAULT state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time.

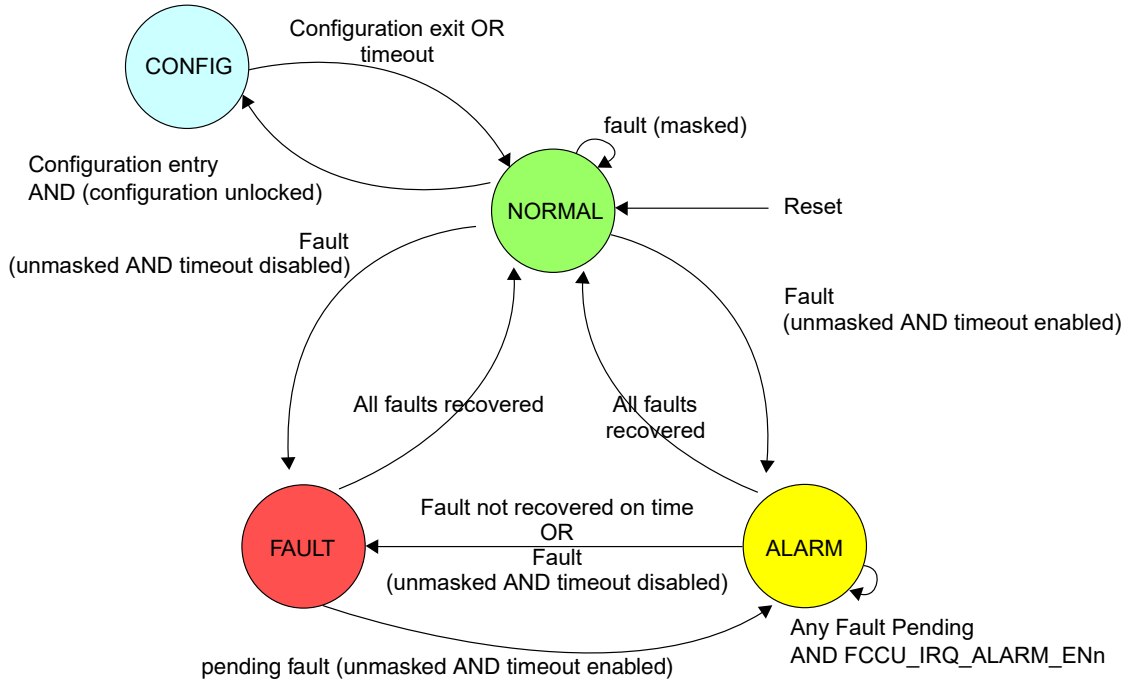

Figure 185. FCCU state diagram

50.6.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU remains in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU moves to the ALARM state (if any non-critical fault is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case, the NCF timer is stopped until the FAULT state is recovered. If FCCU is in the ALARM state and another fault occurs, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

50.6.4 Fault recovery

The following timing diagrams describe the main use cases of FCCU in terms of fault events and related recovery.

A typical sequence related to non-critical fault management (ALARM state), see Figure 186 and Figure 187, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)

- Timeout running

3. System state: RUN
4. Alarm interrupt management: fault recovery
   - FCCU state transition: ALARM to NORMAL

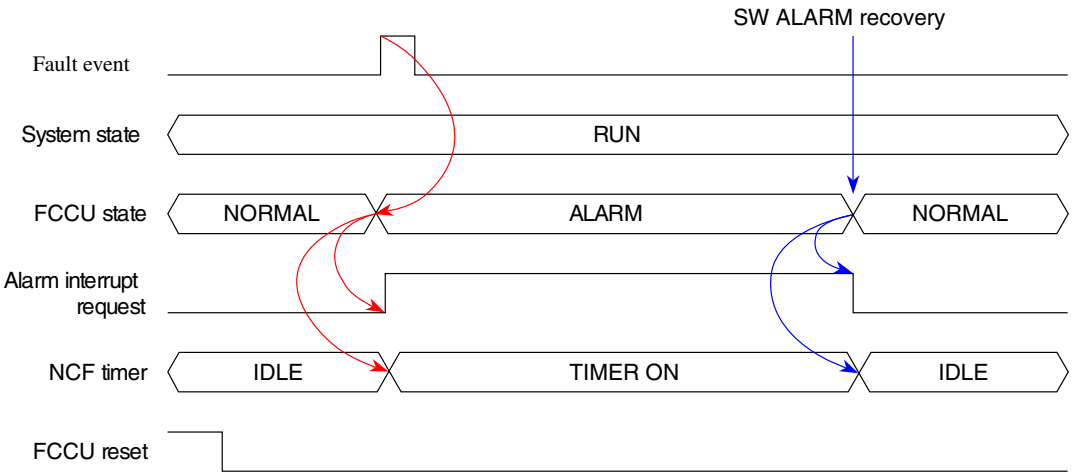

Figure 186. Non-critical fault (ALARM state) SW recovery

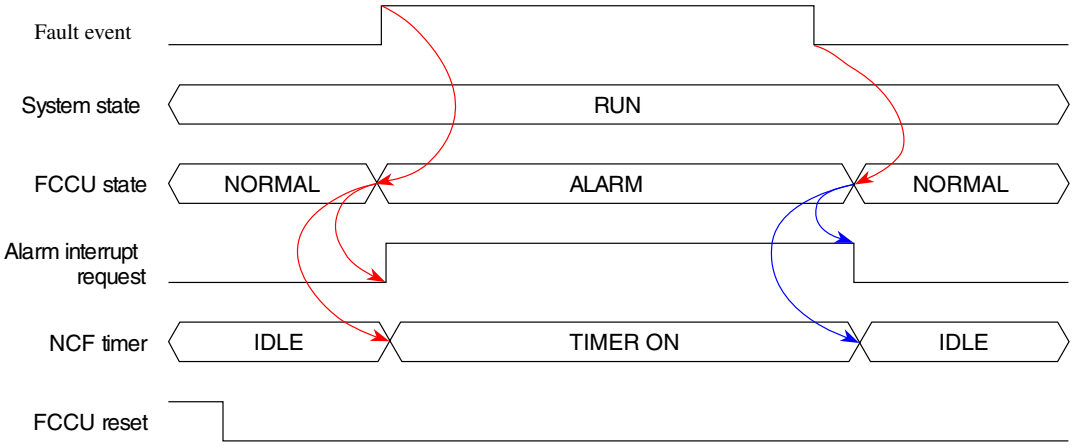

Figure 187. Non-critical fault (ALARM state) HW recovery

A typical sequence related to non-critical fault management (ALARM to FAULT state), see Figure 188, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. FCCU state transition (following the timeout trigger): ALARM to FAULT
   - NMI assertion (if enabled)
4. NMI interrupt management (if enabled)
   - Fault recovery (by software): FCCU state transition: FAULT to NORMAL

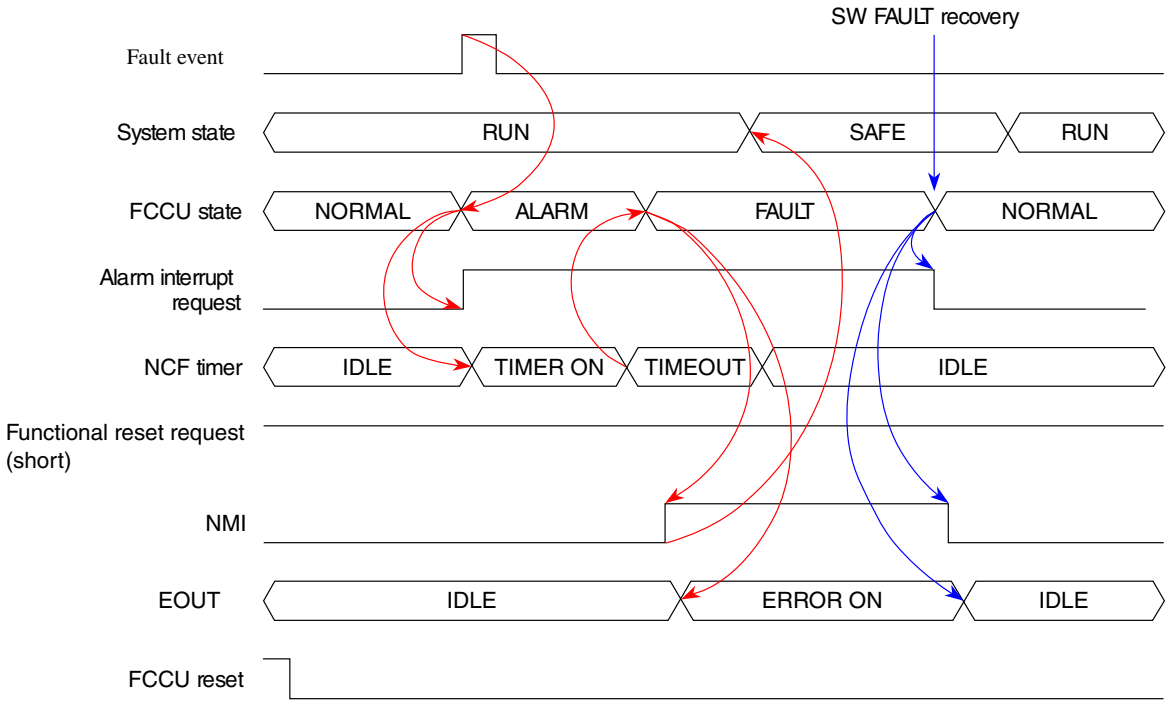

Figure 188. Non-critical fault (ALARM to FAULT state) recovery

50.6.5 EOUT interface

Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition (or, for Fault-Toggle fault-output mode, faults only) to off-chip logic.

NOTE

For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	All of the following are true: • The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works in Bi-Stable fault-output mode). • FCCU is in FAULT state.
Nonfaulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in ALARM or NORMAL state.

Table continues on the next page...

Table continued from the previous page...

Condition	Description
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in CONFIG state.

How the fault-output (EOUT) timer works in Bi-Stable fault-output mode

In Bi-Stable fault-output mode (FOM), FCCU starts the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable FOM, and the EOUT signals are not programmed to be always low (CFG[FCCU_SET_CLEAR]).
- The EOUT timer is not already running.
- FCCU enters the FAULT state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- If FCCU is in the CONFIG state: FCCU does not restart the EOUT timer.
- If FCCU is in the NORMAL or ALARM state:
  - And ALARM state is enabled for the fault (non-critical): FCCU enters (or remains in) the ALARM state but does not restart the EOUT timer.
  - And ALARM state is disabled for the fault (non-critical): FCCU enters the FAULT state and restarts the EOUT timer.
- If FCCU is in the FAULT state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), and T_{min} (see DELTA_T[DELTA_T]) has expired.
- All faults that caused FCCU to enter or remain in the FAULT state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to the NORMAL state.

How the fault-output (EOUT) timer works in Fault-Toggle fault-output mode

In Fault-Toggle fault-output mode, FCCU initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]) and begins decrementing the timer when any of the following are true:

- FCCU enters the FAULT state as the result of a fault.
- In FAULT state, a fault occurs while the EOUT timer is 0 (idle).
- In FAULT state, a fault occurs while the EOUT timer is running because of a previous fault (also called a pending fault), and then in any state the EOUT timer reaches 0 (idle).

FCCU stops the EOUT timer when it reaches 0 (idle).

Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bi-Stable or Fault-Toggle fault-output mode (CFG[FOM]), ensure that the EOUT signals are controlled by FCCU's FSM (CFG[FCCU_SET_CLEAR]).
- Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]).

NOTE

If the EOUT signals are in Bi-Stable or Fault-Toggle fault-output mode, you must deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states.

More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (CFG[FOM]):

- Bi-Stable
- Fault-Toggle

NOTE

See the chip-specific FCCU information for the fault-output modes supported by this chip.

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Configuration mode	CFG[CM]	Different
Polarity selection	CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

EOUT frequency: This frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

$$EOUT_{freq} = \frac{CLKSAFE_{freq}}{2^{18}}$$

For example, with a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time (T_{min}), even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked even when software has set the error signal to high. Also, if the error signals are forced to low by software by writing to CFG[FCCU_SET_CLEAR], then the signals shall remain low (or high) for the entire duration of T_{min}. During the T_{min} by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to the CONFIG state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_{min} interval to expire, after which the FCCU automatically enters the NORMAL state and the error signal indicates OK.

In case another failure event happens within T_{min} after a first one, the T_{min} counter is restarted.

50.6.5.1 Bi-Stable protocol

The encoding scheme is provided in Table 246 and the related timing diagram is shown in Figure 189.

Table 246. Bi-Stable encoding

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Nonfaulty	Static 01	Static 10
Faulty	Static 10	Static 01

Table continues on the next page...

Table 246. Bi-Stable encoding (continued)

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Reset	High-impedance (no toggling)[1]	High-impedance (no toggling)
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0)	High-impedance (no toggling)[2]	High-impedance (no toggling)
Configuration (When CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1)	Static 01	Static 10

1. Final value depends on device specific settings at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

NOTE

Figure 189 is formatted to display the behavior in all four conditions (reset, nonfaulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

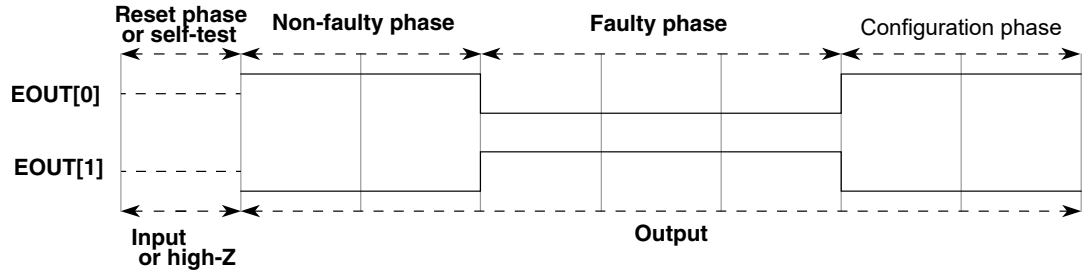

Figure 189. Bi-Stable protocol

50.6.5.2 Fault-Toggle protocol

The Fault-Toggle protocol uses the EOUT signals to indicate only the occurrences of faults, not FCCU's condition like the other protocols. In Fault-Toggle fault-output mode, when controlled by the FSM (CFG[FCCU_SET_CLEAR]), the EOUT signals:

- Have opposite states
- Toggle their states to indicate a fault and then maintain those new states for at least T_{min} (see DELTA_T[DELTA_T]), after which they are free to toggle to indicate another fault

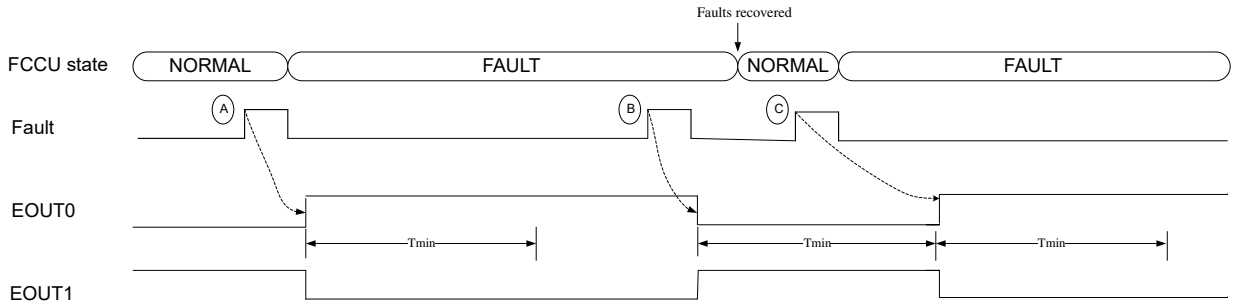
FCCU uses the fault-output (EOUT) timer to measure T_{min}. For more information, see How the fault-output (EOUT) timer works in Fault-Toggle fault-output mode.

The EOUT polarity selection (CFG[PS]) determines the initial states of the EOUT signals, which FCCU applies after you deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]).

If two or more faults occur while the EOUT timer is running, then the EOUT signals toggle only once after the EOUT timer reaches zero (idle). In other words, FCCU can pipeline only one fault.

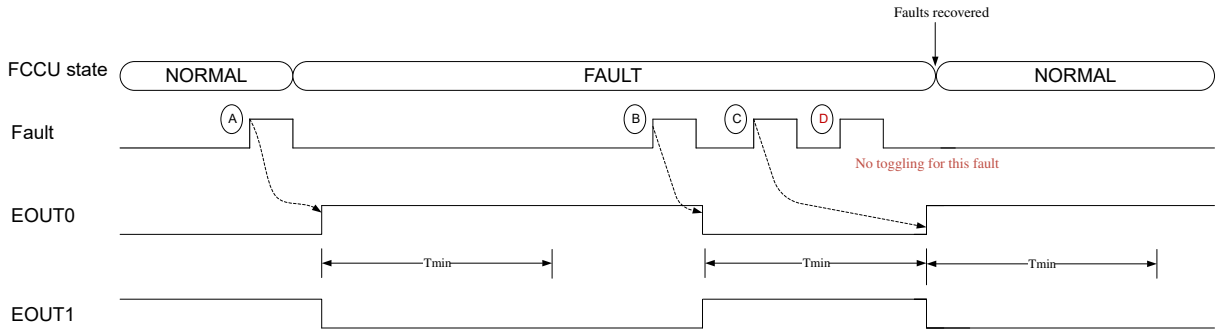
Note that FCCU does not toggle the EOUT signals in CONFIG state. FCCU toggles the EOUT signals only when FCCU enters the FAULT state or when a fault occurs in the FAULT state.

Example 1



Stage	Description
1	A fault source indicates fault A to FCCU.
2	FCCU enters the FAULT state.
3	FCCU toggles the EOUT signals in response to fault A, initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]), and begins decrementing the timer.
4	A fault source indicates fault B to FCCU while FCCU is still in the FAULT state.
5	The EOUT timer has already reached 0 (idle), so FCCU toggles the EOUT signals in response to fault B, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.
6	The source (for hardware-recoverable faults) and software (for software-recoverable faults) recovers the faults.
7	FCCU enters the NORMAL state.
8	A fault source indicates fault C to FCCU.
9	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are.
10	When the EOUT timer reaches 0 (idle), FCCU toggles the EOUT signals in response to fault C, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.

Example 2



Stage	Description
1	A fault source indicates fault A to FCCU.
2	FCCU enters the FAULT state.
3	FCCU toggles the EOUT signals in response to fault A, initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]), and begins decrementing the timer.
4	A fault source indicates fault B to FCCU while FCCU is still in the FAULT state.
5	The EOUT timer has already reached 0 (idle), so FCCU toggles the EOUT signals in response to fault B, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.
6	A fault source indicates fault C to FCCU while FCCU is still in the FAULT state.
7	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are. Fault C is now *pending*.
8	A fault source indicates fault D to FCCU while FCCU is still in the FAULT state. (FCCU can pipeline only one fault, so FCCU ignores fault D.)
9	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are.
10	When the EOUT timer reaches 0 (idle), FCCU toggles the EOUT signals in response to fault C, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer. FCCU never toggles the EOUT signals in response to fault D because FCCU can pipeline only one fault.

50.7 Prepare FCCU for configuration

50.7.1 Introduction

You prepare FCCU for configuration by first configuring the CONFIG state and then putting FCCU in that state.

50.7.2 About preparing FCCU for configuration

When preparing FCCU for configuration, keep the following in mind:

- To put FCCU in CONFIG state, FCCU must be in NORMAL state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in the CONFIG state.
- When FCCU is in the CONFIG state, FCCU does not actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in the NORMAL state. If FCCU automatically leaves the CONFIG state and enters the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

50.7.3 Configure the CONFIG state

1. Set the Configuration-state timeout interval (CFG_TO[TO]).
2. Enable the Configuration-state-timeout interrupt signal (IRQ_EN[CFG_TO_IEN]), if you want FCCU to request an interrupt when a Configuration-state timeout occurs.

50.7.4 Put FCCU in the CONFIG state

1. Unlock the configuration temporarily (TRANS_LOCK[TRANSKEY]) in Supervisor mode.
2. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is CONFIG, FCCU is in the CONFIG state. Stop.
   - If the FCCU status is NORMAL, go to step 3.
   - If the FCCU status is ALARM or FAULT, go to step 5.
3. Run the OP1 operation (see Run an operation).
4. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the CONFIG state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 7.
5. Recover all faults (see Fault recovery).
6. Go to step 2.
7. Reset FCCU.

50.8 Configure FCCU

50.8.1 Introduction

You configure FCCU so it functions according to the needs of your particular application.

50.8.2 About configuring FCCU

When configuring FCCU:

- If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state when necessary but does not perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in the NORMAL state when a fault occurs on the channel, FCCU does not enter the ALARM or FAULT state and therefore does not perform any reaction.

50.8.3 Configure the non-critical fault channels

For each non-critical fault channel that you want FCCU to monitor:

1. Set the recovery type (NCF_CFGa[NCFCn]).
2. Enable at least one type of Fault-state reaction:
   - Chip functional reset (NCFS_CFGa[NCFSCn])
   - Non-maskable interrupt (NMI_ENa[NMIENn])
   - EOUT signaling (EOUT_SIG_ENa[EOUTENn])

   NOTE

   If you enable the chip functional reset as the type of Fault-state reaction for a channel, enable at least one other type of Fault-state reaction for the channel or enable the ALARM state (step 4) for the channel.
3. Set the Alarm-state timeout interval (NCF_TO[TO]), if you plan to enable the ALARM state for any non-critical fault channel.

   NOTE

   Ensure that the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timeout interval (FOSU_COUNT) is a chip-specific value. See the chip-specific FCCU information.
4. Enable the ALARM state (NCF_TOEa[NCFTOEn]) for any non-critical fault channel for which you want FCCU to enter the ALARM state before entering the FAULT state.
5. Enable the Alarm-state reaction (IRQ_ALARM_ENa[IRQENn]) for each non-critical fault channel for which you enabled the ALARM state.
6. Enable the corresponding NCF_Ea[NCFEn] field for each non-critical fault channel that you want FCCU to monitor.

50.9 Put FCCU in the NORMAL state

50.9.1 Introduction

You put FCCU in the NORMAL state to save changes to the configuration, and to allow FCCU to enter the ALARM or FAULT state when a fault occurs on an enabled fault channel.

50.9.2 About putting FCCU in NORMAL state

When putting FCCU in the NORMAL state:

- If you attempt to lock the configuration while FCCU is in CONFIG state, FCCU does not actually lock the configuration until FCCU leaves CONFIG state—that is, either you put FCCU in the NORMAL state, or FCCU puts itself in the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in the CONFIG state.

50.9.3 Put FCCU in the NORMAL state

1. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is NORMAL, go to step 6.
   - If the FCCU status is CONFIG, go to step 2.
   - If the FCCU status is ALARM or FAULT, go to step 4.
2. Run the OP2 operation (see Run an operation).
3. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the NORMAL state. Go to step 6.

- If the operation status is Aborted, go to step 2.

4. Recover all faults (see Fault recovery).
5. Go to step 1.
6. Lock the configuration if you want to prevent any changes to it:
   - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANS_LOCK[TRANSKEY]).
   - To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNT_LOCK[PERMNTKEY]).

     The configuration is permanently locked until FCCU is reset.

50.10 Manage faults

50.10.1 Introduction

After saving changes to the configuration, you are ready to use FCCU to manage faults.

50.10.2 Determine if there are any unrecovered non-critical faults

Check the unrecovered-fault indicators for the non-critical faults (NCF_Sa[NCFSn]).

50.10.3 Recover a software-recoverable non-critical fault

1. Resolve the source of the software-recoverable non-critical fault.
2. Unlock the NCF_Sa registers (NCFK[NCFK]) using a 32-bit write.
3. Initiate clearing of the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]) using a 32-bit write.

   FCCU initiates the OP12 operation.

   NOTE

   If you want to clear multiple unrecovered-fault indicators and those indicators reside in different NCF_Sa registers, you must perform steps 2 and 3 for each individual register.

4. Check the operation status (CTRL[OPS]).
   - If the operation status is In Progress, go to step 4.
   - If the operation status is Successful, go to step 5.
   - If the operation status is Aborted, go to step 2.
5. Check the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]).
   - If the indicator indicates no unrecovered fault, the fault has been recovered. Stop.
   - If the indicator still indicates an unrecovered fault, go to step 2.

50.10.4 Clear the freeze-status indicators

1. Run the OP13 operation (see Run an operation).
2. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, stop .
   - If the operation status is Aborted, go to step 1.

50.11 Run operations

50.11.1 Introduction

You run operations to perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For a complete list of operations you can run, see CTRL[OPR].

50.11.2 About running operations

When running operations:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are locked again.

50.11.3 Run an operation

1. Check the operation status (CTRL[OPS]).
2. Go to step 1 if the operation status is In Progress.
3. Unlock the operation (CTRLK[CTRLK]) using a 32-bit write, if the operation must be unlocked before you can initiate it.

   NOTE

   The Control Key (CTRLK) register used in this step and the Control (CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (CTRL[OPR]) using a 32-bit write.
5. Check the operation status (CTRL[OPS]).
6. Go to step 5 if the operation status is In Progress.

The operation status is now Idle (OP15 only), Aborted, or Successful.

50.12 FOSU

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU's behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from FCCU which indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during the CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: short functional reset
- IRQ (triggered by ALARM state)
- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared to ensure that the timer is not restarted because of faults still 'stuck' in the capture logic. The timer is then restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at DEST0. The FOSU module is reset with the same reset as is used by the FCCU. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times out without reaction.

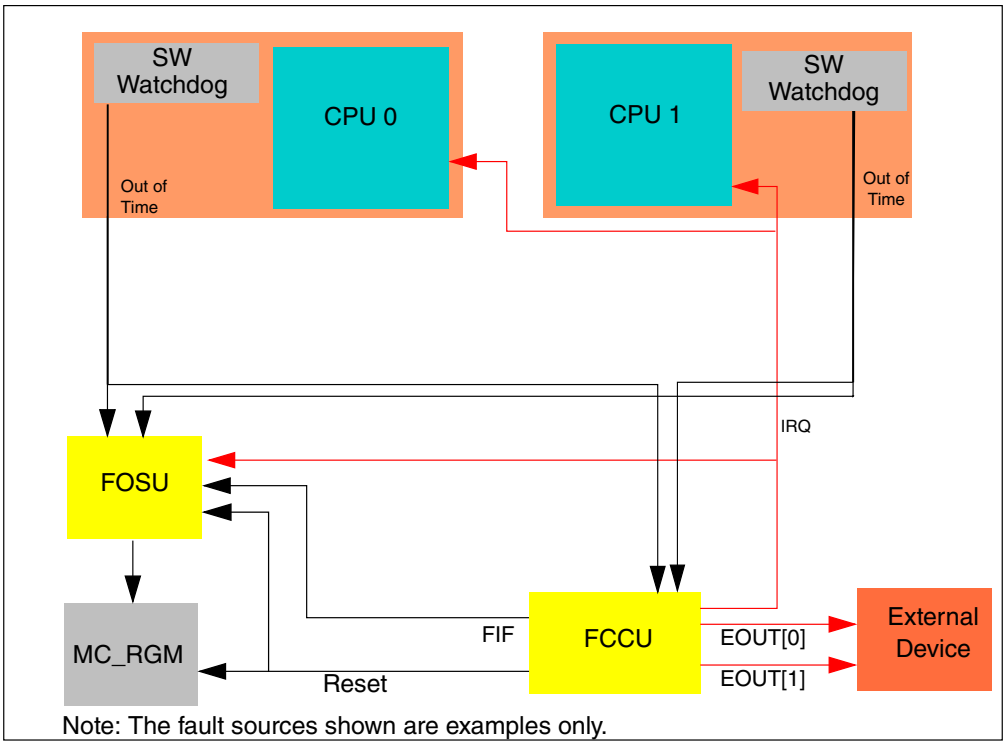


Figure 190. FOSU connections to the FCCU and MC_RGM

50.13 Use cases and limitations

Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a non-critical fault channel:
  - Enable the channel (Non-critical Fault Enable (NCF_E0)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (Non-critical Fault-State Configuration (NCFS_CFG0)), fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)), or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable chip reset as the type of Fault-state reaction for the channel (Non-critical Fault-State Configuration (NCFS_CFG0)), enable either ALARM state (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (Non-critical Fault-State EOUT

Signaling Enable (EOUT_SIG_EN0)) or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).

— If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), enable the Alarm-state reaction (Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)).

— If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), make sure the Alarm-state timer interval (Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

Recommendations to configure FCCU

1. After a power on, or 'destructive' reset (when initiated by the assertion of the chip reset pin, RESET_B), where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out T_{min} to expire
   b. Check and clear fault status
   c. Error pin moves to "non faulty" state, once fault status is cleared and T_{min} expires
   d. Verify FCCU is in NORMAL state, else repeat step(a) above
   e. Read and verify value in NCF_En
   f. Reconfigure FCCU, if necessary

50.14 Register descriptions

50.14.1 FCCU register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Do not read from or write to any addresses that are not shown in the following table. Doing so may or may not result in a transfer error.
- Do not write to any of the configuration registers unless FCCU is in the CONFIG state. Doing so results in a transfer error.
- Do not write to the Transient Configuration Lock (TRANS_LOCK) or Permanent Configuration Lock (PERMNT_LOCK) registers unless your code runs in the Supervisor mode. Doing so results in a transfer error.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short functional resets.

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28-10 —	Reserved
9 DEBUG	Debug Mode Enable Specifies whether the Debug mode is enabled. If so, FCCU enters the Debug mode when the Debug signal is asserted. When FCCU enters the Debug mode, it halts operation and remains in the state it was in before it entered this mode. **NOTE** FOSU does not halt when FCCU enters the Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in the Debug mode. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
8 —	Reserved
7-6 OPS	Operation Status This field can be read and cleared (via OP15 operation) by the software. 00b - Idle 01b - In progress 10b - Aborted 11b - Successful
5 —	Reserved
4-0 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (CTRL[OPS]) is "In progress". After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (CTRL[OPS]) of "Aborted": • Writing to a NCF_Sa register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK[NCFK]) • Initiating an OP1 operation when FCCU is not in the NORMAL state or the configuration is locked • Initiating an OP1, or OP2, operation without first unlocking the operation (CTRLK[CTRLK]) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in the NORMAL state, and immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the CONFIG state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the NORMAL state. 00011 Reserved 00100 Reserved 00101 Reserved 00110 Reserved 00111 Reserved 01000 Reserved 01001 Reserved 01010 Reserved

Fields

Field	Function
31-0 CTRLK	Locked-Operation Control Key Writable only with a 32-bit write. Unlocks locked operations (CTRL[OPR]) so you can initiate them. For information on how to unlock locked operations before you initiate them, see Run an operation. **NOTE** • You must initiate an operation in the FCCU register access that immediately follows the one that unlocks it; otherwise, the operation is again locked. • Reading from this register always returns the value 0000_0000h. Operations not listed here are not locked and do not need to be unlocked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. Any other value: Do nothing.

50.14.1.4 Configuration (CFG)

Offset

Register	Offset
CFG	8h

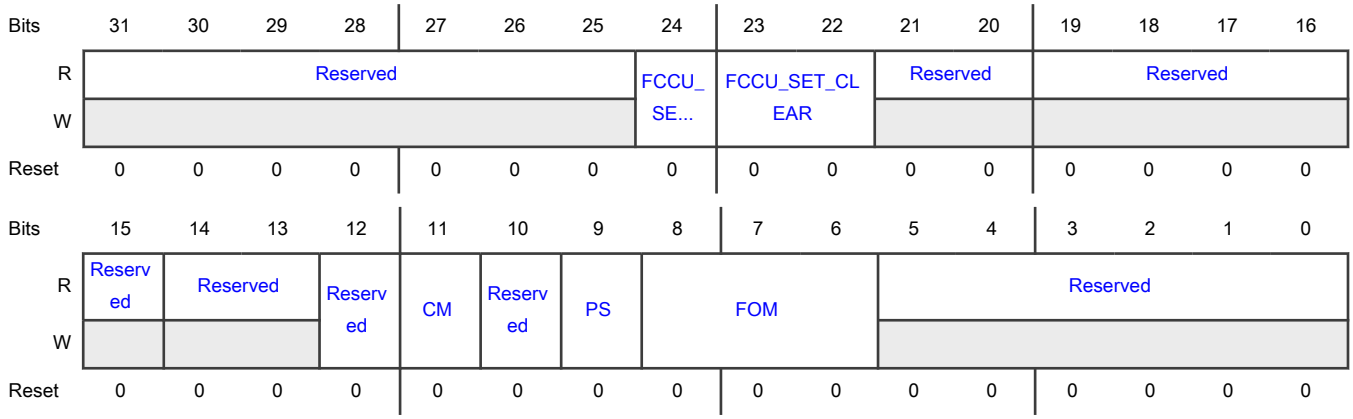
Function

Writable only when FCCU is in the CONFIG state. Changed by FCCU to another value when the chip resets FCCU, a Configuration-state timeout occurs, or you run an OP31 operation. See CFG register bit value at different events for more information. Specifies the global configuration for FCCU.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU does not use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Diagram



Fields

Field	Function
31-25 —	Reserved
24 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0b - Inactive (the EOUT signals are in a high-impedance state) 1b - Active (the EOUT signals indicate FCCU's condition)
23-22 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only to Bi-Stable and Fault-Toggle fault-output modes (CFG[FOM]) and when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). Controls whether the fault-output (EOUT) signals are managed by FCCU's FSM. **NOTE** When the EOUT signals are in the Fault-Toggle fault-output mode, if you change the value of this field, you must also deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states. 00b - Controlled by the FSM 01b - Always low 10b - Controlled by the FSM 11b - High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.

Fields

Field	Function
31-0 TO	Non-critical-Fault Alarm-State Timeout Interval Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls the maximum amount of time that FCCU can be in the ALARM state ($T_{\text{Max Alarm}}$) according to this equation:

Table continues on the next page...

Field	Function
	$T_{Max\ Alarm}$ = TO × $T_{CLKSAFE}$ where $T_{CLKSAFE}$ is the safe-clock period. If FCCU enters the ALARM state (because a fault occurs on an enabled non-critical fault channel for which the ALARM state is enabled) and this timeout interval expires (called an Alarm-state timeout), then FCCU leaves the ALARM state and enters the FAULT state. **NOTE** Make sure the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, a fault that occurs while FCCU is in the ALARM state can cause FOSU to generate a chip reset. The FOSU timeout interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

50.14.1.12 Configuration-State Timeout Interval (CFG_TO)

Offset

Register	Offset
CFG_TO	B8h

2-0	Configuration-State Timeout Interval

Table continues on the next page...

Table continued from the previous page...

Field	Function
TO	Writable only when FCCU is in the NORMAL, ALARM, or FAULT state (not in the CONFIG state). Changed by FCCU to its reset value when a Configuration-state timeout occurs. Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in the CONFIG state ($T_{Max\ configuration}$) according to this equation: $T_{Max\ configuration} = T_{CLKSAFE} \times 2^{(TO + 13)}$ where $T_{CLKSAFE}$ is the safe-clock period. If you put FCCU in the CONFIG state and this timeout interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves the CONFIG state and enters the NORMAL state • Changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (CFG) register's Configuration-state-timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

50.14.1.13 IO Control (EINOUT)

Offset

Register	Offset
EINOUT	BCh

Function

The EINOUT register allows the following operations typically in the NORMAL state:

- To control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (CFG[FOM])
- To control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (CFG[FOM])
- to observe the state of signals at EIN[1:0] pins

The following table shows Bi-Stable encoding.

Table 247. Bi-Stable encoding

Mode = CFG[FOM]	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Because of the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the EINOUT register.

50.14.1.19 Non-critical Fault Fake (NCFF)

Offset

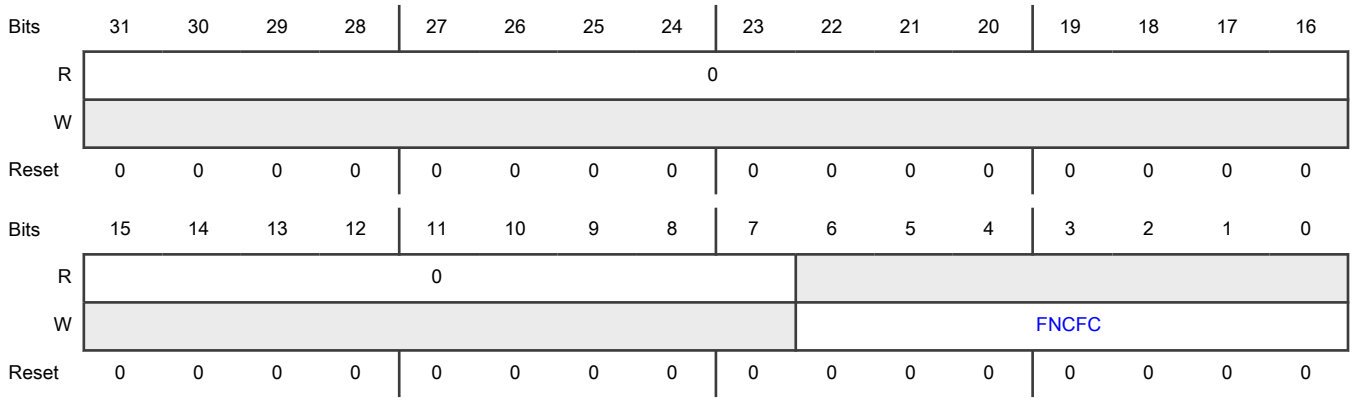
Register	Offset
NCFF	DCh

Function

This register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by injecting the fault directly in the FAULT root, to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked.

This is a write-only register with a set of codes corresponding to each non-critical fault injection.

Diagram



Fields

Field	Function

50.14.1.20 IRQ Status (IRQ_STAT)

Offset

Register	Offset
IRQ_STAT	E0h

Function

This register provides the FCCU interrupt status related to the following events:

- Configuration-state timeout error
- Alarm interrupt
- NMI interrupt

The configuration-state timeout interrupt is asserted if both IRQ_STAT[CFG_TO_STAT] and IRQ_EN[CFG_TO_IEN] bits are asserted. It is cleared when a 1 is written to the IRQ_STAT[CFG_TO_STAT] bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the IRQ_STAT trace the status of the related interrupt lines.

R	0								EOUT EN7	EOUT EN6	EOUT EN5	EOUT EN4	EOUT EN3	EOUT EN2	EOUT EN1	EOUT EN0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 EOUTENn	Non-critical Fault-State EOUT Signaling Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Applies only when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). When FCCU is configured for Bi-Stable fault-output mode (CFG[FOM]), controls whether EOUT signaling is enabled as a Fault-state reaction for the associated non-critical fault channel (n). (For other fault-output modes, EOUT signaling is always enabled, regardless of the value of this field.) When EOUT signaling is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to indicate the faulty condition on the EOUT[1:0] signals when FCCU enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. For all fault-output modes, also controls whether FCCU asserts the FIF signal when a fault on the associated non-critical fault channel (n) causes FCCU to enter the FAULT state. **NOTE** For all fault-output modes, you must set this field to enabled to ensure that FCCU asserts the FIF signal when FCCU enters FAULT state as the result of a fault on the associated non-critical fault channel (n) so the FOSU module does not mistakenly generate a destructive chip reset. 0b - In Bi-Stable fault-output mode, both EOUT signaling and FIF assertion are disabled; in other fault-output modes, EOUT signaling is enabled and FIF assertion is disabled. 1b - Both EOUT signaling and FIF assertion are enabled in all fault-output modes.

50.14.1.28 Alarm-State Timer (TMR_ALARM)

Offset

Register	Offset
TMR_ALARM	12Ch

Function

See TMR_ALARM[COUNT].

This table shows how the Alarm-state timer's state and value vary by FCCU state:

50.14.2 Configuration registers

50.14.2.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in CONFIG state (see Put FCCU in the CONFIG state).
- Save the values you write to them while FCCU is in CONFIG state only after you manually put FCCU in NORMAL state. If FCCU automatically leaves CONFIG state and enters NORMAL state because the configuration-timer interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value; FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events.

50.14.2.2 Configuration registers

Following is the list of configuration registers in this module. They are listed in an offset order from lowest to highest.

- Configuration (CFG)
- Non-critical Fault Configuration (NCF_CFGa)
- Non-critical Fault-State Configuration (NCFS_CFG0)
- Non-critical Fault Enable (NCF_E0)
- Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)
- Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)
- Delta T (DELTA_T)
- Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)
- Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)
- Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)

50.14.3 CFG register bit value at different events

In this chip, there are no events that affect the bits in the configuration register.

50.15 Glossary

CF	Critical fault
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
intf	Interface
IRQ	Interrupt request
NCF	Non-critical fault
NMI	Non-maskable interrupt

Chapter 51
Self-test General-Purpose Registers (SELFTEST_GPR)

51.1 Introduction

SELFTEST_GPR configures the STCU2 LBIST shift cycles. Programming self-test GPRs is a part of the self-test programming sequence. See the "Self-test programming sequence" section in the STCU2 chapter.

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that have been validated by NXP for in-field testing usage.

The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

The values for SELFTEST_GPR registers must be aligned with the NXP supported configurations only.

NOTE

SELFTEST_GPR is not present in S32K312 and S32K311.

NOTE

While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled, i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

51.2 Peripheral shift clock switching (PCS)

The PCS feature is used to avoid current surges at the start and/or end of LBIST. Since LBIST can cause sudden current surges which might lead to chip malfunction.

With PCS enabled, there are additional (SELFTEST_GPR.CONFIG_GPR[PCS_STEP_SIZE] + 1)*16 patterns beyond the configured count. If enabled at the start of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_START]), it would cause the shift clock to scale up in this duration from divide by 16 to the original frequency (by changing divider in each step).

Similarly, if configured at the end of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_END]), the shift clock frequency will be scaled down from original frequency to divide by 16.

51.3 SELFTEST_GPR register descriptions

51.3.1 SELFTEST_GPR memory map

SELFTEST_GPR base address: 403B_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Configuration register (CONFIG_REG)	32	RW	0000_ADD5h
14h	LBIST Program (LBIST_PROG_REG)	32	RW	0003_0050h

51.3.2 Configuration register (CONFIG_REG)

15-9 —	Reserved
8 PCS_ENABLE_END	PCS Enable End Enables Progressive Shift Clock Switching for LBIST at end. The feature gets enabled when this bit is set to 1. It is recommended to run LBIST patterns by enabling this feature.
7 PCS_ENABLE_START	PCS Enable Start Enables Progressive Shift Clock Switching for LBIST at start. The feature gets enabled when this bit is set to 1. It is recommended to run LBIST patterns by enabling this feature.
6-4	PCS Step Size pcs_step_size[2:0] controls the step size for progressive increase of shift frequency:

51.3.3 LBIST Program (LBIST_PROG_REG)

Offset

Register	Offset
LBIST_PROG_REG	14h

Function

Configures the LBIST shift count.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved								LBIST_SHIFT_COUNT							
Reset	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 LBIST_SHIFT_COUNT	LBIST Shift Count Specifies the number of shift cycles in a scan chain in one pattern count for the LBIST partition.

51.4 Glossary

BIST clock	The BIST clock refers to the BIST operational clock which is the clock source used while LBIST is operational by the LBIST controller, which is the MC_CGM clock node LBIST_CLK for the chip. See the system block diagram for details.
LBIST	Logic built-in self-test
Pattern count	The pattern count refers to an empirically determined value of shift patterns run in LBIST on a scan chain to result in predetermined fault coverage, based on device safety integrity level. Since the LBIST scheme is Pseudo Random Testing, a sufficiently good value of pattern count is used which provides the required fault coverage.
Scan chain	A sequential chain of flops in scan mode over which one scan pattern (generated by PRPG, that is, Pseudo Random Pattern Generator) in LBIST will be shifted and the output MISR (Multi Input Signature Register) will be matched with earlier known value to determine pass or fail criterion of that particular chain.

Chapter 52
Self-Test Control Unit (STCU2)

52.1 Chip-specific STCU2 information

52.1.1 Supported BIST sequences

This chip supports only STCU2 BIST sequences that NXP has validated for in-field testing usage. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative for this information).

52.1.2 Self-test overview

STCU2 provides the overall control of both LBIST and MBIST, in serial or parallel, depending on the power, timing, or coverage constraints.

NOTE

LBIST is not available for S32K312 and S32K311.

The application software initiates the self-test sequence or procedure (please use whichever term is correct), and has provisions to bypass the self-test configuration to directly move to normal Run mode.

There is a programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence. In case the selected LBISTs or MBISTs are not complete during the assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

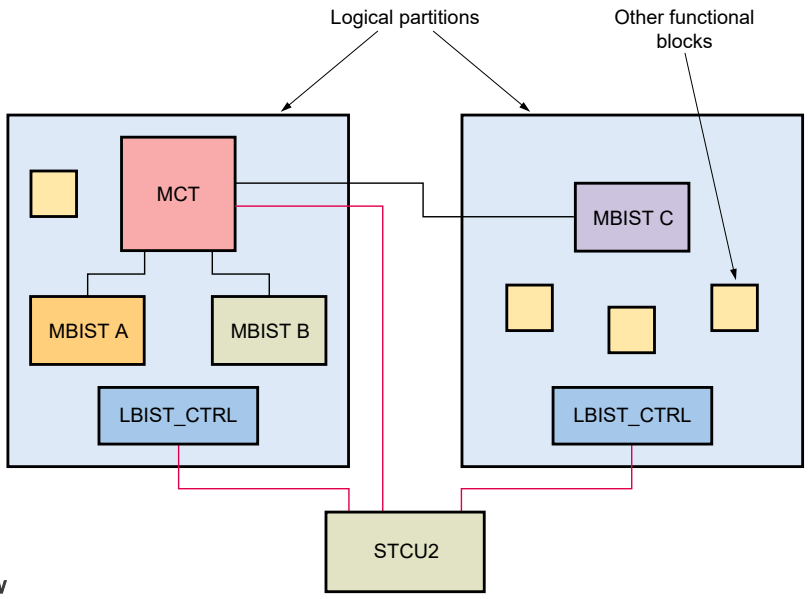
The STCU2 execution includes three phases:

- Software configuration. Load or program the test configuration parameters to be executed, depending on ASIL target and performance requirements. The self-test configuration parameters allow the self-test sequence to run with different times depending on pattern numbers and types, achieving different levels of coverage.
- Start of BIST execution. This involves software register configuration in STCU2. The BIST completion is followed by a functional reset.
- End of BIST execution. After BIST execution and functional reset are complete, the BIST results are made available and you decide how to continue (trigger a new reset or start a safety application). The BIST execution completion is signalized in an internal STCU2 register (LBESWn) bit which is not affected by the functional reset. The BIST test results are also not affected by the functional reset.

The following figure shows a pictorial representation of two LBIST partitions having two and one MBIST groups, respectively. STCU2 interacts with LBIST_CTRL for the respective partitions to configure and control the LBIST sequence and compare results.

It also interacts with MTR controller (MCT) for MBIST. Each LBIST partition has its corresponding controller whereas a single MCT can cater to multiple MBIST groups.

Figure 191.



Self-test overview

NOTE

LBIST_CTRL is not available for S32K312 and S32K311.

Each LBIST partition also includes a block called Self-test GPR involving a set of registers that provide miscellaneous configuration and parameter details for an LBIST operation.

When you trigger a self-test sequence, the chip becomes unavailable for software application during the self-test run.

52.1.3 STCU2 LBIST/MBIST mapping

This topic covers STCU2 LBIST/MBIST mapping.

LBIST mapping

The below table lists the LBIST mapping of the chip. The NLBIST value is 1.

Table 249. LBIST mapping

BIST ID (NLBIST)	BIST instance name	Modules
0	LBIST	DMA: • DMA controller
		EIM
		ERM
		XRDC • MDAC0 • MDAC1

Table continues on the next page...

Table 249. LBIST mapping (continued)

BIST ID (NLBIST)	BIST instance name	Modules
		• MDAC2 • MDAC3 • MDAC4 • MDAC5 • MRC0 • MRC1 • MRC2 • PDAC0 • PDAC1 • PDAC2
		CRC
		FCCU
		FOSU
		PFLASH_CTL
		PRAMC_0
		PRAMC_1 **NOTE** PRAMC_1 is not present in S32K342, S32K312, and S32K311.
		SWT_1 **NOTE** SWT_1 is not present in S32K312 and S32K311.
		CMU: • CMU1 • CMU2 • CMU4 • CMU5
		iAHB Gaskets: • DMA_GSKT • HSE_GSKT • AIPS1_GSKT • AIPS2_GSKT

Table continues on the next page...

Table 249. LBIST mapping (continued)

BIST ID (NLBIST)	BIST instance name	Modules
		• QSPI_GSKT **NOTE** AIPS2_GSKT and QSPI_GSKT are not present in S32K312 and S32K311. • TCM_GSKT • EMAC_GSKT • EDC master checker gaskets (See block diagram in Introduction chapter for details) • EDC slave checker gasket (See block diagram in Introduction chapter for details)
		Crossbars • AXBS • DMA_AXBS • HSE_AXBS • PERIPHERAL_AXBS • TCM_AXBS

MBIST mapping

The below tables lists the MBIST mapping of different variants of this chip. The NMCUT value is 12.

Table 250. S32K314/S32K324/S32K344 MBIST mapping

52.1.4 Clock connectivity

STCU2 works on the system clock domain. The scan operations while LBIST are done on TCK clock.

Table 254. Clock connectivity

STCU2 clock	Clock connected to the chip	Remarks
CORE_CLK	AIPS_SLOW_CLK	System clock divider output clock node for STCU2 operations and register interface accesses
REG_INTF_CLK		
SHIFT_CLK	JTAG_TCK	JTAG_TCK used for shift operations when self-test is in progress

52.1.5 Memory map for self-test GPRs

See the memory map file attached to this document and 'SELFTEST_GPR' chapter for details.

52.1.6 Handling unrecoverable faults

Only recoverable and non-critical faults from STCU2 are mapped to FCCU. The unrecoverable and critical faults are mapped to MC_RGM. Therefore, ignore any references to mapping of unrecoverable and critical faults with FCCU in this chapter.

52.1.7 Indicating fault state during the main reset domain Self-Test

FCCU EOUT indicates the fault state during the Self-Test as soon as the UTEST_MISC[FCCU_EOUT_ DEDICATED] is enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is enabled at the time of Self-Test setup steps.

The fault state remains asserted until the bit DCMRWD2[EOUT_STAT_DUR_STEST] is cleared post Self-Test reset sequence.

In case it is not required to indicate the fault state during the Self-Test, then the bit DCMRWD2[EOUT_STAT_DUR_STEST] should not be programmed.

52.1.8 Error events management in main reset domain Self-Test

Error events should be mapped to unrecoverable faults in STCU2_ERR_FM register for main reset domain Self-Test.

52.1.9 AUTOLOCK_VALUE for register write access via STCU2_SKC

Register write-access watchdog timer explains that access to STCU2 registers via the STCU2_SKC security-key mechanism times out after a number of STCU2 clock cycles equal to AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 32'hFFFF_FFFF.

52.1.10 PLL loss of lock during Self-Test

Detection of PLL loss of lock during LBIST or MBIST causes a destructive reset in the system.

CMU0 programming is required before the Self-Test programming begins.

All the registers present in LBIST domains do not retain their content after Self-Test reset.

52.1.11 STCU2 BIST start (BSTART) register description

Attempted accesses with the undefined reserved values in the BSTART register can result in undefined behavior. The following table defines the BSTART field on this chip.

Table 255. BSTART description

Field value	Description
000b	NOP (reset value)
001b	RUN_ONLY: Run BISTs. MTR controller (MCT) runs the selected BISTs without programming them first.
010b	Reserved
011b	Reserved
100b	PROG_ONLY: Program BISTs only. MCT only programs BISTs and does not start them. This enables different BISTs to be programmed with different algorithms before all the selected BISTs are started using the RUN_ONLY command.
101b	PROG_RUN: Program BISTs and start them.
110b	Reserved
111b	Reserved

52.1.12 STCU2 algorithm select (ALGOSEL) register description

This register selects any one of the predefined algorithms. The value used in this register is mapped to a predefined algorithm register in BIST. After MCT has programmed information on this register and starts some BIST operation, this value is transferred to the predefined algorithm register in every BIST that is selected.

If multiple predefined algorithms are selected, the order of execution is from LSB to MSB.

Any field that does not have a predefined algorithm associated with it is a reserved bit. No data is written to reserved bits and when you read these bits, they always return 0. These predefined algorithms include:

- Backgrounds
- Address modes and other register programming that may be necessary
- The number of BIST runs needed to perform the exact coverage requested.

MCT decodes this information through a series of look-up tables. The following table describes the high-level BIST algorithms that can be invoked through the MCT. The columns in that table have the following meaning:

- Index: The position in this MCT register enables this algorithm.
- Name: The symbolic name for this algorithm.
- Description: The intent and use model for this algorithm.

- BIST runs: The sequence of BIST invocations comprising this algorithm.
- Sequences: The ordered list of march elements to run. Each march element consists of a direction indicator (for increasing addresses and for decreasing addresses) and a set of march phases. A march phase consists of reading (R) or writing (W), the non-inverted (0) or inverted (1) background pattern.
- Used by default: Whether this algorithm is selected in the post-reset state of this register.

Table 256. ALGOSEL description

Index	Name	Description	BIST runs	Sequences	Used by default
3	March C+ single	March C+ with column fast and solid background	MarchC+ column fast 1x (#4)	W0, R0W1, R1W0R0W1, R1W0, R0W1R1W0, R0	Yes
13	BasicChk	Basic selfcontained checkerboard, using column fast	BasicChk (#18)	R0W1R1	-

52.1.13 Self-Test programming sequence

This section describes a high level programming sequence for executing Self-Test. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

- Program clock sources and MC_CGMs as per the clock configuration.

  NOTE

  While running MBIST on EMAC timestamp memory, MC_CGM.MUX_9_DC_0[DIV] should be appropriately configured to ensure EMAC_CLK_TS should be atleast 1.5 times the AIPS_SLOW_CLK frequency.

- Program SELFTEST_GPR[CONFIG_REG] and SELFTEST_GPR[LBIST_PROG_REG] as per the LBIST configurations.

  NOTE

  This is not applicable for S32K312 and S32K311 wherein LBIST is not supported.

- Program STCU2 as per NXP recommended.
- Program dcf_client_utest_misc[FCCU_EOUT_DEDICATED] and DCMRWD2[EOUT_STAT_DUR_STEST] to configure EOUT pins as dedicated and to indicate FCCU error states on EOUT pins during Self-Test respectively.
- Configure ERCTRL[ERASSERT] register bit in MC_RGM to achieve desired behaviour of Reset Pin as documented in Reset Section and Pad States Section.
- Disable functional reset sources to avoid false Self-Test abort scenarios. For example, software watchdog timers cannot be serviced while Self-Test because the software is not accessible and can cause invalid timeout reset. See Reset events and configurations while Self-Test.
- Program the PCS_ENABLE[8:7] fields of the CONFIG_REG register (SELFTEST_GPR) to 0 to disable PCS.
- Trigger Self-Test execution by programming RUNSW register in STCU2.
- At the end of the Self-Test run, a functional reset is generated. Out of reset, the software can check the status registers inside STCU2 and take actions accordingly.

52.1.14 Modules operation during/post Self-Test

The clock, reset, power generation modules, such as RGM, PMC, CGM, FIRC, PLL, and SIRC will be available during and post Self-Test. However, because the chip undergoes the reset sequence, PLL and CGM will be reset.

CMU0 and CMU3 will be available during Self-Test if enabled prior to Self-Test, but will be Reset post Self-Test.

STCU2 will also be available during Self-Test and the results can be read post Self-Test.

52.1.15 Reset events and configurations while Self-Test

As Self-Test is a software initiated Self-Test, it is expected by software to ensure all the peripherals are disabled as documented in Software considerations before Self-Test.

The functional reset sources should be appropriately configured to avoid any functional reset while Self-Test is running (disable SWT_RST and HSE_SWT_RST. JTAGC should not be in EXTEST, HIGHZ or CLAMP instructions). This ensures no selftest abort while running selftest due to functional reset source. The below table specifies the state of functional reset sources for Self-Test.

Table 257. Reset events and configurations while self-test

Reset source	Reset description	Configurations/remarks for selftest
FCCU_RST	FCCU reset reaction	The FCCU is a part of logic which is under Self-Test and thus it would be disabled during the Self-Test
ST_DONE	Self-Test done reset	The selftest done indication resets the device post selftest. While Self-Test is running, the Self-Test done indication will be in disabled state
SWT_RST	SWT reset request	SWT should be disabled in Self-Test configuration sequence.
JTAG_RST	JTAG Reset	JTAG communication should be inactive while Self-Test and JTAGC state machine should not be in EXTEST, HIGHZ or CLAMP instructions
HSE_SWT_RST	HSE SWT timeout	HSE_SWT should be disabled in Self-Test configuration sequence.
SW_FUNC	software 'functional' reset	The software is inactive during Self-Test and hence software functional reset will not arrive while the chip is under Self-Test.
DEBUG_FUNC	debug 'functional' reset	MDM DAP should not be configured for debug functional reset generation while Self-Test is running.

The destructive reset sources are available while in Self-Test. In case of any destructive reset event, the device undergoes a destructive reset sequence, thereby resetting the STCU2 and Self-Test logic itself.

After completion of Self-Test (LBIST or MBIST), a functional reset sequence is executed by MC_RGM.

52.1.16 Software considerations before Self-Test

1. As all the communication peripherals are not in LBIST partitions; hence, it is required by SW to stop all communications and disable all the PCTLs of the communication peripherals before initiating Self-Test as the device will be unusable in Self-Test. This is needed so that there is graceful safe stating of inputs of non-lbisted peripheral modules.
2. Configure RGM functional reset sources as interrupts before Self-Test as per the considerations mentioned in Reset events and configurations while Self-Test, i.e., the SWTs should be disabled, the JTAGC should not be in states which can cause a JTAG reset event (EXTEST, HIGHZ, CLAMP instructions) and the software should not trigger a functional reset event via MC_ME or MDM_AP while the selftest is ongoing. This is to avoid any abort scenario due to any functional reset source as Self-Test is initiated by SW.

There is no issue with Reset pin as Reset pin is a source of destructive reset and will reset STCU2 and Self-Test related logic etc.

52.1.17 End of Self-Test

The Self-Test completion is a source of functional reset to the device, by which the device executes a functional reset sequence. The logic which is LBISTed additionally undergoes a complete POR sequence to ensure that the random content shifted during BIST sequence get cleared.

At the end of MBIST, the software should execute below steps:

1. Software reads the MBIST end flag to identify that the MBIST sequence had ended properly without any interruption or abort, by reading STCU2.MBESWn.
2. Software reads the MBIST status to identify whether the MBIST was successful or not, by reading STCU2.MBSSWn.

NOTE

The MBIST status should always be read in accordance with MBIST end flag. The STCU2.MBSSWn status is irrelevant if STCU2.MBESWn indicates that MBIST execution is incomplete.

At the end of LBIST, the software should execute below steps:

1. Software reads the LBIST end flag to identify that the LBIST sequence had ended properly without any interruption or abort, by reading STCU2.LBESWn.
2. Software reads the LBIST status to identify whether the LBIST was successful or not, by reading STCU2.LBSSWn.

NOTE

The LBIST status should always be read in accordance with LBIST end flag. The STCU2.LBSSWn status is irrelevant if STCU2.LBESWn indicates that LBIST execution is incomplete.

52.2 Introduction

STCU2 is a comprehensive programmable hardware module that:

- Manages the execution of BISTs
- Indicates whether each BIST passed
- Manages the chip's LBIST and the MBIST blocks

52.3 Main features

STCU2 includes:

- System interface for reading from and writing to the STCU2 registers during runtime (online) via the CPU
- Programmable scheduler for BIST execution
- Control over LBIST concurrent or sequential execution
- Control over MBIST concurrent or sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST clocks
- PLL lock signal monitoring during BIST sequences
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the execution status of each BIST, see Types of BIST sequences and Types of BIST partitions
- Fields that indicate the status of each type of online STCU2 internal error condition
- Programmable fault mapping of each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping of each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals to report recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability

- FCCU recoverable and unrecoverable fault-injection mechanism
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving after a BIST sequence is completed when watchdog timer time-out is detected
- Watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- Watchdog automatic power saving when the fixed register-write-access watchdog timer times out

52.4 Block diagram

This diagram shows the parts of STCU2:

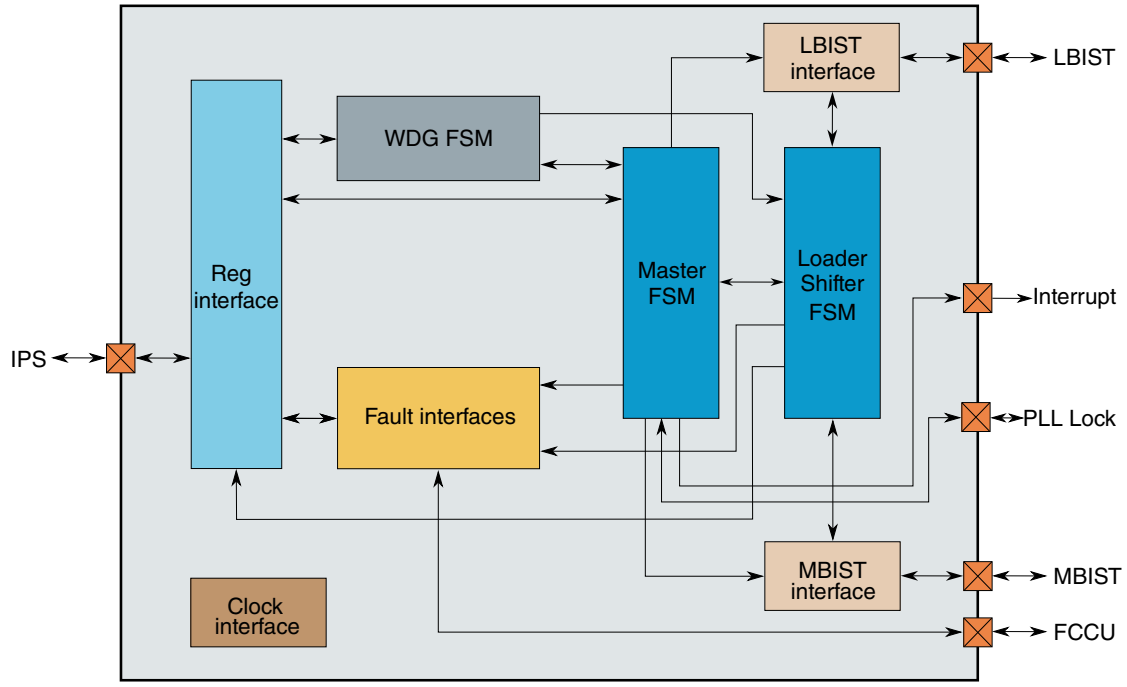

Figure 192. STCU2 block diagram

This table describes the parts of STCU2:

Table 258. STCU2 parts

Part	Function
Reg interface	Provides access to: • Registers • The security key logic • The IPS interface
Fault interface	Performs the following tasks: • Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence

Table continues on the next page...

Table 258. STCU2 parts (continued)

Part	Function
	• Sets the global recoverable or unrecoverable status flag, depending on the fault mapping for a given BIST • Manages the recoverable and unrecoverable fault lines to and from the FCCU module • Manages the set/clear injection mechanism provided by the FCCU module To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
Clock interface	Manages the internal and the BIST clock prescaler, the internal clock-gating power saving, and the wake-up clock feature
WDG FSM	Provides the following: • A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence • A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
Master FSM	Coordinates and schedules all of the operations performed during a BIST sequence
Loader Shifter FSM	Programs the BIST registers and reads back the data to be checked at the end of each test operation
LBIST interface	Provides the interface between the chip's LBIST engines and the STCU2 controllers
MBIST interface	Provides the interface between the MBIST controller and the STCU2 controllers

52.5 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration purposes via CPU. The module supports the following bus read operations:

- Word (32 bits) data read operations to any registers
- Any other operation is not supported.

Word, low and high half-words, byte operations are supported in write mode only:

- Write access is allowed by software only when CFG[WRP] is cleared. The default value of CFG[WRP] is cleared.
- Exceptions are the following read/write fields: CFG[WRP], ERR_STAT[UFSF] and ERR_STAT[RFSF].
- In all the other conditions, the write operations are not supported and all the STCU2 registers can be only read.
- STCU2 Configuration (CFG) should only be accessed in 32 bit (partial access not allowed).

The STCU2 module generates a transfer error in the following cases:

- Any read access to the registers after writing Key1 and before writing Key2 (in online) and before register write-access watchdog timer expires.
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when CFG[WRP] is set and the access is performed through software (internal peripheral interface). The exceptions are SKC register (for valid keys value and sequence) and INT_FLG register(interrupt flag) in which STCU2 does not assert transfer error.
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor, or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

52.6 BISTs and BIST partitions

52.6.1 Definition: BIST

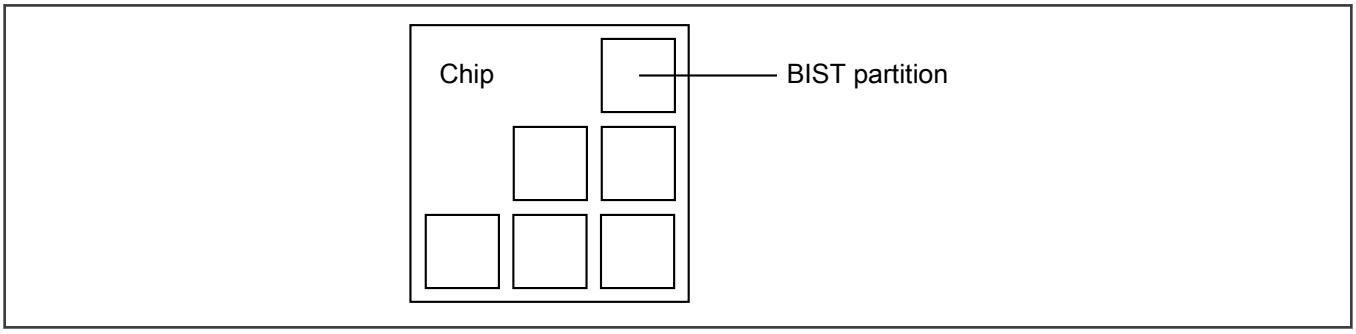
A BIST is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

52.6.2 Definition: BIST partition

A BIST partition is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

52.6.3 Example: BIST partitions on a chip

This is an example of a chip with six BIST partitions:



52.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of BIST partitions:

Table 259. Types of BIST partitions

BIST partition type	Description
MBIST partition	An SRAM or ROM block
LBIST partition	One or more digital modules

52.7 BIST sequences

52.7.1 Definition: BIST sequence

A BIST sequence is a programmable series of one or more phases, each of which executes one or more individual BISTs.

52.7.2 STCU2 executes MBISTs before LBISTs

If a BIST sequence includes both MBISTs and LBISTs; STCU2 executes the MBISTs first.

52.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Table 260. Example: Single-phase BIST sequence

Phase	BIST executed
0	MBIST 16

52.7.4 Example: Multi-phase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Table 261. Example: Multi-phase BIST sequence

Phase	BISTs executed
0	MBISTs 7, 30
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

52.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of BIST sequences:

Table 262. Example: Types of BIST sequences

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.

52.7.6 Supported BIST sequences

NXP supports only a specific set of BIST sequences for this chip. For the list of supported BIST sequences, see the chip-specific STCU2 information.

52.8 Functional description

52.8.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the self-test operations and the other state machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

52.8.2 BIST scheduling

STCU2 is designed to program the parallel/serial execution of the MBIST or LBIST depending on the power, timing, and coverage constraints.

The mechanism used to provide this flexibility is a linked list of BIST descriptors where the starting pointer is defined in CFG[PTR]. The first LBIST is mapped on 0, the second on 1, and so on. A BIST descriptor identifies a LBIST or MBIST via an index that is associated with its control register (STCU2 LBIST Control (LB_CTRL0) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL12)). The first MBIST is mapped on (00000080h + 0), the second on (00000080h + 1), and so on. The additional pointers of the linked list are in LB_CTRL*n*[PTR] for LBIST *n* (where *n* is the selected LBIST) and MB_CTRL*m*[PTR] for MBIST *m* (where *m* is the selected MBIST) and must be populated depending on the selected run sequence. The additional fields LB_CTRL[CSM] and MB_CTRL[CSM] provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list by setting the NIL pointer.

52.8.3 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence. Two independent signals have been used to mitigate the common cause faults.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

52.8.4 Watchdogs

The STCU2 implements different watchdogs to ensure that operations are finished in time.

52.8.4.1 BIST watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (WDG), to account for the overall execution time of the self test sequence. In case the selected LBISTs or MBISTs are not yet completed during assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

In case of multiple sequential run in the same online session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

52.8.4.2 Register write-access watchdog timer

As explained in the STCU2 SK Code (SKC):

- A key mechanism protects STCU2 registers during the self-test configuration phase by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write Key1 and Key2 sequences.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

The hardware watchdog timer is particularly useful in case CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

52.9 Use cases and limitations

For details on use cases and limitations, contact NXP sales representative.

52.10 STCU2 register descriptions

The STCU2 registers are listed in this section.

NOTE

Always write the reset value for the Reserved fields.

During online self-test, after the STCU2 registers are configured, they must not be overridden via internal peripheral system until the self-test is complete.

52.10.1 STCU2 memory map

STCU base address: 403A_0000h

52.10.2 STCU2 Run Software (RUNSW)

Offset

Register	Offset
RUNSW	4h

Function

The RUNSW register defines the RUN bit to start the online self-testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when CFG[WRP] = 0.

Diagram

52.10.3 STCU2 SK Code (SKC)

Offset

Register	Offset
SKC	8h

Function

The SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers.

To unlock STCU2 access after the STCU2 asynchronous reset and at the end of the STCU2 run, the software (IPS bus) need to apply the following sequence:

- write the key1 into the SKC register
- write the key2 into the SKC register

Depending on the online test step, the two keys are different. Byte write operation is not allowed because the full key has to be recognized as one unit.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS is asserted. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined in the hard-coded WDG timeout, the STCU2 write access is locked and the WDG and register interface clocks are switched off. Also, in this case, to enable the write access to the STCU2 again and the WDG and register interface clocks, it is required to apply the sequence again. This hard-coded WDG counter starts decrementing its value right after POR is deasserted.

In case it is required to extend the STCU2 register access cycles before the hard-coded WDG timeout expires, Key1 and Key2 sequences need to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

The SKC register is not readable. The value 00000000h is always returned in case of read operation.

52.10.4 STCU2 Configuration (CFG)

Offset

Register	Offset
CFG	Ch

Function

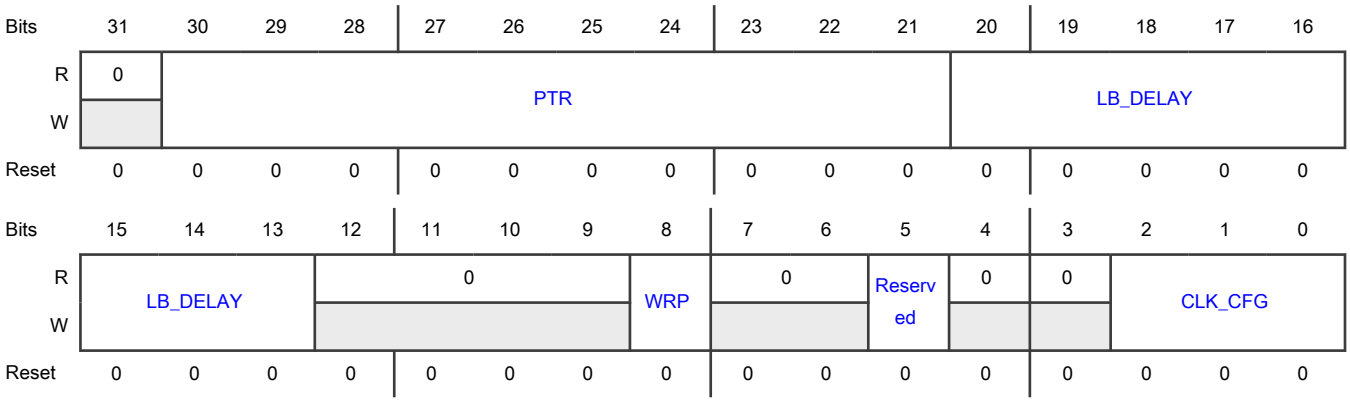
The CFG register includes the global configuration of the STCU2 and can be updated in the online test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the online self-test case without restrictions.
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.

— In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Diagram



Fields

Field	Function
31 —	Reserved
30-21 PTR	First LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled. See BIST scheduling for details. **NOTE** You can write to this field only when WRP = 0. 0h to (01h - 1): pointer to LBIST 00000080h to (00000080h + 00Dh - 1): pointer to MBIST 3FFh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU2 Error (ERR_STAT).
20-13 LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. The allowed delay time are these: 00h: No delay 01h: 1 x 16 STCU2 CORE_CLK cycles 02h: 2 x 16 STCU2 CORE_CLK cycles 03h: 3 x 16 STCU2 CORE_CLK cycles ...

52.10.5 STCU2 Watchdog Granularity (WDG)

Offset

Register	Offset
WDG	14h

Function

The WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or endless conditions during the self-test procedure.

In case online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

52.10.6 STCU2 Error (ERR_STAT)

Offset

Register	Offset
ERR_STAT	24h

Function

The ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the online self-testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

LBIST	Logic BIST
MBIST	Memory BIST
NLBIST	Number of logic built-in self-test controller
NMCUT	Number of memory checked using memory built-in self-test controller
RF	Recoverable faults
UF	Unrecoverable faults
WDG FSM	Watchdog finite state machine

Chapter 53
Register Protection (REG_PROT)

53.1 Chip-specific REG_PROT information

53.1.1 REG_PROT configuration

The MCU safety relevant configuration registers are protected against unauthorized HW/S changes during read/write/clear access by implementing them with register protection module. See the REG_PROT details file attached to this document.

53.1.1.1 CMU_BRIDGE register protection

The CMUs in the device reside on a common peripheral slot as CMU_BRIDGE in the system memory map. Figure 193 indicates the locations of the CMUs alongwith the memory map.

Based on the CMU location in system peripheral memory map, the below locations in the CMU 16KB space are reserved and any access on these locations results in a bus transfer error.

402B_C018 – 402B_C01F

402B_C030 – 402B_C03F

402B_C050 – 402B_C05F

402B_C078 – 402B_C07F

402B_C098 – 402B_C09F

402B_C0B8 – 402B_CFFF

Since the register protection is available in the device for CMU_BRIDGE, the 4KB offset locations (refers as the Area 2 in register protection) are also reserved and accesses over these regions also result in bus transfer error.

402B_D018 – 402B_D01F

402B_D030 – 402B_D03F

402B_D050 – 402B_D05F

402B_D078 – 402B_D07F

402B_D098 – 402B_D09F

402B_D0B8 – 402B_DFFF

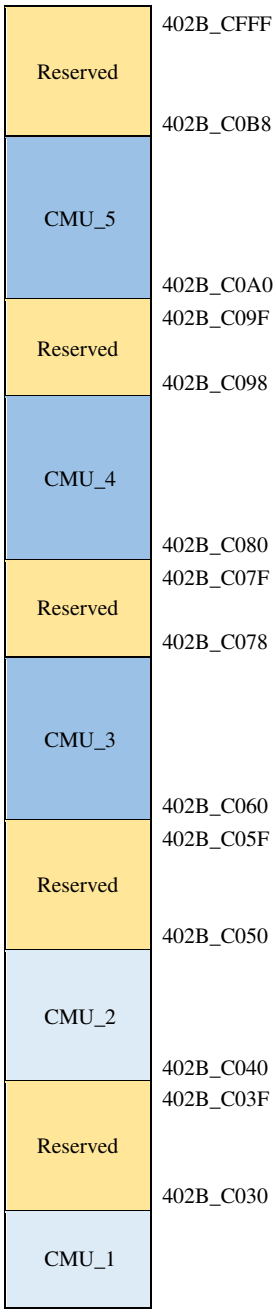

Figure 193. Location of CMUs

53.2 Introduction

REG_PROT offers a mechanism to protect defined memory-mapped address locations, in a module under protection, from being written.

REG_PROT is a protection module that is located between the module under protection and the peripheral interface. The address locations to be protected exist in the module under protection and the address locations that can be protected are module specific. Writes to these protected address locations are locked using a Soft Lock Bit Register (SLBR*n*). Any access to address locations in the module under protection is restricted if their corresponding Soft lock fields in a Soft Lock Bit Register (SLBR*n*) are 1.

The configured soft-lock fields can also be write-restricted by using GCR[HLB]. When GCR[HLB]=1, you cannot write to the soft-lock fields. The address locations in the module under protection can be restricted to Supervisor mode access using GCR[UAA]. This is shown in the following figure.

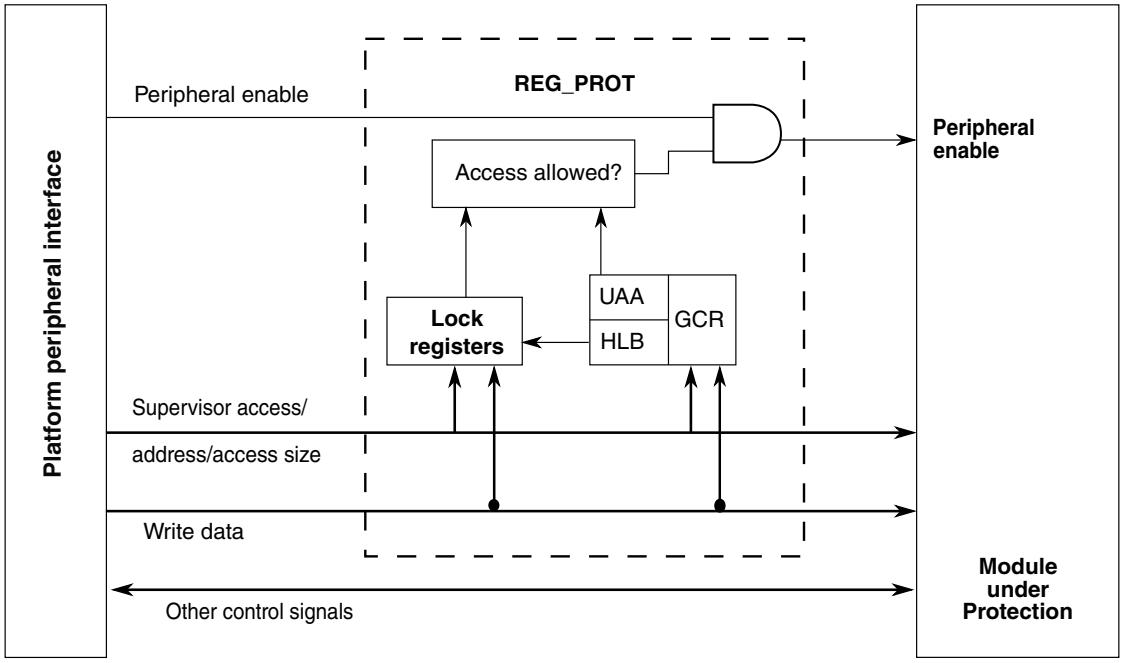

Figure 194. Block diagram

53.3 Features

REG_PROT includes these distinctive features:

- Write accesses for the module under protection can be restricted to the supervisor mode only.
- Registers of modules with their register slot size occupying 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory map and register definition.
- Multiple ways are present to set the lock bits.
- After the lock bits are configured, they can be protected from changes.

53.4 Modes of operation

The REG_PROT module is operable when the module under protection is operable.

53.5 External signal description

There are no external signals.

53.6 Functional description

The following sections describe the functional characteristics of the REG_PROT module.

53.6.1 Memory map and register definition

This section provides a detailed description of the memory map of a module using REG_PROT.

The PROT_MEM size varies per chips. It can be:

- 1 KB
- 2 KB
- 4 KB
- 8 KB
- 16 KB
- 32 KB

The resulting memory space is divided into four areas. Memory locations within area #1 and area #2 are a part of the module under protection. Area #3 and area #4 are a part of REG_PROT.

The proper register slot size for each protected module is mentioned in the REG_PROT_details file attached to this document.

Following is the memory map for a module that is protected by the REG_PROT module. Reserved registers in area #1 are handled as specified in the protected module's documentation. There is a single register in configuration space that corresponds to area #4 while the size mentioned in Area size column is to turn the whole area multiple of 4 KB. See the Offset column to know the exact location of the GCR register.

Table 263. Area offset based on protection size

PROT_MEM	Area	Area size	Use	Offset
1 KB	Area 1	1 KB	Module Register(MR0—MR1023)	0000h—03FFh
	Area 2	1 KB	Module Register and Set Soft Lock Bit (LMR0—LMR1023)	0400h—07FFh
	Area 3	256 B	Soft Lock Bit Register (SLBR0—255)	0800h—08FFh
	Area 4	256 B	Global Configuration Register (GCR)	0900h—09FFh
		1.5 KB	Reserved	0A00h— 0FFFh
2 KB	Area 1	2 KB	Module Register (MR0—MR2047)	0000h—07FFh
	Area 2	2KB	Module Register and Set Soft Lock Bit (LMR0—LMR2047)	0800h—0FFFh
	Area 3	512 B	Soft Lock Bit Register (SLBR0—511)	1000h—11FFh
	Area 4	256 B	Global Configuration Register (GCR)	1200h—12FFh
		3.25 KB	Reserved	1300h—1FFFh
4 KB	Area 1	4 KB	Module Register (MR0—MR4095)	0000h—0FFFh
	Area 2	4 KB	Module Register and Set Soft Lock Bit (LMR0—LMR4095)	1000h—1FFFh
	Area 3	1 KB	Soft Lock Bit Register (SLBR0—1023)	2000h—23FFh
	Area 4	256 B	Global Configuration Register (GCR)	2400h—24FFh
		6.75 KB	Reserved	2500h—3FFFh
8 KB	Area 1	8 KB	Module Register (MR0—MR8191)	0000h—1FFFh
	Area 2	8 KB	Module Register and Set Soft Lock Bit (LMR0—LMR8191)	2000h—3FFFh
	Area 3	2 KB	Soft Lock Bit Register (SLBR0—2047)	4000h—47FFh
	Area 4	256 B	Global Configuration Register (GCR)	4800h—48FFh
		1.75 KB	Reserved	4900h—4FFFh
16 KB	Area 1	16 KB	Module Register (MR0—MR16383)	0000h—3FFFh

Table continues on the next page...

Table 263. Area offset based on protection size (continued)

PROT_MEM	Area	Area size	Use	Offset
	Area 2	16 KB	Module Register and Set Soft Lock Bit (LMR0—LMR16383)	4000h—7FFFh
	Area 3	4 KB	Soft Lock Bit Register (SLBR0—4095)	8000h—8FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	9000h—9FFFh
32 KB	Area 1	32 KB	Module Register (MR0—MR32767)	0000h—7FFFh
	Area 2	32 KB	Module Register and Set Soft Lock Bit (LMR0—LMR32767)	8000h—FFFFh
	Area 3	8 KB	Soft Lock Bit Register (SLBR0—8191)	10000h—11FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	12000h—12FFFh

- Area #1 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB, which holds the normal functional module registers and is transparent for all read/write operations.
- Area #2 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB and is a mirror of area #1. For an example, if area #1 takes 8 KB of memory space, then read/write access to an offset 2000+X reads/writes the register at offset X. However, a write access to offset 2000+X additionally sets the optional soft lock bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area #1 need to have protection defined by the associated soft lock bits. For unprotected registers at offset Y, accesses to offset 2000+Y are identical to accesses at offset Y.
- Area #3 can take the memory space of 256 B/512 B/1 KB/2 KB/4 KB/8 KB and hold soft lock bits, one bit per byte in area #1. The four soft lock bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area #4 can take the memory space of 1.75 KB/3.5 KB/7 KB/2 KB/4 KB/4 KB and holds the configuration bits of the protection mode. There is one configuration Hard lock bit per module that prevents all further modifications to the soft lock bits and can only be cleared by a system reset after it is set. When user access allowed bit is set, it allows user access to the protected module.

If you access a locked byte with a write transaction, a bus error is issued to the system and the write transaction is not executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32—bit registers in area #3 results in a bus transfer error. In area #4, there will not be any transfer error for the address range mentioned in the table above because these address spaces of area #4 are mapped to the GCR register. Accesses in area #4, beyond the address range mentioned in the Module memory map table, are prohibited and might or might not result into a bus abort.

53.6.1.1 Module register (MR)

Each functional module has its own unique set of registers. This chapter refers to these registers generically as module registers (MR), which exist in the lower module memory space (memory area 1), and receive protection from the REG_PROT module.

53.6.1.2 Module Register and Set Soft Lock Bit (LMR)

This is memory area #2 that provides mirrored access to module registers with the side-effect of setting soft lock bits in case of a write access to a register that is defined as protectable by the locking mechanism. Each MR byte is protectable by one associated bit in SLBR*n* [SLB*m*], according to the mapping described in Soft Lock Bit Register (SLBR*n*).

53.6.2 General

This module provides a generic register (address) write-protection mechanism. The register protection size can be:

- 32 bits (address == multiples of 4)

- 16 bits (address == multiples of 2)
- 8 bits (address == multiples of 1)

The addresses that are protected and the register protection size depends on the chip and/or module.

For all addresses that are protected, there are SLBR*n*[SLB*m*] bits that specify whether the address is locked. When an address is locked, it can only be read but not written in any mode (supervisor/normal). If an address is unprotected, the corresponding SLBR*n*[SLB*m*] bit is always 0, regardless of what the software writes to that field.

NOTE

For more information on register protection specification, see the REG_PROT details file attached to this document.

53.6.3 Change lock settings

To change the setting whether an address is locked or unlocked, the corresponding SLBR*n*[SLB*m*] bit needs to be changed. This can be done using the following methods:

- Set the SLBR*n*[SLB*m*] bit(s) by writing to area #2
- Modify the SLBR*n*[SLB*m*] directly by writing to area #3

Both methods are explained in the following sections.

53.6.3.1 Change lock settings via area #2

You can lock a register after writing to it. Note that reading area #2 does not affect soft lock bits. To do so, you must use area # 2.

The following shows an example with PROT_MEM = 8 KB where SLBs are modified using area #2.

When writing 16-bit to address 0008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields remain unchanged (see the left part of Figure 195).

When writing 16-bit to address 2008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields SLBR2[SLB0:1] become 1, and the lock fields SLBR2[SLB2:3] remain unchanged (see the right part of Figure 195).

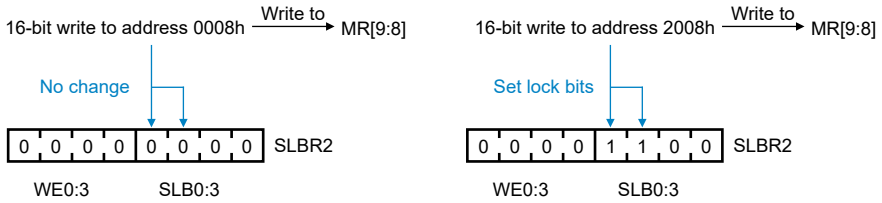

Figure 195. Enable locking via area #2

The following figure shows an example where some addresses are protected and some are not.

In Figure 196, addresses 000Ch and 000Dh are unprotected. Therefore, their corresponding lock fields SLBR3[SLB0:1] are always 0 (shown in bold). During a 32-bit write access to address 200Ch, the lock fields in SLBR3 change as follows:

- SLBR3[SLB2:3] become 1.
- SLBR3[SLB0:1] remain 0.

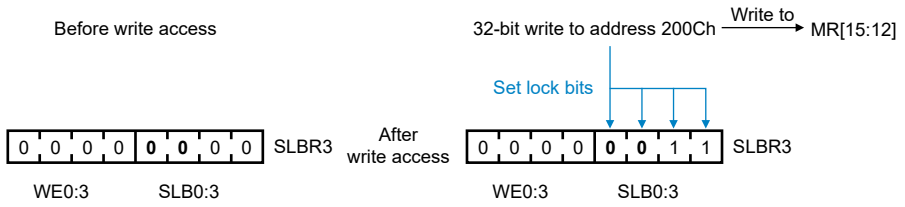

Figure 196. Enable locking for protected and unprotected addresses

53.6.3.2 Change lock settings via area #3

The lock bits are located in area #3 (see Table 263). You can modify them by writing to them. Each SLB*m* field in Soft Lock Bit Register (SLBR*n*) has a mask field, WE*m*, that protects SLB*m* from modification. This masking makes read-modify-write operations unnecessary.

Figure 197 shows two modification examples for registers with 8-bit protection. In part A, a write access to SLBR*n* specifies a mask value that allows modification of all SLBR*n*[SLB0:3] fields. Part B specifies a mask that allows modification only to SLBR*n*[SLB1:3].

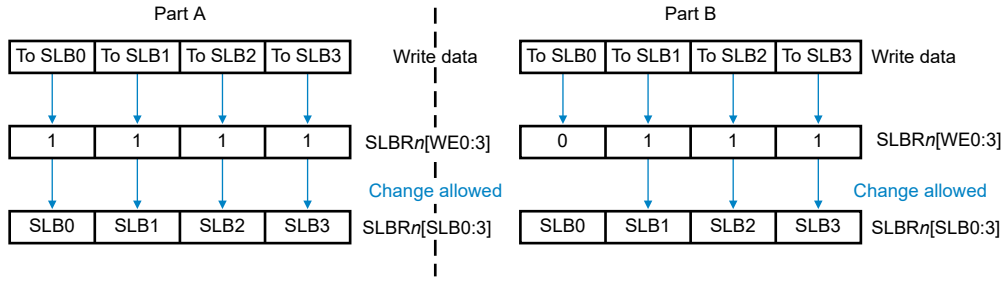

Figure 197. Change lock settings directly via area #3

Figure 198 shows examples for registers with 16-bit protection.

Part A of Figure 198 shows that for SLBR*n*:

- The data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1].
- The data written to SLBR*n*[SLB2] is automatically written to SLBR*n*[SLB3].

This is because the address reflected by SLBR*n*[SLB0] and SLBR*n*[SLB2] are protected 16-bit wise. Note that in this case, the write enable SLBR*n*[WE0] and SLBR*n*[WE2] must be set while SLBR*n*[WE1] and SLBR*n*[WE3] don't matter.

Part B of Figure 198 shows that the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1]. This is done because the address reflected by SLBR*n*[SLB0] has 16-bit protection. In this case, SLBR*n*[WE0] must be 1 and SLBR*n*[WE1] does not matter. SLBR*n*[SLB2] and SLBR*n*[SLB3] remain unchanged because SLBR*n*[WE2] and SLBR*n*[WE3] are 0.

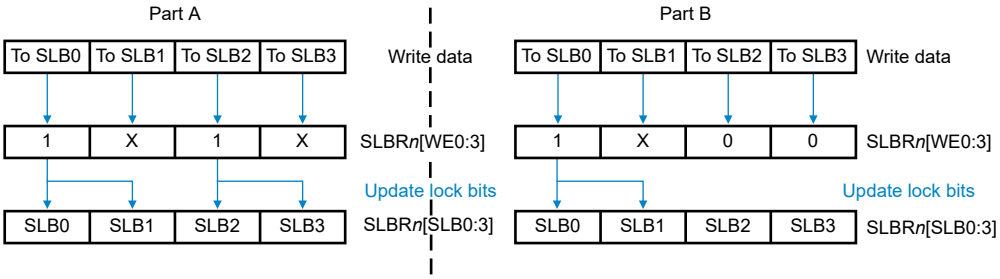

Figure 198. Change lock settings for addresses with 16-bit protection

Figure 199 shows a register with 32-bit protection. In SLBR*n*:

- When SLBR*n*[WE0]=1, the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1:3] as well.
- When SLBR*n*[WE0]=0, then SLBR*n*[SLB0:3] remain unchanged. Note that in this case, the write enable SLBR*n*[WE0] must be set while SLBR*n*[WE1:3] does not matter.

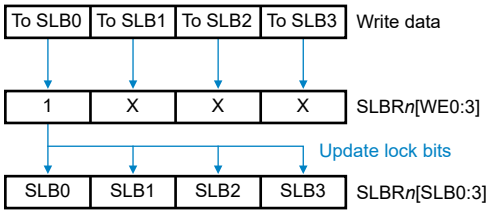

Figure 199. Change lock settings for addresses with 32-bit protection

The following figure shows a mixed protection size configuration.

In SLBR*n*:

- The data written to SLBR*n*[SLB0] is mirrored to SLBR*n*[SLB1] because the corresponding register has 16-bit protection.
- The data written to SLBR*n*[SLB2] is blocked because the corresponding register is unprotected.
- The data written to SLBR*n*[SLB3] is successfully written to SLBR*n*[SLB3] because the corresponding register has 8-bit protection.

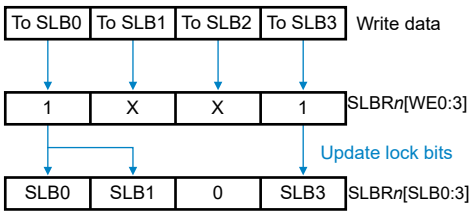

Figure 200. Change lock settings for mixed protection

53.6.3.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings via area #3 and Change lock settings via area #2 is only possible as long as the field GCR.HLB is cleared. After you write 1 to this field, the locking bits cannot be modified until there is a system reset.

53.6.4 Access errors

REG_PROT generates transfer errors under several circumstances, as described below. For the area definition, see Memory map and register definition.

- If accessing area #1 or area #2, REG_PROT sends any access error from the underlying module under protection.
- If User mode is not allowed, the attempted User mode writes to all areas cause a transfer error, and the writes are blocked.
- If accessing the reserved area, a transfer error is asserted.
- If accessing unimplemented 32-bit registers in areas #3 and #4, a transfer error is asserted.
- If writing to a register in areas #1 and #2, and an SLB field is 1 for any of the affected bytes, then:
  - A transfer error is asserted.
  - The write is blocked.
  - The complete write operation to non-protected bytes in this word is ignored.

- If writing to an SLBR in area #3 with GCR[HLB]=1, a transfer error is asserted.
- Any write operation in any access mode to area #2, when GCR[HLB]=1, is not allowed.

53.6.5 Sequence

You must configure the REG_PROT first. And then, you need to write 1 to the HLB field in REG_PROT. This ensures that registers under protection are not updated in the user access mode. You need to follow these steps:

1. Enable XRDC protection for the module to enable writes in the supervisor mode only. This step is mandatory, if protected registers of the module are expected to be configured multiple times.
2. Configure REG_PROT to enable write on registers of module under protection.
3. Configure the registers of module under protection.
4. Configure the REG_PROT for the required SLB fields.
5. Set the HLB field in REG_PROT. This step is mandatory, if protected registers of module are expected to be configured only once.

53.7 REG_PROT register descriptions

This register information documents memory area #3 and area #4.

53.7.1 REG_PROT memory map

REG_PROT base address: base address of protected module instance

Table 264. REG_PROT memory map

	0x12000 – 0x12FFF	Global Configuration Register (GCR)	32	RW	0000_0000h

53.7.2 Soft Lock Bit Register (SLBR*n*)

Offset

See REG_PROT memory map for SLBR*n* offset ranges. For SLBR*n* addresses, see the REG_PROT details file attached to this document.

Function

These registers hold the Soft Lock Bits (SLBs) for the protected registers in memory area #1, which is the normal register address space of the protected module. Multiple Soft Lock Bit Registers (SLBR*n*) can be implemented, depending on the number of protected module register bytes. Each SLBR*n* has four soft lock fields (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each soft lock field also has a corresponding write enable field in the same register that controls whether the soft lock field can be written. The following table shows the mapping between the soft lock fields to the bytes in memory area #1.

Table 265. SLBs vs. protected address

SLB	Protected address

53.7.3 Global Configuration Register (GCR)

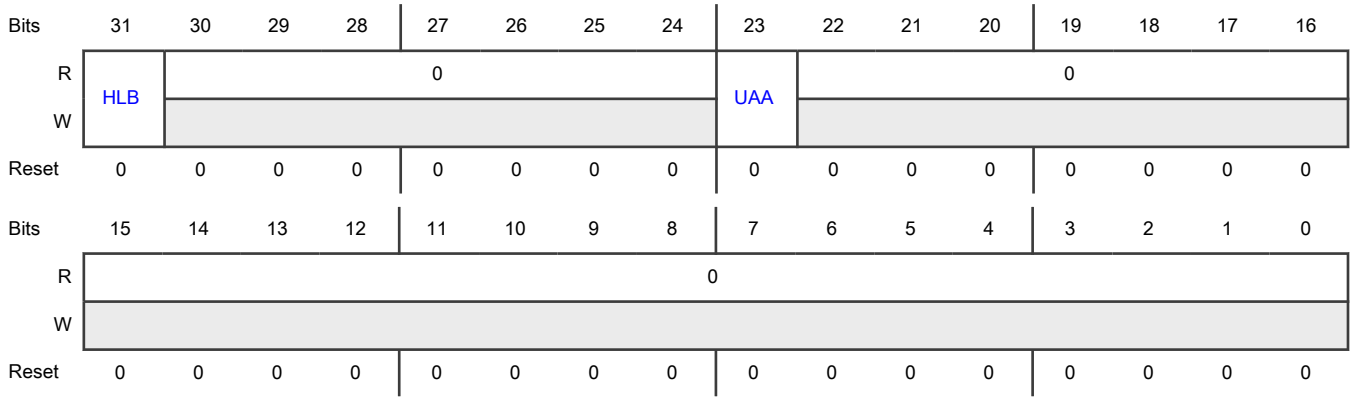
Offset

See REG_PROT memory map for GCR offset.

Function

This register controls module level configurations.

Diagram



Fields

Field	Function
31 HLB	Hard Lock Bit This field cannot be cleared after it is set by the software. It can only be cleared by a system reset. 0b - All SLB fields are accessible and can be modified. 1b - All SLB fields are write protected and cannot be modified.
30-24 —	Reserved
23 UAA	User Access Allowed Controls the user and supervisor mode access to registers of the module under protection. 0b - The registers in the module under protection can only be written in the supervisor mode. All the write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module. 1b - The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions.
22-0 —	Reserved

53.8 Glossary

PROT_MEM Integration parameter that specifies the size of the module register slot protected. The PROT_MEM size depends on the chip or module.

Hard lock A lock that restricts access to any register bit. You can unlock or clear this lock through the hardware reset.

Soft lock A lock that restricts access to any register bit. You can unlock or clear this lock through the software.

Chapter 54
Clock Monitoring Unit – Frequency Check (CMU_FC)

54.1 Chip-specific CMU_FC information

54.1.1 CMU_FC configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are 6 clock monitoring units present in the device out of which 4 are of type CMU_FC. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

NOTE

CMU_5 is accessible by Cortex-M0+ core only.

CMU_FC combined spec variation: The combined spec variation for CMU (used for configuring CMU_FCx.HTCR[HFREF] and CMU_FCx.HTCR[LFREF]) is the absolute sum of frequency variations of the clock sources. Refer device datasheet for frequency variations for the corresponding clock sources.

54.2 Introduction

CMU_FC ensures the clock integrity of selected clocks and allows continuous clock integrity verification.

CMU_FC checks if the frequency of a monitored clock (*monitored_clock*) is within a programmable frequency range specified by the user. If the frequency is outside the specified limits, it could lead to performance, protocol, and timing failures. CMU_FC requires a clock used as a base reference for the frequency check operation. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FC operation.

54.2.1 Basic operation

CMU_FC counts clock cycles of the monitored clock during a user programmable time duration of *n* clock cycles of the reference clock. There is a comparison between the final count of the monitored clock and the user programmable upper and lower threshold count limits. The control logic determines whether the cycle count is within the programmed limits. If not it sets the Frequency Higher than High frequency reference threshold event status (FHH) field or the Frequency Lower than Low frequency reference threshold event status (FLL) field in the Status Register (SR). If you enable interrupts, an interrupt asserts when the status flag sets.

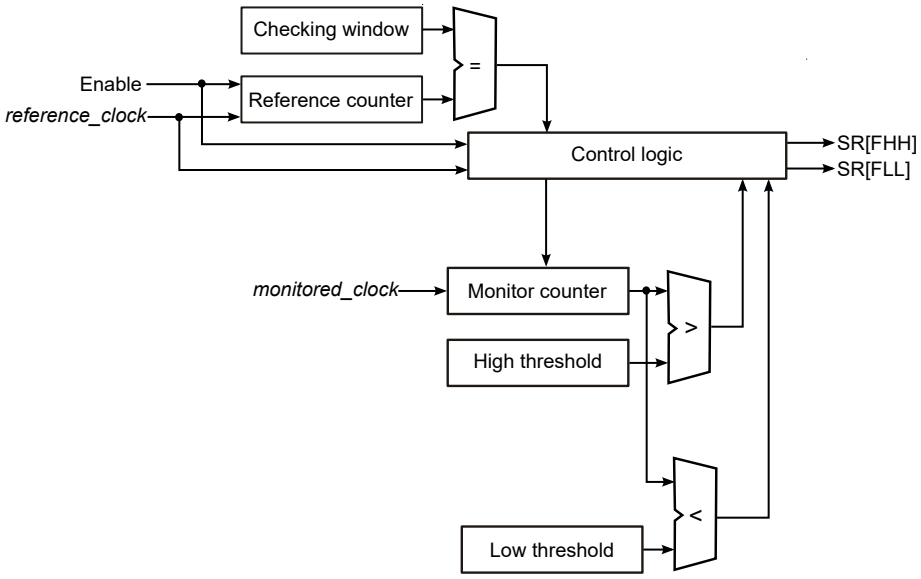


Figure 201. CMU_FC block diagram

CMU_FC cannot detect the following:

- Monitored clock duty cycle variations
- Instantaneous monitored clock frequency variations that do not cross upper or lower threshold limits

54.2.2 Features

The CMU_FC features are:

- Programmable duration of reference clock cycles
- Initiates an event if a monitored clock frequency is higher than high frequency reference (FHH)
- Initiates an event if a monitored clock frequency is lower than low frequency reference (FLL)
- Timeout functionality generates an FLL event if a monitored clock stops functioning
- Masking of FHH event interrupt
- Masking of FLL event interrupt

Table 266. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *monitored_clock*
monitored_clock	I	Clock signal on which frequency check is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of monitored and reference clocks used on this chip.

54.3 Functional description

54.3.1 Frequency checking

Frequency checking starts when software writes GCR[FCE] = 1. The Run Status field SR[RS] shows 1 after frequency check operation starts.

CMU_FC performs continuous periodic clock checking of the monitored clock. Each checking window involves the following operations:

- Stage 1 – Reference clock counter runs for RCCR[REF_CNT] reference clock cycles. Monitored clock counter runs in parallel for the same time duration as reference clock counter.
- Stage 2 – After stage 1, the module compares the final monitored clock count against the programmed thresholds.

If the monitored clock count is greater than the high threshold value in HTCR[HFREF], an FHH event occurs.

If the monitored clock count is lower than the low threshold value in LTCR[LFREF], an FLL event occurs.

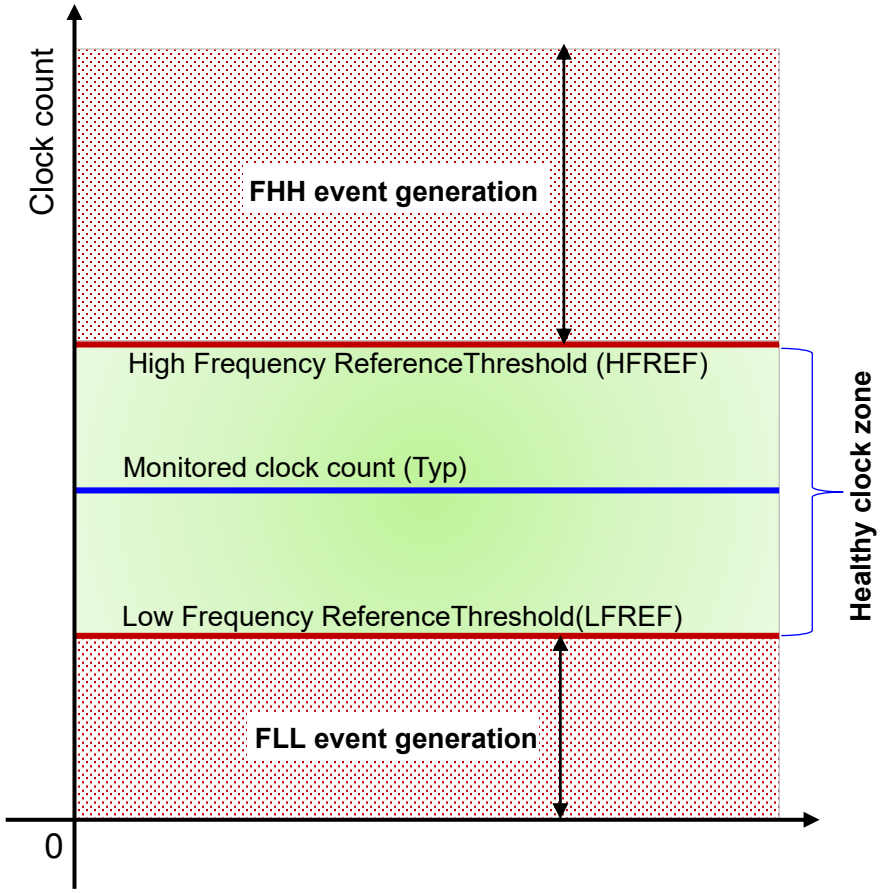

Figure 202. Frequency checking HFREF and LFREF thresholds

54.3.1.1 Monitored clock lost

If a monitored clock ceases operation before evaluation of that clock (Stage 2, see Frequency checking), CMU_FC waits for RCCR[REF_CNT] reference clock periods by extending Stage 2 before triggering an FLL event.

- If *monitored_clock* is not running when enabling CMU_FC:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 12) *reference_clock* cycles + 15 *bus_clock* cycles

- If *monitored_clock* stops when the CMU_FC is running:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 2) *reference_clock* cycles + 3 *bus_clock* cycles

54.4 Programming guidelines

54.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the checking operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

Minimum RCCR [REF_CNT] = CEILING value of MAX $\left(3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)\right)$

...where:

- $f_{reference_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{monitored_clock}$ is the frequency of the monitored clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference_clock}$ = 8 MHz
- $f_{monitored_clock}$ = 48 MHz

Formula #1: $3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right)$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2: $8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)$

Inserting the values: 8 + 5 × (8 / 48) ≈ 8.83

MAX (1.5, 8.83): 8.83

CEILING value of MAX: 9

Therefore, minimum RCCR[REF_CNT]: 9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency check completion response time and overall accuracy required from CMU_FC.

- Higher values of RCCR[REF_CNT] results in longer measurement window, leading to better accuracy in monitored clock check.
- Lower values of RCCR[REF_CNT] results in shorter measurement window, leading to faster FHH and FLL event response, but higher inaccuracy in reported result.

For measurement window calculation, see step 8 in Programming HFREF and LFREF

54.4.2 Programming HFREF and LFREF

You must consider the following when programming HFREF/LFREF:

- Tolerable monitored clock frequency variation
- Maximum reference clock frequency variation
- Inherent module inaccuracy

CMU_FC has an expected maximum deviation of ± 3 *monitored_clock* cycles (CMU_FC_{VAR+} = 3, CMU_FC_{VAR-} = –3).

The following procedure shows how to calculate optimum values for HTCR[HFREF] and LTCR[LFREF] (numbers shown are from example in table):

1. Determine the ideal *monitored_clock* frequency ($f_{monitored_clock}$ (ideal), 48 MHz).
2. Determine the specified variation of the *monitored_clock* (1.1%).
3. Calculate *monitored_clock* frequency variation: .

$$f_{monitored_clock}\ (ideal)\ \text{x}\ (1 \pm variation\ (\text{step 2}))$$

   - $f_{monitored_clock}$ (max) = 48 MHz × (1 + (1.1 ÷ 100)) = 48.53 MHz
   - $f_{monitored_clock}$ (min)= 48 MHz × (1 – (1.1 ÷ 100)) = 47.47 MHz
4. Determine the ideal *reference_clock* frequency ($f_{reference_clock}$ (ideal), 8 MHz).
5. Determine the specified variation of the *reference_clock* (3.3%).
6. Calculate ideal *reference_clock* frequency variation:

$$f_{reference_clock}\ (ideal)\ \text{x}\ (1 \pm variation\ (\text{step 5}))$$

   - $f_{reference_clock}$ (max) = 8 MHz × (1 + (3.3 ÷ 100)) = 8.26 MHz
   - $f_{reference_clock}$ (min) = 8 MHz × (1 – (3.3 ÷ 100)) = 7.74 MHz
7. Select the value of RCCR[REF_CNT] needed (80). See Programming RCCR[REF_CNT].
8. Calculate ideal measurement window:

$$\frac{RCCR\ [REF_CNT]}{f_{reference_clock}\ (ideal)}$$

   - 80 ÷ 8 MHz = 10000 ns
9. Calculate ideal *monitored_clock* count:

$$\frac{RCCR[REF_CNT]}{f_{reference_clock}(ideal)} \times f_{monitored_clock}\ (ideal)$$

   - 80 ÷ 8 MHz × 48 MHz = 480.00 (round off this value, 480 in this case)
10. Calculate high threshold value (HTCR[HFREF]):

$$\text{Ceiling value of } \left(\frac{f_{monitored_clock}\,(max)}{f_{reference_clock}\,(min)} \times RCCR[REF_CNT] \right) + CMU_FC_{VAR+}$$

- HTCR[HFREF] = Ceiling(48.53 MHz ÷ 7.74 MHz × 80 + 3) = 505

11. Calculate low threshold value (LTCR[LFREF]):

$$\text{Floor value of } \left(\frac{f_{monitored_clock}\,(min)}{f_{reference_clock}\,(max)} \times RCCR[REF_CNT] \right) - CMU_FC_{VAR-}$$

- LTCR[LFREF] = Floor(47.47 MHz ÷ 8.26 MHz × 80 – 3) = 456

Table 267. HTCR[HFREF] and LTCR[LFREF] calculation example

Property	Value	Unit
Bus clock frequency (f_{bus_clock})	16	MHz
Monitored clock frequency ($f_{monitored_clock}$ (ideal))	48	MHz
Specified variation of monitored clock	1.1	%
Monitored clock frequency (maximum after specified variation, $f_{monitored_clock}$ (max))	48.53	MHz
Monitored clock frequency (minimum after specified variation, $f_{monitored_clock}$ (min))	47.47	MHz
Reference clock frequency ($f_{reference_clock}$ (ideal))	8	MHz
Specified variation of reference clock	3.3	%
Reference clock frequency (maximum after specified variation, $f_{reference_clock}$ (max))	8.26	MHz
Reference clock frequency (minimum after specified variation, $f_{reference_clock}$ (min))	7.74	MHz
Minimum reference count (RCCR[REF_CNT])	9	—
Programmed reference count (RCCR[REF_CNT]) (must be ≥ minimum RCCR[REF_CNT])	80	—
Measurement window	10000.00	ns
Calculated monitored clock count	480.00	—

54.4.3 Module programming sequence

The recommended programming sequence for CMU_FCfrequency checking is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency measuring window duration in *reference_clock* cycles.
   - Program LTCR[LFREF] and HTCR[HFREF] to set the permissible frequency range of the *monitored_clock*.
   - Program IER to enable interrupt.
2. Write GCR[FCE] = 1 to start the frequency check operation.

   NOTE

   When GCR[FCE] = 1, you must not write to RCCR, HTCR, LTCR, or IER. Attempting to do so generates a bus transfer error.
3. To reconfigure RCCR, LTCR, HTCR , and IER or to stop frequency check operation, wait for SR[RS] = 1, then write GCR[FCE] = 0.

54.5 CMU_FC register descriptions

54.5.1 CMU_FC memory map

This section describes the address order of all the CMU_FC registers. Each description includes a standard register diagram and associated field descriptions.

CMU_0 base address: 402B_C000h

CMU_3 base address: 402B_C060h

CMU_4 base address: 402B_C080h

CMU_5 base address: 402B_C0A0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	High Threshold Configuration Register (HTCR)	32	RW	00FF_FFFFh
Ch	Low Threshold Configuration Register (LTCR)	32	RW	0000_0000h
10h	Status Register (SR)	32	W1C	0000_0000h
14h	Interrupt Enable Register (IER)	32	RW	0000_0000h

54.5.2 Global Configuration Register (GCR)

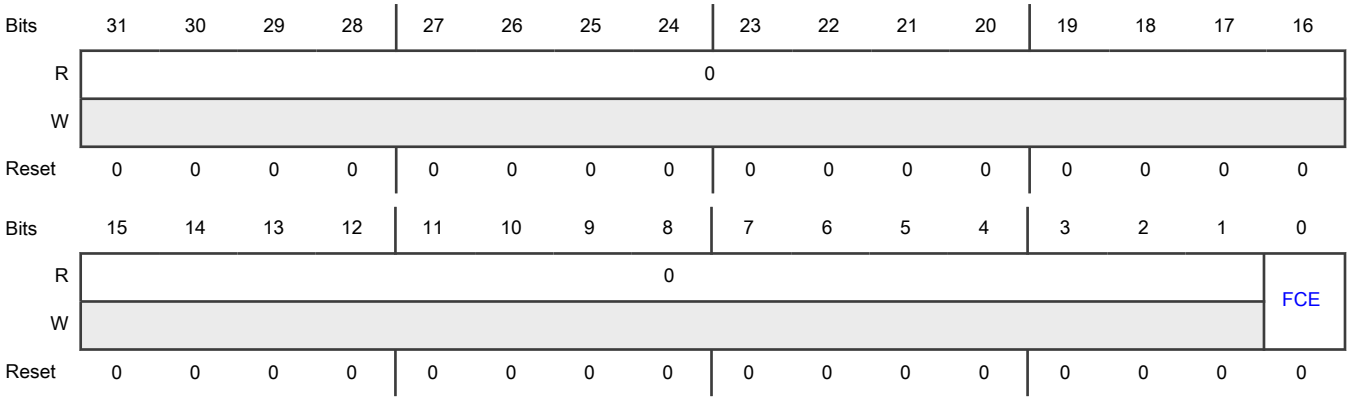
Offset

Register	Offset
GCR	0h

Function

Controls module level configurations such as enabling frequency check.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FCE	Frequency Check Enable Starts or stops frequency checking. FCE is disabled by default. Software can enable FCE at any time. To stop the ongoing operation, write 0 to FCE only when SR[RS] = 1. 0b - Stops frequency checking 1b - Starts frequency checking

54.5.3 Reference Count Configuration Register (RCCR)

Offset

Register	Offset
RCCR	4h

Function

Programs reference count duration of the frequency check window.

NOTE

Write to RCCR only when GCR[FCE] = 0. A bus transfer error results if software writes RCCR when GCR[FCE] = 1.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 REF_CNT	Reference clock count Total number of counts of *reference_clock* for which frequency check runs. This field defines the duration of one frequency check window. See Programming RCCR[REF_CNT] for RCCR calculation.

54.5.4 High Threshold Configuration Register (HTCR)

Offset

Register	Offset
HTCR	8h

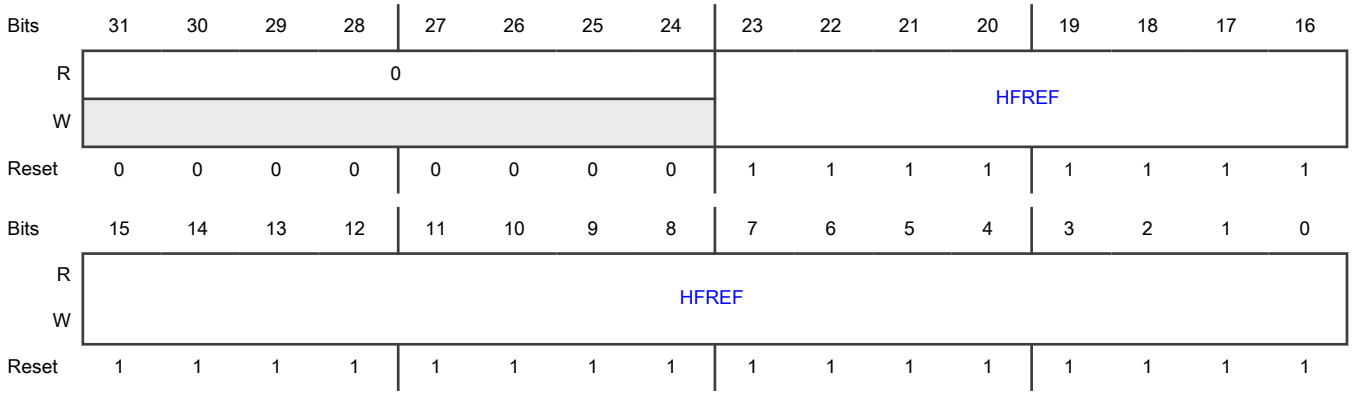
Function

Determines the high threshold limit of the monitored clock counter.

NOTE

Write HTCR only when GCR[FCE] = 0. A bus transfer error results if software writes HTCR when GCR[FCE] = 1.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 HFREF	High frequency reference threshold HFREF determines the high reference value for the monitored clock frequency. See Programming HFREF and LFREF for HFREF calculation. **NOTE** Do not program HFREF to a value greater than 0x00FFFFFC.

54.5.5 Low Threshold Configuration Register (LTCR)

Offset

Register	Offset
LTCR	Ch

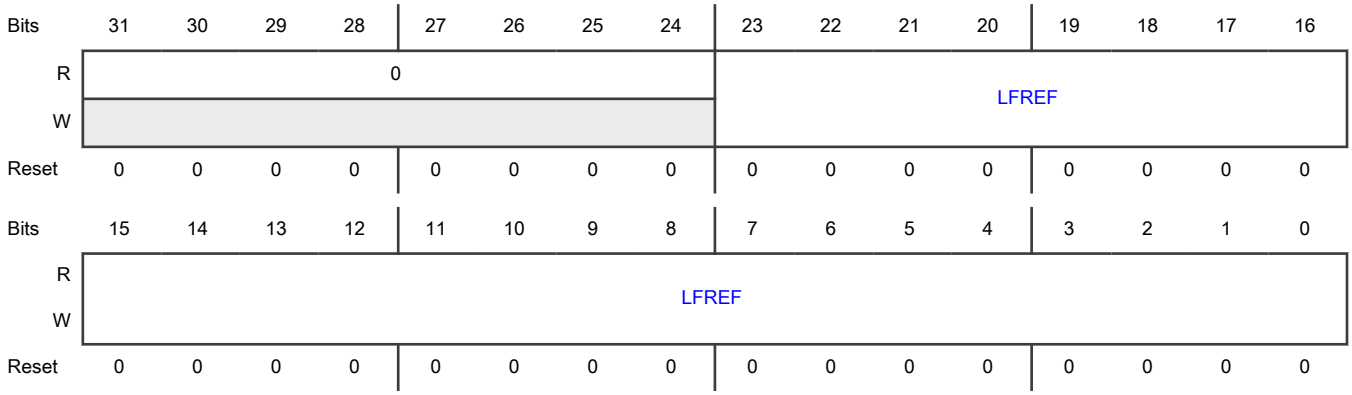
Function

Determines the low threshold limit of the monitored clock counter.

NOTE

Write LTCR only when GCR[FCE] = 0. A bus transfer error results if software writes LTCR when GCR[FCE] = 1.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 LFREF	Low Frequency Reference Threshold LFREF determines the low reference value for the monitored clock frequency. See Programming HFREF and LFREF for LFREF calculation. **NOTE** Do not program LFREF to a value less than 0x00000003.

54.5.6 Status Register (SR)

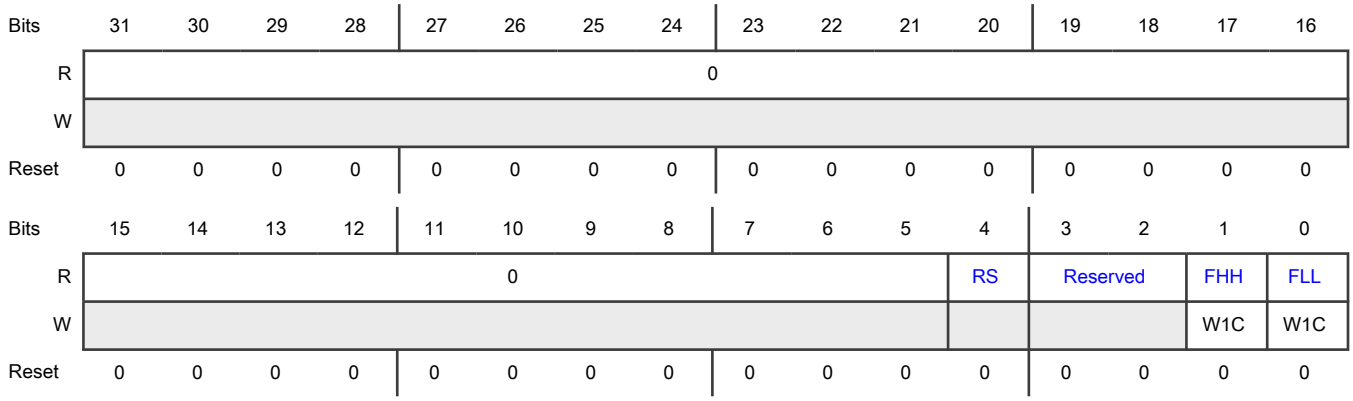
Offset

Register	Offset
SR	10h

Function

Provides the internal status of the module.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 RS	Run Status Shows the running status of module internal operation. After enabling the frequency check operation (GCR[FCE] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency check operation, then the software should read this register and write GCR[FCE] = 0 only when this field is 1. 0b - Frequency check stopped 1b - Frequency check running
3-2 —	Reserved
1 FHH	Frequency higher than high frequency reference threshold event status Hardware writes 1 to FHH when the monitored clock frequency becomes higher than the high threshold value in HTCR[HFREF]. FHH clears when software writes 1. 0b - No FHH event 1b - FHH event occurred
0 FLL	Frequency lower than low frequency reference threshold event status Hardware writes 1 to FLL when the monitored clock frequency becomes lower than the low threshold value in LTCR[LFREF]. FLL clears when software writes 1. 0b - No FLL event 1b - FLL event occurred

54.5.7 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	14h

Function

Enables CMU_FC interrupts.

NOTE

Write IER only when GCR[FCE] = 0. A bus transfer error results if software writes IER when GCR[FCE] = 1.

Enable only either asynchronous FHH event interrupt or synchronous FHH event interrupt at a time.

For example:

- If IER[FHHIE] is set to 1 then set IER[FHHAIE] to 0.
- If IER[FHHAIE] is set to 1 then set IER[FHHIE] to 0.

Enable only either asynchronous FLL event interrupt or synchronous FLL event interrupt at a time.

For example:

- If IER[FLLIE] is set to 1 then set IER[FLLAIE] to 0.
- If IER[FLLAIE] is set to 1 then set IER[FLLIE] to 0.

See Clocking chapter for interrupt usage information based on CMU_FC instances.

54.6 Glossary

FHH The state that the monitored clock frequency is higher than the high frequency reference. FHH is also the name of the register field that indicates this state.

FHH event The event that the module triggers when it detects FHH.

FLL The state that the monitored clock frequency is lower than the lower frequency reference. FLL is also the name of the register field that indicates this state.

FLL event The event that the module triggers when it detects FLL.

Chapter 55
Clock Monitoring Unit – Frequency Meter (CMU_FM)

55.1 Chip-specific CMU_FM information

55.1.1 CMU_FM configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are 6 clock monitoring units present in the device out of which 2 are of type CMU_FM. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

NOTE

CMU metering interrupt is not generated if the clock which is being metered is lost. A timeout status flag, CMU.SR[FMTO] is updated in this case.

NOTE

Software must ensure that CMU1 interrupt is serviced within POR_WDG timeout. In absence of CMU1 interrupt servicing, the POR_WDG detects this as an FIRC failure and initiates a POR recovery.

55.2 Introduction

CMU_FM measures the frequency of the metered clock (*metered_clock*) using another clock as reference. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FM operation. CMU_FM operation is only guaranteed if a reference clock is within normal operating parameters.

55.2.1 Basic operation

The CMU_FM counts the clock cycles of a metered clock in the user programmable time duration *n* number of clock cycles of the reference clock. After completion of a metered clock operation, a register field sets, indicating the operation has completed. The count of the metered clock also updates in the Status Register (SR) after completion of a metered clock operation.

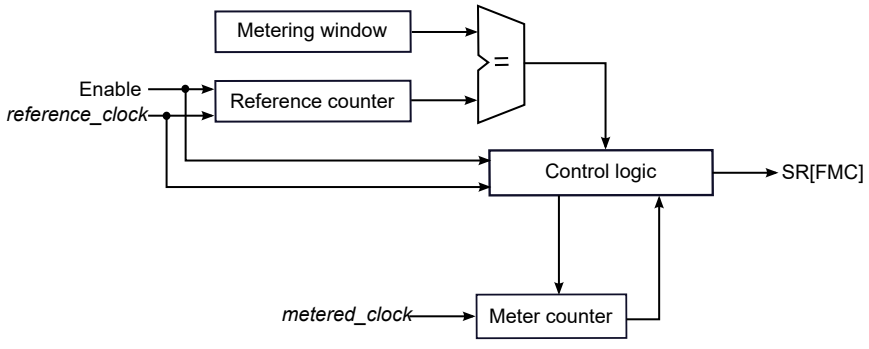

Figure 203. Block diagram

55.2.2 Features

Features of the CMU_FM are:

- Programmable duration of *reference_clock* cycles
- Maskable interrupt generation when frequency metering completes
- Timeout feature indicates loss of *metered_clock*

Table 268. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *metered_clock*
metered_clock	I	Clock signal on which frequency metering is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of metered and reference clocks used on this chip.

55.3 Functional description

The frequency meter operation initiates when software writes GCR[FME] = 1. When the operation starts, hardware writes SR[RS] = 1. Safety critical applications must poll SR[RS] to determine when metering operation starts.

Frequency metering window involves these operations:

1. Stage 1 — The reference clock counter runs for RCCR[REF_CNT] cycles of *reference_clock*. The metered clock counter runs in parallel for the same time duration as the *reference_clock* counter.
2. Stage 2 — At the end of stage 1, SR[FMC] = 1, SR[MET_CNT] updates with the *metered_clock* count, and CMU_FM writes GCR[FME] = 0.

55.4 Programming guidelines

55.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the metering operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)\right)$$

...where:

- $f_{reference_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{metering_clock}$ is the frequency of the metered clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference_clock}$ = 8 MHz
- $f_{metered_clock}$ = 48 MHz

Formula #1:

$$3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}} \right)$$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2:

$$6 + 4 \text{ X } \left(\frac{f_{reference_clock}}{f_{metered_clock}} \right)$$

Inserting the values: 6 + 4 × (8 / 48) ≈ 6.67

MAX (1.5, 6.67): 6.67

CEILING value of MAX: 7

Therefore, minimum RCCR[REF_CNT]: 7

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency metering completion response time and overall accuracy required from CMU_FM.

- Higher values of RCCR[REF_CNT] results in longer metering window, leading to better accuracy in metered clock measurement.
- Lower values of RCCR[REF_CNT] results in shorter metering window, leading to faster FMC response, but higher inaccuracy in reported result.

55.4.2 Module programming sequence

The recommended programming sequence of CMU_FM is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency metering window duration in *reference_clock* cycles.
   - Program IER[FMCIE] to enable interrupt.
2. Write GCR[FME] = 1 to start frequency metering operation. Writes to RCCR and IER are disabled after GCR[FME] = 1. Attempting a write to any of them after GCR[FME] = 1 generates a bus transfer error.
3. To reconfigure RCCR and IER or to stop frequency metering operation, wait for SR[RS] = 1, then write GCR[FME] = 0.

Upon completion of metering operations:

- Hardware writes SR[FMC] = 1
- SR[MET_CNT] updates with metered count value
- Hardware writes GCR[FME] = 0

55.5 CMU_FM register descriptions

55.5.1 CMU_FM memory map

This section describes the address order of all the CMU_FM registers. Each description includes a standard register diagram and associated field descriptions.

CMU_1 base address: 402B_C020h

CMU_2 base address: 402B_C040h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	Status Register (SR)	32	W1C	0000_0000h
Ch	Interrupt Enable Register (IER)	32	RW	0000_0000h

55.5.2 Global Configuration Register (GCR)

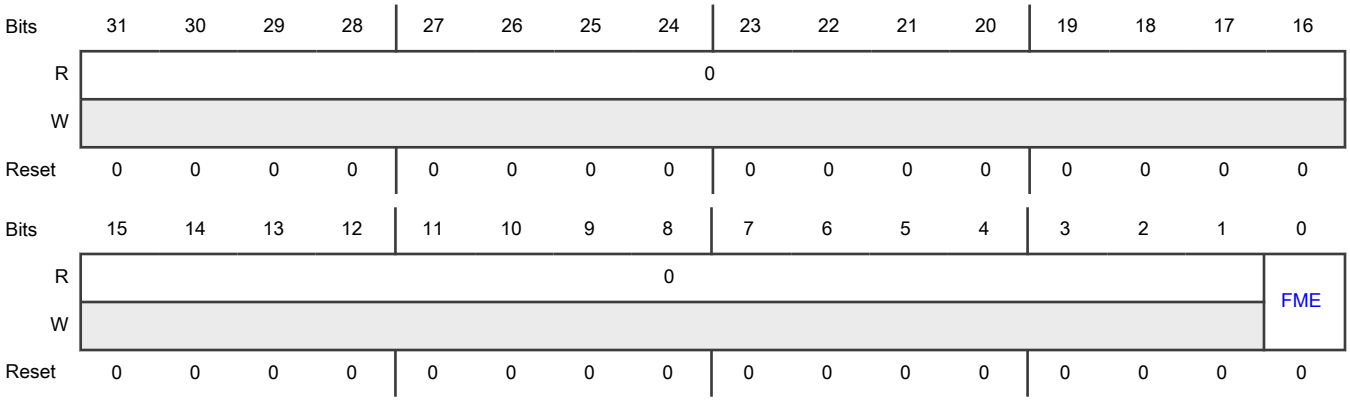
Offset

Register	Offset
GCR	0h

Function

Controls module level configurations such as enabling frequency metering.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FME	Frequency Meter Enable Starts or stops frequency metering. FME is disabled by default. Software can enable FME at any time. To stop the ongoing operation, write 0 to FME only when SR[RS] = 1. FME automatically clears upon frequency metering completion or timeout event.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Stops frequency metering 1b - Starts frequency metering

55.5.3 Reference Count Configuration Register (RCCR)

Offset

Register	Offset
RCCR	4h

Function

Programs reference count duration of the frequency meter window.

NOTE

Write to RCCR only when GCR[FME] = 0. A bus transfer error results if software writes RCCR when GCR[FME] = 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

R	MET_CNT								0			RS	Reserved		FMTO	FMC
W															W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 MET_CNT	Meter Clock Count This field stores the count value of the metered clock cycles when frequency metering operation is complete, in other words, SR[FMC] = 1. CMU_FM has a maximum deviation of ± 3 *metered_clock* cycles over the ideal *metered_clock* cycles expected by the user.
7-5 —	Reserved
4 RS	Run Status Shows the running status of module internal operation. After enabling the frequency metering operation (GCR[FME] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency metering operation, then the software should read this register and write GCR[FME] = 0 only when this field is 1. 0b - Frequency meter stopped 1b - Frequency meter running
3-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 FMTO	Frequency Meter Time Out Sets if there is a loss of metered clock during the metering operation. After metering window, the module waits for a timeout duration of RCCR[REF_CNT] cycles before writing one to this field. GCR[FME] = 0 and SR[FMC] = 0 when FMTO = 1. Writing one clears this field.
0 FMC	Frequency Meter Operation Complete On completion of frequency metering operation, FMC = 1, SR[MET_CNT] field updates, and GCR[FME] clears. Writing one clears this field.

55.5.5 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	Ch

Function
Enables CMU_FM interrupts.

NOTE

Write IER only when GCR[FME] = 0. A bus transfer error results if software writes IER when GCR[FME] = 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Chapter 56
Cyclic Redundancy Check (CRC)

56.1 Chip-specific CRC information

This chip supports one instance of CRC module.

56.2 Overview

The Cyclic Redundancy Check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

56.2.1 Block diagram

The following is a block diagram of the CRC.

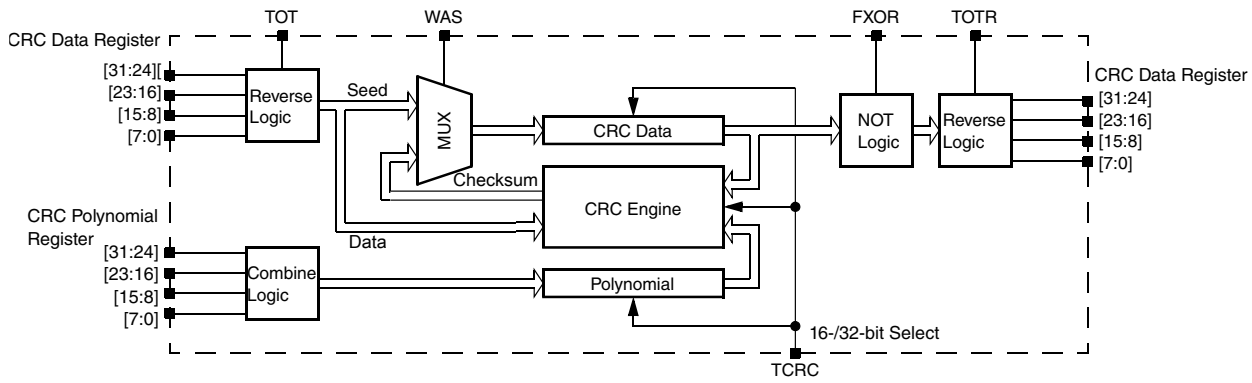

Figure 204. Programmable cyclic redundancy check (CRC) block diagram

56.2.2 Features

Following are the features of the CRC module.

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or bytewise. This option is required for certain CRC standards. A bytewise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the bytewise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

56.3 Functional description

56.3.1 Modes of operation

Following sections provide a brief description of various modes which affect the functionality of the CRC module.

56.3.1.1 Run mode

This is the basic mode of operation.

56.3.1.2 Low-power modes

Any CRC calculation in progress stops when the device enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the device.

56.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

56.3.2.1 16-bit CRC

The steps to compute a 16-bit CRC are listed as follows.

1. Clear CRC_CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 16-bit polynomial to the CRC_GPOLY[LOW] field. The CRC_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC_DATA[LU:LL]. CRC_DATA[HU:HL] are not used.
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[LU:LL].

Transpose and complement operations are performed on-the-fly while reading or writing values. See Transpose feature and CRC result complement for details.

56.3.2.2 32-bit CRC

The steps to compute a 32-bit CRC are listed as follows.

1. Set CRC_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 32-bit polynomial to CRC_GPOLY[HIGH:LOW].
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC_DATA[HU:HL:LU:LL].
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[HU:HL:LU:LL]. The CRC is calculated bytewise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on-the-fly while reading or writing values. See Transpose feature and CRC result complement for details.

56.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on-the-fly while being read or written.

Some protocols use little-endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

56.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC Data register.

1. CTRL[TOT] or CTRL[TOTR] is 0b00.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 0b01

   Bits in a byte are transposed, while bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}. See the following figure.

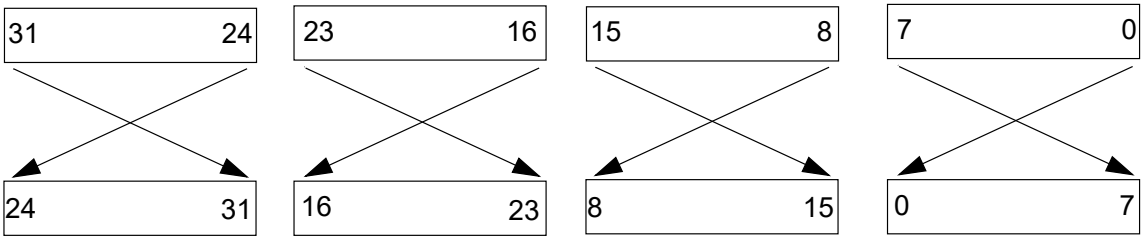

Figure 205. Transpose type 0b01

3. CTRL[TOT] or CTRL[TOTR] is 0b10.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes = {reg[0:7], reg[8:15],reg[16:23], reg[24:31]}. See the following figure.

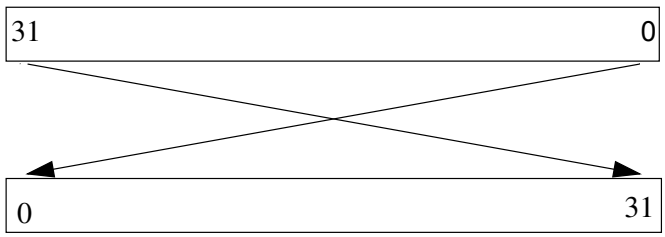

Figure 206. Transpose type 0b10

4. CTRL[TOT] or CTRL[TOTR] is 0b11.

   Bytes are transposed, but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}. See the following figure.

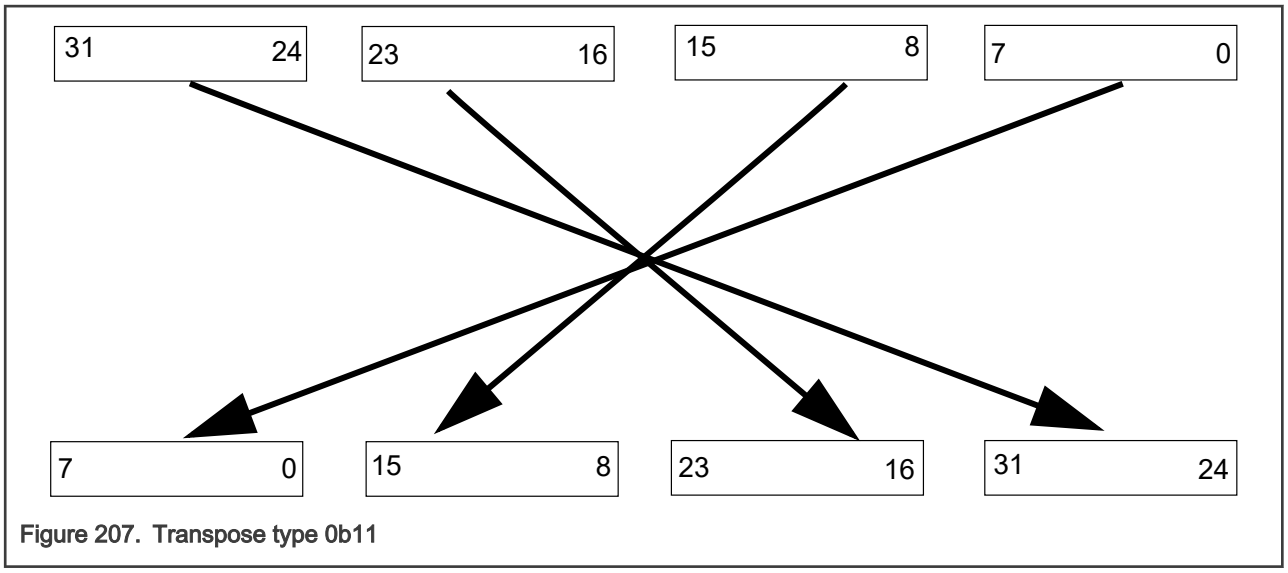

Figure 207. Transpose type 0b11

NOTE

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[HU:HL] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

56.3.4 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC Data (DATA) Register every time the CRC Data (DATA) register is read. When CTRL[FXOR] is cleared, reading the CRC Data (DATA) Register accesses the raw checksum value.

56.4 Use cases

NOTE

The following tables apply to little-endian format.

56.4.1 CRC Control Register programming

The following table shows the CRC Control Register programming for 16-bit CRC.

Table 269. Control Register (CTRL) programming for 16-bit CRC

56.5 External signals

There is no CRC signal that connects off chip.

56.6 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC_CTRL[WAS], CRC_GPOLY, necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting CRC_CTRL[WAS] enables the programming of the seed value into the CRC_DATA register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

56.7 Memory map and register descriptions

NOTE

Write access to the register addresses not mapped to the peripheral but included in the address space of the peripheral may result in unpredictable functionality. The CRC module should be reconfigured if a transfer error occurs.

56.7.1 CRC register descriptions

56.7.1.1 CRC memory map

CRC base address: 4038_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	CRC DATA register (DATA)	32	RW	FFFF_FFFFh
4h	CRC Polynomial register (GPOLY)	32	RW	0000_1021h
8h	CRC Control register (CTRL)	32	RW	0000_0000h

56.7.1.2 CRC DATA register (DATA)

Offset

Register	Offset
DATA	0h

Function

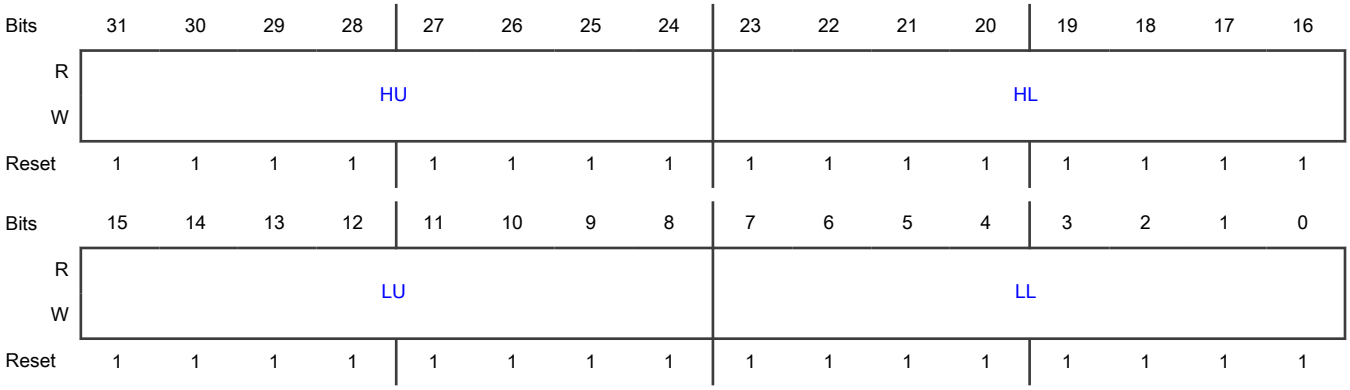
The CRC DATA register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Diagram



Fields

Field	Function
31-24 HU	CRC High Upper Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23-16 HL	CRC High Lower Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15-8 LU	CRC Low Upper Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
7-0 LL	CRC Low Lower Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

56.7.1.3 CRC Polynomial register (GPOLY)

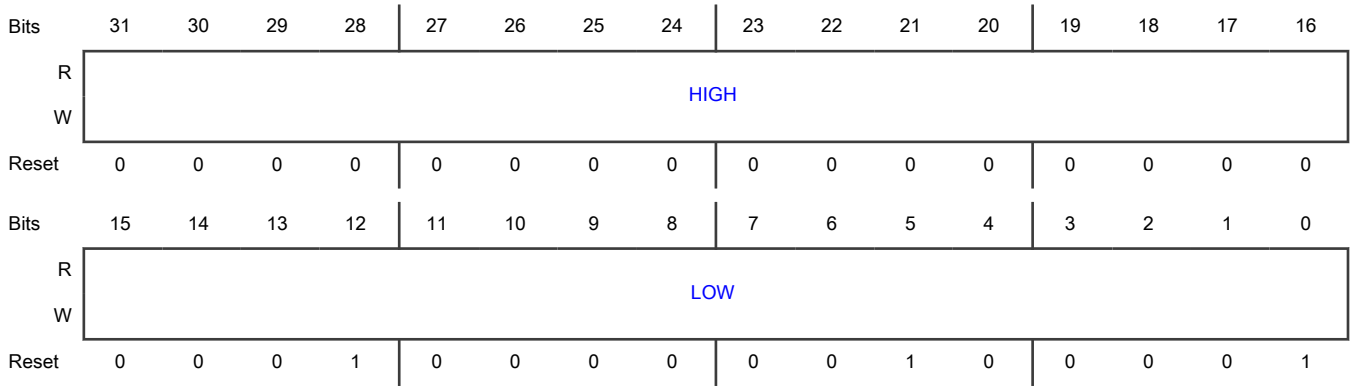
Offset

Register	Offset
GPOLY	4h

Function

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Diagram



Fields

Field	Function
31-16 HIGH	High Polynominal Half-word Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0).
15-0 LOW	Low Polynominal Half-word Writable and readable in both 32-bit and 16-bit CRC modes.

56.7.1.4 CRC Control register (CTRL)

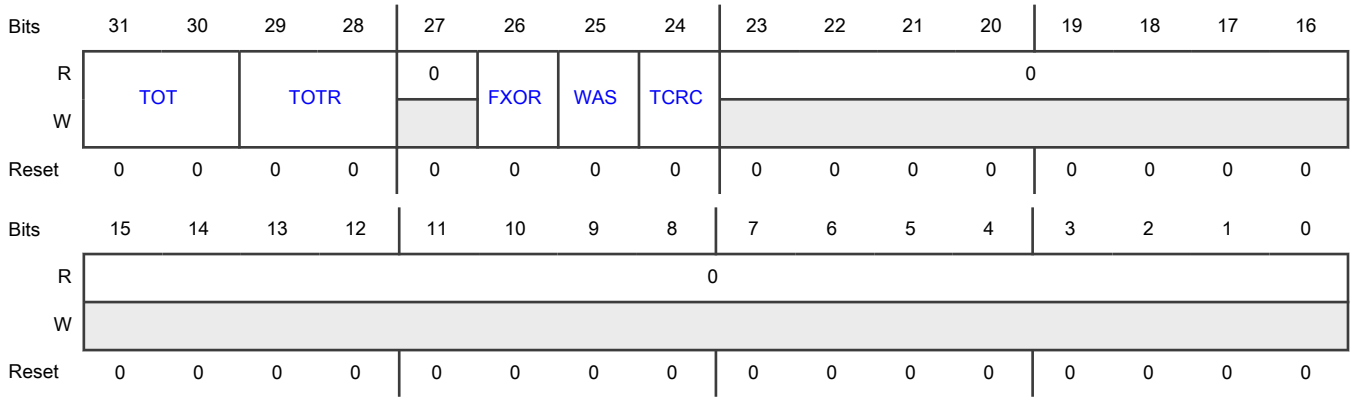
Offset

Register	Offset
CTRL	8h

Function

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC DATA register.

Diagram



Fields

Field	Function
31-30 TOT	Type Of Transpose For Writes Defines the transpose configuration of the data written to the CRC DATA register. See Transpose feature for the available transpose options. 00b - No transposition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Bits in bytes are transposed; bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed; no bits in a byte are transposed.
29-28 TOTR	Type Of Transpose For Read Identifies the transpose configuration of the value read from the CRC DATA register. See Transpose feature for the available transpose options. 00b - No transposition. 01b - Bits in bytes are transposed; bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed; no bits in a byte are transposed.
27 —	Reserved
26 FXOR	Complement Read Of CRC DATA register Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on-the-fly complementing of read data. 0b - No XOR on reading. 1b - Invert or complement the read value of the CRC DATA register.
25 WAS	Write CRC DATA register As Seed When asserted, a value written to the CRC DATA register is considered a seed value. When deasserted, a value written to the CRC DATA register is taken as data for CRC computation. 0b - Writes to the CRC DATA register are data values. 1b - Writes to the CRC DATA register are seed values.
24 TCRC	TCRC Width of CRC protocol. 0b - 16-bit CRC protocol. 1b - 32-bit CRC protocol.
23-0 —	Reserved

56.8 Glossary

Transpose	Flipping input or output data bits (or bytes)
Seed value	Initial value of CRC calculation

Chapter 57
Power Conversion and Motor Control (PCMC)

57.1 Introduction

The PCMC subsystem is a group of modules that can be interconnected to perform a variety of real-time tasks, such as:

- Motor control
- Power conversion
- Advanced PWM generation
- Lighting control

The modules that make up PCMC are:

- ADC
- BCTU
- eMIOS
- LCU
- LPCMP
- TRGMUX

See Feature comparison for the number of instances of each module in your chip.

57.2 Block diagram

The figure and table below show a typical configuration.

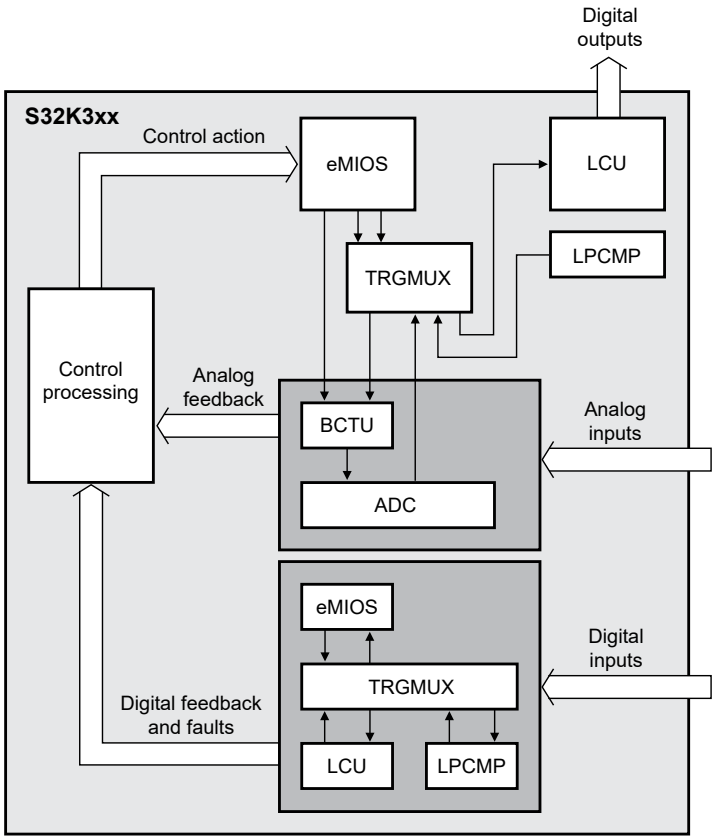


Figure 208. Block diagram

Table 273. Block diagram components

Component	Description
ADC	Measures external analog signals
BCTU	Performs advanced ADC triggering
Control processing	Arm Cortex-M7 core: • Processes digital and analog inputs to generate control outputs • Writes control outputs to peripherals
eMIOS	• Generates high-resolution PWM outputs • Measures time-based digital inputs
LCU	Performs programmable logic functions and fault control
LPCMP	Compares analog values to detect faults
TRGMUX	• Routes signals between internal peripherals • Routes external signals to internal peripherals

57.3 Functional overview

57.3.1 Analog signal measurement

ADC measures the voltage of external analog signals and converts that voltage to a digital value. Each ADC instance operates independently of other instances. Software or hardware can trigger conversions. Together with BCTU and eMIOS, ADC can preempt normal measurements by injecting high-priority measurements when needed.

See Analog-to-Digital Converter.

57.3.2 Advanced ADC triggering

BCTU works with ADC to initiate conversions triggered by outputs from other modules in the PCMC subsystem, such as PWM signals from eMIOS or LCU sequential logic outputs.

With BCTU, you can group measurements into configuration lists containing up to 32 items. Each item contains information such as:

- ADC instance to use for the conversion
- The ADC channel
- The trigger event for initiating the next conversion
- The conversion list address

BCTU can store conversion results by routing them through DMA or putting them in FIFO queues. The FIFO queues enable conversions to occur seamlessly by storing conversion results without software intervention.

BCTU has 72 trigger inputs, 69 of which come from the eMIOS channel outputs. The three remaining trigger inputs come from other on-chip modules via TRGMUX. You can also trigger conversions by software through the BCTU register interface.

BCTU can issue a single conversion or a list of conversions based on a single trigger occurrence. BCTU signals the eMIOS timers when ADC receives a single command or a list of commands. ADC sends conversion data back to BCTU, which loads it in the ADC*n* Result Data (ADC*n*DR) register for the CPU to read.

BCTU-to-ADC interface illustrates the connections between BCTU and an ADC.

57.3.3 BCTU-to-ADC interface

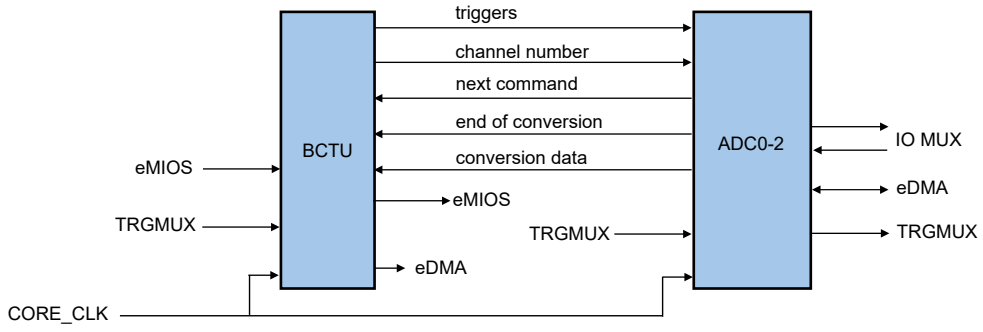

Figure 209. BCTU-to-ADC interface

57.3.4 Generate PWM outputs and measure digital inputs

eMIOS generates high-resolution PWM outputs. Each eMIOS instance has 23 dedicated channel outputs. You can configure each channel to operate in a different mode. Depending on the mode, eMIOS channels can:

- Measure the period of an input signal
- Measure the width of an input pulse
- Function as general-purpose I/O
- Count pulses or edges
- Capture input values
- Compare outputs

For example, eMIOS can generate periodic ADC triggers. Using TRGMUX, you can route eMIOS triggers to other on-chip peripherals such as LCU, another eMIOS instance, external chip I/O, and so on.

eMIOS connections illustrates the input and output connections for eMIOS.

- Trigger Mux (TRGMUX)

57.3.5 eMIOS connections

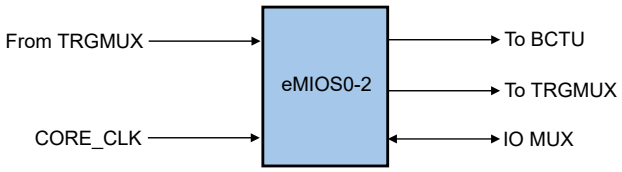

Figure 210. eMIOS connections

57.3.6 Create combinatorial and sequential logic functions

LCU enables you to implement hardware-based combinatorial and sequential logic on the chip. This capability reduces cost and decreases application size.

Each LCU instance has 12 dedicated inputs and 12 outputs. You can use LCU to implement a variety of combinatorial and sequential logic functions with no CPU intervention, including a simple OR gate, flip flops, and motor control logic. As detailed in Fault detection, LCU also plays a significant role in fault management.

LCU connections shows the input and output connections for LCU.

See also:

- Logic Control Unit (LCU)
- LCU use case examples
- Trigger MUX (TRGMUX)
- TRGMUX connectivity file attached to this document

57.3.7 LCU connections

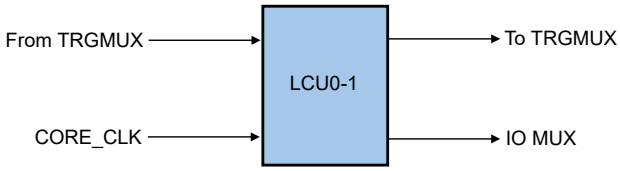

Figure 211. LCU connections

57.3.8 Fault detection

The PCMC subsystem uses LPCMP and LCU to implement fault detection.

LPCMP can detect fault conditions (such as short circuits, over-voltages, and excessive temperature) by comparing an external input voltage to a programmable reference voltage. It produces a digital output that indicates whether the input voltage is higher or lower than the reference voltage.

The chip can detect faults via external digital or analog signals. TRGMUX routes digital signals from SIUL to a peripheral to trigger the appropriate behavior.

LCU has four force inputs that you can use to manage fault assertion via its own internal logic mechanism.

The typical reaction to the presence of fault is to put the system in a safe state by:

- Deasserting output signals such as PWM outputs controlling a power stage.
- Disconnecting an entire circuit by switching off a relay.

See also Low Power Comparator (LPCMP).

57.3.9 Programmable module interconnections

TRGMUX enables you to interconnect on-chip peripherals to create application-specific configurations. TRGMUX has 128 inputs and 111 outputs, which you can interconnect in hundreds of combinations through software during runtime.

You can also route on-chip peripheral outputs to chip I/O pins to enable signal debugging. Similarly, you can route external signals to on-chip peripheral inputs.

NOTE

There is a two-cycle AIPS_SLOW_CLK delay through TRGMUX.

For details of PCMC interconnections, see PCMC connections diagram.

The attached TRGMUX connectivity file, a portion of which appears below, shows the interconnections possible between module instances. Column B in the spreadsheet lists TRGMUX inputs. Row 3 lists TRGMUX outputs. A connection between an input and an output is possible if the intersecting cell of the input row and the output column is blank. "NA" indicates that a connection is not possible.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N
1					Output no.	0	1	2	4	5	6	8	9	10
2					Output register no.	0	0	0	1	1	1	2	2	2
3					S32K314	Y	Y	Y	Y	Y	Y	Y	Y	Y
4					S32K324	Y	Y	Y	Y	Y	Y	Y	Y	Y
5					S32K344	Y	Y	Y	Y	Y	Y	Y	Y	Y
6	Input no.	S32K314	S32K324	S32K344	TRGMUX output	ADC12_0_EXTRG for normal conversion	ADC12_0_EXTRG for injected conversion	ADC12_0_EXTRG to sync the start pulses	ADC12_1_EXTRG for normal conversion	ADC12_1_EXTRG for injected conversion	ADC12_1_EXTRG to sync the start pulses	ADC12_2_EXTRG for normal conversion	ADC12_2_EXTRG for injected conversion	ADC12_2_EXTRG to sync the start pulses
7	0	Y	Y	Y	Logic 0 (VSS)	NA	NA	NA	NA	NA	NA	NA	NA	NA

57.4 Reset, clocking, and other considerations

57.4.1 Reset

ADC, BCTU, eMIOS, LCU, and TRGMUX fully reset during a POR, destructive reset, or functional reset.

See also:

- Module reset status
- Software reset

57.4.2 Clocking

Detailed clocking information is given in the links below. In summary:

- CORE_CLK clocks ADC, BCTU, eMIOS, and LCU.
- AIPS_SLOW_CLK clocks TRGMUX.
- In general, you must set AIPS_SLOW_CLK to one-fourth or one-half the frequency of CORE_CLK.

See also:

- ADC and motor control modules
- System clocking configurations
- System clock frequency limitations
- Clock frequency

57.4.3 Power modes

All ADC, BCTU, eMIOS, LCU, and TRGMUX instances operate only in Run mode. None of the instances operate in Standby mode.

See also:

- Module reset status
- ADC modes of operation
- LCU modes of operation

57.5 Use case examples

57.5.1 Motor control use case

The following sections show:

- A PMSM control system
- A BLDC control system

Both PMSM and BLDC use a rotating magnetic stator field to turn the stator consisting of permanent magnets. The stator is driven by 3-phase AC voltage. The difference between PMSM and BLDC is in how stator position is calculated.

- PMSM calculates stator position by measuring back EMF from the motor.
- BLDC calculates stator position based on feedback from motor sensors.

57.5.1.1 PMSM motor control use case

57.5.1.1.1 Generic PMSM motor control

The following figure and table illustrate a generic PMSM motor control system. The feedback loops in the system create a motor control loop.

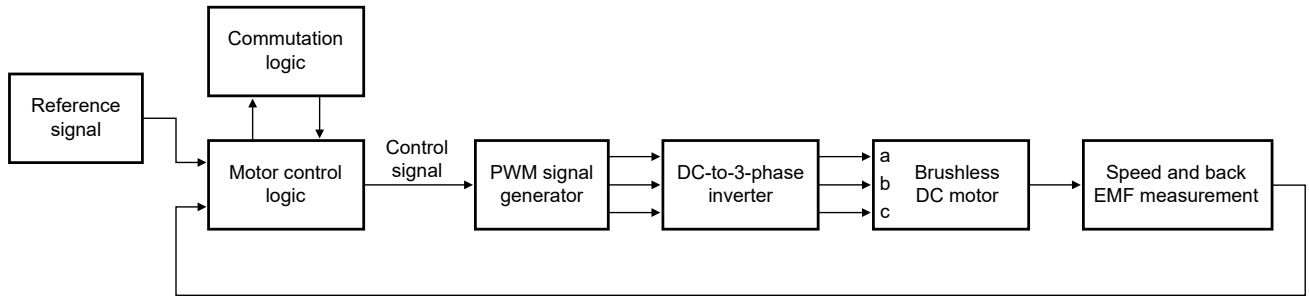

Figure 214. Generic PMSM motor control

Table 274. Block diagram components

Block	Description
Angular position sensor	Generates data that enables commutation logic to calculate rotor position.
Brushless DC motor	Electronically commutated electric motor.
Commutation logic	Compares values from the rotor angular position sensors to entries in a lookup table, and applies voltage to stator winding corresponding to same set of values in lookup table.

Table continues on the next page...

Table 274. Block diagram components (continued)

Block	Description
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
Motor control logic	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
PWM signal generator	Generates PWM signal voltage source.
Reference signal	Signal that indicates required motor speed.
Speed and back EMF measurement	An ADC is linked to a shunt resistor to perform measurements and detect over-current conditions. If one is found, then hardware generates a fault interrupt.

57.5.1.1.2 PMSM motor control

The PCMC subsystem consists of a group of modules that enable you to implement PMSM motor control loops in a variety of ways. The following figure and table illustrate one possible implementation.

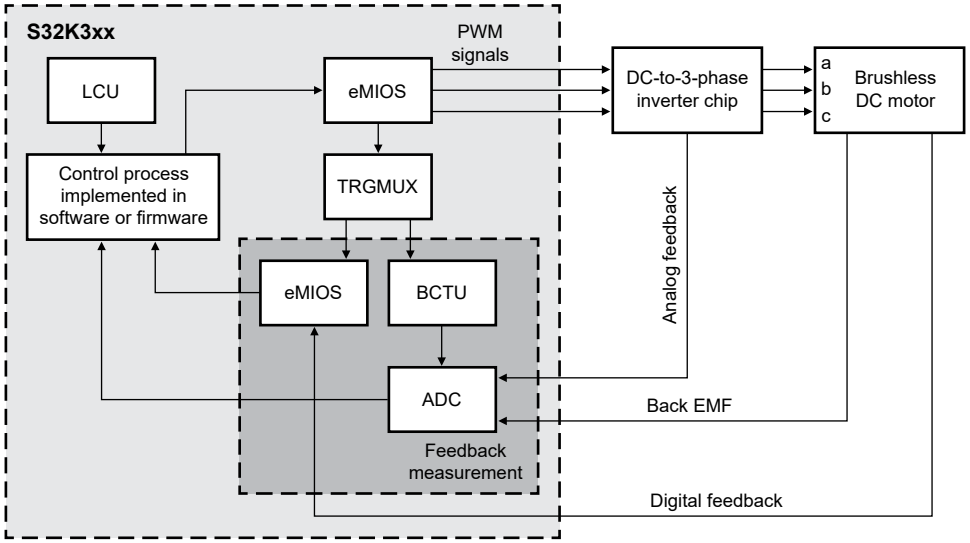

Figure 215. PMSM motor control

Table 275. Block diagram components

Block	Description
ADC	Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC or another feasible control algorithm:

Table continues on the next page...

Table 275. Block diagram components (continued)

Block	Description
	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC to 3-phase inverter. • Measures digital feedback inputs—BLDC position sensors, for example.
LCU	Implements commutation lookup table. Control Process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table.
TRGMUX	• Enables interconnect to the required set of on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

57.5.1.2 Sensored BLDC motor control use case

57.5.1.2.1 Generic sensored BLDC motor control

The following figure and table illustrate a generic sensored BLDC motor control system. The feedback loops in the system create a motor control loop.

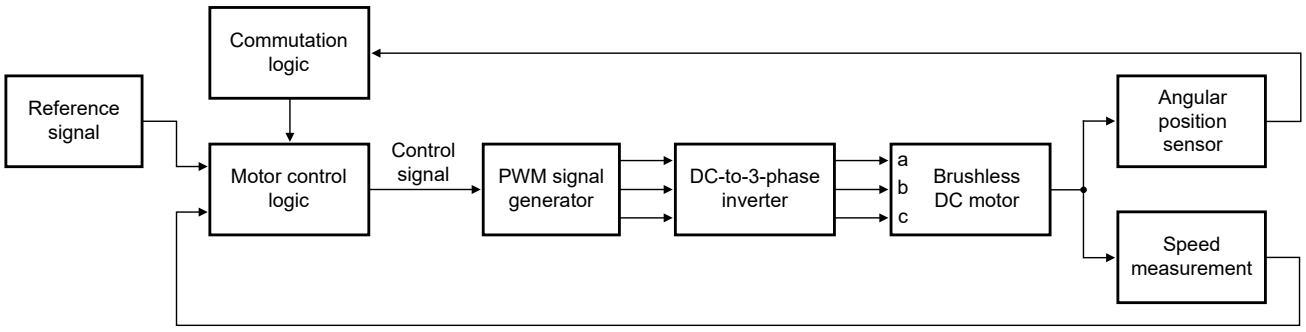

Figure 216. Generic sensored BLDC motor control

Table 276. Block diagram components

Block	Description
Angular position sensor	Hall effect sensors or optical decoders detect rotor position
Commutation logic	Compares values from the angular position sensors to entries in a lookup table and applies voltage to stator winding corresponding to same set of values in lookup table
Reference signal	Signal that indicates required motor speed

Table continues on the next page...

Table 276. Block diagram components (continued)

Block	Description
DC-to-3-phase inverter	Switching network that transmits power to the stator windings according to a control signal
Motor control logic	• Compares speed measurement to required speed and adjusts the PWM signal generator • Generates the assertions for the PWM signal generator according to commutation logic input
Speed measurement	Uses an ADC linked to a shunt resistor to perform measurements and detect over-current conditions, in which case hardware generates an interrupt.

57.5.1.2.2 PCMC sensored field-oriented control (FOC) of 3-phase BLDC motor

FOC is a VFD control method in which the stator currents of a 3-phase AC electric motor (such as BLDC, PMCM, reluctance motor, or other spinning electrical machine) is identified as a vector.

The PCMC subsystem consists of a group of modules that enable you to implement sensored FOC BLDC motor control loops in a variety of ways. The following figure and table show one possible implementation.

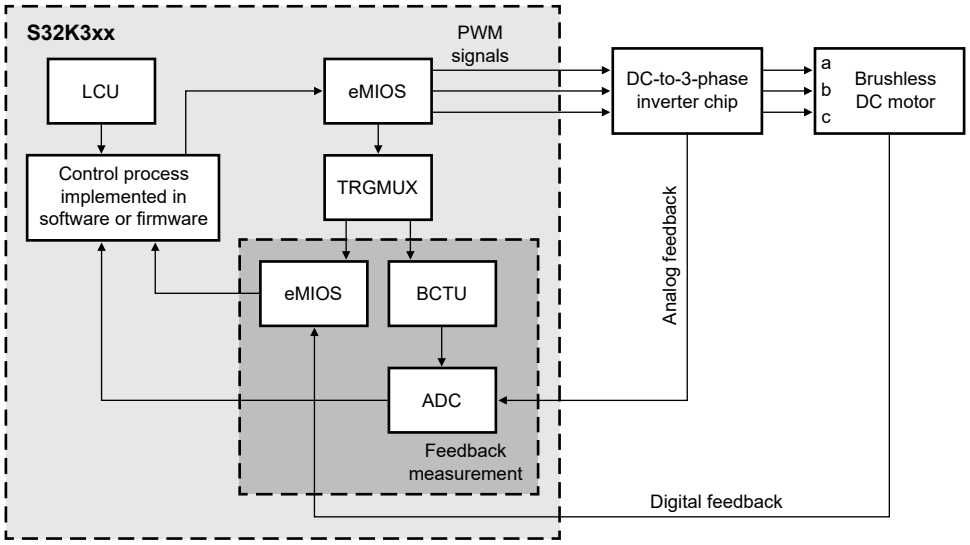

Figure 217. PCMC sensored BLDC motor control

Table 277. Block diagram components

Block	Description
ADC	Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents, and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC control:

Table continues on the next page...

Table 277. Block diagram components (continued)

Block	Description
	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC to 3-phase inverter. • Measures digital feedback inputs—BLDC position sensors, for example.
LCU	Implements commutation lookup table. Control process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table.
TRGMUX	• Enables interconnect of the required set on on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

57.6 Design considerations

57.6.1 ADC design considerations

The following topics discuss factors that affect ADC function in applications.

57.6.1.1 ADC measurement accuracy

The FOC motor control algorithm requires a high degree of confidence in the reliability of conversion data. Here are some best practices that contribute to ADC precision.

- Use precision channels (see ADC precision channels).
- Minimize input noise (see ADC input noise).
- Use BCTU triggering (see ADC triggering).

57.6.1.1.1 ADC precision channels

See the chip-specific ADC configuration information for the number of precision channels for each ADC instance.

See the channel mapping table for the channel numbers for the precision channels.

57.6.1.1.2 ADC input noise

Regardless of the application, ADCs are inherently sensitive to input noise. The following best practices help minimize input noise.

- Avoid simultaneous conversions.
- Consider using a low-pass filter on input pins.

All variants of this chip include multiple, independent ADC instances, so it is easily possible to have simultaneous sampling by different ADC instances. This should be avoided, though, because ADC sampling can cause noise on adjacent device ADC inputs. Avoidance of simultaneous sampling should be ensured by software design. This is important for implementations of the FOC algorithm.

Additionally, an RC low-pass filter on ADC input pins can help reduce noise and enhance accuracy.

57.6.1.1.3 ADC triggering

Some applications, including FOC motor control, must use BCTU for precise triggering of ADC measurement. This is because the FOC algorithm requires sampling at specific times to implement the “observer/predictor”. BCTU makes it possible to perform precisely-timed ADC measurement.

For less exigent algorithms or non-closed-loop controlled motors, BCTU triggering and precision ADC channels are not necessarily required.

57.6.1.2 Example ADC configurations

Following are some ADC configurations that might be used for FOC motor control.

Table 278. Example ADC configurations

Description	Settings
Single-shot mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Disable BCTU triggering (BCTUEN=0) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)
Normal conversion scan mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select looped conversions (MODE=1) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Disable BCTU triggering (BCTUEN=0) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)
BCTU control mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Enable BCTU triggering (BCTUEN=1) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)

Table continues on the next page...

Table 278. Example ADC configurations (continued)

Description	Settings
BCTU trigger mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Enable BCTU triggering (BCTUEN=1) • Enable all trigger sources (BCTU_MODE=1) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)

57.6.2 BCTU design considerations

For reasons discussed in ADC triggering, some applications require precise ADC triggering and BCTU provides that capability. The following topics discuss some design considerations when using BCTU.

57.6.2.1 BCTU or ADC data retrieval

Although the primary function of BCTU is to provide precisely timed triggers for ADC conversions, there is some overlap in BCTU and ADC function in that conversion data can be retrieved from either module. For applications in which frequent conversions are performed, such as real-time motor control, BCTU offers a distinct advantage over ADC, because BCTU trigger sources can be configured to route conversion results to a BCTU internal FIFO. Doing so prevents subsequent conversion data from overwriting previous data, making it available for either direct access or DMA transfer to system RAM.

57.6.2.2 Disabling BCTU triggers

There are fault scenarios in which an application must disable BCTU triggers as part of putting the system into a safe state. Examples include:

- Over-voltage condition
- Under-voltage condition
- Calibration parameter mismatch between the embedded motor control system and the motor

Application fault reaction design must include the disabling of BCTU triggers in scenarios in which either system conditions indicate an impending failure, or ADC conversion data is outside control boundaries.

57.6.3 eMIOS design considerations

In a BLDC motor control application, eMIOS plays a central role, providing the driving PWM signal as well as performing feedback signal measurements. The following topics discuss eMIOS considerations in the application design.

57.6.3.1 PWM considerations

In a BLDC motor control application, PWM/power signal requirements are affected by a number of parameters, including:

- Displacement Power Factor
- DF
- THD
- DVA

- CF
- FF

Ensure that the above parameters are included when choosing the timebase and prescaler combination for eMIOS channels producing PWM signals.

57.6.3.2 Input measurement

In a BLDC motor control application, eMIOS measures feedback signals for the motor and provides critical information to the control system. Selecting a timebase and prescaler for eMIOS channels performing input measurement tasks is usually a tradeoff between application requirements for precision and the computational cost in relation to the selected clock speed.

For example, some applications like electric steering demand an extremely precise control for position and torque. This is different from a compressor e-motor, where speed and torque do not demand rigid precision requirements.

Other considerations are related to control of:

- THD
- FF
- GM
- pf correction

The above considerations are significant from the perspective of the PWM reaction speed for the output signal for BLDC applications. These parameters must be considered in the design.

57.6.3.3 eMIOS channel modes useful in motor control

Table 279. eMIOS channel modes useful in motor control

Mode	Description	Use in motor control
MCB	Modulus Counter Buffered (Up/Down)	Time base • PWM frequency • Reload
IPWM	Input Pulse Width Measurement	Capture modes: • Speed measurement • Position measurement • Voltage (duty cycle)
IPM	Input Period Measurement	Speed measurement
PEC	Pulse Edge Counting	Position measurement
OPWMCB	Center aligned Output PWM Buffered with dead time	PWM duty cycle
OPWMB	Output Pulse Width Modulation Buffered	Trigger placement within the period
OPWMT	Output Pulse Width Modulation Trigger	Trigger placement within the period

57.6.3.3.1 MCB PWM and trigger generation

The following figure shows one option for PWM and trigger generation.

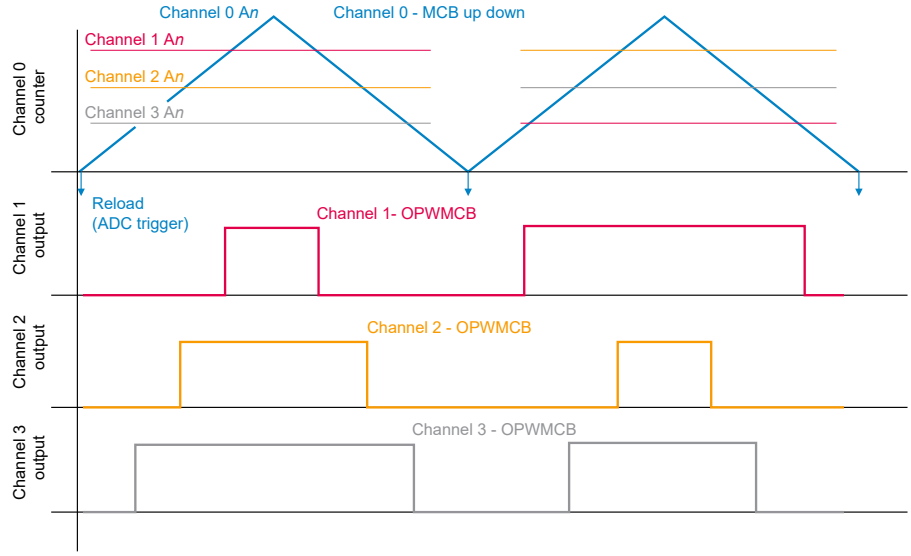

Figure 218. MCB PWM trigger generation

57.6.3.3.2 OPWMCB PWM and trigger generation

The following figure shows another option for PWM and trigger generation.

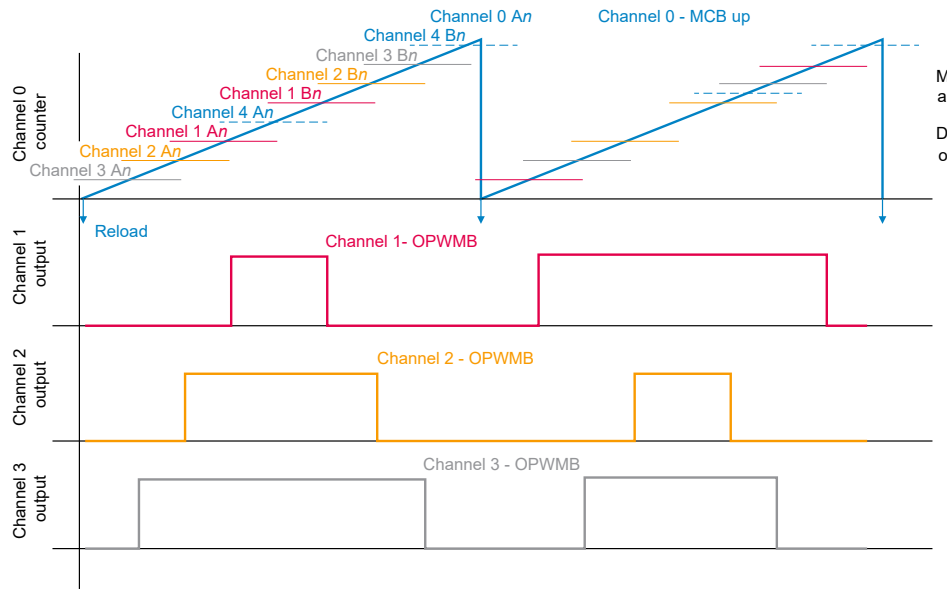

Figure 219. OPWMCB PWM trigger generation

57.7 Glossary

BLDC	Brushless DC. An electronically commutated DC motor.
CF	Crest Factor. A waveform parameter that is the ratio of peak values to its RMS value.
DF	Distortion Factor.

Displacement Power Factor	In power electronics, the phase relationship between voltage and current: $\cos(\theta_v - \theta_i)$, where θ_v is the phase of the voltage and θ_i is the phase of the current.
DVA	Distortion Volt-Amps.
FF	Form Factor.
FOC	Field-Oriented Control.
GM	Gain Margin.
pf	Power factor. In power electronics, it is the ratio of average power to RMS power.
PMSM	Permanent Magnet Synchronous Motor.
THD	Total Harmonic Distortion.
VFD	Variable-Frequency Drive.

1. Channels marked with “-“ means they are reserved and access to any reserved channel may result in inappropriate data.

NOTE

The decoding signals for the selection of external ADC channels (ADC_X) are gray-encoded.

NOTE

Value of ANAMUX_OUT is selected by DCMRWF1[SUPPLY_MON_SEL] field.

NOTE

The module clock mentioned in this chapter is CORE_CLK for this chip.

58.1.2 ANAMUX for internal supply monitoring

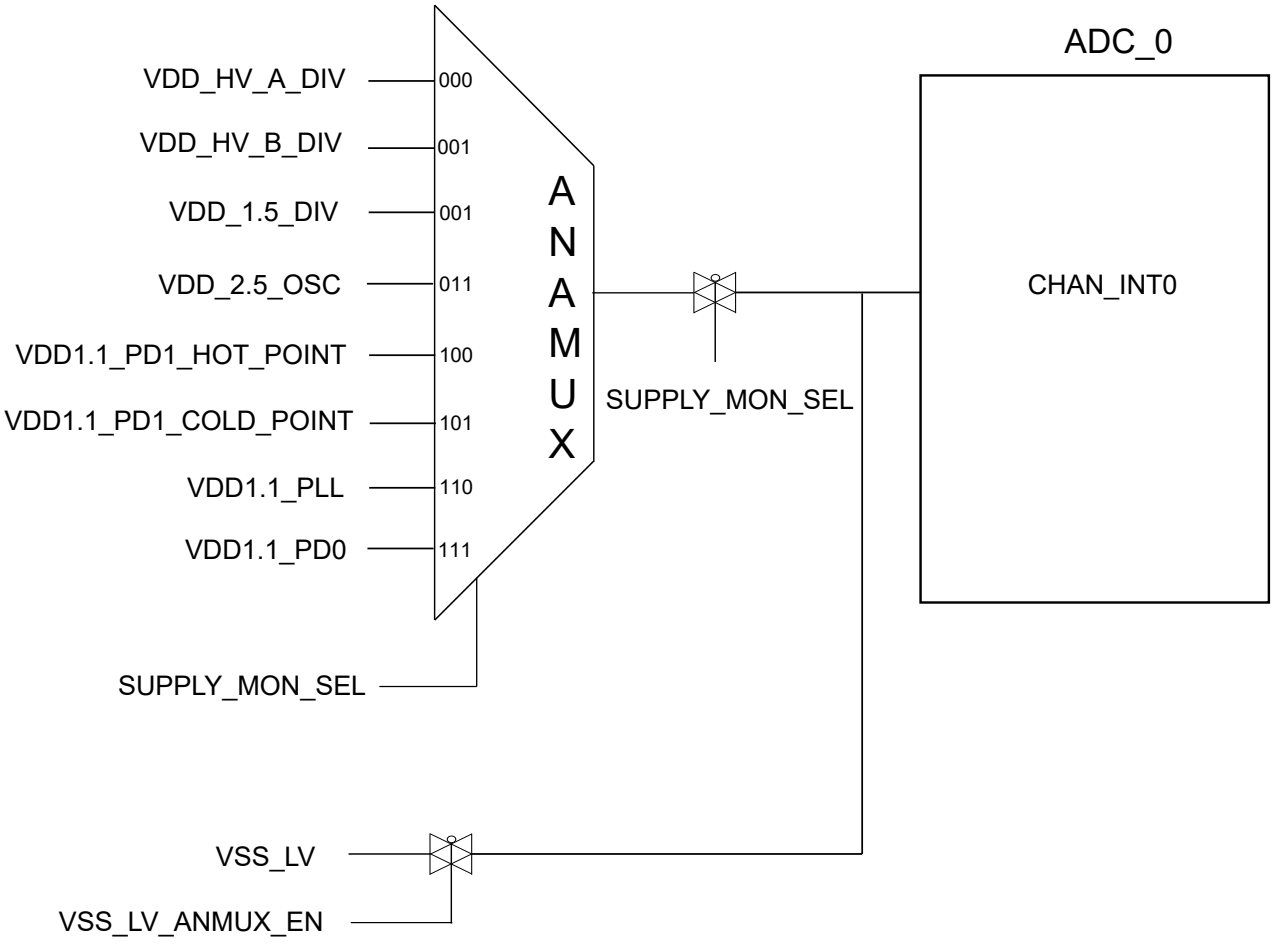

Figure 220.

NOTE

VDD_HV_B_DIV, VDD_1.5_DIV are not available in S32K312 and S32K311.

58.1.3 BCTU Interface

All 3 instances of ADC are triggered from the BCTU. The BCTU provides channel conversion commands to the ADC (includes channel number information). In addition, the ADC provides the conversion result back to the BCTU.

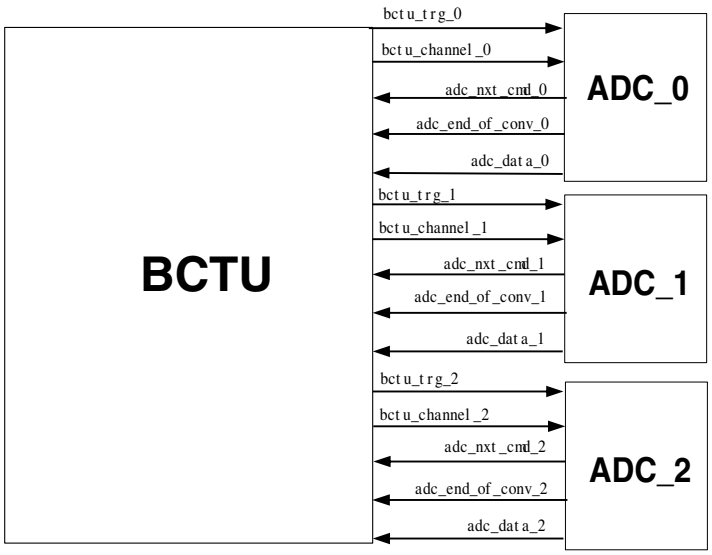

Figure 221. ADC Cross-triggering Unit

BCTU gives trigger pulse to all the 72 channels of ADC to initiate a conversion based on BCTU channel number.

BCTU-ADC result register

ADC result registers (ADCx_PCDRn[CDATA], ADCx_ICDRn[CDATA] and ADCx_ECDRn[CDATA]) store 15 bit conversion data. The BCTU ADC registers store 15-bit conversion data (BCTU_ADC0DR[ADC0_DATA], BCTU_ADC1DR[ADC1_DATA] and BCTU_ADC2DR[ADC2_DATA]).

58.1.4 DMA interface

Each ADC supports a single DMA request that can be requested after the conversion of every channel. The conversion result is stored into a register DMAR and is transferred via DMA or host access.

NOTE

The last ongoing conversion will be aborted as soon as ADC gets STOP request from the software and it will move to STOP mode.

58.1.5 Hardware triggers

In this chip, hardware trigger signals can be provided from TRGMUX outputs. This feature enables synchronous conversion of two independent ADC instances in parallel. If ADC is in Idle state (that is, no conversion phase ongoing and the MCR[PWDN] and MCR[ACKO] fields are 0) and the MCR[XSTRTEN] is set, an event on the external start signal causes ADC to start either normal or injected conversion operation. The MCR[NSTART]/MCR[JSTART] field is automatically set respectively. The normal conversion sync pulse is used with normal conversion trigger to synchronize the start timing of normal conversion between multiple ADC instances.

Table 284. Hardware triggers

TRGMUX output number	Hardware trigger functions
0	ADC_0 Normal Conversion
1	ADC_0 Injected Conversion
2	ADC_0 Normal Conversion Sync Pulse

Table continues on the next page...

Table 284. Hardware triggers (continued)

TRGMUX output number	Hardware trigger functions
4	ADC_1 Normal Conversion
5	ADC_1 Injected Conversion
6	ADC_1 Normal Conversion Sync Pulse
8	ADC_2 Normal Conversion
9	ADC_2 Injected Conversion
10	ADC_2 Normal Conversion Sync Pulse

58.1.6 ADC Self-Test

It is important to check at regular intervals if the ADC is operating correctly. For this purpose a self test feature is provided. When self-test is enabled, the ADC automatically checks its components and flags errors.

58.1.7 ADC mux-mode channels

There are some channels in ADC which are driven by multiple pads. For this, GPR bits from DCM are used to define which pad is connected to a particular ADC channel.

For example as below, where ADC0 S8 is driven by GPIO_PAD0 (default) and GPIO_PAD45 (mux_mode). ADC2 S8 is driven by GPIO_PAD133 (default) and GPIO_PAD45 (mux_mode). ADC1 S8 has a dedicated pad GPIO45, so its TGATE doesn't need GPR bit gating. Similar implementation is for ADC0_S9 and ADC2_S9. Following DCM GPR bits have been used:

Table 285. ADC mux_mode GPR

ADC channel	GPR_bit	Connected pad
ADC0 Standard channel 8 (ADC0 S8)	DCM.DCMRWF4[1]	0: GPIO PAD0 (default) 1: GPIO PAD45
ADC0 Standard channel 9 (ADC0 S9)	DCM.DCMRWF4[2]	0: GPIO PAD1 (default) 1: GPIO PAD46
ADC 1 standard channel 14 (ADC1 S14)	DCM.DCMRWF4[3]	0: GPIO PAD69 (default) 1: GPIO PAD32
ADC 1 standard channel 15 (ADC1 S15)	DCM.DCMRWF4[4]	0: GPIO PAD4 (default) 1: GPIO PAD33
ADC1 Standard channel 22 (ADC1 S22)	DCM.DCMRWF4[5]	0: GPIO PAD124 (default) 1: GPIO PAD145
ADC1 Standard channel 23 (ADC1 S23)	DCM.DCMRWF4[6]	0: GPIO PAD125 (default) 1: GPIO PAD146
ADC2 Standard channel 8 (ADC2 S8)	DCM.DCMRWF4[9]	0: GPIO PAD133 (default) 1: GPIO PAD45
ADC2 Standard channel 9 (ADC2 S9)	DCM.DCMRWF4[10]	0: GPIO PAD132 (default) 1: GPIO PAD46

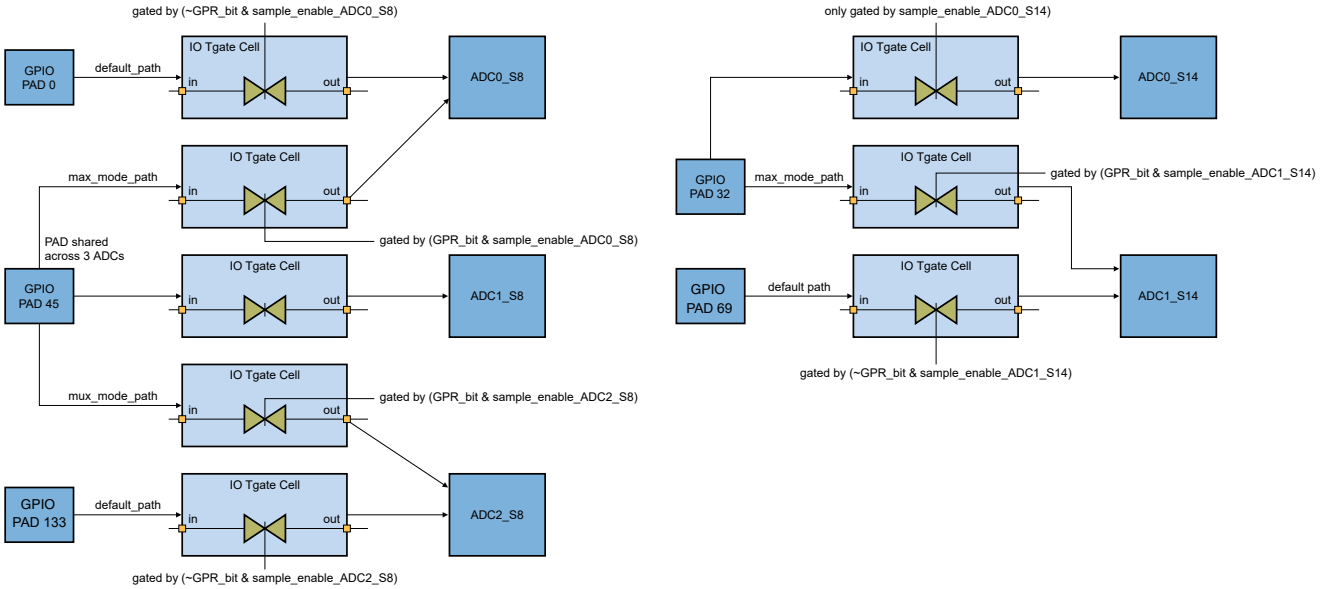

Figure 222. ADC channel interleaving

58.2 Introduction

ADC produces a digital value from an input analog voltage using the SAR algorithm. It features various methods to trigger a conversion and offers flexibility in the selection of input channels. ADC is useful for a wide range of applications.

A configurable self-test capability supports use cases with increased requirements for functional safety.

58.2.1 Features

- Selectable resolution (8-, 10-, 12-, 14-bit). Note that the conversion result is always 15 bits wide, even though the selected resolution is smaller (see CALBISTREG[RESN])
- Conversion data captured in a separate register for each input channel.
- Option to improve accuracy via averaging, which calculates conversion data by averaging the data of up to 32 conversions.
- Conversion triggers:
  - Normal conversion trigger converts a number of input channels, either once per trigger or continuously.
  - Injected conversion trigger interrupts an ongoing normal conversion and converts another set of input channels.
  - BCTU conversion trigger interrupts an ongoing conversion and converts an input channel, in which the input is selected and the conversion is started via the BCTU.
- An analog watchdog optionally monitors conversion data for each input channel and issues an interrupt if the converted data is below or above configurable limits.
- DMA functionality transfers conversion data to other modules.
- Programmable interrupts optionally issue an interrupt when conversion of one or of a set of input channels is finished.
- Self-test functions validate ADC structural integrity during functional operation and generate events with different severities on any finding.
- Conversion clock (AD_clk) control enables the use of ADC in systems with a higher clock frequency by using internal clock dividers.
- Auto turn-off of the conversion clock when ADC is idle.

58.2.2 Block diagram

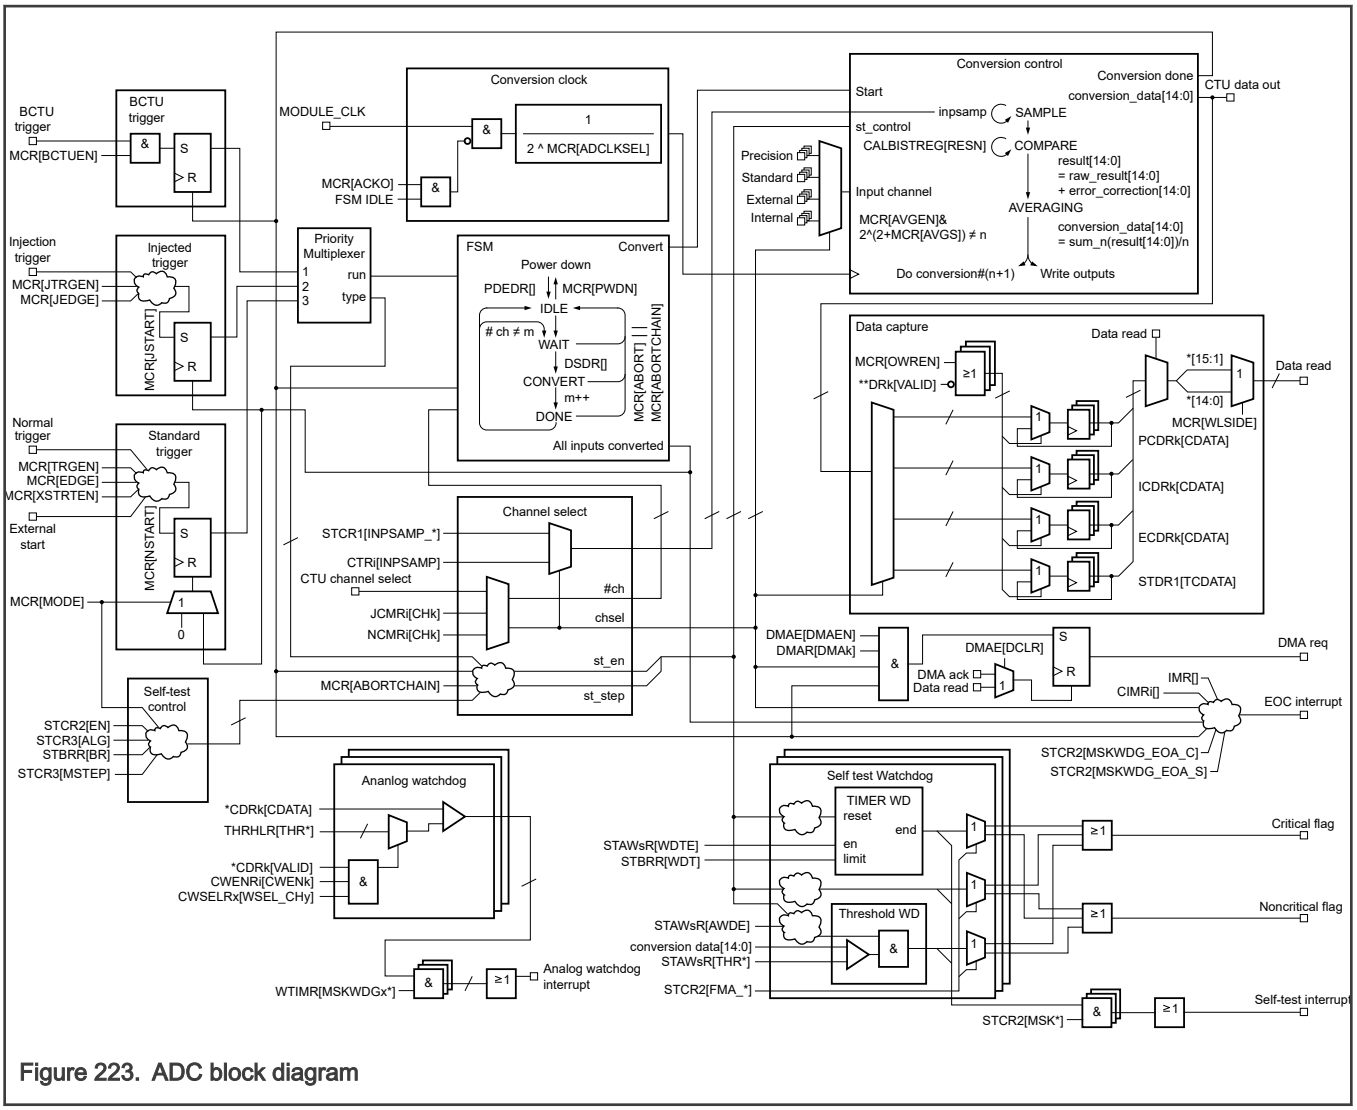

Figure 223. ADC block diagram

Guide to the diagram:

- The signal flow through the diagram is from left to right: inputs to blocks are on the left side, outputs are on the right.
- Block names have the first letters in uppercase and the other letters in lowercase—"Conversion Control," for example).
- Register names are in uppercase followed by a field name in brackets ("MCR[NSTART]," for example). Letters in lowercase are indexes. Asterisks are placeholders for letters (wildcards). Register names in the block diagram map to the names in ADC register descriptions.
- Signal names are in lowercase ("conversion done," for example).
- All digital signals shown are synchronous signals. Asynchronous inputs to the ADC are internally synchronized (synchronizers not shown).

The block diagram shows the signal flow through ADC from the left to the right and from the top to the bottom:

1. When ADC receives one of the three different types of triggers (BCTU, injected, or normal), the priority multiplexer initiates the conversion.
2. The input to be converted is selected in the Channel Select subblock, based on the type of trigger and on the self-test configuration.

3. The state machine (FSM) transitions from Idle state to Convert state. In case the channel to convert changed since the last conversion and this new channel is an external channel, the conversion starts after a delay configured by DSDR[DSD].
4. After a conversion begins, the Conversion Control block holds the internal capacitance network CDAC in the sample phase for a time defined by CTRi[INPSAMP].
5. During the compare phase, CALBISTREG[RESN] defines the number of steps used to execute the successive approximation algorithm. The error_correction values, determined during calibration, are added to the raw result. If averaging is enabled (MCR[AVGEN] = 1), up to 32 (specified via MCR[AVGS]) conversion results are averaged to obtain the result.
6. When the conversion completes and all averaging steps have completed:
    a. The conversion done signal indicates completion.
    b. Conversion_data[14:0] is written to the result registers in the Data Capture subblock.
    c. The FSM transitions into Done state.
7. The next input in the Channel Select block is selected and the next conversion is started by the transition of the FSM to Convert state. This continues until all selected inputs have been converted.
8. If an analog watchdog is enabled, the conversion result is compared to the configured threshold. If the limits are exceeded, an interrupt can be triggered.
9. Self-test can check the integrity of ADC, either interleaved with normal conversions or as a standalone check.
10. If an ongoing conversion is aborted (by writing 1 to MCR[ABORT]) or an ongoing conversion of a set of input channels is aborted (by writing 1 to MCR[ABORTCHAIN]), the FSM transitions into Idle state. The Conversion Control block stops the current conversion if MCR[ABORT] was written with 1, or finishes the current conversion if MCR[ABORTCHAIN] was written with 1. In both cases, the conversion done output signal of the Conversion Control block is set to 1.

Some details are not shown in the block diagram:

- Calibration must be performed to determine the error_correction values (see Calibration) before ADC can do meaningful conversions.
- An input can presample the internal low or high reference voltages to avoid a memory effect that may be present in the comparison due to a previous conversion (see Presampling).
- Monitor ADC status via status flags.
    - See Main Status (MSR) for the FSM state.
    - See Interrupt Status (ISR) to monitor interrupts.
    - See Channel End Of Conversion Flag For Precision Inputs (CEOCFR0) for conversion phase per input.
    - See the following registers to monitor analog watchdogs:
        - Analog Watchdog Out Of Range For Precision Inputs (AWORR0)
        - Analog Watchdog Out Of Range For Standard Inputs (AWORR1)
        - Analog Watchdog Out Of Range For External Inputs (AWORR2)

      See Analog Watchdog Threshold Interrupt Status (WTISR) to monitor analog watchdog interrupts.
    - See Self-Test Status 1 (STSR1) – Self-Test Status 4 (STSR4) to monitor self-test.

58.2.3 Modes of operation

ADC is always in Functional mode. No other mode selection exists.

- Put ADC into Power Down state by writing 1 to MCR[PWDN] to reduce power consumption.
- Gate the clock signal by writing 1 to MCR[ACKO] when ADC is in Idle state.

58.3 Functional description

58.3.1 Clock

ADC is controlled by one clock signal, the module clock. Internally, the conversion circuit is controlled by the conversion clock, which is derived from the module clock.

The frequency of the conversion clock has to be within the limits defined in the data sheet. If the module clock frequency is higher than the maximum frequency of the conversion clock allowed during the functional conversion or during the calibration (see the chip data sheet), then you must configure the ADC conversion clock divider (MCR[ADCLKSEL]) so that the frequency of the conversion clock is within allowed limits. For some conversion clock frequencies, you must write 3d to AMSIO[HSEN]. See Table 286.

Table 286. Clock configuration for highest conversion speeds

Module Clock Frequency f_mc[1]	Configuration during calibration	Configuration during functional conversion
40 MHz < f_mc ≤ 80 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 0h
80 MHz < f_mc ≤ 120 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 3h	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 3h
120 MHz < f_mc ≤ 160 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 0h	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h
160 MHz < f_mc ≤ 240 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 3h	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 3h
240 MHz < f_mc ≤ 320 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 0h	MCR[ADCLKSEL] = 2h AMSIO[17] = 0h
320 MHz < f_mc ≤ 480 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 3h	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 3h

1. Lower resulting frequencies are allowed—see the chip data sheet.

When ADC is not converting (state machine is in Idle state), the conversion clock can be turned off (MCR[ACKO]).

58.3.2 Conversion

ADC measures the voltage of a signal—it converts an analog input value into a digital representation. When you read the conversion result, you must divide this conversion result by the number of codes (defined by selected conversion resolution in CALBISTREG[RESN]), and multiply it with the reference voltage value. This calculation provides the voltage value of the converted signal.

To convert an analog input voltage into its digital representation, ADC:

1. Receives a signal, referred to as a trigger, indicating it is to perform a conversion.
2. Captures the voltage of a signal via internal capacitances in a process referred to as sampling.
3. Compares the voltage to the reference voltage, using the SAR algorithm.

Before a conversion can be performed, you must select:

- The trigger source(s) to use (on the chip level)

- The input channel(s) to convert (NCMR0–2, JCMR0–2)

Additionally, you can tailor the conversion to meet your needs by changing the default configuration. For example, you can:

- Configure ADC to convert the selected input channel(s) only once or continuously in a loop (MCR[MODE]).
- Specify the duration that ADC samples the input signal (CTR0/1/2).
- Specify the resolution of the conversion result by selecting the number of bits (CALBISTREG[RESN]).
- Enable an analog watchdog to generate an interrupt when a conversion result falls outside a specified range (see Analog watchdog functions).
- Enable the DMA interface to send requests and receive acknowledgments (see DMA functionality).
- Check the operational integrity of ADC by running a self-test (see Self-test).

After power-up or a functional reset, ADC remains in Power Down state until enabled by writing 0 to MCR[PWDN]. After the system is powered on, you must run the calibration (see Calibration), before you can do a meaningful conversion with ADC.

Some configuration fields (listed below) are writeable only in Power Down state. If you intend to write to them, you must do so before exiting Power Down state.

- Select the conversion clock frequency to be within the allowed limits for a conversion.

58.3.3 Normal trigger

Select the input channels to convert by configuring the fields in NCMR0, NCMR1, and NCMR2.

These registers must be programmed before the start of conversion. You cannot reconfigure them until the conversion of all selected channels is complete. The sequence is always to convert the selected input channels in this order:

1. Start from the lowest input channel of the precision input channels.
2. Proceed through the standard input channels in ascending order.
3. End with the highest input channel of the external input channels.

58.3.3.1 Starting conversions in normal conversion mode

After programming the required fields of the following registers, you can start a conversion by writing 1 to MCR[NSTART]:

- Normal Conversion Enable For Precision Inputs (NCMR0)
- Normal Conversion Enable For Standard Inputs (NCMR1)
- Normal Conversion Enable For External Inputs (NCMR2)
- Main Configuration (MCR)

A hardware trigger can also start a normal conversion.

- If the external trigger is enabled (MCR[TRGEN] = 1), an external trigger enable is detected to start the conversion. The enable is checked only during start of conversion.
- Detection of an active edge defined by MCR[EDGE] (rising = 1, falling = 0) on an external trigger transitions MCR[NSTART] to 1 and starts the normal conversion.
- When MCR[TRGEN] = 1 (for example, when external trigger is enabled), conversion can be started by software.
- Any external trigger or software initiated conversion in normal conversion mode is ignored during any ongoing conversion chain.

NOTE

To have reliable operation there must be a gap of 3 clock cycles between configuration of NCMRx and the start of a conversion (by writing 1 to MCR[NSTART], or arrival of an external or internal hardware start trigger). ADC calculates the number of channels to be converted during this period.

58.3.3.2 Operation modes in normal conversions

Two operational modes are available during normal conversion:

- One-Shot mode
- Scan mode

For normal conversion, select the mode via MCR[MODE]. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, curing which the sampled analog value is converted to digital as shown in the following figure.

Figure 224. Normal conversion flow

In One-Shot mode (MCR[MODE] = 0), a sequential conversion specified in the NCMR*n* mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored in the corresponding data register (CDR*n*).

For example: Channels A→B→C→D→E→F→G→H are present in a device where channels B→D→E are to be converted in One-Shot mode. Conversion begins with channel B, followed by conversion of channels D and E. At the end of conversion of channel E, the scanning of channels stops.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. At the same time, MCR[NSTART] is reset to zero by hardware, enabling software to program a new start of conversion in advance. In this case, the new requested conversion starts after completion of the running/current conversion. However, for correct functioning of the device, you should program MCR[NSTART] for the new conversion only after completion of the current conversion. The application can wait for an ECH interrupt prior to writing 1 to MCR[NSTART] again.

If an external trigger starts the conversion chain, ADC does not observe the trigger input until the conversion chain is finished. After the chain is finished, the next chain can be triggered by another hardware trigger edge.

In Scan mode operation (MCR[MODE]=1), a sequential conversion of N channels specified in the NCMR*n* registers is continuously performed. At the end of each conversion, the result is stored in the corresponding data register, as in One-Shot mode.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. Unlike One-Shot mode, MCR[NSTART] is not reset to 0 in Scan mode. It can be reset by software when you must exit Scan mode. In that case, ADC completes the current chain and after the last conversion, it resets MCR[NSTART] to 0.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan mode. MCR[MODE] = 1 selects Scan mode operation. Conversion starts from channel B followed by conversion of channels D→E. After conversion of channel E, the scanning of channel B starts followed by conversion of the channels D→E. This sequence repeats itself until MCR[NSTART] is reset to 0 by software.

If an external trigger starts a conversion, then MCR[NSTART] does not transition to 1. This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished. Consequently, after it starts, the only way to stop Scan mode conversion is to write 0 to MCR[MODE].

End of conversion

In both modes, at the end of each conversion, an End of Conversion (EOC) interrupt is issued if enabled by the corresponding mask fields in CIMR*n* and IMR).

After conversion of all selected channels in NCMR*n* is complete, the conversion operation is considered finished. Then ISR[ECH] transitions to 1 and the End of Chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]).

The corresponding channel field in the CEOCFR*n* register(s) is updated to indicate that data is available on data register CDR*n* of the respective channel.

If there is no channel selected in NCMR*n* and there is a start-of-conversion trigger, then ISR[ECH] is set to 1 and the End of Chain (ECH) interrupt is immediately issued (if enabled).

58.3.4 Injected trigger

An injected trigger enables you to convert a set of input channels although the standard trigger has already started conversion of another set of input channels. Each channel can be individually enabled by writing 1 to the corresponding field in JCMR0, JCMR1, or JCMR2.

The set of input channels of the injected trigger is converted only once. A continuous conversion of a set of input channels in a loop is only possible when started by a standard trigger. When an injected trigger is received, an ongoing conversion started by a standard trigger is interrupted. After the set of input channels of the injected trigger is converted once, the interrupted conversion of the set of input channels of the standard trigger resumes from the input channel that was interrupted, as shown in the following figure.

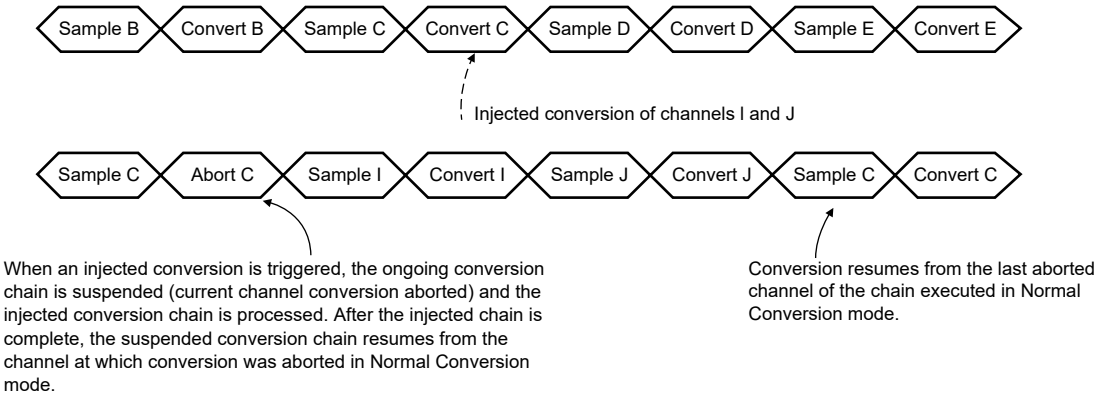

Figure 225. Injected trigger conversion sequence

58.3.4.1 Starting conversions in injected conversion mode

An injected conversion chain can be started:

- By software: When external triggering is disabled (MCR[JTRGEN] = 0), you can write 1 to MCR[JSTART], which causes the current conversion chain processed in Normal Conversion mode to be suspended and the injected chain to be processed.
- By external trigger: When external triggering is enabled (MCR[JTRGEN] = 1), a programmed event (rising/falling edge depending on the value of MCR[JEDGE]) on the injection external input starts the injected conversion.

MCR[JSTART] automatically transitions to 1 when the injected conversion chain starts. At the same time MCR[JSTART] is reset to 0, enabling software to program a new start of conversion in advance. In that case the new requested conversion starts after the running conversion completes.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued, if enabled by the corresponding mask field in Interrupt Mask (IMR). At the end of a chain, an End Of Injected Chain (JECH) interrupt is issued, if enabled by the corresponding mask field. Additionally, ADC writes 1 to ISR[JECH].

NOTE

If the content of all the Injected Conversion mask registers (JCMR*n*) is zero, that is, no channel is selected, the JECH interrupt is immediately issued after the start of conversion.

To have reliable ADC operation, there must be a gap of 3 cycles between configuration of JCMRx and starting of conversion (writing 1 to MCR[JSTART] or arrival of either an external or internal hardware start trigger). ADC calculates the total channel numbers to be converted during this period.

The corresponding channel bit in the CEOCFR*n* register is updated to indicate data is available in the channel's conversion data register, CDR*n*.

After starting, an injected chain conversion cannot be interrupted.

58.3.5 BCTU interface

The BCTU interface enhances ADC's injected conversion capability. It contains control inputs to select the channels to be converted from the appropriate event configuration register. Figure 226 shows the interface.

The BCTU generates a trigger (bctu_trigger) and a channel number (bctu_numchannel) to be converted. A single channel is converted for each request. After performing the conversion, ADC returns the result on the bctu_dataout bus together with two output signals named bctu_nextcmd and bctu_push. The assertion of signal bctu_nextcmd means ADC is ready to accept the next trigger from BCTU. The bctu_push signal is asserted at the end of conversion, meaning that conversion is finished and the conversion result available at output bctu_dataout is valid.

The conversion result is also saved in the corresponding channel's data register and is compared with analog watchdog thresholds if requested.

The signals bctu_trigger, bctu_nextcmd and bctu_push are all of type single-cycle active-high-pulse in the ADC clock domain. The channel number provided from BCTU must be valid when bctu trigger is active-high. The result data from ADC is valid with bctu_push high.

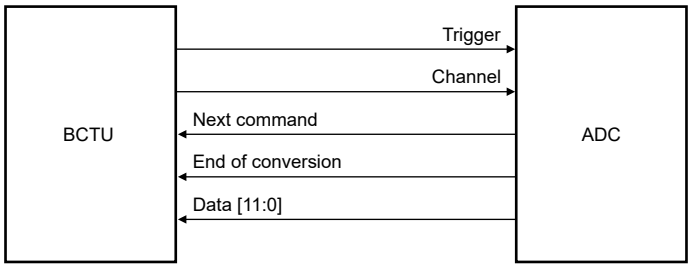

Figure 226. BCTU interface

The BCTU interface has two modes of operation:

- Trigger
- Control

To enable the BCTU interface, write 1 to MCR[BCTUEN]. The operating mode (Trigger or Control) can be fixed or programmable.

58.3.5.1 BCTU Trigger mode

In Trigger mode, normal and injected conversions can also be performed. All types of conversions can be initiated in this mode. The priorities among the three types of conversions are discussed below.

When a trigger is received, the channel number is taken as an injected channel value and the triggered injected conversion starts. MSR[BCTUSTART] transitions to 1 automatically at this point and it is also automatically reset to 0 when the triggered injected conversion is completed.

BCTU conversions must be requested only after successful ADC calibration. The application must prevent any BCTU trigger during calibration.

If a BCTU trigger is received during an ongoing injected conversion, the injected chain is aborted immediately and only the BCTU-triggered injected conversion proceeds. Additionally, MSR[JSTART] is reset to zero. The abort of an injected conversion is indicated by MSR[JABORT].

If a BCTU trigger is received during an ongoing normal conversion, the ongoing normal channel conversion is suspended and the BCTU-triggered injected conversion is processed. Normal conversion resumes from the suspended channel after completion of the BCTU-triggered conversion.

If a normal conversion is requested during BCTU conversion (MSR[BCTUSTART] = 1), the normal conversion starts after the BCTU conversion completes (MSR[BCTUSTART] is reset to zero).

Any injected conversion is discarded if requested during BCTU conversion and MCR[JSTART] is immediately reset to zero.

58.3.5.2 BCTU Control mode

In BCTU control mode (MCR[BCTU_MODE] = 0), only the BCTU can start a conversion. All other trigger sources are ignored.

Along with BCTU trigger, the information provided with signal bctu_numchannel is taken as the channel number for injected channel and BCTU triggered conversion starts. MSR[BCTUSTART] transitions to 1 automatically at the start of the conversion and it remains 1 unless BCTU is disabled by writing 0 to MCR[BCTUEN].

The conversion must be requested (generating bctu_trigger) when calibration has finished successfully. If a BCTU trigger is received during calibration execution, calibration is stopped immediately in order to satisfy the BCTU request. Calibration fails in this case.

58.3.6 Aborting a conversion

Two abort functions are provided:

- Abort of a single channel
- Abort of a chain

To abort an ongoing conversion, write 1 to MCR[ABORT]. The current conversion aborts and conversion of the next channel of the chain begins immediately.

Depending on the current state of a conversion, an Abort action may take 1 to 4 cycles of the bus clock. At the start of any conversion, and at the end of a particular conversion when internal state counters are changing, an abort action is delayed by a maximum of 3 cycles to put all states in a stable condition.

To ensure that the abort action completes, do not change MCR[ABORT] for the next 3 cycles.

Avoid writing 1 to MCR[ABORT] along with, and within 3 cycles of, writing 1 to MCR[NSTART] or MCR[JSTART].

During an abort:

- MCR[NSTART] and MCR[JSTART] remain 1, if not in the last channel of the chain.
- MCR[ABORT] is reset to 0 when the channel is aborted.
- The EOC interrupt corresponding to the aborted channel is not generated. This behavior applies to normal and injected conversions. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is possible to abort the current chain of conversions by writing 1 to MCR[ABORTCHAIN]. In this case, the behavior of ADC depends on the value of MCR[MODE] (One-Shot/Scan operation modes). If Scan operation mode is disabled, MCR[NSTART] is automatically reset to 0 along with MCR[ABORTCHAIN]. Otherwise, in Scan Operation mode, a new chain is started. The EOC interrupt of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

NOTE

For a single channel chain, an ECH interrupt is not generated for an abort or abort chain.

When an abort chain is requested while an injected chain is running over a suspended normal chain, both the injected and normal chains are aborted, and both MCR[NSTART] and MCR[JSTART] are reset to 0.

58.3.7 Configuring ADC clock divider and sample time settings

You can scale the AD_clk frequency via MCR[ADCLKSEL]. ADCLKSEL can only be written in Power Down state (MCR[PWDN] = 1). Depending on the frequency of the module clock, there might be different settings necessary for functional conversion and for calibration. See the chip data sheet for ADC electrical characteristics.

Three conversion timing registers are used (CTR*n*) to support different sampling times for the different types of channels. An exception exists for the temperature sensor channel, which always uses the Conversion Timing For Standard Inputs (CTR1) value. See the register description for details.

58.3.8 Presampling

The presampling feature enables precharge or discharge of the ADC internal sample capacitor node to a defined level before sampling of the selected analog input channel starts. This is useful for resetting information (history effect/offset) from the most recent conversion. During presampling, ADC samples the internally generated voltage. During the sampling phase, ADC samples analog input coming from pads.

Enable presampling on a per-channel basis by setting the corresponding fields in the PSR*n* registers to one.

After enabling presampling for a channel, the normal sequence of operation for the channel is:

1. Presampling
2. Sampling
3. Evaluation

You can bypass sampling of all channels by writing 1 to PSCR[PRECONV]. When sampling of a channel is bypassed, the sampled and stored internal voltage applied during the presampling phase is converted (Figure 227). See Conversion time for the timing equation for conversion.

Presampling does not apply for self-test channels.

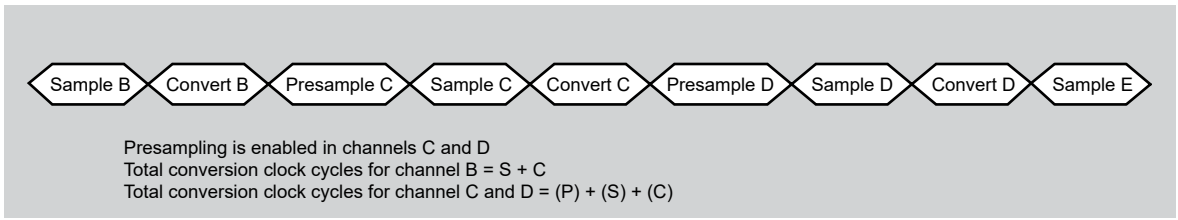

Figure 227. Presampling sequence

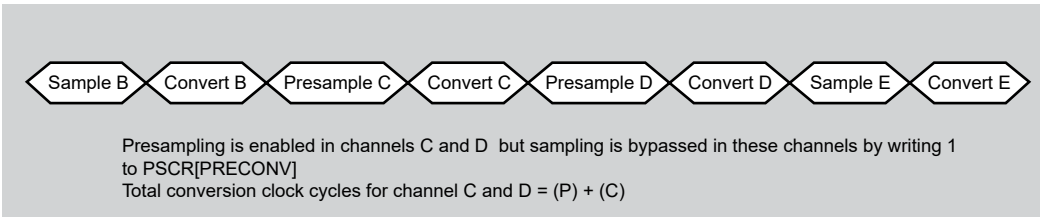

Figure 228. Presampling sequence with PRECONV=1

58.3.8.1 Enabling presampling per channel

Enable presampling for specific channels by programming Presampling Control (PSCR). You can select between two internally generated voltages by configuring the PREVAL*n* fields in Presampling Control (PSCR) to the appropriate values, as given in the following table.

Table 287. Presampling voltage selection via PREVAL*n*

PREVAL*n*	Presampling voltage
0	Presample voltage – 0: VREFL
1	Presample voltage – 1: VREFH

The presampling configuration field(s) (PSCR[PREVAL0], PSCR[PREVAL1], PSCR[PREVAL2]) are located in Presampling Control (PSCR). These fields enable selection of the presampling channel.

The temperature sensor channel has an exception. This channel is mapped with a fixed channel depending on device configuration, but it uses the presampling configuration defined for channel group 2. So, when the temperature sensor channel is selected, the presampling voltage defined by PSCR[PREVAL1] is selected. This voltage might be different from the one selected for channel group 1 via PSCR[PREVAL0].

58.3.9 Analog watchdog functions

When enabled, an analog watchdog monitors conversion results for an associated channel and reports an issue if it determines a result is outside customer-defined limits (as shown in Analog watchdog configuration (up to 16 watchdogs)). These limits are specified by an upper and a lower threshold value named THRH and THRL respectively.

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value is outside that threshold value, then ADC generates a corresponding threshold violation interrupt.

The comparison result is stored as HAWIFx and LAWIFx fields in Analog Watchdog Threshold Interrupt Status (WTISR), as explained in the following table. Depending on the values of WTIMR[LAWIFENx] and WTIMR[HDWIFENx] mask fields, an interrupt is generated on a threshold violation.

Table 288. Values of HAWIFx and LAWIFx

HAWIFx	LAWIFx	Conversion result
1	0	Conversion result > THRH
0	1	Conversion result < THRL
0	0	THRH ≥ conversion result ≥ THRL

Depending on the chip's factory settings, up to 16 analog watchdogs are available. See the chip-specific configuration information for availability.

There are two types of mutually exclusive settings for analog watchdogs. Both types are described in the following sections. The availability depends on device configuration. See the chip-specific configuration information for availability.

Different capabilities are available with the two settings, as described below.

58.3.9.1 Channel analog watchdog select registers

ADC configuration includes selecting the analog watchdog threshold register (THRHLR*n*) that provides limits to monitor inputs of a given type. You select the THRHLR*n* using CWSELR*a*l*n* registers.

Table 289. CWSELR*a*l*n* register naming

Index	Description
a	ADC input type associated with a CWSELR*a*l*n* register. • P = Precision inputs • S = Standard inputs • E = External inputs
n	0-indexed register number.

58.3.9.2 Analog watchdog configuration (up to 16 watchdogs)

ADC can have up to 16 watchdogs in the factory configuration. (See the chip-specific configuration information for availability.) For each watchdog there is one threshold value register, THRHLR*n*, that contains the high and low thresholds.

You can independently enable the analog watchdog for each channel by programming the appropriate CWENR*n* register.

The threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLR*n*) using the corresponding WSEL_CH*n* field in the appropriate CWSELR*a*l*n*, where *a* indicates the input type:

- P = precision
- S = standard
- E = external

Each CWSELR*a*l*n* register is associated with 8 consecutive channels. CWSELR*a*l0 holds 8 WSEL_CH fields for channels 0 to 7. CWSELR*a*l1 is for channels 8 to 15 and so on. The availability of fields and registers depends on device configuration. See the chip-specific configuration information for availability.

If the conversion result of a selected channel is outside the range specified by threshold values, then the corresponding field in the Analog Watchdog Out of Range register (AWORR*n*) transitions to 1. For example, if channel 7 is to be monitored with the threshold values in THRHLR3, then CWSELR*a*l0[WSEL_CH7] must be programmed with 3. Enabling the watchdog is done by writing 1 to the corresponding field for channel 7 in CWENR0.

In this configuration, a set of threshold values (THRHLR*n*) can be linked to several ADC channels. The threshold values to be selected for a channel must be programmed only once in CWSELR*a*l*n*,.

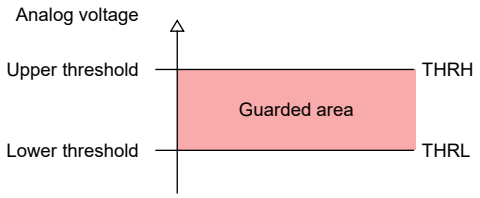

Figure 229. Guarded area

NOTE

If the higher threshold of the analog watchdog is programmed below the lower threshold and the conversion result is below the lower threshold, then the WDG*n*L interrupt for the low threshold violation transitions to 1. If the conversion result is greater than the lower threshold (and therefore also greater than the higher threshold), then the interrupt WDG*n*H for high threshold violation is generated. Thus you should take care to avoid that situation, as it could lead to misinterpretation of the watchdog interrupts.

58.3.10 DMA functionality

Conversion result data from any channel can be transferred from a register to system memory via Direct Memory Access (DMA). DMA transfers are enabled by writing 1 to DMAE[DMAEN]. After being enabled, the on-chip DMA controller can receive a DMA request after the conversion of each channel by writing 1 to the respective masking field in:

- DMA Request Enable For Precision Inputs (DMAR0)
- DMA Request Enable For Standard Inputs (DMAR1)
- DMA Request Enable For External Inputs (DMAR2)

DMA masking registers must be programmed before starting any conversion.

A DMA request to the DMA controller can be cleared at different times in two modes:

- Mode-1: Clearing of DMA request on acknowledgment from DMA controller (DMAE[DCLR] = 0)
- Mode-2: Clearing of DMA request on read to data registers (DMAE[DCLR] = 1)

The figures below show the operation of DMA in two modes (cycle counts are typical values).

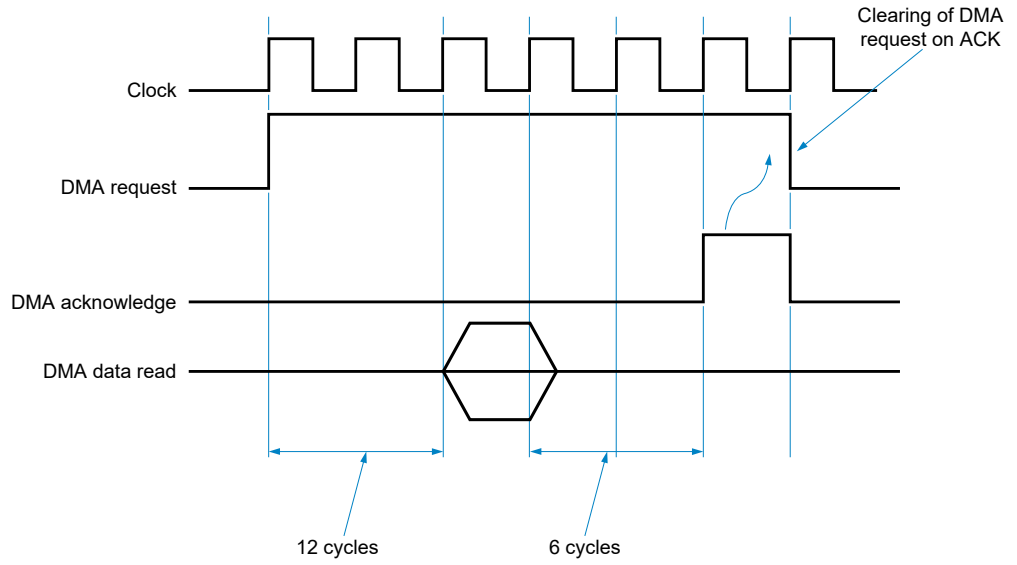

Figure 230. DMA operation Mode-1 (DMAE[DCLR] = 0)

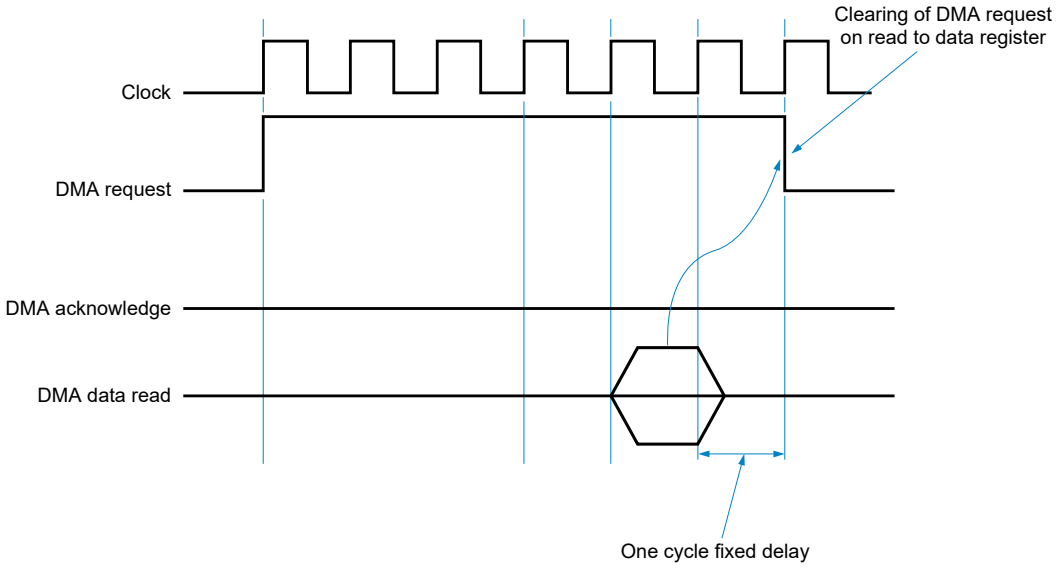

Figure 231. DMA operation Mode-2 (DMAE[DCLR] = 1)

58.3.11 Interrupts

ADC generates the following maskable interrupts:

- EOC (End of Conversion)
- ECH (End of Chain)
- JEOC (End of Injected Conversion)
- JECH (End of Injected Chain)
- EOBCTU (End of BCTU-triggered Conversion)
- LAWIFx and HDWIFx (Watchdog threshold)

- Self-testing interrupts

Interrupts are generated during the conversion process to signal events such as End Of Conversion (EOC), and so on, as described in Interrupt Status (ISR). ISR and another register, Interrupt Mask (IMR), are provided to check and enable the interrupt request to an external interrupt controller.

Interrupts can be individually enabled on a per-channel basis by programming EOC Interrupt Enable For Precision Inputs (CIMR0).

CEOCFR*n* are used for pending End of Conversion interrupts, with one field per channel to indicate completed conversions on a per-channel basis.

Interrupts generated due to the analog watchdogs are managed by two 32-bit registers, Analog Watchdog Threshold Interrupt Status (WTISR) and Analog Watchdog Threshold Interrupt Enable (WTIMR), to check and enable the interrupt request. A watchdog interrupt causes two corresponding fields to transition to 1 for each channel monitored. One field is in WTISR[WDG*n*H] and another in WTISR[WDG*n*L].

Generated events are logged into status registers and used to generate interrupts if enabled in corresponding Mask registers.

There are three different interrupt outputs. The interrupt structure is shown in Figure 232.

Each interrupt is generated by combining a group of events.

The following interrupts are combined (logic OR) into one interrupt output.

- EOC
- ECH
- EOBCTU
- JEOC
- JECH
- End of self-test algorithm (WDG_EOA_S and WDG_EOA_C)

Interrupts of all HDWIFx and LAWIFx are combined on the second interrupt output.

Interrupts of all self-test errors (watchdog threshold, sequence, and timer violations) in Self-Test Status 1 (STSR1) are combined on the third interrupt output. The errors are:

- WDSERR
- WDTERR
- ERR_S0
- ERR_S1
- ERR_S2
- ERR_C

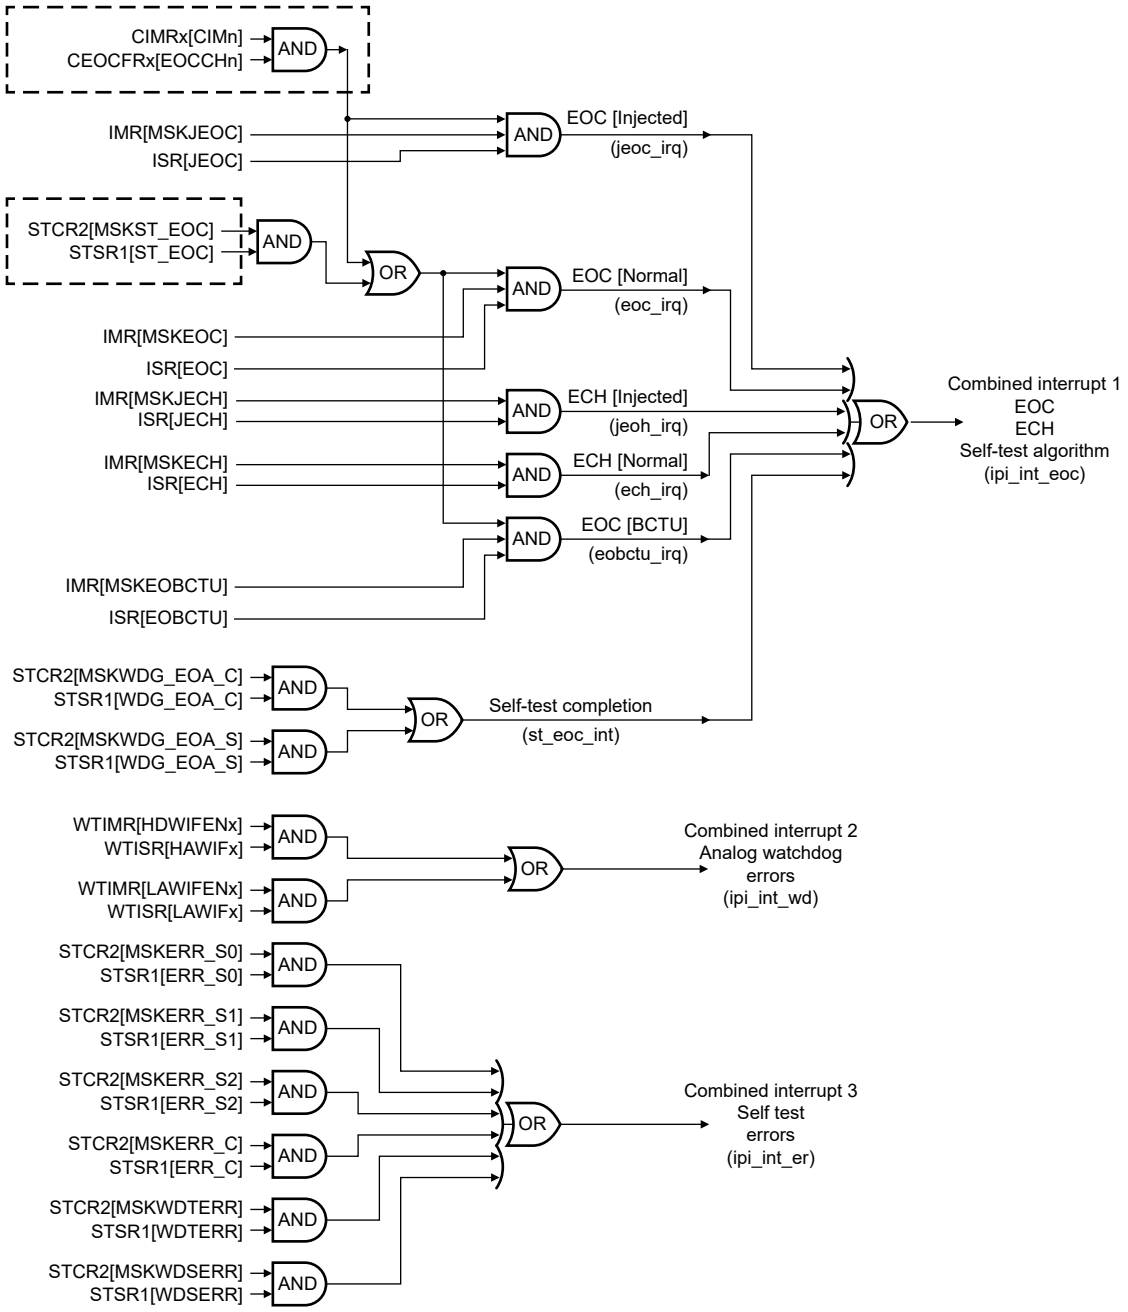

Figure 232. Interrupt structure of ADC

Interrupt Status (ISR) Indicates the interrupt pending request status. Write 1 to the corresponding status field to clear the pending interrupt flag (at this write operation all the other fields in Interrupt Status (ISR) must be maintained at 0).

ISR checks for three types of interrupts.

The first type, Interrupt 1, relates to the following:

- End of normal or injected conversion (EOC or JEOC)
- End of normal or injected conversion chain (ECH or JECH)
- End of algorithm C or algorithm S self-test (WD_EOA_C or WD_EOA_S)

Perform the following actions for this type of interrupt:

1. Read Interrupt Status (ISR) to determine whether the event is an EOC, JEOC, ECH, JECH, or EOBCTU event.
2. Read Self-Test Status 1 (STSR1) to identify the end of self-test algorithm events (WDG_EOA_S or WDG_EOA_C), if present.
3. If the interrupt is an EOC or JEOC event:
   - Clear the respective channel pending field in the appropriate CEOCFR*n* register for an EOC by writing a 1 to it.
   - Clear ISR[EOC] or ISRJEOC] by writing a 1 to it.
4. If the interrupt is an ECH or JECH, clear ISR[ECH] or ISR[JECH] by writing 1 to it.
5. If the interrupt is EOBCTU, clear ISR[EOBCTU] by writing 1 to it.
6. If the interrupt is for self-test end of algorithm, clear STSR1[WDG_EOA_S] or STSR1[WDG_EOA_C] by writing 1 to it.

The second type, Interrupt 2, relates to analog watchdog errors. Perform the following actions for this type of interrupt:

1. Read Analog Watchdog Threshold Interrupt Status (WTISR) to determine which watchdog triggered the interrupt.
2. Read the AWORRx register(s) to determine which channel's data caused the interrupt (if present).
3. Clear the respective field of the WTISR[WDG*n*H/WDG*n*L] register, where *n* = watchdog number, by writing 1 to it.
4. Clear the respective field of the AWORR*n*[AWOR_CH*n*] register, where x = register, n = channel, by writing 1 to it.

The third type, Interrupt 3, relates to self-test errors. Perform the following actions for this type of interrupt:

1. Read Self-Test Status 1 (STSR1) to determine the type of error encountered in self-test (WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, ERR_C, and so on) if present.
2. Clear the respective field in Self-Test Status 1 (STSR1) by writing 1 to it.

The connectivity of interrupt lines at the chip level (external to ADC) determines whether software must read all the registers for all three interrupts or any one or combination of any two.

58.3.12 External decode signals delay

The ADC provides three external decode signals which it uses to select one channel out of eight in the external analog multiplexers. There can be a maximum of four such multiplexers used to connect the 32 external channels. The ADC automatically sets the decode signals to control these external analog multiplexers, based on the current channel selected for conversion. Delay Start Of Data Conversion (DSDR) is provided to take the switching time of the external analog multiplexer into account. It enables you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled, the DSD delay starts after the presample phase (presampling time is the same duration as sample time).

58.3.13 Power Down state

The analog part, along with the ADC controller, can be put in Power Down state by writing 1 to MCR[PWDN]. This shuts down ADC and stops the clock to the ADC controller. After release of reset, MCR[PWDN] remains 1, so the ADC analog module is kept in Power Down state by default. You must exit this state before starting any operation, by writing 0 to MCR[PWDN]. In Power Down state, no conversion can be started. If a BCTU trigger pulse is received during this state, it is discarded. You must ensure that a BCTU trigger is not initiated to ADC before writing 0 to MCR[PWDN], as it may cause the BCTU module to be stuck in a wait state.

You can set MCR[PWDN] by writing 1 to it at any time. If a conversion is ongoing, ADC does not move into Power Down state immediately. ADC enters Power Down state only after completion of the ongoing conversion. During scan operation, the ongoing operation should be aborted manually by writing 0 to MCR[NSTART] before or after writing 1 to MCR[PWDN].

ADC Power Down state status is indicated by MSR[ADCSTATUS] when ADC enters into Power Down state.

If the BCTU is enabled and MSR[BCTUSTART] = 1, then you cannot write 1 to PWDN. When BCTU Trigger mode is enabled, the application must wait for the end of conversion (MSR[BCTUSTART] is automatically reset to 0). When BCTU Control mode is enabled, before entering Power Down state the application must write 0 to BCTUEN also.

If Power Down state is entered by writing 1 to MCR[PWDN], the process running before entry into Power Down state must be restarted manually (by writing 1 to the appropriate START field in Main Configuration (MCR)) after exiting Power Down state.

NOTE

Writing 0 to MCR[PWDN] and writing 1 to MCR[NSTART] or MCR[JSTART] during the same cycle is not supported.

58.3.14 Low Power mode support

For low-power operation, ADC must be in Idle state and then put into Power Down state to ensure proper signal condition at the analog boundary.

From any of the states listed below, follow the sequence of steps shown to put ADC into Power Down state.

1. Idle condition
    a. Verify that ADC is in Idle state (MSR[ADCSTATUS] = 000b).
    b. Write 1 to MCR[PWDN], to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
2. During calibration

    NOTE

    Writing 1 to MCR[PWDN] during calibration is prohibited. After calibration is started it should be allowed to finish normally. Alternatively, it can be terminated by starting a normal conversion before writing 1 to MCR[PWDN].

    a. Check the current ADC state either via MSR[ADCSTATUS] (000b = Idle, 011b = Calibration), or via CALBISTREG[C_T_BUSY] (1 = calibration is in progress).
    b. When ADC is in Idle state, write 1 to MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
3. During conversion (normal [one-shot]/Injected/BCTU):
    a. Write 1 to MCR[PWDN].
    b. ADC enters Power Down mode after completing the current conversion chain (for normal and injected conversions) or the conversion for conversion triggered by BCTU.
    c. Check the ADC state via MSR[ADCSTATUS] (000b = Idle state, 001b = Power Down state).
4. During Scan mode operation of normal conversion

    NOTE

    Writing 1 to MCR[PWDN] during scan mode operation has no effect other than to prevent software from starting a new normal or injected conversion. It does not stop a conversion in progress and cannot put ADC into Power Down state.

    a. Software must write 0 to MCR[NSTART] to stop the ongoing scan conversion before (or after) writing 1 to MCR[PWDN]. This stops conversion at the current chain boundary.
    b. ADC enters Power Down mode after coming to an Idle state after MCR[PWDN] is written with 1. This shuts the clock off to the hard macro and puts analog inputs in the proper state required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).

58.3.15 Auto Clock Off mode

To reduce power consumption during Idle state (without going into Power Down state), an auto-clock-off feature can be enabled by writing 1 to MCR[ACKO]. When enabled, the internal ADC operating clock (AD_Clk) is automatically switched off during an idle period (for example, no conversion is programmed).

58.3.16 Calibration and self-test

58.3.16.1 Calibration

ADC must be calibrated before it can do meaningful conversions. The application must prevent any start of conversion before the ongoing calibration has finished successfully. No conversion trigger may be received during calibration.

During calibration, a known reference voltage is sampled and converted under controlled conditions to determine the correction values (calibration values) for offset, gain, and capacitor mismatch.

These calibration values (except gain calibration) are used in a post-processing step after conversion, reducing or eliminating the various error contribution effects. The gain calibration is used during sample phase to define the additional charge to be loaded to compensate for gain failure.

You must run calibration after every power-up reset (check device-specific reset connectivity for appropriate reset applied). You must also run calibration if it is indicated by the self-test (see Self-test).

Configuration and start of calibration is done by programming the Control And Calibration Status (CALBISTREG). During calibration, internal hardware averaging function should be enabled. Maximum averaging is recommended, and 16 should be the minimum.

Calibration status is captured by a status flag (CALBISTREG[TEST_FAIL]) to indicate any fault detected during calibration execution or if calibration was prematurely aborted. Calibration is aborted if any normal conversion is initiated during the calibration execution, which is called premature termination. (Flag TEST_FAIL = 1 indicates a calibration fail, for example when a calibration value is out of internally defined limits.)

To execute the calibration algorithm, perform the following steps:

1. Select the conversion clock frequency to be within the allowed limits for the calibration.
2. Bring ADC from Power Down state to active conversion (program MCR[PWDN] = 0b).
3. Configure the Control And Calibration Status (CALBISTREG). The default values are set for maximum accuracy (recommended).
4. Disable the error correction for the smaller capacitances in the CDAC of the ADC (write 0h to CAL2[ENX]).
5. Start calibration (program CALBISTREG[TEST_EN] = 1b), and calibration starts immediately.
6. Poll the status of CALBISTREG[C_T_BUSY] for 0 (wait until it transitions to 0).
7. Check CALBISTREG[TEST_FAIL] to determine the final status. If 1, then calibration failed.
8. Check the status of MSR[CALIBRTD]. If calibration was successful this field is 1.

58.3.16.2 Self-test

For safety applications, it is important to verify correct operation at regular intervals. ADC has a self-test feature for this purpose. When self-test is enabled, ADC automatically checks its components and flags errors, if any are found.

Tests can be enabled to check the reference (VrefH) and calibrated values.

The following test algorithms have been implemented:

- Supply self-test (algorithm S): It includes the conversion of the band gap and VREF voltages. It includes a sequence of num_supply_steps test conversions (steps). The supply test conversions must be an atomic operation (that is, all supply algorithm conversions must be performed one after another with no functional conversions in between).

- Capacitive self-test (algorithm C): It includes a sequence of test steps per definition of algorithm C (see Table 290) which executes the capacitive matrix of the CDAC used for sampling and conversion.

Individual steps can take up to 1 µs at 80 MHz ADC clock frequency.

Table 290. Self-test steps

STCR3[ALG]	STCR3 [step](per algorithm definition)	Description	Outcome	Comment
00 (algorithm S)	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	
	1	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
	2	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
01 (Reserved)	Reserved			
10 (algorithm C)	0 – 11	Capacitive self-test. One of the calibration steps is being run.	The difference/error of the individual offset value from the previously calibrated value is being returned as an ADC result that is compared with the programmed value in the self-test analog watchdog register(s) to detect any fault.	The ideal result value is expected to be 0. If the returned value is higher, it indicates a runtime fault or accuracy shift. The error is indicated in the status register and can be used to generate an interrupt also. It that indicates ADC should be recalibrated to check whether the reported error can be managed by calibration or that permanent damage occurred to ADC.
11 (algorithm S + C)	0 – 2 (S), 0 – 11 (C)	Supply for One-Shot mode and (supply + capacitive) for Scan mode only.	Same as above.	

ADC:

- Schedules self-testing algorithms using configuration registers.
- Monitors the converted data using analog watchdog registers.
- Flags any errors to a fault control unit (FCCU), if one exists.

Self-test steps can be activated from software (CPU) or BCTU.

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
CPU mode (MCR[BCTUEN] = 0)	Yes	No

Table continues on the next page...

Table continued from the previous page...

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
	• One-Shot operation mode • Scan operation mode	
BCTU mode	No	Yes

58.3.16.2.1 CPU mode

In this mode, self-test conversion is similar to normal conversion. You enable self-test by writing 1 to STCR2[EN].

Self-test conversions execute along with the functional conversions. The sequencing of steps of the selected algorithm depends on the operating mode of normal conversions (selected by MCR[MODE]).

In One-Shot operation mode, if self-test is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in Self-Test Status 3 (STSR3). In One-Shot operation mode the sequence is:

1. Program NCMR*n* to select channels to be converted for normal conversion.
2. Write 0 to MCR[MODE] to select one-shot operation.
3. Configure the self-test algorithm threshold values (see Table 291).
4. Program sampling duration values in STCR1[INPSAMP*m*] (*m* = S, C).
5. Select the self-testing algorithm (in STCR3[ALG]), and step (in STCR3[MSTEP]). The default is algorithm S, step 0.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions in the chain, the step number (programmed in STCR3[MSTEP]) of the self-testing algorithm (selected by STCR3[ALG]), is executed similar to a normal functional channel.
10. At the end of the conversion for the self-test channel:
    - The result is written to STDR1[TCDATA].
    - STDR1[VALID] transitions to 1.
    - ISR[EOC], ISR[ECH], and STSR1[ST_EOC] transition to 1.
11. ADC returns to Idle state.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in One-Shot operation mode. At the end of conversion for channels B→D→E, self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1. The sequence is B→D→E→self-test step.

MSR[NSTART] transitions to 1 when the normal conversion starts and transitions to 0 at the end of conversion for the test channel.

In Scan operation mode, consecutive steps of the selected self-test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed sequentially without any functional conversion interleaved). So, in Scan operation mode the sequence is:

1. Program NCMR*n* to select the channels to be converted for normal conversion.
2. Write 1 to MCR[MODE] to select Scan operation mode.
3. Configure the self-test algorithm threshold values (see Table 291).
4. Program sampling duration values in STCR1[INPSAMP*m*] field (*m* = S, C).

5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected, that is, all algorithms are executed step-by-step, one after the other.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of the chain of normal conversions (assuming the default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] transitions to 1.
10. At the end of the conversion of the self-test channel for the last step of algorithm S, the result is written to STDR1[TCDATA] and STDR1[VALID] transitions to 1. At the same time, MSR[SELF_TEST_S] transitions to 0. The following registers also transition to 1:
    - ISR[EOC]
    - ISR[ECH]
    - STSR1[ST_EOC]
11. The next chain of normal conversions then starts.
12. At end of the chain of normal conversions, ADC executes step 0 of algorithm C.
13. At the end of the conversion of the test channel for step 0 of algorithm C, the result is stored in STDR1[TCDATA] and STDR1[VALID] transitions to 1 (if STSR1[OVERWR] is 1). Also, ISR[EOC] and ISR[ECH] transition to 1. STSR1[ST_EOC] also transitons to 1.
14. The next chain of normal conversion then starts.
15. At the end of the normal conversion chain, ADC executes step1 of algorithm C.

This process continues for all steps of all three algorithms. The state machine returns to Idle state when MCR[NSTART] transitions to 0.

For example: channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan operation mode. At the end of every conversion chain for channels B→D→E, one step of the self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1.

The sequence is:

B→D→E→ST-S0→ST-S1→ST-S2→B→D→E→ST-C0→B→D→E→ST-C1→B→D→E→ST-C2→ . . . B→D→E→ST-C11→B→D→E→ST-S0 . . .

ST-Sx - Self-test supply step x (x = 0, 1, 2)

ST-Cx - Self-test capacitive step x (x = 0 to 11)

MSR[NSTART] transitions to 1 when normal conversion starts.

NOTE

- If instead of starting normal conversion by software (by writing 1 to MCR[NSTART]), it is started by an external trigger, the self-test behavior remains the same.
- Self-test channel conversion is not performed for injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, an injected conversion arrives, the test conversion is aborted (just as a normal functional channel) and the injected conversion is performed. After the injected conversion is complete, the test conversion resumes from the step at which it was aborted. In this case, MSR[SELF_TEST_S] remains 1 during the injected conversion.
- For self-test, MCR[MODE] should be programmed (at least one cycle) before writing 1 MCR[NSTART] and should not be changed until the conversion is finished or terminated.

Table 291. Recommended self-test threshold values

Register field	Hex value	Decimal value	Comment
STAW0R[THRH]	3669h	13929	The threshold values depend on the stability of the supply and the reference voltage. When you see voltage variations, widen the limits.
STAW0R[THRL]	5 V reference: 1A7Fh 3 V reference: 2B27h	5 V reference: 6784 3 V reference: 11047	
STAW1R[THRL]	3FF9h	16377	
STAW2R[THRL]	3FF9h	16377	
STAW4R[THRH]	20h	32	
STAW4R[THRL]	7FE0h	–32	
STAW5R[THRH]	20h	32	
STAW5R[THRL]	7FE0h	–32	

58.3.16.2.2 BCTU mode

BCTU mode is enabled by writing 1 to MCR[BCTUEN].

Self-test conversion behaves in the same way for all BCTU operating modes (Trigger mode and Control mode). In both cases, if MCR[BCTUEN] = 1, the self-test conversion can be started only by BCTU—software cannot start it. MCR[BCTUEN] must not be changed during normal conversion. The interface between BCTU and ADC (for self-test) is shown in the following figure.

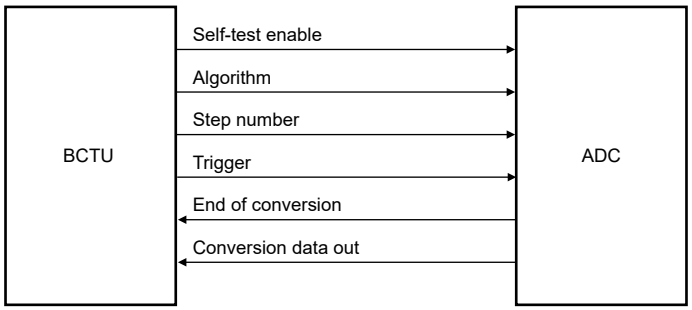

Figure 233. Self-test interface between ADC and BCTU

For self-test conversions in BCTU mode, BCTU asserts self-test enable along with the Trigger command. The algorithm and the step number to be executed is put on algorithm and step number, respectively. The other commands (Trigger, End Of Conversion, and Conversion Data Out) have the same meaning, like normal BCTU functional conversion.

As already mentioned for algorithm S, the three steps must be atomic. In BCTU mode, this is managed by BCTU, that is, BCTU sends three triggers (one for each step) asserting self-test enable and updating test_step for each step.

58.3.16.2.3 Abort and abort chain for self-testing channel

Writing 1 to MCR[ABORT] during self-test channel conversion has no effect.

In One-Shot operation mode, if you write 1 to MCR[ABORTCHAIN] during the self-test channel conversion, the self-test channel is aborted and ISR[ECH] transitions to 1. In this case, ISR[EOC] for the self-test channel is not generated.

In Scan operation mode, if MCR[ABORTCHAIN] = 1 when self-test channel step *n* is ongoing, self-test channel step *n* is aborted and the next chain conversion begins. At the end of the chain, the step *n* conversion is performed again. (For algorithm S, the full algorithm is executed again).

58.3.16.2.4 Self-test analog watchdog

ADC provides monitoring options for conversion data generated by self-test algorithms. Analog watchdogs determine whether the conversion results for self-test algorithms are in the range of a particular guard area. ADC provides separate self-test analog watchdog registers for each algorithm.

After the conversion of each step of a self-test algorithm, ADC compares the converted value and the threshold values if the analog watchdog feature has been enabled by writing 1 to STAW*n*R[AWDE] (for example, STAW0R[AWDE]). If the converted value is not between the upper and lower threshold values specified by the Self-Test Analog Watchdog Register for the particular algorithm, the corresponding error flag, STSR1[ERR_x], transitions to 1 and the step number in which error occurred is captured in STSR1[STEP_x] (for algorithm C). Erroneous data is written to STSR4[DATA*n*]. The STSR1[ERR_x] flags generate an interrupt if enabled by the corresponding mask bit in Self-Test Configuration 2 (STCR2). The fault indication is also forwarded to the fault control unit, if present, so that necessary action can be taken at the chip level. The fault type (critical or noncritical) is specified by the configuration in Self-Test Configuration 2 (STCR2).

The analog watchdog feature works differently for algorithm S. Algorithm S is always an atomic operation. Self-Test Status 1 (STSR1) has a separate error field for each step of algorithm S to avoid overwrite in case an error occurs in more than one step. Therefore, there are separate mask bits for each step in STCR1. For the same reason, the status registers (Self-Test Status 2 (STSR2) and Self-Test Status 3 (STSR3)) have separate fields for each step to store erroneous data.

In step 0 of the supply algorithm, ADC measures the band gap voltage (1.2 V), which is assumed to be stable. The conversion result of step 0 is compared against high (THRH) and low (THRL) thresholds as defined in Self-Test Analog Watchdog S0 (STAW0R), if enabled (STAW0R[AWDE] = 1). The STSR1[ERR_S0] flag transitions to 1 if any of the thresholds are violated. STSR1[ERR_S0] is cleared by writing 1 to it. The conversion result of ADC can be calculated with the following formula:

- ADC data (decimal) = (Vin × 2^{15} ÷ (Vrh - Vrl))

Where:

- Vin: input voltage (band gap voltage in this case)
- Vrh: ADC reference high voltage
- Vrl: ADC reference low voltage

The upper and lower threshold value can be calculated with the above formula using maximum and minimum values of Vin, Vrh, Vrl (Vin is the band gap supply voltage in this case):

- Upper threshold (THRH, decimal) = (Vin[max] × 2^{15}) ÷ (Vrh[min] - Vrl[max])
- Lower threshold (THRL, decimal) = (Vin[min] × 2^{15}) ÷ (Vrh[max] - Vrl[min])

The minimum and maximum voltages can be obtained from the chip data sheet. The band gap voltage tolerance, as well as the actual reference voltage used and its tolerances, must be considered when calculating high and low thresholds.

For algorithm S steps 1 and 2, (VREF/VREF) is measured in order to check the integrity of the sampling signal. For these particular conversions, no higher threshold value is required as the ideal value is FFFh. Only the lower threshold value is programmed in Self-Test Analog Watchdog S1 (STAW1R) and Self-Test Analog Watchdog S2 (STAW2R).

For algorithm C, a separate register is provided for step 0. In step 0 an offset for other steps is measured. The converted data is compared with the threshold values in Self-Test Analog Watchdog C (STAW5R) if STAW4R[AWDE] = 1. For other steps, this offset is subtracted from converted data before performing watchdog checks.

58.3.16.2.5 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm that has been implemented, and also checks whether the algorithm is completed within a safe time period. The watchdog timers are enabled for CPU as well as BCTU conversions. Each algorithm has an independent watchdog timer. The watchdog timer for a particular algorithm is enabled by writing 1 to STAWxR[WDTE]. The safe time value is programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point where step 0 of the same algorithm starts again.

The programming sequence is:

1. Program NCMR*n* to select the channels for normal conversion in Scan operation mode (MCR[MODE] = 1).
2. Select the self-test algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected (all algorithms are executed step-by-step, one after the other).
3. Enable the self-test channel by writing 1 to STCR2[EN].
4. Program the safe period value in STBRR[WDT].
5. Enable the watchdog timer by writing 1 to STAWxR[WDTE]. Assume writing 1 to STAWxR[WDTE] occurs at time *t*0. It is important to do all configuration programming before writing 1 to STAWxR[WDTE], because the safe time check is also performed between writing 1 to STAWxR[WDTE] and the start of step 0. This is to verify that the algorithm has started within the safe time.
6. Start the normal conversion by writing 1 to MCR[NSTART].
7. At the end of the first conversion chain, three steps (steps 0, 1, and 2) of algorithm S are executed in sequence. Assume the start of Step 0 occurs at time *t*1.
8. After completion of algorithm S, ADC performs conversion of the next chain.
9. At the end of the the conversion chain, the first step (step 0) of algorithm C is performed.
10. In this way, one step of algorithm C is performed after completion of one conversion chain until all steps are finished. Steps are executed in sequence (steps 0–11)
11. After the last step of algorithm C, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S is started again, repeating the whole sequence. Assume this time (starting of step 0 of the supply algorithm) to be at time *t*2.
12. For algorithm S, if (*t*1 - *t*0) > safe period or (*t*2 - *t*1) > safe period, the watchdog timer flags an error and STSR1[WDTERR] transitions to 1. ADC asserts a fault signal per the criticality configuration (critical or noncritical) and an interrupt is generated, if enabled (STCR2[MSKWDTERR] = 1). Otherwise, the watchdog timer counter is reset and starts again to monitor the next sequence.
13. A similar sequence is followed for watchdog timers for algorithm C.

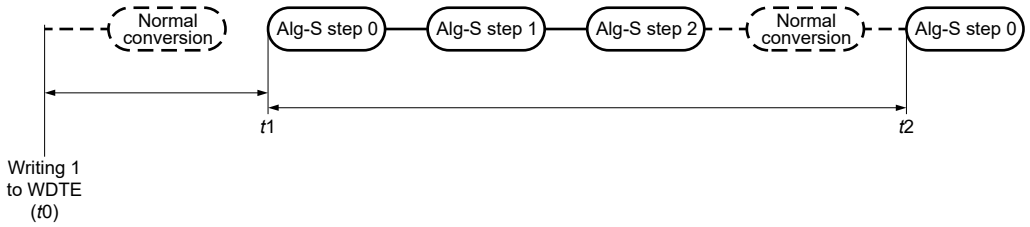

Figure 234. Watchdog timer monitor for algorithm S

NOTE

1. Because BCTU may not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for BCTU conversions.
2. You must disable watchdog timers for self-test algorithms that are not executed.

58.3.16.2.5.1 Watchdog sequence checking

The self-test watchdog timer incorporates sequence checking features to verify that the steps of each algorithm are executed in the correct order. If the steps are not in the correct order, STSR1[WDSERR] transitions to 1 to indicate the error. A fault is indicated by an interrupt flag if STCR2[MSKWDSERR] = 1. A fault is also asserted as per criticality configuration (critical or noncritical) and an interrupt generated if STCR2[MSKWDSERR] = 1.

A watchdog sequence error is flagged in the following cases:

- The steps of any algorithm are not executed in proper order.
- The step numbers provided by BCTU for a BCTU conversion are not in order. Watchdog sequence checking is significant only for BCTU burst mode.
- When an abort chain occurs during a self-test channel conversion, that step must be repeated at the end of the next chain. This generates a sequence error as soon as the self-test channel conversion resumes. There is an exception, however. If an abort chain occurs during the last step of algorithm S, the sequence error is not flagged because the whole algorithm must be repeated.

If an injected conversion occurs during self-test channel conversion, a watchdog sequence error is not flagged, although the ongoing step number is aborted and is repeated.

NOTE

The watchdog timer feature is applicable for Scan operation mode but not for One-Shot operation mode.

58.3.16.2.6 Baud rate control for test channel

The baud rate control feature controls the scheduling of self-test channel conversions between normal conversion chains. The scheduling rate is specified by STBRR[BR].

By default, if the self-test channel is enabled, one step of the selected algorithm is executed after each normal conversion chain. The bandwidth consumed by the self-test channel depends on the number of channels in the normal chain. For example, if you have 50 normal conversions in a chain, then the self-test channel consumes only 2% of the total bandwidth, which is very small. If the number decreases to just 3 channels, the bandwidth consumed by the self-test channel is 25%, which is significant (and may not be desirable because it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the self-test channel conversion to be performed not at the end of every chain, but at the end of BR + 1 chains. For example, if STBRR[BR] = 5, a single step of the selected algorithm for the test channel is performed after 6 chain conversions. The next step is performed at the end of the next six chain conversions, and so on. By default, STBRR[BR] = 0.

NOTE

This feature is applicable only for Scan operation mode and not for One-Shot operation mode. STBRR[BR] should be written with 0 for One-Shot operation mode.

To use the baud rate control feature in Scan operation mode, NCMR*n* should have a nonzero value.

58.3.16.2.6.1 Abort chain when baud rate is nonzero

As already described, for a nonzero value of STBRR[BR], the self-test channel conversion is performed at the end of BR + 1 chains. If an abort chain occurs during the chain in which a self-test channel conversion is scheduled to be performed, the self-test channel conversion is performed after the next BR + 1 chains.

For example, if STBRR[BR] = 2, the sequence is two normal chains (without any self-test channel conversion), followed by a chain with the self-test channel converted at the end. If an abort chain occurs during the first two chains, it is treated as a normal chain abort and the self-test channel is converted at the end of the third chain only (as in the case without any abort chain). However, if an abort chain occurs during the third chain in which the self-test channel is scheduled to be converted, the self-test channel is converted after the next three chains (for example, at the end of the sixth chain, counting from the beginning).

58.3.17 Conversion time

Total conversion time depends on the conversion clock frequency, which is configured by programming MCR[ADCLKSEL].

The components of conversion time and affecting configurations are:

- PST
- ST
- CT

- DP
- TPT

Presample phase time is equal to the sample time with a one AD_clk cycle delay for phase transition from presample phase to sample phase. CTR*n*[INPSAMP] controls sample time for different types of channels and is specified in terms of AD_clk cycles, so the presampling time is sample time plus one cycle of AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, it has no effect on sample time and the sample time is 8 AD_clk cycles.

Compare phase time is controlled by:

- The evaluation time of a single bit
- The number of bits converted

For *n*-bit conversions, the value of CT is *n* multiplied by the evaluation time of a single bit in terms of AD_clk cycles.

The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HS] = 0h, and 5 AD_clk cycles if AMSIO[HS] = 1h.

The data processing time is 2 cycles of AD_clk. During these cycles raw converted data is corrected for offset, gain, capacitor mismatch, and so on.

Trigger processing time consists of:

- One module_clock cycle, which is required to prepare the channel and calculate the initial gain value used by ADC for the first conversion.
- BCTU triggering time:
  - Triggers from the synchronous BCTU interface require 1 cycle of the module clock for processing. One more cycle is required to register the BCTU trigger in synchronous mode.

The total conversion time, in terms of the module clock cycles, is calculated using the following equation for normal and injected conversions:

Total_conversion_time = ([(PST + ST + CT + DP) × chain_length] + TPT) × TAD_clk

Example:

The ADC controller clock is equal to the module clock (80 MHz, clock cyle = 12.5 ns)

- ADC resolution 12 bit + 1 bit for a special capacitor (CS)
- Three channels are programmed in NCMR*n*, so a chain of three is to be converted
- Default sample time (22 cycles) is specified
- No presampling
- Conversion time (4 cycles per bit)

The total time for the three conversions = [(0 + 22 + (4×13) + 2) × 3] + 1 = 229 cycles ~= 2.862 µs

Conversion timing in Calibration for full test:

- Single conversion time = [sample time (CALBISTREG[TSAMP]) + compare time (11 × 4) + data proc(2)]
- Inter-conversion gap = 1 cycle
- Total number of tests = 12
- Averaging = 32

One test duration = (single conversion time + inter-conversion gap) × averaging samples

Total test duration = ((one test duration) × total number of tests).

Example: sample time = 22

Total test time = ((((22 + (11×4) +2)+1) × 32) × 12) = 26496 cycles × 12.5 ns (80 MHz) = 331200 ns

Conversion time in self-test:

Self-test conversion time equals one test period multiplied by the number of consecutive (atomic) steps. For supply self-test, the atomic step is 3 and for other tests it is 1.

One test period for self-test is as below.

- For supply tests: ([sample_time + (13 × 4) + 2])
- For other algorithms: ([sample_time + (11 × 4) + 2])

NOTE

Algorithm S steps (conversions) always run in atomic operation, required for an algorithmic procedure. In Scan operation mode, when all algorithms are selected, three steps of algorithm S run together after the end of the conversion chain. algorithm C steps are not required to be run together, so after each conversion chain one step is executed serially. Conversion time with self-test must also be calculated accordingly.

Example.

- Channels in chain A→B→C.
- Scan operation mode.
- All self-test algorithms are selected.

So, the resulting conversion order is:

[A→B→C→AS_step0→AS_step1→AS_step2→A→B→C→AC_step0→A→B→C→AC_step1→A→B→C→AC_step2→.....→A→B→C→AC_step11]→[same sequence repeats]

NOTE

- AS = Algorithm S (supply self-test)
- AC = Algorithm C (capacitive self-test)

58.3.18 Conversion data processing

Raw converted data contains many types of errors, such as offset, gain, and so on. ADC processes raw conversion data before writing the result to a data register, to reduce or eliminate error contributions. The process of error correction happens in parallel with bit-by-bit evaluation, using the correction values generated during the offset determination and calibration process.

The error correction value is subtracted from the raw conversion result whenever the comparator output for one of the calibrated capacitors evaluates high during the conversion period.

To reduce data processing time, error correction is done in parallel during each bit evaluation of a conversion. Lower-weighted capacitors (smaller than C9) are not calibrated, so no error correction is performed for these capacitors. However, they are self-tested to guarantee that the error contribution is below specified accuracy limits.

The final result is checked for any overflow or underflow. When the processed data is above the maximum value that can be represented by ADC resolution, the output data is forced to all 1s (FFFh for 12-bit resolution). Similarly, if the processed data is negative then output data is forced to all 0s (000h for 12-bit resolution).

58.3.19 User-defined offset and gain values

In addition to the ADC-calculated offset value and gain value, ADC enables you to specify another set of offset and gain values in Offset And Gain User (OFSGNUSR). These values must be stored in two's complement format, where the leftmost bit (the most significant bit) is the sign bit.

ADC subtracts these values from the final processed conversion result. The values are used to removed fixed DC bias or any other known errors—for instance those caused by board design, sensors, and so on.

58.4 Clock frequency

ADC's internal blocks are designed for an input clock frequency up to the Fin (Input Signal Bandwidth) maximum (see the ADC electrical specification section in the chip data sheet). The specified speed can be achieved with this clock frequency. If the

input clock frequency exceeds the specified maximum frequency, ADC accuracy degrades and, in the worst case scenario, ADC malfunctions. ADC accuracy also degrades if the input clock frequency is below the specified minimum frequency. Sampling time has an absolute maximum value to guarantee the specified parameters and accuracy. For slower clocks, the sampling clock count must be programmed accordingly.

58.5 Memory map and register definition

ADC has a wide range of configurations to tailor its operation to application requirements. This comes with the drawback of possible corner cases. To avoid unintended behavior, configure ADC before starting a conversion and change any configuration only when ADC is idle, in other words when MSR[ADCSTATUS] = 0.

58.5.1 Transfer error description

The following register accesses cause a transfer error and do not change register content:

- Any access to an unused address.
- Any write access to a read-only register.

58.5.2.2 Main Configuration (MCR)

Offset

Register	Offset
MCR	0h

Function

Configures most ADC features. You must change field values only when ADC is in Idle state, except for the ABORTCHAIN and ABORT fields.

Diagram

Fields

Field	Function
31 OWREN	Overwrite Enable Specifies whether a conversion data register accepts new data before the current conversion data has been read. When enabled, the new conversion result overwrites the older data, regardless of the validity of the older conversion data. When PCDR*n*[VALID] = 1, the conversion data has not been read. 0b - Disable 1b - Enable
30 WLSIDE	Write Left-Aligned Specifies whether conversion data is right-aligned or left-aligned when written to one of the conversion data registers: • PCDR*n* • ICDR0*n* • ECDR*n* Right-aligned data occupies *CDR[14:0]. Left-aligned data occupies *CDR[15:1], 0b - Right aligned

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Left-aligned
29 MODE	Normal Conversion Mode Specifies whether the set of input channels selected for a normal conversion are converted only once per start event or continuously after a start event. If a conversion is done only once, ADC enters an idle state after conversion is complete. For continuous conversion, all input channels selected for the normal conversion are converted continuously in a loop. Stop the loop by writing 0 to NSTART. 0b - Single conversion 1b - Continuous conversion
28 —	Reserved
27 TRGEN	External Trigger Enable Specifies whether the normal trigger input starts a conversion. 0b - Normal trigger input does not start a conversion 1b - Normal trigger input starts a conversion
26 EDGE	External Trigger Edge Selection Selects which edge of the normal trigger input starts a conversion. 0b - Falling edge 1b - Rising edge
25 XSTRTEN	Auxiliary External Start Enable Enables the auxiliary normal trigger source to start a conversion. You can use this field to synchronize the start of a conversion of two ADC instances. 0b - Disable 1b - Enable
24 NSTART	Start Normal Conversion Starts a normal conversion. If the continuous mode is selected (MODE = 1), the value of this field remains 1. Write 0 to this field to stop the in-progress conversion loop after conversion of the last input channel of the selected set of input channels is complete. If continuous mode is not selected (MODE = 0), this field automatically resets to 0 after writing 1. 0b - No effect 1b - Starts conversion
23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
22 JTRGEN	Injection Trigger Enable Enables the injected trigger input as a source to start a conversion. 0b - Disable 1b - Enable
21 JEDGE	Injected Trigger Edge Selection Selects which edge of the injected trigger input starts an injected conversion. 0b - Falling edge 1b - Rising edge
20 JSTART	Injected Start Interrupts any ongoing normal conversion and starts an injected conversion. This field automatically resets to 0. If an injected conversion is already ongoing, the field value remains 1 until the next injected conversion starts. This field can only be written with 1. 0b - Injected conversion can be started 1b - Starts an injected conversion
19-18 —	Reserved
17 BCTUEN	Body Cross Trigger Unit Enable Enables BCTU as a trigger source. 0b - Disable 1b - Enable
16 BCTU_MODE	Body Cross Trigger Unit Mode Select Specifies whether sources other than BCTU can start a conversion when the BCTU is enabled as a trigger source (BCTUEN = 1). This field is writeable only when ADC is in Power Down state (PWDN = 1). 0b - Only BCTU can trigger conversion 1b - All trigger sources can trigger conversion
15 STCL	Self-Test Configuration Lock Protects the following registers from writing: • STCR1 • STCR2 • STCR3 • STBRR • STAW0R

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• STAW1R • STAW2R • STAW4R • STAW5R 0b - Registers are writeable 1b - Registers are read-only
14-12 —	Reserved
11 AVGEN	Averaging Enable Enables conversion averaging. 0b - Disable 1b - Enable
10-9 AVGS	Averaging Select Specifies the number of conversions ADC uses to calculate the conversion result. 00b - 4 conversions 01b - 8 conversions 10b - 16 conversions 11b - 32 conversions
8 —	Reserved
7 ABORTCHAIN	Abort Chain Aborts the conversion of the selected set of input channels (chain of input channels). The currently ongoing conversion completes. This field always reads 0. This field cannot be programmed during BCTU conversion. **NOTE** This field behaves differently for read and write operations. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 ABORT	Abort Conversion Aborts an ongoing conversion. This field always reads 0 and cannot be written during BCTU conversion. **NOTE** This field behaves differently for read and write operations. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted
5 ACKO	Auto Clock Off Reduces power consumption by turning off the clock of the analog part of ADC when it is in Idle state. 0b - Clock always active 1b - Clock gated
4-3 —	Reserved
2-1 ADCLKSEL	Conversion Clock (AD_clk) Frequency Selection Selects the frequency for the clock signal of the conversion circuit (AD_clk = module clock ÷ ($2^{ADCLKSEL}$)). This field can be written only when ADC is in Power Down state (PWDN = 1). 00b - Module clock frequency 01b - Module clock frequency ÷ 2 10b - Module clock frequency ÷ 4 11b - Module clock frequency ÷ 8
0 PWDN	Power Down Reduces power consumption by turning off power to the analog portion of ADC. 0b - ADC enters a functional state 1b - ADC enters Power Down state

58.5.2.3 Main Status (MSR)

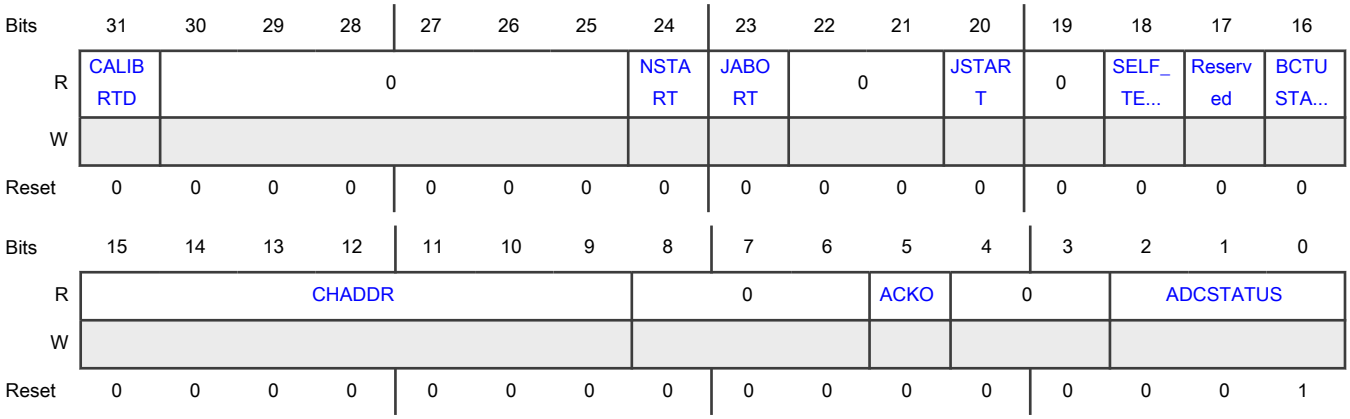
Offset

Register	Offset
MSR	4h

Function

Contains flags that indicate the current ADC state.

Diagram



Fields

Field	Function
31 CALIBRTD	Calibration Status Indicates ADC calibration status. 0b - Uncalibrated or calibration unsuccessful 1b - Calibrated
30-25 —	Reserved
24 NSTART	Normal Conversion Started Shows whether a normal conversion is in progress. 0b - Not in progress 1b - In progress
23 JABORT	Injected Conversion Aborted Indicates whether the conversion of a set of inputs selected for injected conversion has been aborted. This field resets to 0 when a new injected conversion is started. 0b - Not aborted 1b - Aborted
22-21 —	Reserved
20 JSTART	Injected Conversion Started Indicates whether an ongoing conversion was started by the injection trigger.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not an injected conversion 1b - Injected conversion
19 —	Reserved
18 SELF_TEST_S	Indicates whether an ongoing conversion is for self-test. 0b - Not self-test 1b - Self-test
17 —	Reserved
16 BCTUSTART	BCTU Conversion Started Indicates whether a BCTU conversion is ongoing. This field is 1 when a BCTU trigger event is received and the BCTU conversion starts. When the BCTU trigger mode is selected, this field is automatically reset to 0 when conversion is completed. Otherwise, if BCTU control mode is selected, this field resets to 0 when the BCTU is disabled (BCTUEN = 0). 0b - Conversion was not triggered by BCTU 1b - Ongoing conversion was triggered by BCTU
15-9 CHADDR	Input Under Measure Contains the number of the input that is currently converted. 000_0000b-011_1111b - Input number
8-6 —	Reserved
5 ACKO	Auto Clock-Off On Indicates whether the auto clock-off feature is active, and the conversion circuit is not receiving a clock signal. When auto clock-off is inactive, the conversion circuit is clocked. 0b - Inactive 1b - Active
4-3 —	Reserved
2-0 ADCSTATUS	ADC State Indicates the current state of the ADC Finite State Machine (FSM).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Idle 001b - Power Down 010b - Wait 011b - Calibrate 100b - Convert 110b - Done

58.5.2.4 Interrupt Status (ISR)

Offset

Register	Offset
ISR	10h

Function

Contains flags that indicate whether an interrupt has been generated.

7-0 INPSAMP	Input Sample Cycles Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8.

58.5.2.24 Conversion Timing For Standard Inputs (CTR1)

Offset

Register	Offset
CTR1	98h

Function

Specifies the duration, in terms of the number of conversion clock cycles, of the sampling of standard inputs or the temperature sensor.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	0

Fields

Field	Function
31-8 —	Reserved
7-1 INPSAMP	Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field uses the TSENSOR_SEL bit as its low-order bit. In other words, INPSAMP is effectively an 8-bit field, but the low-order bit has a dual function.
0 TSENSOR_SEL	Temperature Sensor Voltage Select Selects the voltage for external temperature sensors (if available). If a temperature sensor is available, this field may be used as the selector for the mux between two temperature sensors. **NOTE** This field is applicable only when there is more than one temperature sensor. 0b - Selects temperature sensor source 0 1b - Selects temperature sensor source 1

58.5.2.25 Conversion Timing For External Inputs (CTR2)

Offset

Register	Offset
CTR2	9Ch

Function

Specifies the number of conversion clock cycles when the external inputs are sampled.

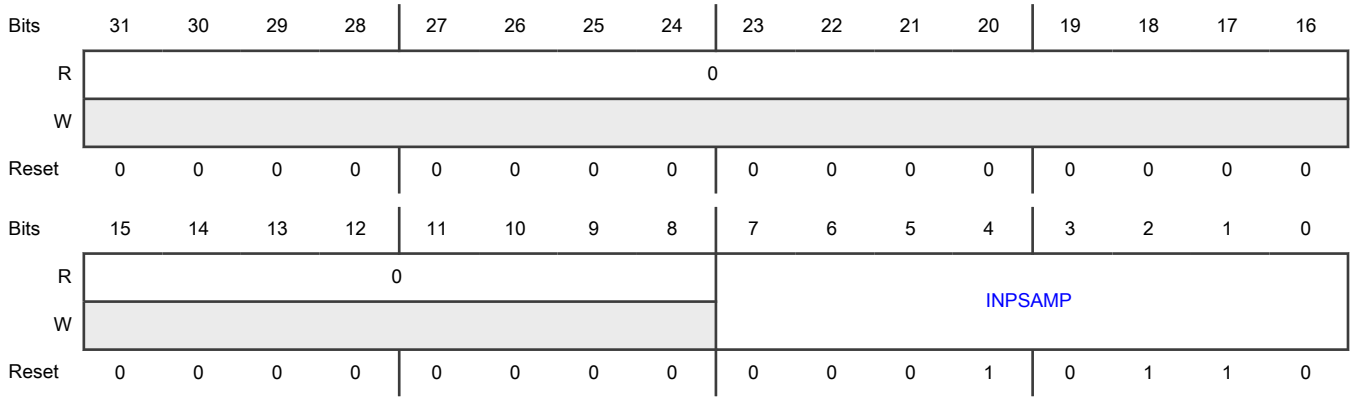
The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ADC_0	CTR2	—
ADC_1	CTR2	—
ADC_2	—	CTR2

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 INPSAMP	Input Sample Cycles Specifies the sample duration in terms of conversion clock cycles. The minimum acceptable value is 8. Specifying a lower value automatically forces a value of 8.

58.5.2.26 Normal Conversion Enable For Precision Inputs (NCMR0)

Offset

Register	Offset
NCMR0	A4h

Function

Selects the precision inputs to be converted during a normal conversion.

58.5.2.32 Delay Start Of Data Conversion (DSDR)

Offset

Register	Offset
DSDR	C4h

Function

Delays the start of the conversion when another input channel is selected. The necessary delay depends on the device characteristics of, for example, the input channel multiplexer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ADC_0	DSDR	—
ADC_1	DSDR	—
ADC_2	—	DSDR

Fields

Field	Function
31-16 —	Reserved
15-0 DSD	Delay Specifies the delay in terms of the number of module clock cycles.

58.5.2.33 Power Down Exit Delay (PDEDR)

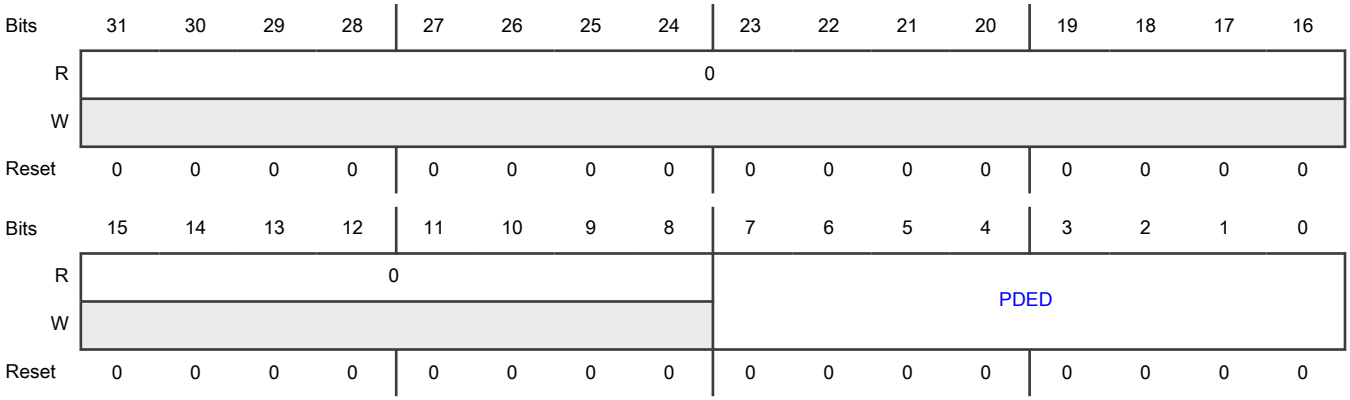
Offset

Register	Offset
PDEDR	C8h

Function

Delays the transition out of Power Down into Idle state to wait for necessary settling times. See the device data sheet for the minimal time between the power-down exit request and when ADC can start a conversion.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 PDED	Delay Specifies a delay in terms of the number of conversion clock cycles.

58.5.2.34 Precision Input n Conversion Data (PCDR0 - PCDR7)

Offset

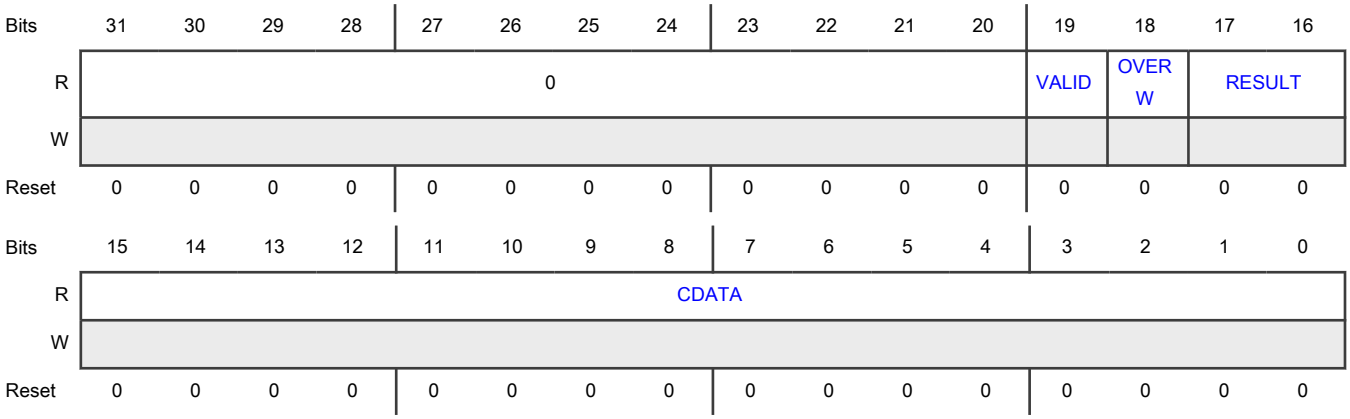
For n = 0 to 7:

Register	Offset
PCDRn	100h + (n × 4h)

Function

Contains conversion data from precision input *n*.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Conversion Data Available Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read. 0b - No unread conversion data 1b - Unread conversion data is available
18 OVERW	Overwrite Status Flag Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost. The ability to overwrite conversion data is controlled by MCR[OWREN]. 0b - No unread data is overwritten 1b - Unread data is overwritten
17-16 RESULT	Conversion Data Type Indicates the type of trigger that started the conversion for this conversion data. 00b - Normal trigger 01b - Injected trigger 10b - BCTU trigger
15-0 CDATA	Conversion Data Contains conversion data from precision input *n*, determined by the successive approximation algorithm. The conversion data is always 15 bits wide, regardless of the conversion resolution selected (CALBISTREG[RESN]). Depending on the value of MCR[WLSIDE], the conversion data can be in bits [14:0] (MCR[WLSIDE] = 0), or in bits [15:1] (MCR[WLSIDE] = 1).

58.5.2.35 Standard Input n Conversion Data (ICDR0 - ICDR23)

Offset

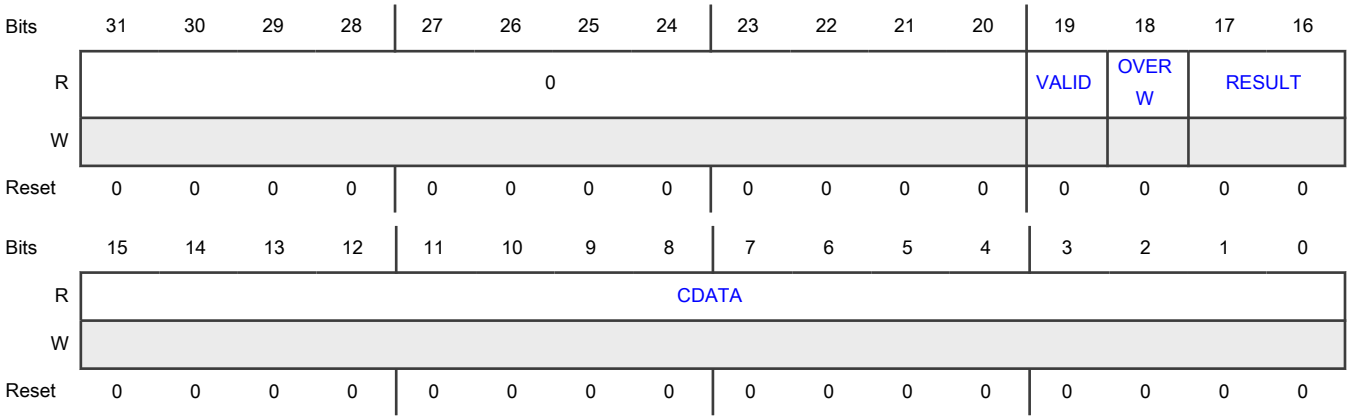
For a = 0 to 23:

Register	Offset
ICDRa	180h + (a × 4h)

Function

Contains conversion data from standard input *n*.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Conversion Data Available Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read. 0b - No unread conversion data 1b - Unread conversion data is available
18 OVERW	Overwrite Status Flag Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost. 58.5.2.52 Self-Test Configuration 1 (STCR1)

Offset

Register	Offset
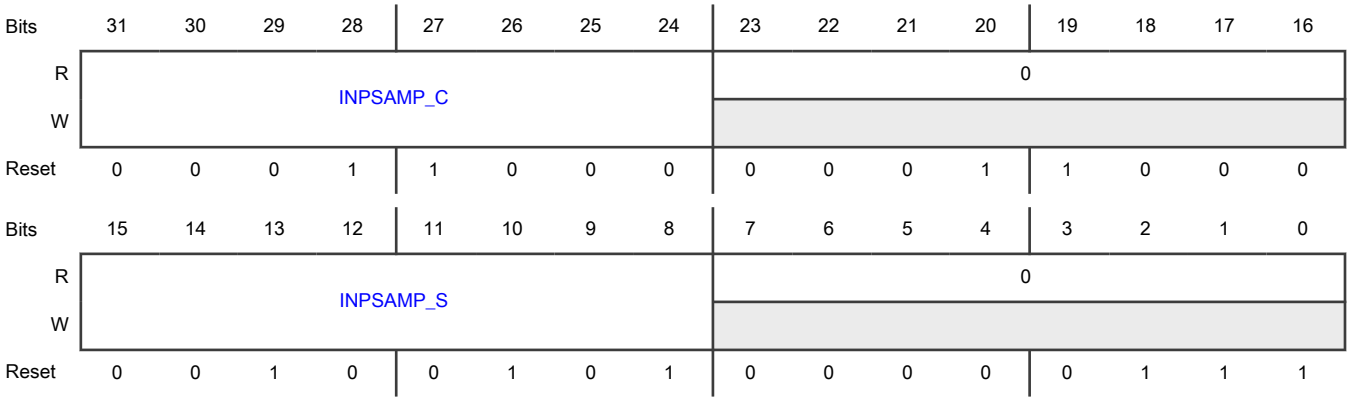
STCR1	340h

Function

Specifies the input sampling duration in terms of conversion clock cycles.

Conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-24 INPSAMP_C	Input Sampling Time Algorithm C Specifies the sample duration for test conversions related to algorithm C. The minimum acceptable value is 8. Specifying a lower value automatically forces a value of 8.
23-16 —	Reserved
15-8 INPSAMP_S	Input Sampling Time Algorithm S Specifies sample duration for test conversions related to algorithm S. The minimum value is 8. Specifying a lower value automatically forces a value of 8.
7-0 —	Reserved

58.5.2.53 Self-Test Configuration 2 (STCR2)

Offset

Register	Offset
STCR2	344h

Function
Configures ADC self-test functions.

Diagram

Fields

Field	Function
31-28 —	Reserved
27 MSKWDSERR	Mask Interrupt Self-Test Watchdog Sequence Error Generates an interrupt when the WDSERR flag transitions to 1. 0b - No interrupt is generated 1b - Interrupt is generated
26 SERR	Self-Test Error Injection Writes 1 to the STSR1[ERR_C], STSR1[ERR_S0], STSR1[ERR_S1], and STSR1[ERR_S2] status fields, causing an error. This field is reset to 0 immediately after writing. **NOTE** This field behaves differently for read and write operations. When reading 0b - Error can be injected 1b - Error is being injected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When writing 0b - No effect 1b - Injects a self-test error
25 MSKWDTERR	Mask Interrupt Self-Test Watchdog Timer Error Generates an interrupt when the WDTERR flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
24 —	Reserved
23 MSKST_EOC	Mask Interrupt Self-Test End Of Conversion Generates an interrupt when the ST_EOC flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
22-19 —	Reserved
18 MSKWDG_EOA_C	Mask Error Interrupt End Of Algorithm C Generates an interrupt when the WDG_EOA_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
17 —	Reserved
16 MSKWDG_EOA_S	Mask Error Interrupt End Of Algorithm S Generates an interrupt when the WDG_EOA_S flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
15 MSKERR_C	Mask Error Interrupt Algorithm C Generates an interrupt when the ERR_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
14	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
13 MSKERR_S2	Mask Error Interrupt Algorithm S2 Generates an interrupt when the ERR_S2 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
12 MSKERR_S1	Mask Error Interrupt Algorithm S1 Generates an interrupt when the ERR_S1 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
11 MSKERR_S0	Mask Error Interrupt Algorithm S0 Generates an interrupt when the ERR_S0 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
10-8 —	Reserved
7 EN	Self-Test Enable Enables ADC structural self-test. When BCTU is enabled, this field has no effect. This field must be 1 before starting normal conversion and must not be changed during conversion. This field must be reset to 0 only after end of conversion for the last self-test channel has been received. 0b - Disable 1b - Enable
6-5 —	Reserved
4 FMA_WDSERR	Fault Mapping Self-Test Watchdog Sequence Error Specifies whether a self-test watchdog sequence error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
3 FMA_WDTERR	Fault Mapping Self-Test Watchdog Timer Error Specifies whether a self-test watchdog timer error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 FMA_C	Fault Mapping Algorithm C Specifies whether a fault in algorithm C sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
1 —	Reserved
0 FMA_S	Fault Mapping Algorithm S Specifies whether a fault in algorithm S sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line

58.5.2.54 Self-Test Configuration 3 (STCR3)

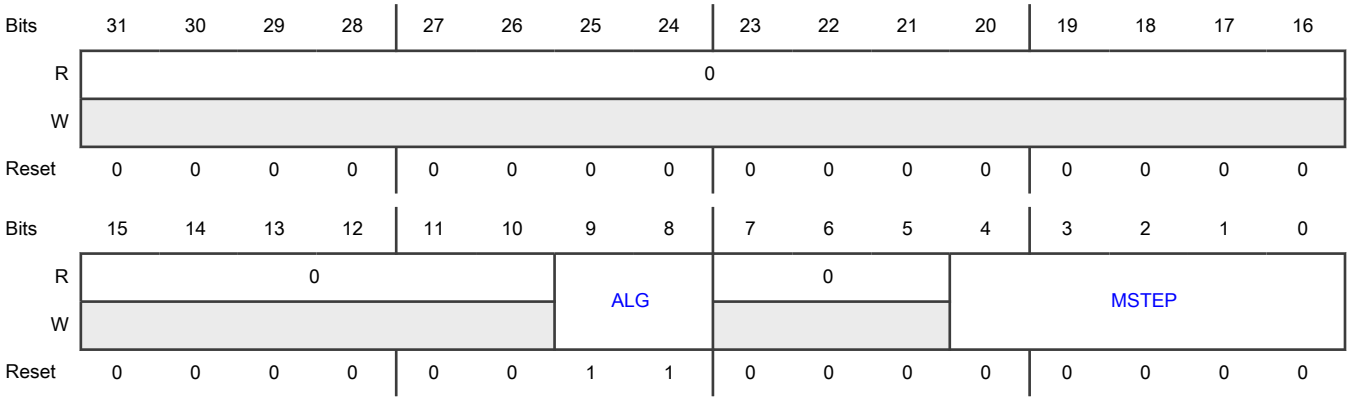
Offset

Register	Offset
STCR3	348h

Function

Configures ADC self-test functions. When BCTU is enabled, writes to the fields registers have no effect. This register must be programmed before starting a conversion and must not be changed when conversion is ongoing.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-8 ALG	Algorithm Selection One-Shot operation mode: • 00 Algorithm S (single step = MSTEP) • 01 Reserved • 10 Algorithm C (single step = MSTEP) • 11 Algorithm S (default) (use for test/debug purposes) Continuous conversion mode: • 00 Algorithm S • 01 Reserved • 10 Algorithm C • 11 Algorithm S + algorithm C (default)
7-5 —	Reserved
4-0 MSTEP	Algorithm Step For One-Shot operation mode: • MSTEP = 0 to 2 for algorithm S • MSTEP = 0 to 11 for algorithm C Unused codes are reserved and must not be used. For Scan operation mode: This field is not used in Scan operation mode because single-step execution (interleaved mode) is always performed. This field must be programmed to zero in Scan operation mode.

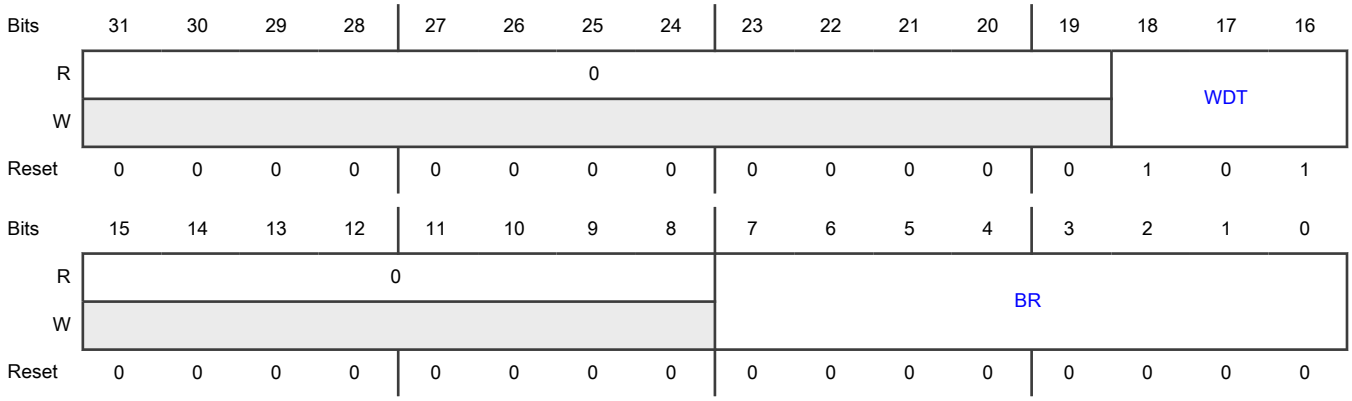
58.5.2.55 Self-Test Baud Rate (STBRR)

Offset

Register	Offset
STBRR	34Ch

Function
Specifies when the self-test algorithm steps are executed and the maximum time allowed for self-test to finish.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 WDT	Self-Test Watchdog Timer Specifies the safe time period in terms of conversion clock cycles. The safe time period is the maximum duration until the running self-test is expected to finish. 000b - 8192 conversion clock cycles (~0.1 ms at 80 MHz) 001b - 39,936 conversion clock cycles (~0.5 ms at 80 MHz) 010b - 79,872 conversion clock cycles (~1 ms at 80 MHz) 011b - 159,744 conversion clock cycles (~2 ms at 80 MHz) 100b - 400,384 conversion clock cycles (~5 ms at 80 MHz) 101b - 799,744 conversion clock cycles (~10 ms at 80 MHz) 110b - 1,599,488 conversion clock cycles (~20 ms at 80 MHz) 111b - 3,999,744 conversion clock cycles (~50 ms at 80 MHz)
15-8 —	Reserved
7-0 BR	Baud Rate Selects the number of conversions of the selected inputs, after which the next self-test algorithm step executes. This field must be programmed when STCR2[EN] is zero, that is, before enabling self-test. 0000_0000b - A step of the selected self-test algorithm is executed every time after the set of selected inputs has been converted. 1111_1111b - A step of the selected self-test algorithm is executed after the set of selected inputs has been converted 256 times.

58.5.2.56 Self-Test Status 1 (STSR1)

Offset

Register	Offset
STSR1	350h

Function
Indicates self-test status.

Diagram

Fields

Field	Function
31-28 —	Reserved
27 WDSERR	Self-Test Watchdog Sequence Error Indicates whether the selected self-test algorithm has executed in the correct sequence. **NOTE** This field behaves differently for read and write operations. When reading 0b - Algorithm executed in correct sequence 1b - Algorithm did not execute in correct sequence When writing 0b - No effect 1b - Clears flag
26	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25 WDTERR	Self-Test Watchdog Timer Error Indicates whether the self-test algorithm has finished within the defined safe time period. **NOTE** This field behaves differently for read and write operations. When reading 0b - Algorithm finished within the safe time period (or safe time period not yet elapsed). 1b - Algorithm did not finish within safe time period. When writing 0b - No effect 1b - Clears flag
24 OVERWR	Self-Test Error Status Overwrite Indicates whether an error occurred when the respective error status flag (ERR_S0, ERR_S1, ERR_S2, or ERR_C) was set. **NOTE** This field behaves differently for read and write operations. When reading 0b - No self-test error status flag overwritten 1b - Self-test error status flag overwritten When writing 0b - No effect 1b - Clears flag
23 ST_EOC	Self-Test End Of Conversion Indicates whether a self-test conversion has completed. **NOTE** This field behaves differently for read and write operations. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
22-19 —	Reserved
18 WDG_EOA_C	Self-Test Watchdog End Of Algorithm C Indicates whether self-test algorithm C has completed. **NOTE** This field behaves differently for read and write operations. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
17 —	Reserved
16 WDG_EOA_S	Self-Test Watchdog End Of Algorithm S Indicates whether self-test algorithm S has completed. **NOTE** This field behaves differently for read and write operations. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
15 ERR_C	Error Algorithm C Indicates whether an error occurred during execution of algorithm C. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clears flag
14 —	Reserved
13 ERR_S2	Error Algorithm S Step 2 Indicates whether an error occurred during execution of step 2 of algorithm S. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
12 ERR_S1	Error Algorithm S Step 1 Indicates whether an error occurred during execution of step 1 of algorithm S. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
11 ERR_S0	Error Algorithm S Step 0 Indicates whether an error occurred during execution of step 0 of algorithm S. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clears flag
10 —	Reserved
9-5 STEP_C	Step Of Algorithm C Indicates the step of self-test algorithm C in which an error occurred. Although this register field is read-only, no transfer error is generated when writing to it.
4-0 —	Reserved

58.5.2.57 Self-Test Status 2 (STSR2)

Offset

Register	Offset
STSR2	354h

Function

Contains the conversion result when an error in step 1 of algorithm S has occurred.

15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_S2 flag when a self-test conversion value is less than this value.

58.5.2.64 Self-Test Analog Watchdog C0 (STAW4R)

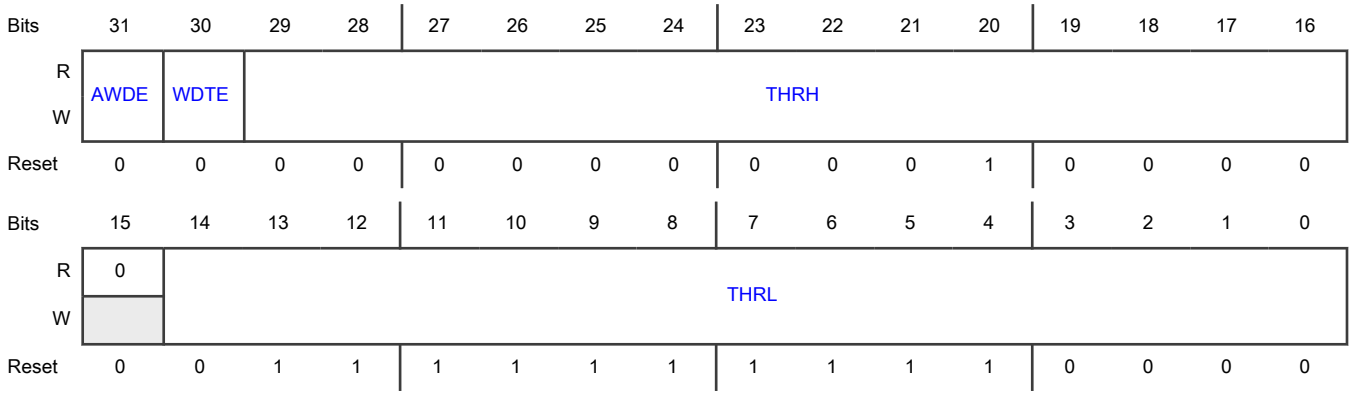
Offset

Register	Offset
STAW4R	394h

Function

Configures self-test for step 0 of algorithm C.

Diagram



Fields

Field	Function
31 AWDE	Self-Test Watchdog Enable Enables the self-test watchdog for algorithm C. 0b - Disable 1b - Enable
30 WDTE	Self-Test Watchdog Timer Enable Enables the self-test watchdog timer for algorithm C. The self-test watchdog timer verifies: • Correct sequence of execution of algorithm steps • Execution of the algorithm within the safe time period as defined by STBRR[WDT] This field must be 1 only in continuous conversion mode (MODE 1). The safe time period starts when this field is written with 1. If the safe time period elapses before algorithm C starts, the WDTERR flag is set. The safe time period is restarted each time algorithm C starts. 0b - Disable 1b - Enable
29-16 THRH	Higher Threshold Value Sets the ERR_C flag when a self-test conversion value is greater than this value. This value must be in two's complement format and must be positive. This value is valid only for step 0 of algorithm C (see STAW5R for the values used for the other steps of algorithm C).
15 —	Reserved
14-0 THRL	Lower Threshold Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Sets the ERR_C flag when a self-test conversion value is less than this value. This value must be in two's complement format and must be negative. (With the reset value of this bit field, the test always fails. You must set at least STAW4R[14]=1, in order to have a negative value in this bit field.) This value is used only for step 0 of algorithm C (see STAW5R for the values used for the other steps of algorithm C).

58.5.2.65 Self-Test Analog Watchdog C (STAW5R)

Offset

Register	Offset
STAW5R	398h

Function

Configures self-test for steps 1–11 of algorithm C.

Diagram

58.5.2.67 Control And Calibration Status (CALBISTREG)

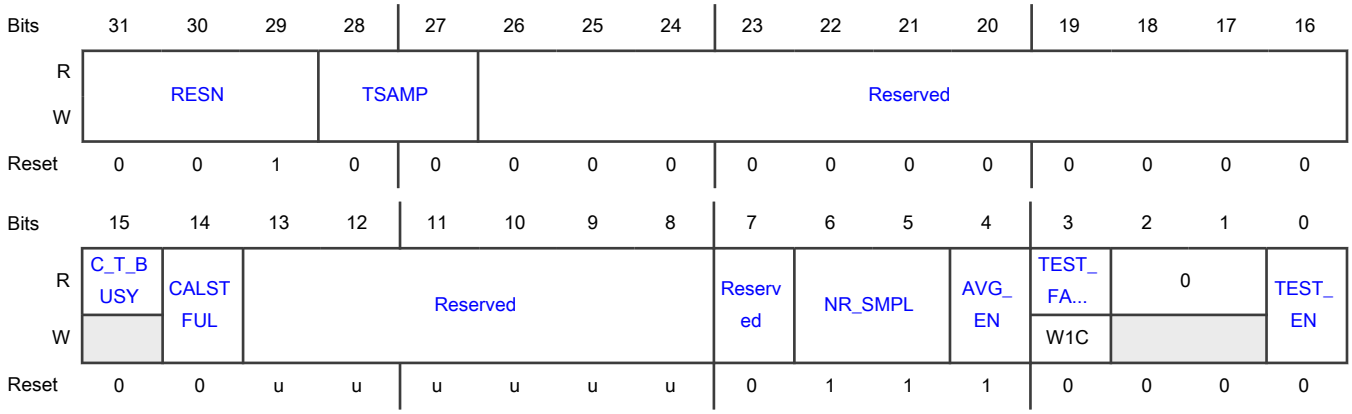
Offset

Register	Offset
CALBISTREG	3A0h

Function

Controls several ADC functions for data conversion, calibration, and calibration status.

Diagram



Fields

Field	Function
31-29 RESN	Conversion Resolution Specifies the number of significant bits per conversion data (functional conversion only, not for calibration or self-test). Reducing this number speeds up the conversion because the SAR algorithm executes fewer steps. This field must be modified only when ADC is idle. 000b - 14-bit resolution 001b - 12-bit resolution 010b - 10-bit resolution 011b - 8-bit resolution
28-27 TSAMP	Sample Period In Calibration Specifies the number of conversion clock cycles during which the reference voltage is sampled. 00b - 22 conversion clock cycles 01b - 8 conversion clock cycles 10b - 16 conversion clock cycles 11b - 32 conversion clock cycles
26-16 —	Reserved The value of this field must not be modified.
15 C_T_BUSY	Calibration Busy Indicates whether calibration is running. 0b - Calibration can be started 1b - Calibration is in progress
14 CALSTFUL	Calibration And Self-Test Full Range Comparison Specifies the range of conversion data bits compared when ADC is calibrated or running self-test. Because the results from calibration and self-test are so low that the significant bits are in the lower 11

Table continues on the next page...

Table continued from the previous page...

Field	Function
	bits only, the comparison cycles for the upper 4 bits can be skipped to reduce the execution duration of the calibration and of the self-test. 0b - Lowest 11 bits are compared. 1b - All 15 bits are compared.
13-8 —	Reserved **CAUTION** This field contains a value that ADC uses internally. Writing to this field can cause ADC to operate unreliably.
7 —	Reserved This field is reserved and always has the value 0. Only the reset value can be written to this field.
6-5 NR_SMPL	Calibration Averaging Number Specifies the number of data conversions per result (averaging) during calibration. 00b - 4 samples 01b - 8 samples 10b - 16 samples 11b - 32 samples
4 AVG_EN	Calibration Averaging Enable Enables averaging of the calibration results over several conversion iterations to improve accuracy. This field only affects the calibration process. 0b - Disable 1b - Enable
3 TEST_FAIL	Calibration Status Indicates calibration status. This field reads 0 when calibration is in progress. This field is reset to 0 when calibration starts. **NOTE** This field behaves differently for read and write operations. When reading 0b - Calibration finished successfully or has not been run since the last reset 1b - Calibration did not finish successfully When writing 0b - No effect 1b - Clears flag
2-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function

58.6 Glossary

CDAC	Capacitive digital to analog converter
CT	Compare phase time
DMA	Direct memory access
DP	Data processing time
PST	Presample phase time
ST	Sample phase time
SAR	Successive approximation
TPT	Trigger processing time
VrefH	Reference voltage high
VrefL	Reference voltage low

Chapter 59
Low Power Comparator (LPCMP)

59.1 Chip-specific LPCMP information

59.1.1 Instantiation information

Table 292. LPCMP instances

Chip	Instance	No. of external inputs
K358, K3x4	LPCMP_0	8
	LPCMP_1	4
	LPCMP_2	4
K312, K342	LPCMP_0	8
	LPCMP_1	4
K311	LPCMP_0	8

59.1.2 LPCMP input output connections

See the IOMUX file attached to this document for pin/pad assignments corresponding to CMP pins.

The LPCMP channels can be used as a wakeup source in trigger mode to wakeup the device from standby mode.

59.1.3 LPCMP-DAC "vrefh0" and "vrefh1" references

The 8-bit DAC sub-block supports selection of "vrefh0" and "vrefh1" by CMPx_DCR[VRSEL]. For this device, the references are connected as follows:

- vrefh0 (External Reference): VDD_HV_A
- vrefh1 (Internal Reference): 1.2 V PMC bandgap reference

NOTE

1.2 V internal reference voltage is not available in Standby mode.

59.1.4 LPCMP window control

The window mode operation of all the comparator instances in the chip can be enabled/disabled by the TRGMUX. See the TRGMUX connectivity file attached to this document for details.

NOTE

Window signal must be of minimum 4 cycle pulse for window mode to function.

59.1.5 Comparator Trigger Mode

The comparator modules in the device support trigger mode operation as described in 'Trigger Mode' section. Device can operate in trigger mode in both standby and run mode to continuously scan the input channels. The main features of the device trigger mode operation are:

- Round robin clock: RTC_CLK
- Round robin trigger source: RTC_API

NOTE

It must be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of C0[PMODE]. It is also required to **not** select the internal reserved channels, if available on the package, for trigger mode operation by INPSEL and INNSEL. See the IOMUX file attached to this document for the pins available in various packages supported for the device.

NOTE

Only SIRC and SXOSC are supported as RTC_CLK for trigger mode operation. The LPCMP initialization delay is not supported by RRCR0[RR_INITMOD] with FXOSC or FIRC as RTC_CLK.

NOTE

In run mode, the generated trigger is delayed by 3 RTC_CLK cycles before being given to comparator trigger input.

59.1.6 Interaction with RTC API to cause wakeup

LPCMP can be used for waking up the chip from standby. For this, RTC-API and LPCMP must be configured before entering into standby mode as per below shown figure.

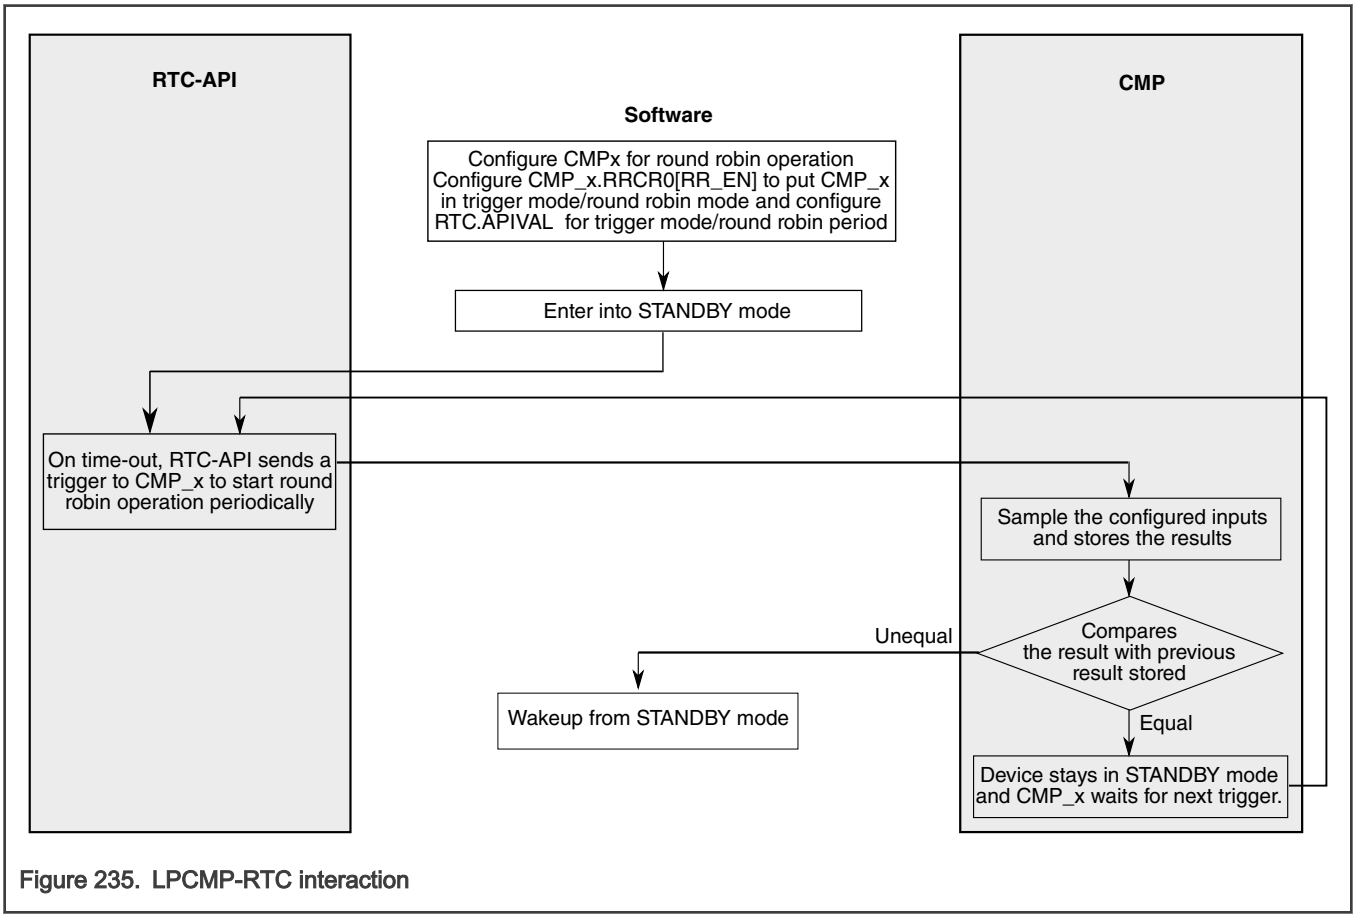

Figure 235. LPCMP-RTC interaction

In the trigger mode operation, only the continuous mode is supported. None of the window/filter/sample functions should be used. Refer to the "Functional Modes" section for details on comparator modes of operation.

Register configurations before entering Standby mode for LPCMP trigger mode operation:

1. Configure RTC.APIVAL to set the period of the round robin operation.
2. Execute standby mode entry.

59.2 Overview

The Low Power Comparator (LPCMP) module provides a circuit for comparing two analog input voltages. It comprises a comparator (CMP), a DAC and an analog mux (ANMUX). See Block diagram for details.

CMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. The 256-tap resistor ladder network divides the supply reference V_{in} into 256 voltage levels. A 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$. V_{in} can be selected from two voltage sources, vrefh0 and vrefh1. See the chip-specific LPCMP information for the source of vrefh0 and vrefh1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external device pin.

ANMUX allows software to select an analog input signal from among eight channel options. One channel option is the DAC output. Other device resources are connected to the other channels; see the chip-specific LPCMP information section for details. ANMUX can operate across the full range of the supply voltage.

59.2.1 Block diagram

The following figure shows the LPCMP block diagram includes the CMP, DAC, and ANMUX modules.

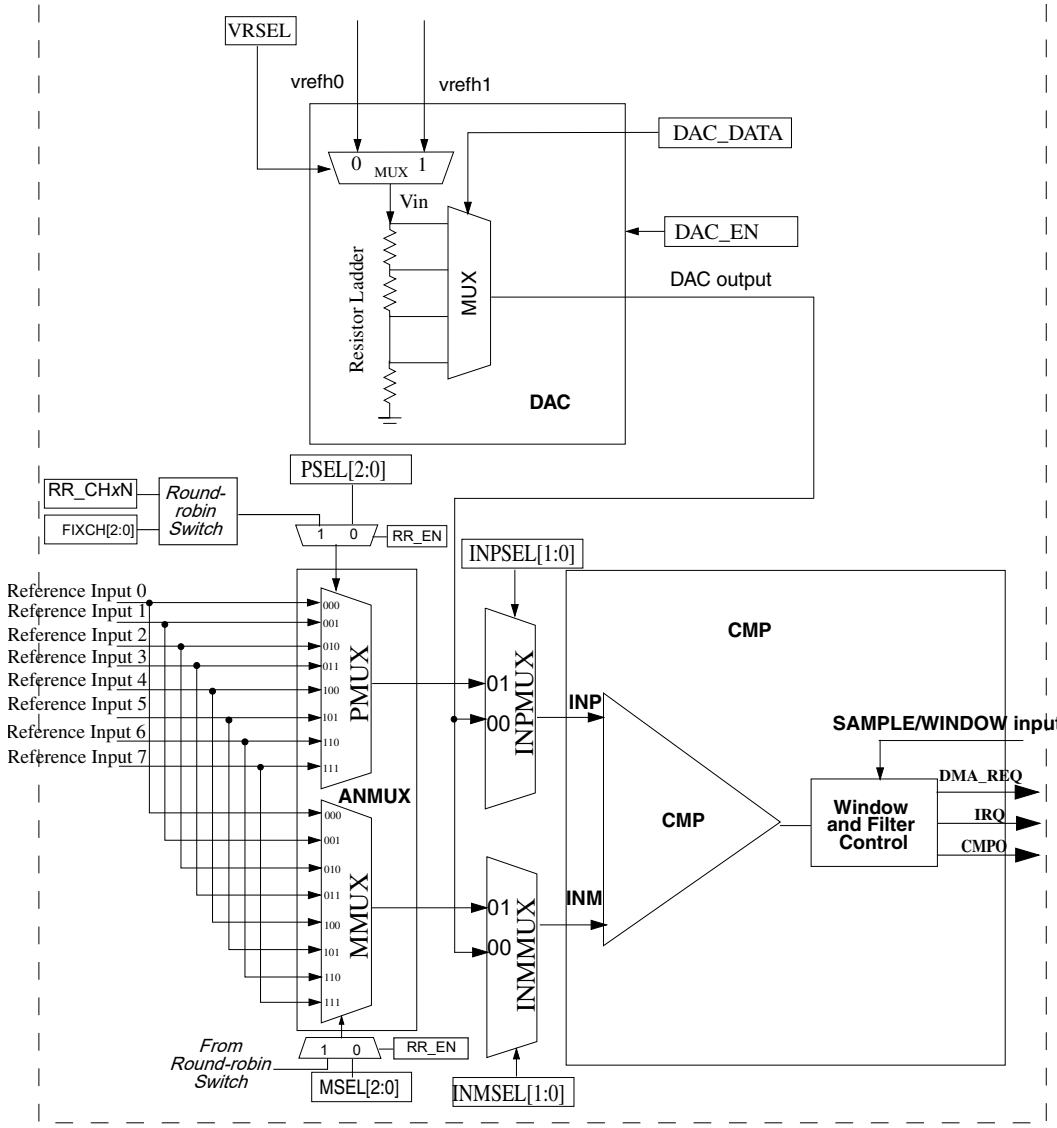

Figure 236. Block Diagram

59.2.2 Features

The features of the LPCMP module include:

- Two 8-to-1 channel MUXes to select input signal from eight channels
- Multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally Filtered
- Advanced feature for window and sample
  - WINDOW/SAMPLE signal can be inverted
  - Window can be closed by CMPO rising, falling or both edges

— User can define CMPO level, when window is closed

- Selectable performance levels: low power (speed) mode, high power (speed) mode
- Programmable hysteresis control
- Selectable inversion on comparator output
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Interrupt and DMA support
- Trigger mode
- Includes a 8-bit resolution DAC
- Selectable supply reference source for DAC

59.3 Functional Description

59.3.1 Functional Block Diagram

The following figure shows the functional block diagram.

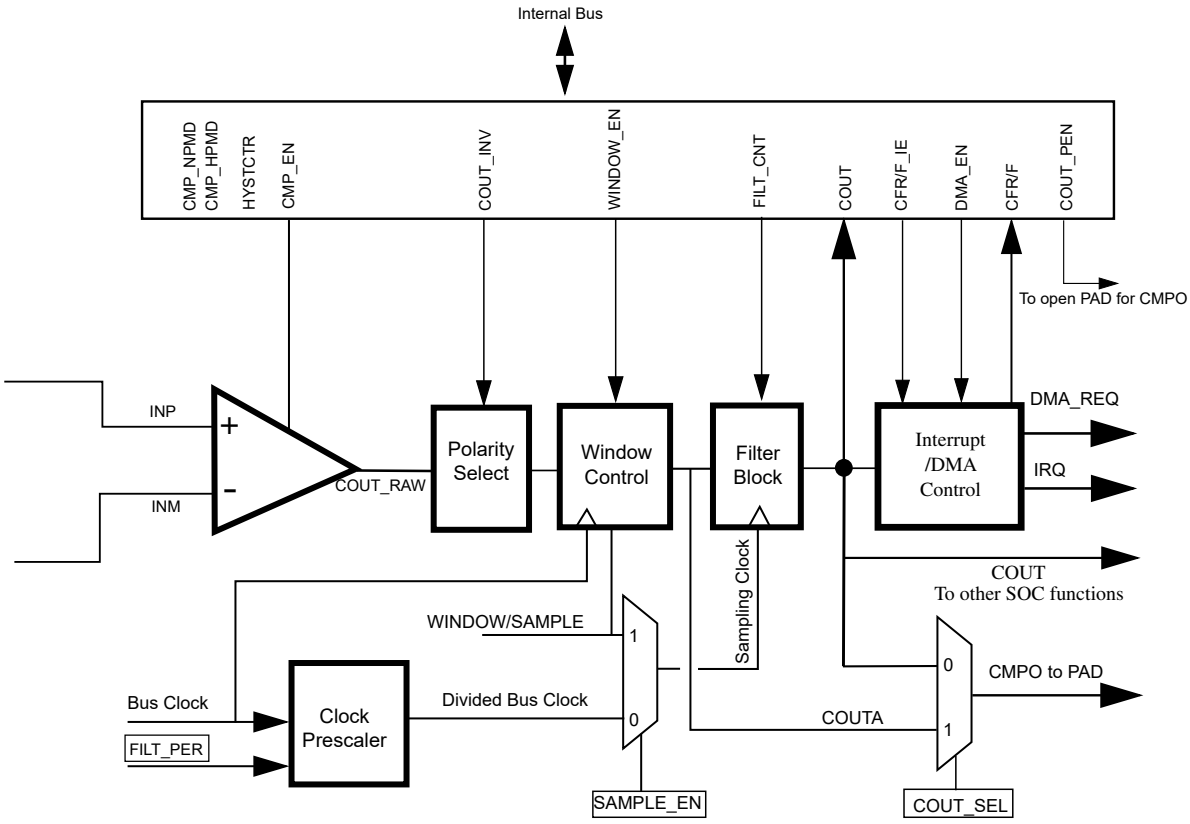

Figure 237. Functional Block Diagram

In the block diagram:

- Two analog input voltages applied to INP and INM are compared. COUT_RAW is high when the INP input voltage is greater than the INM input, and is low when the INP input voltage is less than the INM input.
- This COUT_RAW signal can be inverted if CCR1[COUT_INV] is enabled.

- If CCR1[WINDOW_EN] is enabled, the optionally inverted comparator output COUT_RAW is sampled on every bus clock when window is enabled to generate COUTA. Sampling does NOT occur when window is disabled. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.
- The window control block can be bypassed if CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler if CCR1[FILT_CNT] is set to 0x01.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set greater than 0x01.
  - If CCR1[SAMPLE_EN] = 1, the external SAMPLE input is used as the sampling clock.
  - If CCR1[SAMPLE_EN] = 0, the divided bus clock is used as the sampling clock.
- The filter block can be bypassed when not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring the CCR1[COUT_SEL] bit and are used for different purposes within the system.
- The optionally filtered COUT can be read directly through register bit CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge or rising edge or both edge by setting CCR1[WINDOW_CLS] in window mode.
- In the window mode, when window is closed, COUTA value can be defined as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value when window is closed

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

59.3.2 Functional Modes

The comparator window and filter features can be combined as shown in the following table. Individual modes are discussed below the table.

Table 293. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled Mode (#1).	N/A
2A	1	0	X	0x00	X	See the Continuous Mode (#2A & 2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, Non-Filtered Mode (#3A & 3B).	T_{PD} + T_{SAMPLE} + $3T_{per}$
3B	1	0	0	0x01	> 0x00		T_{PD} + (FILT_PER * T_{per}) + $3T_{per}$
4A	1	0	1	> 0x01	X		T_{PD} + (FILT_CNT * T_{SAMPLE}) + $3T_{per}$

Table continues on the next page...

Table 293. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
4B	1	0	0	> 0x01	> 0x00	See the Sampled, Filtered Mode (#4A & 4B).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
5A	1	1	0	0x00	X	See the Windowed Mode (#5A & 5B).	T_{PD} + $2T_{per}$
5B	1	1	0	X	0x00		
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled Mode (#6).	T_{PD} + (FILT_PER * T_{per}) + $3T_{per}$
7	1	1	0	> 0x01	> 0x00	See the Windowed/ Filtered Mode (#7).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

59.3.2.1 Disabled Mode (#1)

In disabled mode, the analog comparator is non-functional and consumes no power. CSR[COUT] and CMPO is same as CCR1[COUT_INV] in this mode.

59.3.2.2 Continuous Mode (#2A & 2B)

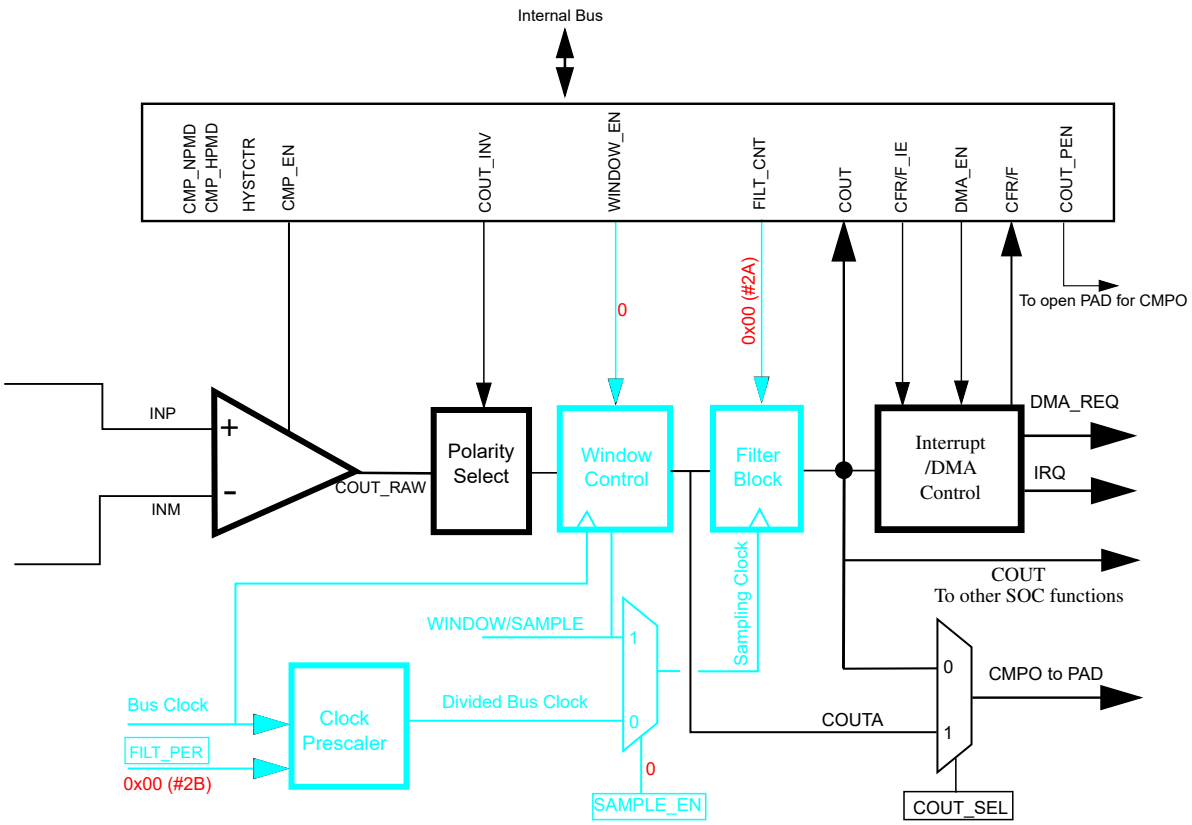

Figure 238. Comparator Operation in Continuous Mode

In this mode, COUT_RAW may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. CSR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational(unclocked) mode. COUT and COUTA are identical.

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it should generally be configured to operate in continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

59.3.2.3 Sampled, Non-Filtered Mode (#3A & 3B)

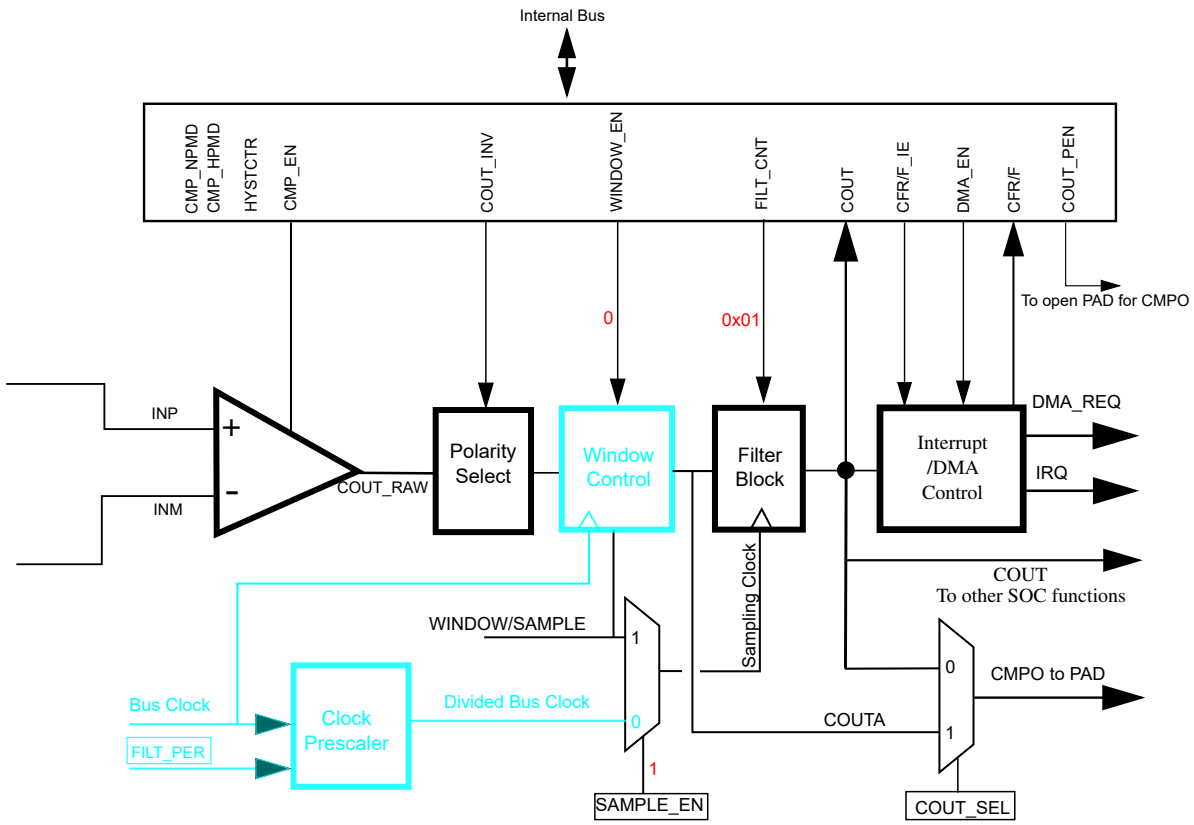

Figure 239. Sampled, Non-Filtered (#3A): Sampling Point Externally Driven

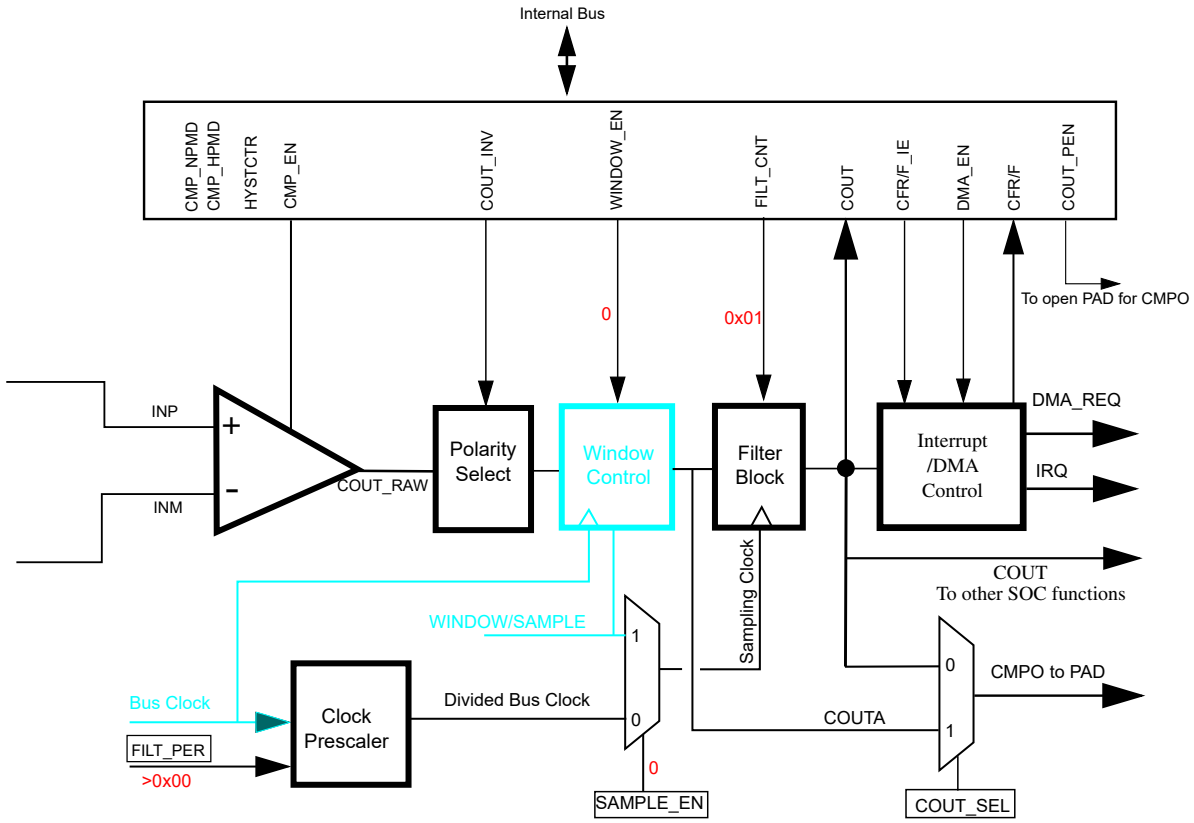

Figure 240. Sampled, Non-Filtered (#3B): Sampling Interval Internally Derived

In this mode, the path from analog inputs to COUTA is combinational(unclocked). Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) and sampled, non-filtered (#3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The filter block has no other function than sample/hold of the comparator output in this mode.

The following figure illustrates comparator operation in this mode, assuming that the polarity select is set to non-inverting state.

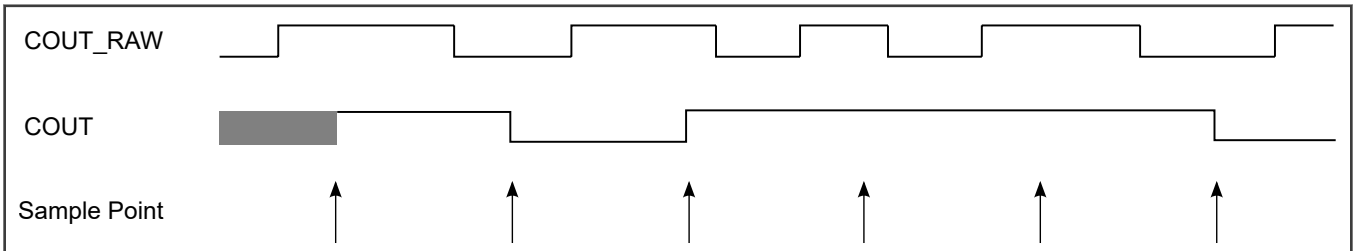

Figure 241. Sampled, Non-Filtered Mode Timing Diagram

59.3.2.4 Sampled, Filtered Mode (#4A & 4B)

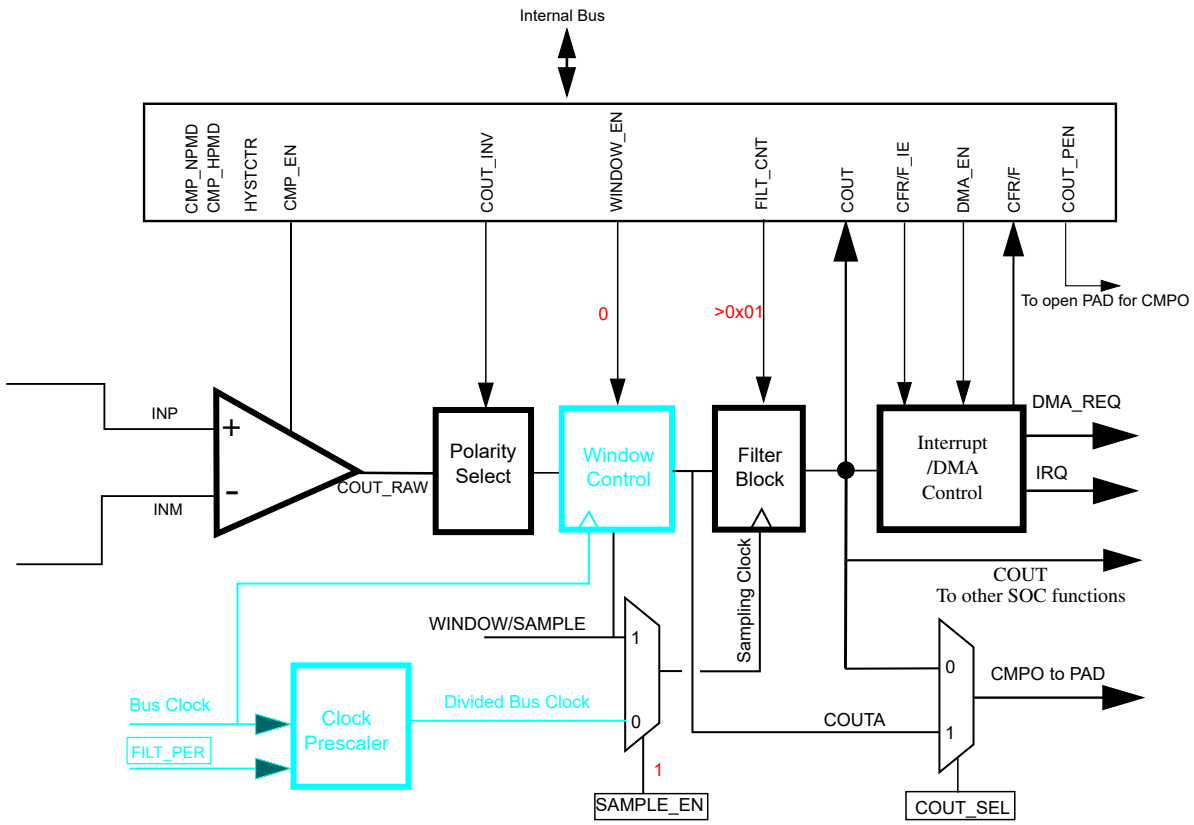

Figure 242. Sampled, Filtered (#4A): Sampling Point Externally Driven

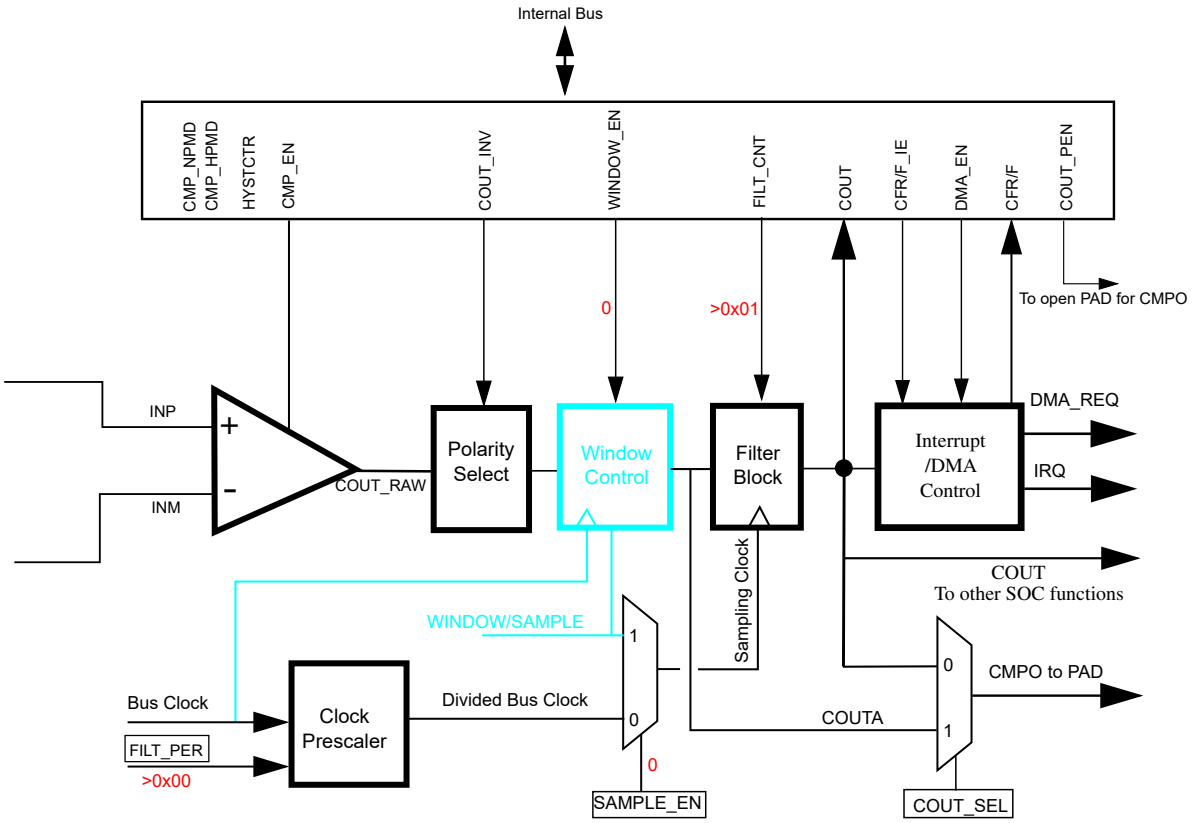

Figure 243. Sampled, Filtered (#4B): Sampling Point Internally Derived

In this mode, the path from analog inputs to COUTA is combinational(unclocked). Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) and sampled, filtered (#4A) is that, now, CCR1[FILT_CNT]>1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) and sampled, filtered (#4B) is that now, CCR1[FILT_CNT]>1, which activates filter operation.

59.3.2.5 Windowed Mode (#5A & 5B)

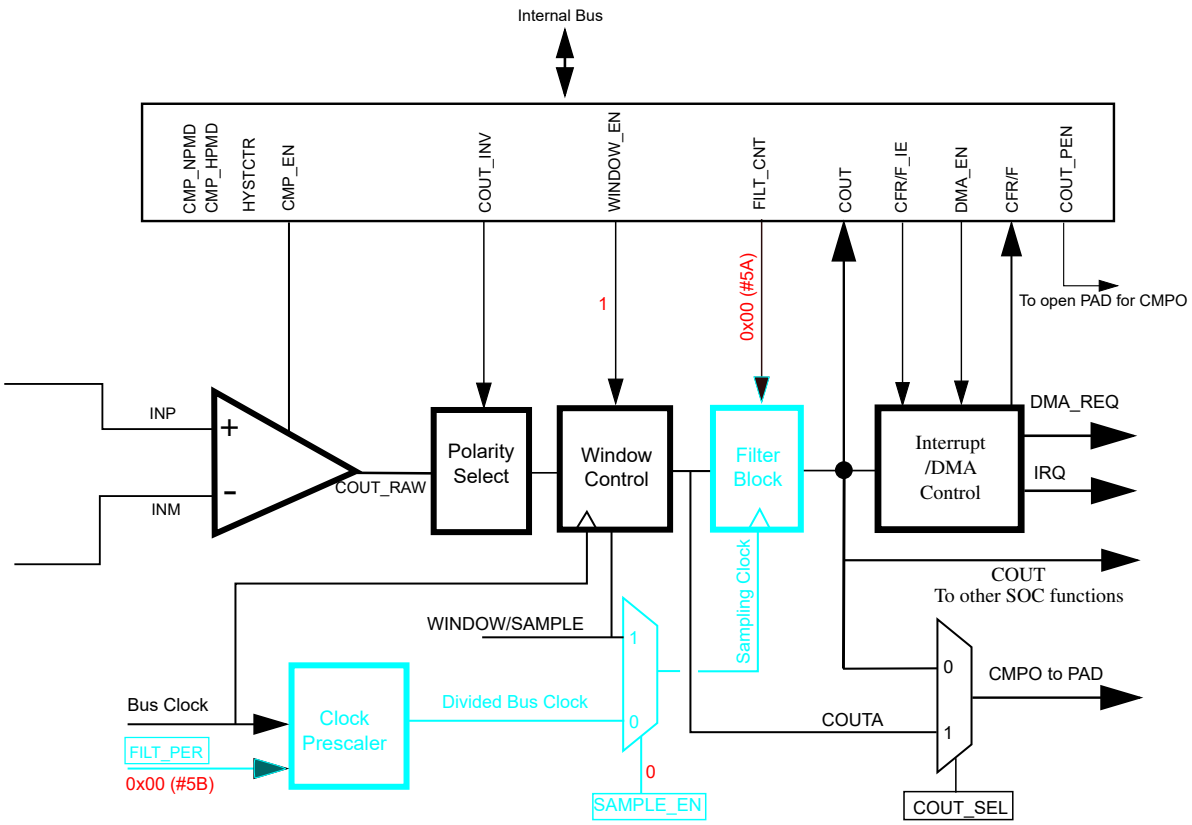

Figure 244. Windowed Mode

In this mode, COUTA is clocked by the bus clock whenever window is enabled. The last latched value is held when window is disabled. The filter block is bypassed.

The following figure illustrates comparator operation in this mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

In actual operation, COUTA may lag the analog inputs by up to two bus clock cycles plus the combinational path delay through the comparator and polarity select logic.

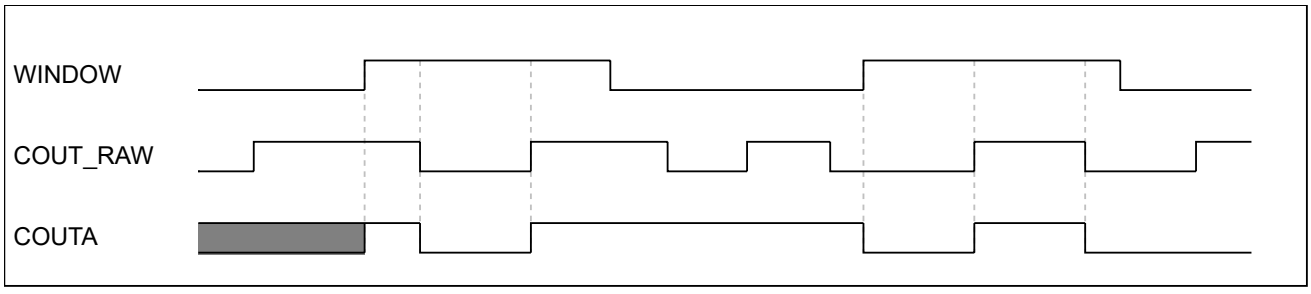

Figure 245. Windowed Mode Timing Diagram

If CCR1[COUTA_OWEN] is set, user can define COUTA level as CCR1[COUTA_OW], when window is closed. Following figures show this case.

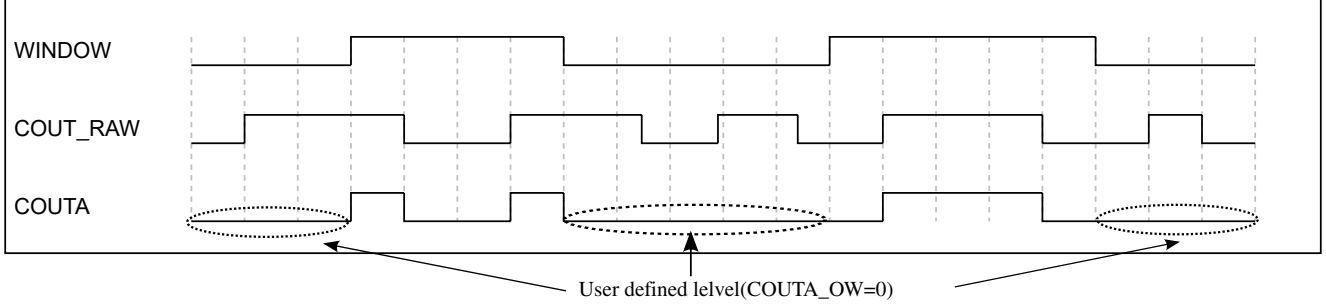

Figure 246. Windowed Mode Timing Diagram With User Defined Value 0 outside WINDOW

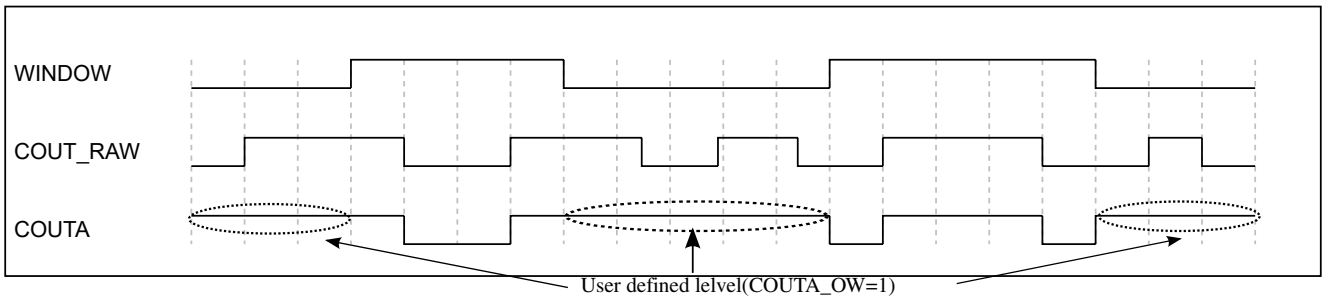

Figure 247. Windowed Mode Timing Diagram With User Defined Value 1 outside WINDOW

NOTE

Obviously, when the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] is set, user can define the CMPO event (rising, falling or both edges, selected by CCR1[EVT_SEL]) to close the window. The external WINDOW signal has to go to zero and back to one to enable the internal window again. Following figure shows an example that CMPO rising edge close the internal window.

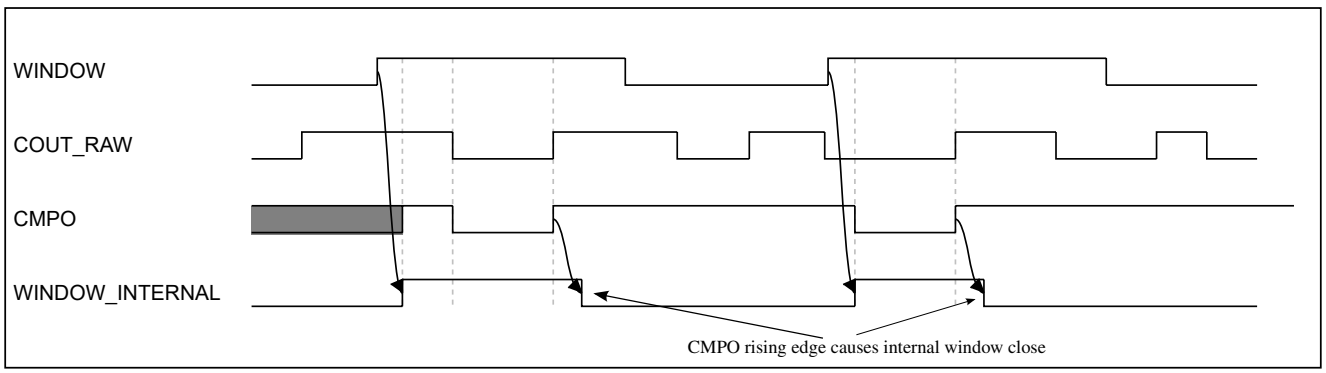

Figure 248. Windowed Mode Timing Diagram With CMPO Rising Edge Close Window

If CCR1[WINDOW_INV] is set, user can invert the window signal before it is used. The following figure shows this case.

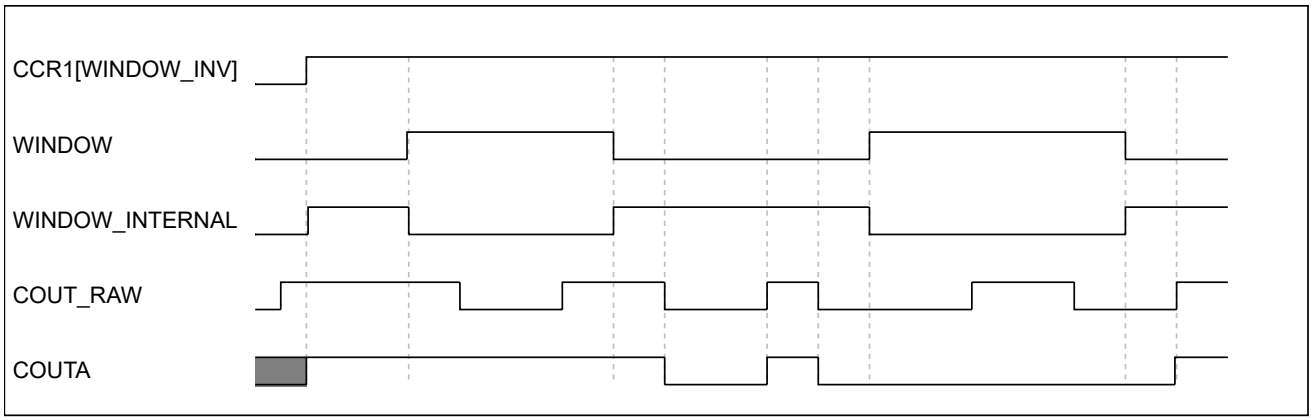

Figure 249. Windowed Mode Timing Diagram With WINDOW Signal Inverted.

59.3.2.6 Windowed/Resampled Mode (#6)

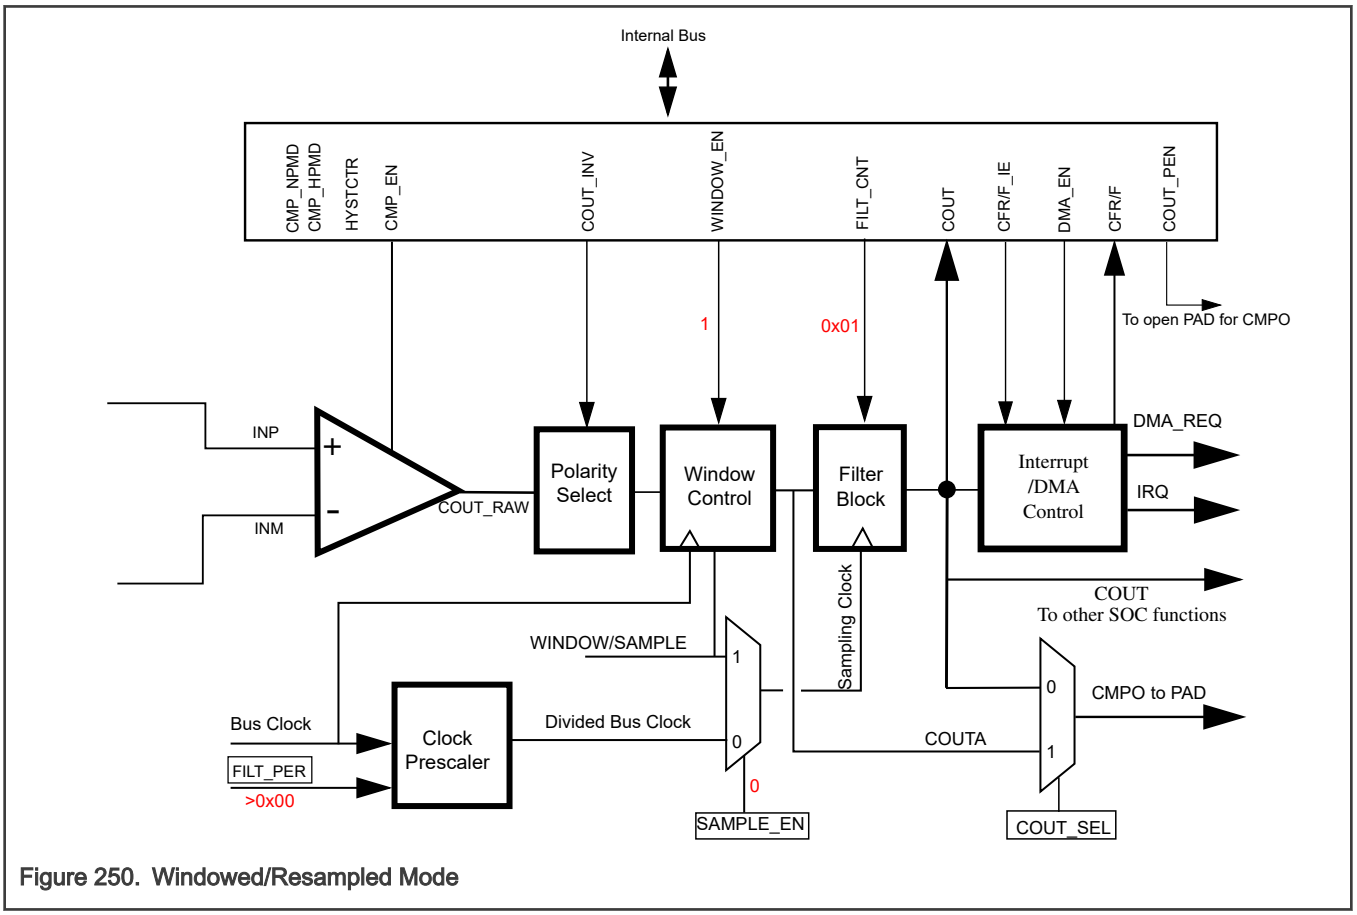

Figure 250. Windowed/Resampled Mode

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by CCR1[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the windowed/filtered mode shown in the next section. The only difference is that the value of CCR1[FILT_CNT] in this mode must be 1.

The following figure uses the same input stimulus shown in Figure 245, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

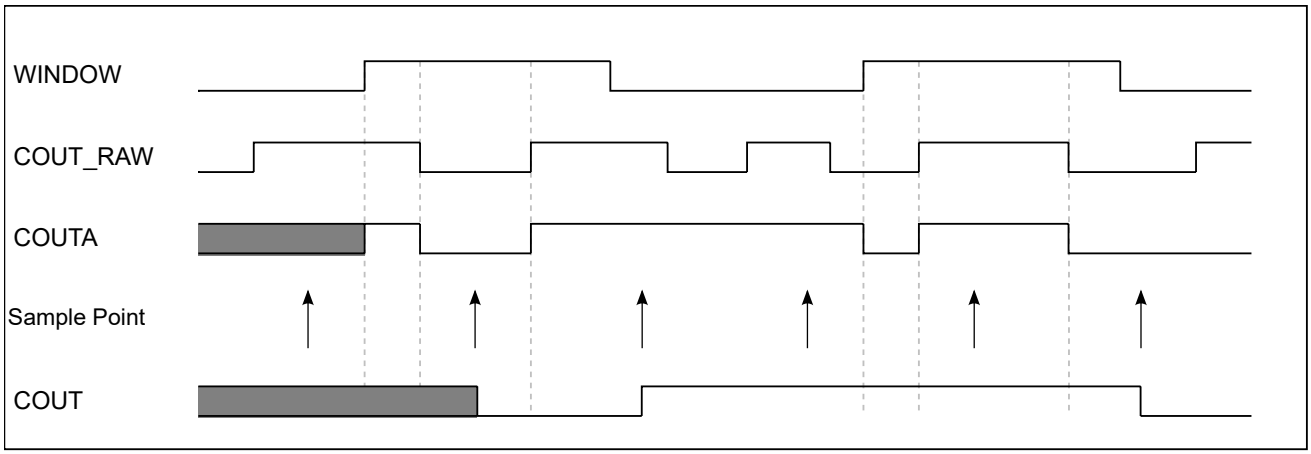

Figure 251. Windowed/Resampled Mode Operation

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

59.3.2.7 Windowed/Filtered Mode (#7)

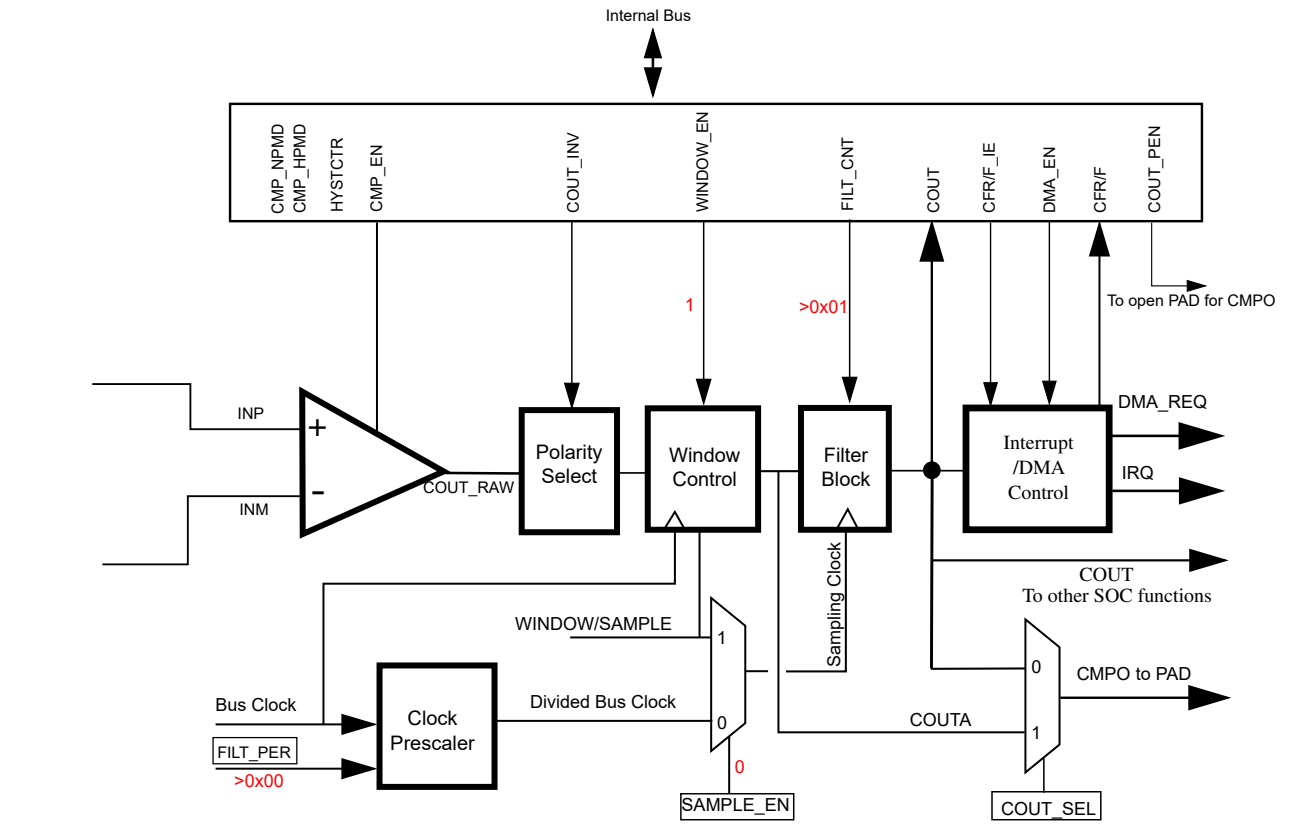

Figure 252. Windowed/Filtered Mode

The only difference in operation between Windowed/Resampled Mode (#6) and Windowed/Filtered Mode (#7) is that, now, CCR1[FILT_CNT]>1, which activates filter operation.

This is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] X CCR1[FILT_PER]) + 1) X peripheral clock for the filter function.

59.3.3 Round Robin Trigger mode

The Round Robin Trigger mode is enabled with RRCR0[RR_EN] and CCR0[CMP_EN]. A trigger event initiates a comparison sequence. The next trigger event should not come before the current sequence completes.

The reference channel for either the plus side MUX or the minus side MUX is selected by RRCR1[RR_FIXP] and RRCR1[FIXCH]. The active channels are selected by RRCR1[RR_CH*n*EN].

When a trigger comes, the analog comparator is enabled. After the comparison sequence completes, the analog comparator is disabled again. The analog stabilization time is controlled by RRCR0[RR_INITMOD]. Make sure that the (RR_INITMOD*round robin clock period) should be longer than the initialization delay in the chip data sheet.

When the stabilization process completes, the round robin manner comparison sequence begins. After the configurable number of operation clocks defined by RRCR0[RR_NSAM], the comparison result is sampled for the selected active channel.

After all the active channels are sampled/compared, if the comparison result changes from its pre-programmed state, the corresponding flag in RRSR[RR_CH*n*F] is set. The pre-programmed state for each channel is configured by writing to RRCSR[RR_CH*n*OUT] field. RRCSR[RR_CH*n*OUT] is updated to store the last comparison result for each channel. If any flag in RRSR[RR_CH*n*F] is set, flag CSR[RRF] will be set. If IER[RRF_IE] is set, an asynchronous interrupt is asserted. Note that these flags do not support generating a DMA transfer event.

The following diagram shows the basic flow of this mode. In the diagram, RRCR1[RR_CH1EN], RRCR1[RR_CH3EN], and RRCR1[RR_CH4EN] are set, so channels #1, #3, and #4 are selected for round robin depended on their priority setting. RRCR0[RR_NSAM] is set to 2'b01, so one clock later the comparison result of the selected channel is sampled. When channel #4 is compared, the result is sampled, and round robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to RRCSR[RR_CH1OUT], RRCSR[RR_CH3OUT], and RRCSR[RR_CH4OUT]), an interrupt is generated. Software can then poll the RRSR[RR_CH*n*F] to see which channel input(s) changed value.

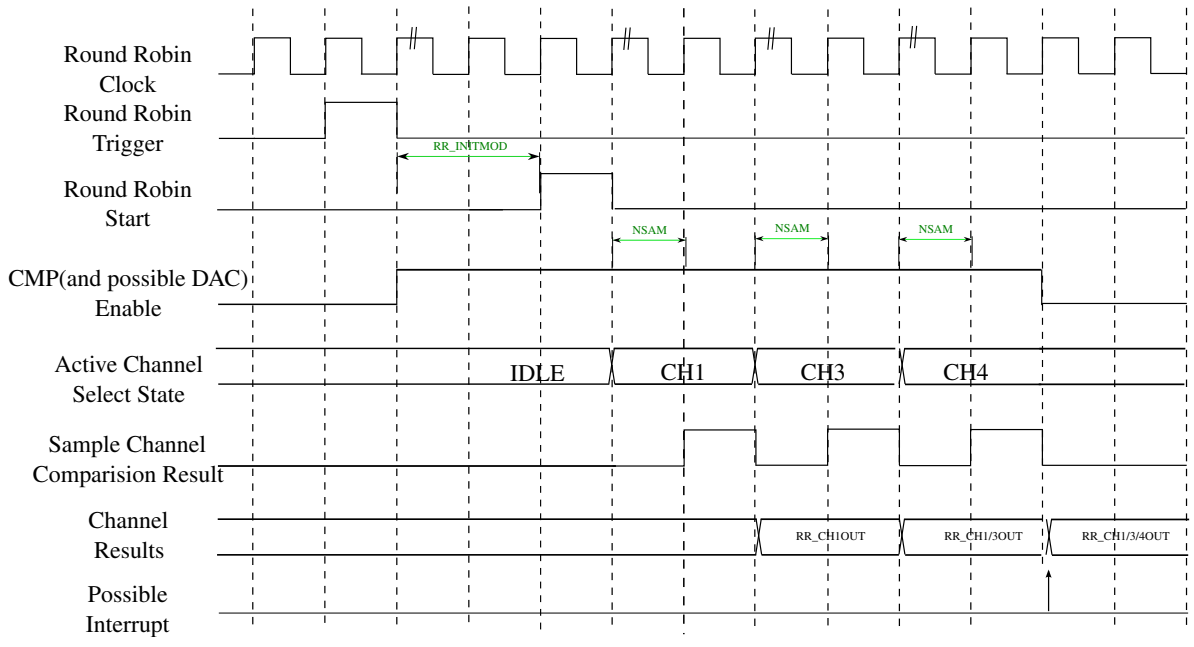

Figure 253. Trigger Mode

The table below shows the channel decode in both functional mode and trigger mode. Other cases not in the table are illegal.

Table 294. CMP Channel Decode in Functional Mode and Trigger mode

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	INPSEL[1:0]	INMSEL[1:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
Functional Mode	0	x[1]	0~7	0	1	x	x	x	DAC	Channel decoded from MSEL[2:0]	Channel 0~7 can be compared with DAC
		0~7	x	1	0	x	x	x	Channel decoded from PSEL[2:0]	DAC	Channel 0~7 can be compared with DAC
		0~7	0~7	1	1	x	x	x	Channel decoded from PSEL[2:0]	Channel decoded from MSEL[2:0]	Channel 0~7 can be compared with channel 0~7[2]
Trigger Mode	1	x	x	0	1	0	x	0~7	DAC	Channel sweep (RR_CHxN)	Channel 0~7 can be swept with DAC
		x	x	1	0	1	x	0~7	Channel sweep (RR_CHxN)	DAC	Channel 0~7 can be swept with DAC
		x	x	1	1	0	0~7	0~7	Channel fixed by FIXCH[2:0]	Channel sweep (RR_CHxN)	Channel 0~7 can be swept with a fixed channel(0~7)[3]
		x	x	1	1	1	0~7	0~7	Channel sweep (RR_CHxN)	Channel fixed by FIXCH[2:0]	Channel 0~7 can be swept with a fixed channel(0~7)[3]

1. "x" means "don't care"
2. PSEL should not be same as MSEL.
3. Channel in the sweep side should not be same as the fixed side.

Trigger Mode Programming Recommendation

Configure the Trigger Mode as follows. Register fields in the same register can be configured at the same time.

1. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must be set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
2. Configure CMP initialization delay by RRCR0[RR_INITMOD] Note: In programming the RRCR0[RR_INITMOD] registers, the RR_INITMOD x round robin clock period must be longer than the initialization delay, which can be referred from the chip data sheet.
3. Configure the RRCR1[FIXP] to select the fixed port of CMP and
    a. If using one input channel to compare with other channels, configure the RRCR1[FIXCH] to select the fixed channel
    b. If using DAC output to compare with input channels, configure the CCR2[INPSEL] or CCR2[INMSEL](according to RRCR1[FIXP])to select the DAC output
4. Configure channels for comparison by RRCR1[RR_CHnEN]
5. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
6. Clear channel flags RRSR[RR_CHnF]
7. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE])
8. Enable round robin mode by RRCR0[RR_EN]
9. Enable comparator by CCR0[CMP_EN]

59.3.4 Low-Pass Filter

The low-pass filter operates on the unfiltered, optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by CCR1[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

59.3.4.1 Enabling Filter Modes

Filter modes can be enabled by:

- Setting CCR1[FILT_CNT] > 0x01 and
- Setting CCR1[FILT_PER] to a nonzero value or setting CCR1[SAMPLE_EN]=1

If using the divided bus clock to drive the filter, it samples COUTA every CCR1[FILT_PER] bus clock cycles.

If CCR1[SAMPLE_EN]=1, the filter samples COUTA on each positive transition of the SAMPLE input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

59.3.4.2 Latency issues

Program the value of CCR1[FILT_PER] or SAMPLE period such that the sampling period is just longer than the period of the expected noise to ensure that a given noise spike corrupts only one sample. The value of CCR1[FILT_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

The values of CCR1[FILT_PER] or SAMPLE period and CCR1[FILT_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 293 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency is restarted each time an actual output transition is masked by noise.

59.3.5 Low Power Mode Operation

The following table shows the false mode operation of the LPCMP module.

Table 295. Low Power Mode Operation

Mode of Operation	Description
false	LPCMP can operate only in continuous mode or trigger mode.

59.3.6 DMA

When DMA support is enabled by setting CCR1[DMA_EN] and the interrupt is enabled by setting IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator signal that de-asserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and force another DMA request.

59.3.7 Clocking

LPCMP requires the following clocks to operate:

- Bus clock is used for register access and window/filter function.
- Round robin clock for trigger mode.

59.3.8 Resets

The global chip reset signal resets LPCMP.

59.3.9 Interrupts

When corresponding interrupt enable register bit is set, flags CSR[CFR], CSR[CFF], CSR[RRF] can generate interrupt, assuming the DMA enable bit is not set. The interrupt is de-asserted by clearing either the flag or the interrupt enable register bit.

59.4 External Signals

Table 296. External Signal Descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels(Refer to the chip-specific information for the connections)	I
VREFH_EXT	External reference voltage for the CMP-DAC(Refer to the chip-specific information for the connections)	I

59.5 Initialization

To enable LPCMP, configure the control registers (CCR1, CCR2, DCR, and so on) before setting CCR0[CMP_EN]. To disable the module, clear CCR0[CMP_EN]. Switching operation modes or changing control register bits on the fly (when CCR0[CMP_EN]

is 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, be sure to disable the module before switching modes or changing control bits.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. See the data sheet for power-on delays of the comparators. The delay caused by windowing and filter function is specified in the Table 293.

During operation, the propagation delay of the selected data paths must always be considered. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

59.6 Application Information

59.6.1 Round-robin clock(RCLK) frequency requirement

(1) RCLK High Frequency Limit

RCLK high frequency limit depends on two facts:

1. The analog CMP and DAC initialization time(See the chip data sheet for the initialization time.)
   - Register field RR_INITMOD provides a maximum 63 RCLK cycles for the analog CMP and DAC initialization.
   - Rclk must be slow enough to satisfy: 63 * (1/f_{RCLK}) > $T_{inialization}$, where f_{RCLK} is in MHz, and $T_{inialization}$is in microsecond.
   - so f_{RCLK} < 63 / $T_{inialization}$
   - Example: $T_{inialization}$ = 40 microsecond, then f_{RCLK} should be smaller than 1.575MHz.
2. The analog CMP propagation delay(See the chip datasheet for the CMP propagation delay.)
   - Register field NSAM field provides a maximum 4 RCLK cycles for the analog CMP propagation delay.
   - Rclk must be slow enough to satisfy: 4 * (1/f_{RCLK}) > $T_{propagation}$, where f_{RCLK} is in MHz, and $T_{propagation}$ is in microsecond.
   - so f_{RCLK} < 4 / $T_{propagation}$
   - Example: $T_{propagation}$ = 0.1 microsecond, then f_{RCLK} should be smaller than 40 MHz.

(2) RCLK Low Frequency Limit

In theory, RCLK frequency has no low limit. But the lower the RCLK frequency, the longer the scan time. Therefore, the lower limit of the RCLK frequency depends on the system application.

59.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error. Read access to reserved address will also generate a transfer error and the read data bus will show all 0s.

59.7.1 LPCMP memory map

Fields

Field	Function
31-3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 LINKEN	CMP-to-DAC Link Enable Controls the link from the CMP enable to the DAC enable. 0b - Disable the CMP-to-DAC link: enabling or disabling the DAC is independent from enabling or disabling the CMP. 1b - Enable the CMP-to-DAC link: the DAC enable/disable is controlled by the CMP_EN bit instead of DCR[DAC_EN]. Also, when the CMP is auto-disabled because software selects the same signal for both the plus and minus comparator inputs, the DAC is disabled too.
1 CMP_STOP_EN	Comparator false Mode Enable Allows software to enable the analog comparator or the DAC when the device is in false mode. **NOTE** CMP_STOP_EN has no effect in trigger mode. 0b - Disable the analog comparator regardless of CMP_EN. 1b - Allow the analog comparator to be enabled by CMP_EN.
0 CMP_EN	Comparator Enable Enables the analog comparator. **NOTE** When CCR0[LINKEN]=1, CMP_EN also controls the enabling/disabling of the DAC instead of DCR[DAC_EN]. 0b - Disable (The analog logic remains off and consumes no power.) 1b - Enable

59.7.5 Comparator Control Register 1 (CCR1)

Offset

Register	Offset
CCR1	Ch

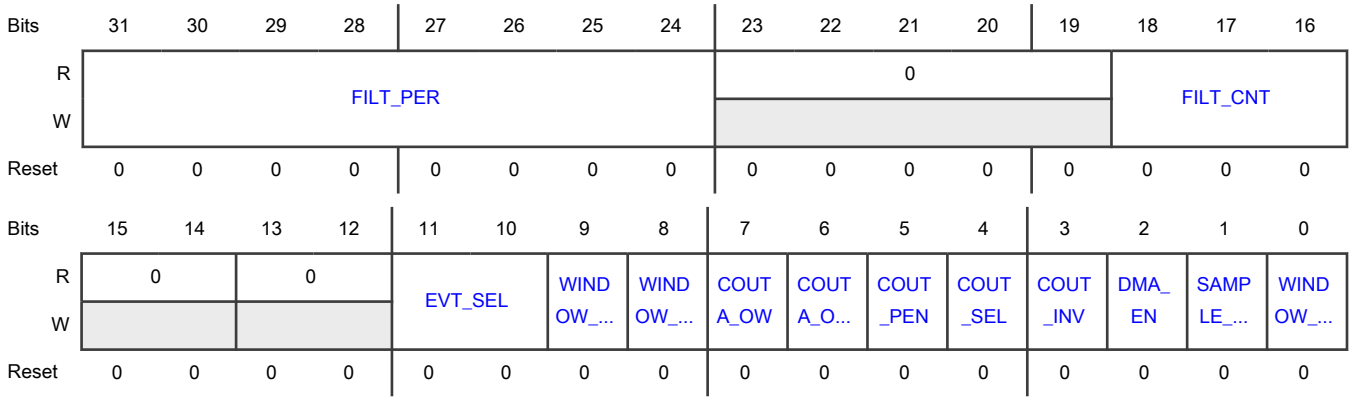
Function

Contains configuration options for comparator operation, such as enabling Sampling or Windowing mode.

NOTE

Sampling and Windowing modes cannot both be enabled at the same time. Sampling mode takes precedence over Windowing mode. If software attempts to set both SAMPLE_EN and WINDOW_EN, only SAMPLE_EN is set.

Diagram



Fields

Field	Function
31-24 FILT_PER	Filter Sample Period Specifies the sampling period (in bus clock cycles) of the comparator output filter. Programming FILT_PER to 0x00 bypasses the filter. Filter programming and latency details are provided in the functional description section. **NOTE** FILT_PER has no effect in Sampling mode (CCR1[SAMPLE_EN]=1).
23-19 —	Reserved
18-16 FILT_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree before the comparator ouput filter accepts the sample as a new valid output state. For information regarding filter programming and latency, see the functional description section. 000b - Filter is bypassed: COUT = COUTA 001b - 1 consecutive sample (Comparator output is simply sampled.) 010b - 2 consecutive samples 011b - 3 consecutive samples 100b - 4 consecutive samples 101b - 5 consecutive samples 110b - 6 consecutive samples 111b - 7 consecutive samples
15-14 —	Reserved
13-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-10 EVT_SEL	CMPO Event Select Selects which CMPO signal edge (rising, falling, or both) defines a CMPO event. **NOTE** Valid only in Windowing mode. 00b - Rising edge 01b - Falling edge 1xb - Both edges
9 WINDOW_CLS	CMPO Event Window Close Enables a CMPO event (defined as a CMPO rising edge, falling edge, or both) to close an active window. See the EVT_SEL field to configure the CMPO event. **NOTE** The WINDOW signal has to go to zero and back to one again to re-activate the window. Valid only in Windowing mode. 0b - CMPO event cannot close the window 1b - CMPO event can close the window
8 WINDOW_INV	WINDOW/SAMPLE Signal Invert Inverts the WINDOW/SAMPLE signal. 0b - Do not invert 1b - Invert
7 COUTA_OW	COUTA Output Level for Closed Window Defines the COUTA signal value when the window is closed. **NOTE** Valid only in Windowing mode and when COUTA_OWEN=1. 0b - COUTA is 0 1b - COUTA is 1
6 COUTA_OWEN	COUTA_OW Enable Enables the COUTA signal value to be defined by the COUTA_OW bit when the window is closed. **NOTE** Valid only in Windowing mode. 0b - COUTA holds the last sampled value 1b - COUTA is defined by the COUTA_OW bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 COUT_PEN	Comparator Output Pin Enable Enables the comparator output to become an available signal option for a selected package pin. 0b - Not available 1b - Available
4 COUT_SEL	Comparator Output Select Selects which comparator output option, COUT or COUTA, to use for CMPO. 0b - Use COUT (filtered) 1b - Use COUTA (unfiltered)
3 COUT_INV	Comparator Invert Selects the polarity of the analog comparator function, affecting the value driven to the COUT output (on both the device pin and as CSR[COUT]) when CCR0[CMP_EN] is 0. **NOTE** COUT_INV has no effect in trigger mode. 0b - Do not invert 1b - Invert
2 DMA_EN	DMA Enable Enables DMA transfers triggered from the LPCMP module. When DMA_EN and the corresponding interrupt enable bit are set, a DMA request is asserted when CFR or CFF is set. 0b - Disable 1b - Enable
1 SAMPLE_EN	Sampling Enable Enables Sampling mode. 0b - Disable 1b - Enable
0 WINDOW_EN	Windowing Enable Enables Windowing mode. **NOTE** Valid only when SAMPLE_EN=0. 0b - Disable 1b - Enable

59.7.6 Comparator Control Register 2 (CCR2)

Offset

Register	Offset
CCR2	10h

Function

Contains configuration options for comparator operation, such as selecting the plus and minus comparator inputs and the hysteresis levels.

NOTE

When an inappropriate operation selects the same signal for both the plus and minus comparator inputs, the analog comparator automatically shuts down (regardless of CMP_EN) to prevent itself from becoming a noise generator.

0 DAC_EN	DAC Enable Enables the DAC. When disabled, the DAC is powered down to conserve power. 0b - Disable 1b - Enable

59.7.8 Interrupt Enable Register (IER)

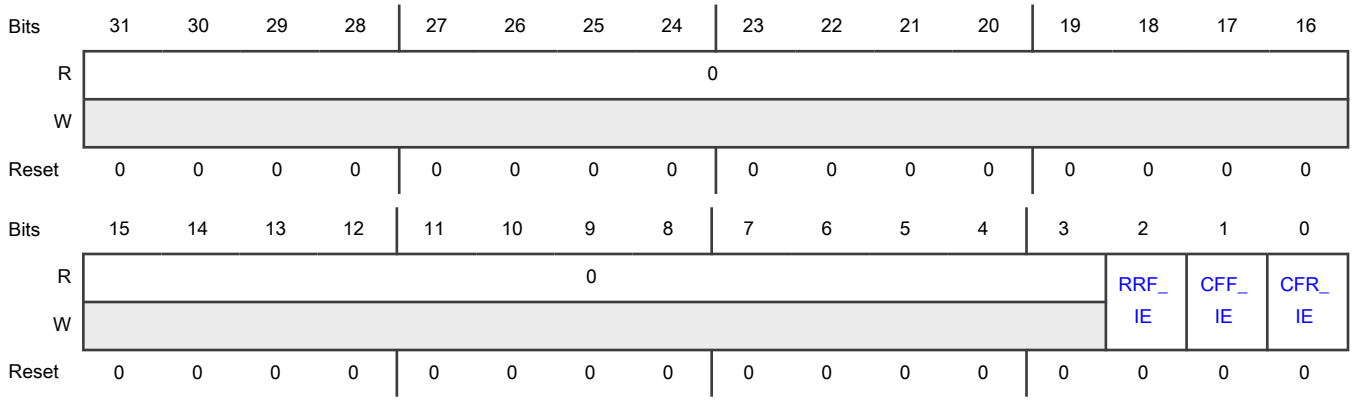
Offset

Register	Offset
IER	1Ch

Function

Provides enable bits for the comparator and round-robin flag interrupts.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 RRF_IE	Round-Robin Flag Interrupt Enable Enables the Round-Robin Flag interrupt. 0b - Disable 1b - Enable: Assert an interrupt when the comparison result changes for a given channel.
1 CFF_IE	Comparator Flag Falling Interrupt Enable Enables the Comparator Flag Falling interrupt. 0b - Disable 1b - Enable: Assert an interrupt when CFF is set.
0 CFR_IE	Comparator Flag Rising Interrupt Enable Enables the Comparator Flag Rising interrupt. 0b - Disable 1b - Enable: Assert an interrupt when CFR is set.

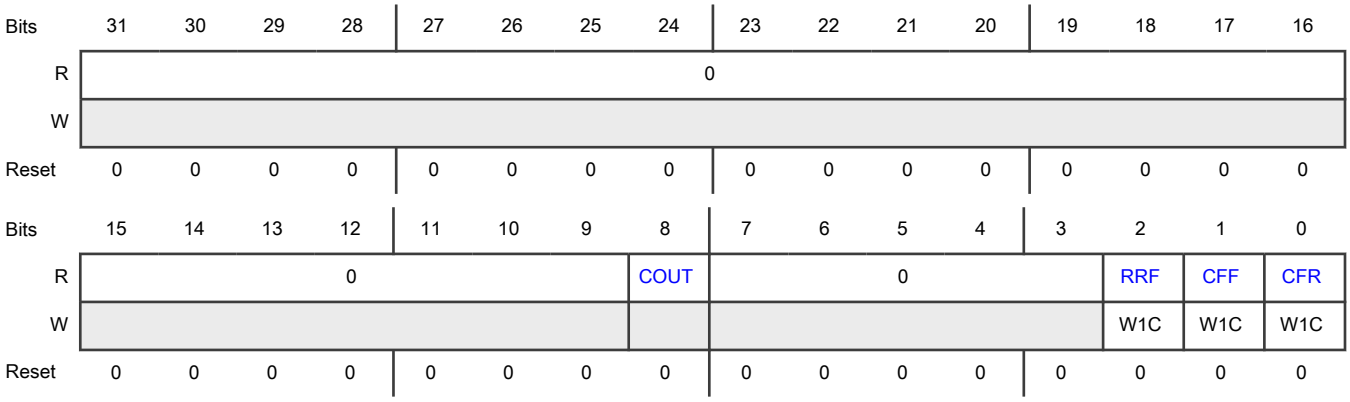
59.7.9 Comparator Status Register (CSR)

Offset

Register	Offset
CSR	20h

Function
Provides the COUT, and CFF, CFR, RRF flags.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 COUT	Analog Comparator Output Returns the current value of the analog comparator output, when read. The field is reset to 0 and reads as CCR1[COUT_INV] when the analog comparator module is disabled, that is, when CCR0[CMP_EN] = 0. Writing to this field is ignored.
7-3 —	Reserved
2 RRF	Round-Robin Flag Detects when any channel's last comparison result is different from the pre-set value in trigger mode. To clear RRF, write 1 to it. RRF is cleared when CCR0[CMP_EN] or RRCR0[RR_EN] is not set. 0b - Not detected 1b - Detected
1 CFF	Analog Comparator Flag Falling Detects when a falling edge on COUT occurs. CFF is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFF is cleared when CCR0[CMP_EN] is not set. 0b - Not detected 1b - Detected
0 CFR	Analog Comparator Flag Rising Detects when a rising edge on COUT occurs. CFR is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFR is cleared when CCR0[CMP_EN] is not set. 0b - Not detected 1b - Detected

59.7.10 Round Robin Control Register 0 (RRCR0)

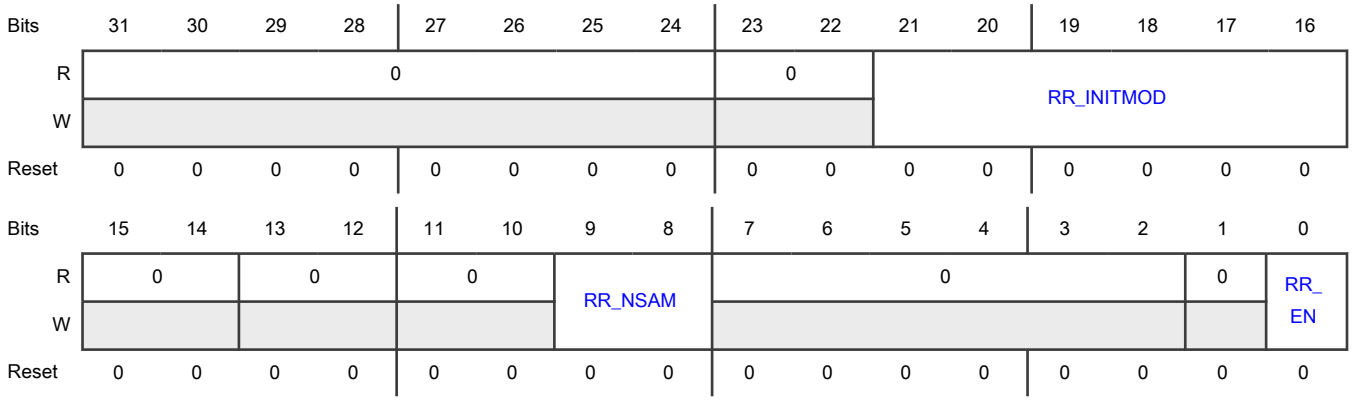
Offset

Register	Offset
RRCR0	24h

Function

Contains configuration options for round robin operation, such as enabling it and specifying the initialization delay.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-22 —	Reserved
21-16 RR_INITMOD	Initialization Delay Modulus Specifies the number of round-robin clock cycles used to determine the comparator and DAC initialization delay as specified in the chip datasheet. The initiallization delay is calculated as: RR_INITMOD * (round-robin clock period). For example, if the initialization delay is 80us and the round-robin clock is 100kHz, program RR_INITMOD to be 80us/10us = 8. 00_0000b - 63 cycles (same as 111111b) 00_0001b-11_1111b - 1 to 63 cycles
15-14 —	Reserved
13-12 —	Reserved
11-10 —	Reserved
9-8 RR_NSAM	Number of Sample Clocks Specifies how many round-robin clock cycles to wait after the active channel is scanned before sampling the channel's comparison result. After the next cycle of the round-robin clock, the sampling takes place RR_NSAM clocks later.

Table continues on the next page...

59.7.11 Round Robin Control Register 1 (RRCR1)

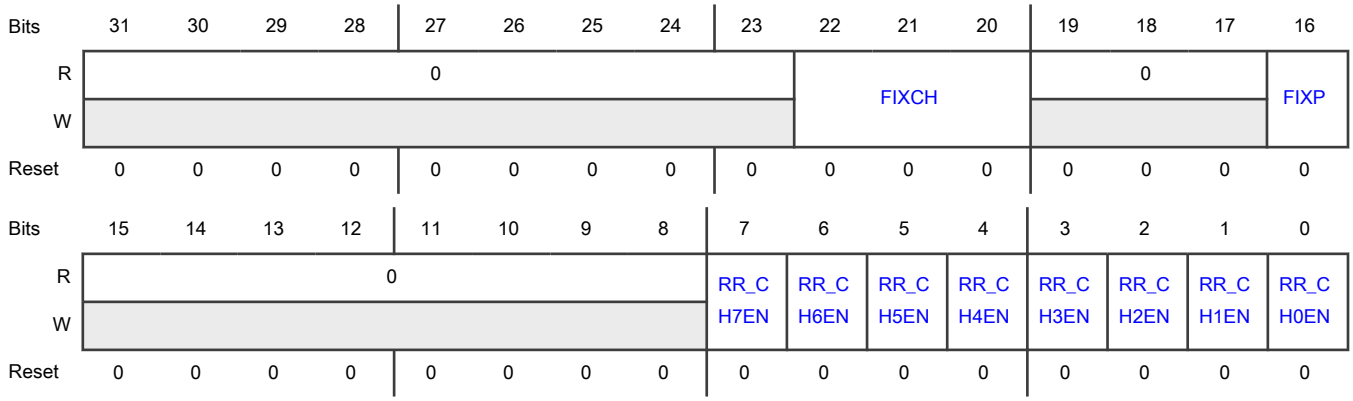
Offset

Register	Offset
RRCR1	28h

Function

Contains configuration options for round robin operation, such as enabling individual channels to participate.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 FIXCH	Fixed Channel Select Selects which channel in the mux port to fix for a given trigger mode application. 000b - Channel 0 001b - Channel 1 010b - Channel 2 011b - Channel 3 100b - Channel 4 101b - Channel 5 110b - Channel 6 111b - Channel 7
19-17 —	Reserved
16 FIXP	Fixed Port Fixes (locks) an analog mux port (Plus or Minus) for trigger mode. The inputs to the non-fixed port are swept during each round. 0b - Fix the Plus port. Sweep only the inputs to the Minus port. 1b - Fix the Minus port. Sweep only the inputs to the Plus port.
15-8 —	Reserved
7-0 RR_CHnEN	Channel n Input Enable in Trigger Mode Enables channel n of the non-fixed mux port to have its voltage value checked when in trigger mode. **NOTE** RR_CHnEN has no effect when the same channel is selected as the reference voltage. 0b - Disable 1b - Enable

59.7.12 Round Robin Control and Status Register (RRCSR)

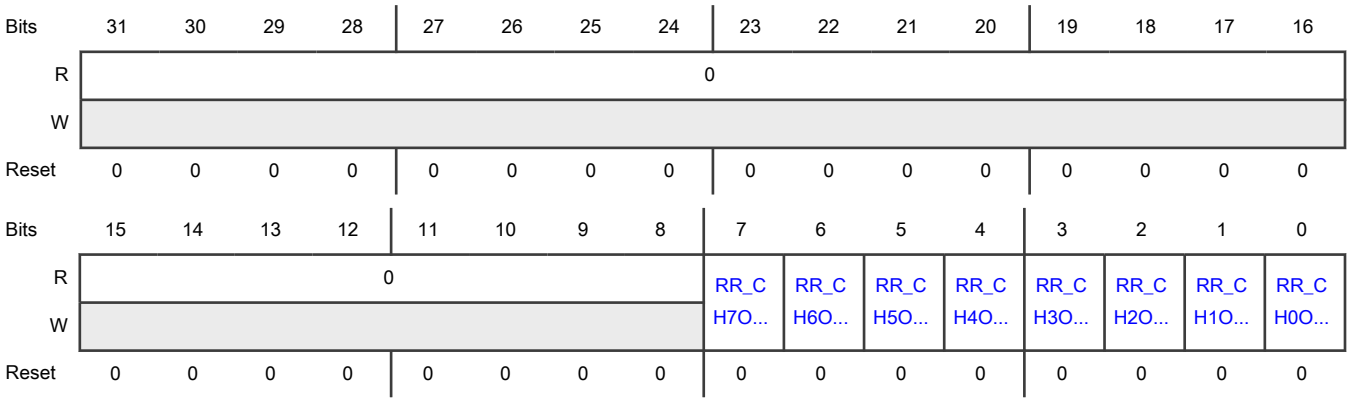
Offset

Register	Offset
RRCSR	2Ch

Function

Contains the latest comparison results of the individual channels with the fixed mux port. It also allows software to define the pre-set state for each channel.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RR_CHnOUT	Comparison Result for Channel n Reading RR_CHnOUT returns the latest comparison result for channel n. Writing RR_CHnOUT defines the pre-set state for channel n.

59.7.13 Round Robin Status Register (RRSR)

Offset

Register	Offset
RRSR	30h

Function

Contains individual channel flags indicating when a channel's last comparison result is different from its pre-set value.

Chapter 60
Logic Control Unit (LCU)

60.1 Chip-specific LCU information

60.1.1 LCU instances

This chip has two identical LCU instances, LCU_0 and LCU_1.

60.2 Introduction

LCU selects multiple inputs from timers, pulse width modulation (PWM) signals, and input/output (I/O) pads, and combines them using a programmable logic function to create output waveforms for use by other IPs.

It consists of 3 LCs, each of which takes four inputs and creates four outputs using user-defined logic mapping. LCU also has 3 force inputs that can override the output logic and force a user-defined value directly on the output signals. Additionally, LCU has 2 sync inputs that can control when the inputs are updated to produce new output signals.

LCU generates the interrupts and DMA requests based on output signals and force input signals.

60.3 Feature list

- 3 LCs with programmable logic function for generating output results
- 12 inputs to and 12 outputs from each LC
- Muxing to map any input to any LC
- Independent filters for the rising and falling output states of each LC
- Software override logic for inputs using multiple modes
- 3 force inputs with programmable edge filtering to force output states using multiple modes
- 2 sync inputs to control transition timing
- Lock bit to block writes to configuration registers
- Interrupt request generation based on output change or force event
- DMA transfer request generation based on output change or force event

60.4 Block diagram

This figure illustrates an example implementation of LCU with:

- Three LCs
- Four force inputs
- Four sync inputs

For the number of each resource in this chip, see Feature list.

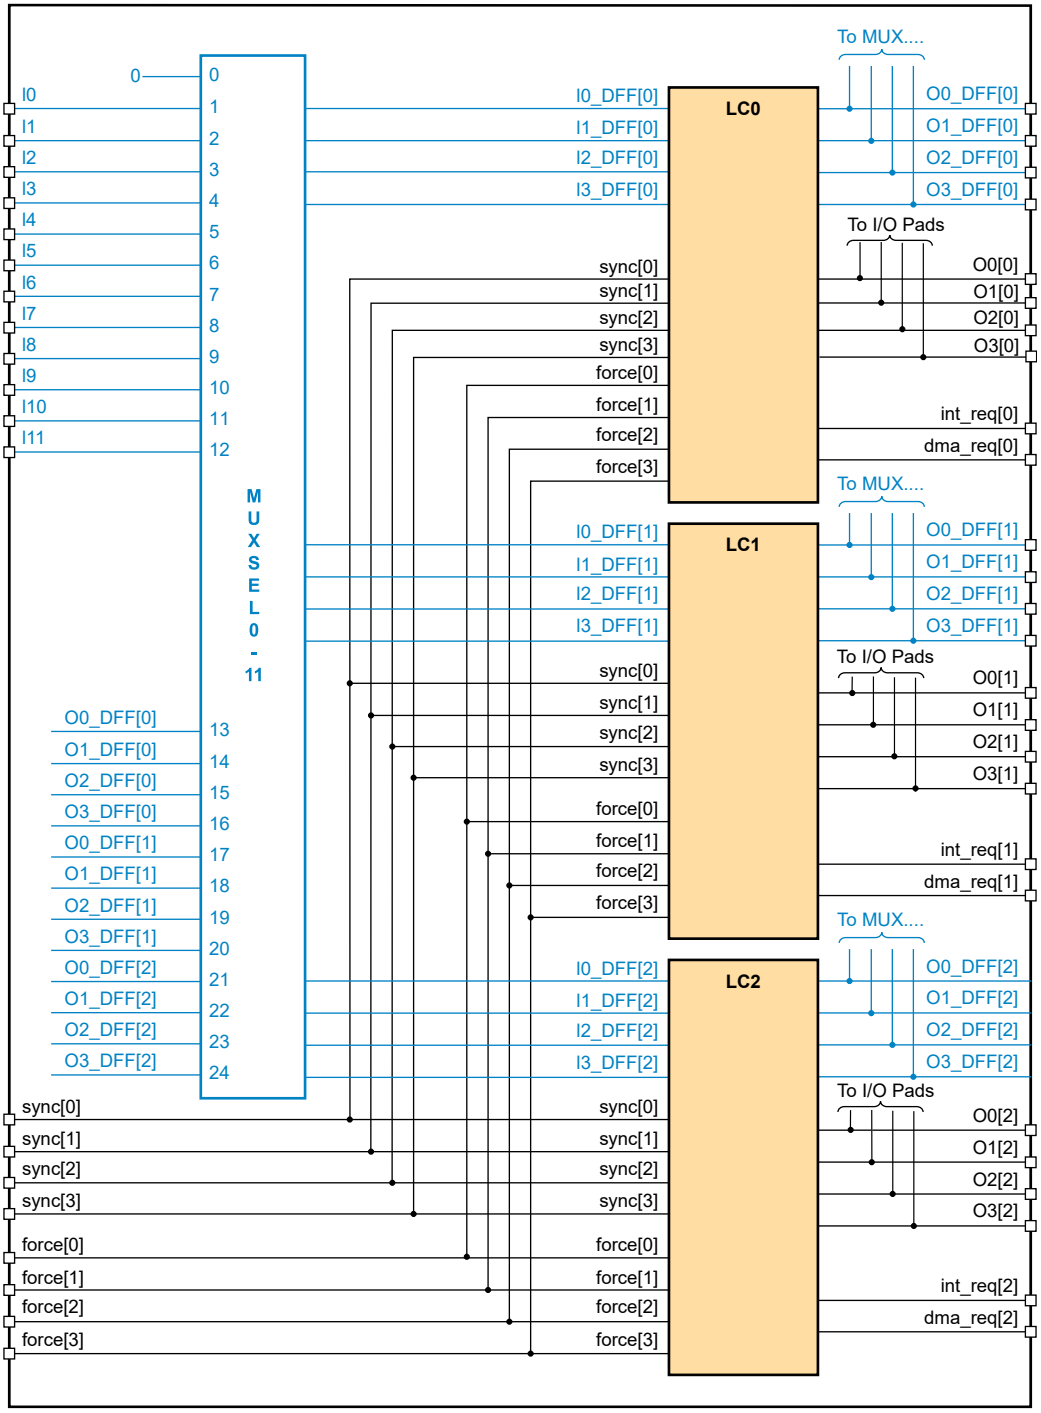

Figure 254. Block diagram

60.5 LC operation

60.5.1 Overview

An LC performs logic operations based on the LUT principle, as described in Logic operations.

Each LC supports the following features:

- Independent filter thresholds for the rising and falling output states support different transition delays.
- Bypass of the output state filter by setting the filter threshold to zero. Bypassing the filter causes the aynchronous signal to propagate to the output of the LC.
- Force logic that instantly switches an LC output to the inactive state upon external fault signal assertion. The return from the inactive state to the output state is either:
  - Instantaneous: when LCU deasserts the force signal.
  - Instantaneous synchronized: when LCU deasserts the force signal and then the sync input asserts.
  - Manual: when you write 1 to the force status bit and then the LCU deasserts the force input.
  - Manual synchronized: when you write 1 to the force status bit and LCU deasserts the force input, and then the sync input asserts.
- Input software override logic to override external inputs by writing to the following registers:
  - LC*n* Sync Control (LC*n*_SCTRL[SW_MODE])
  - Software Override Value (SWVALUE[SWVALUE])
  - Software Override Enable (SWEN[SWEN])
- Generation of interrupt requests or DMA transfer requests.

60.5.2 LC diagram

This figure illustrates an example LC implementation with:

- One LC
- Four force inputs
- Four sync inputs

For the number of each resource in this chip, see Feature list.

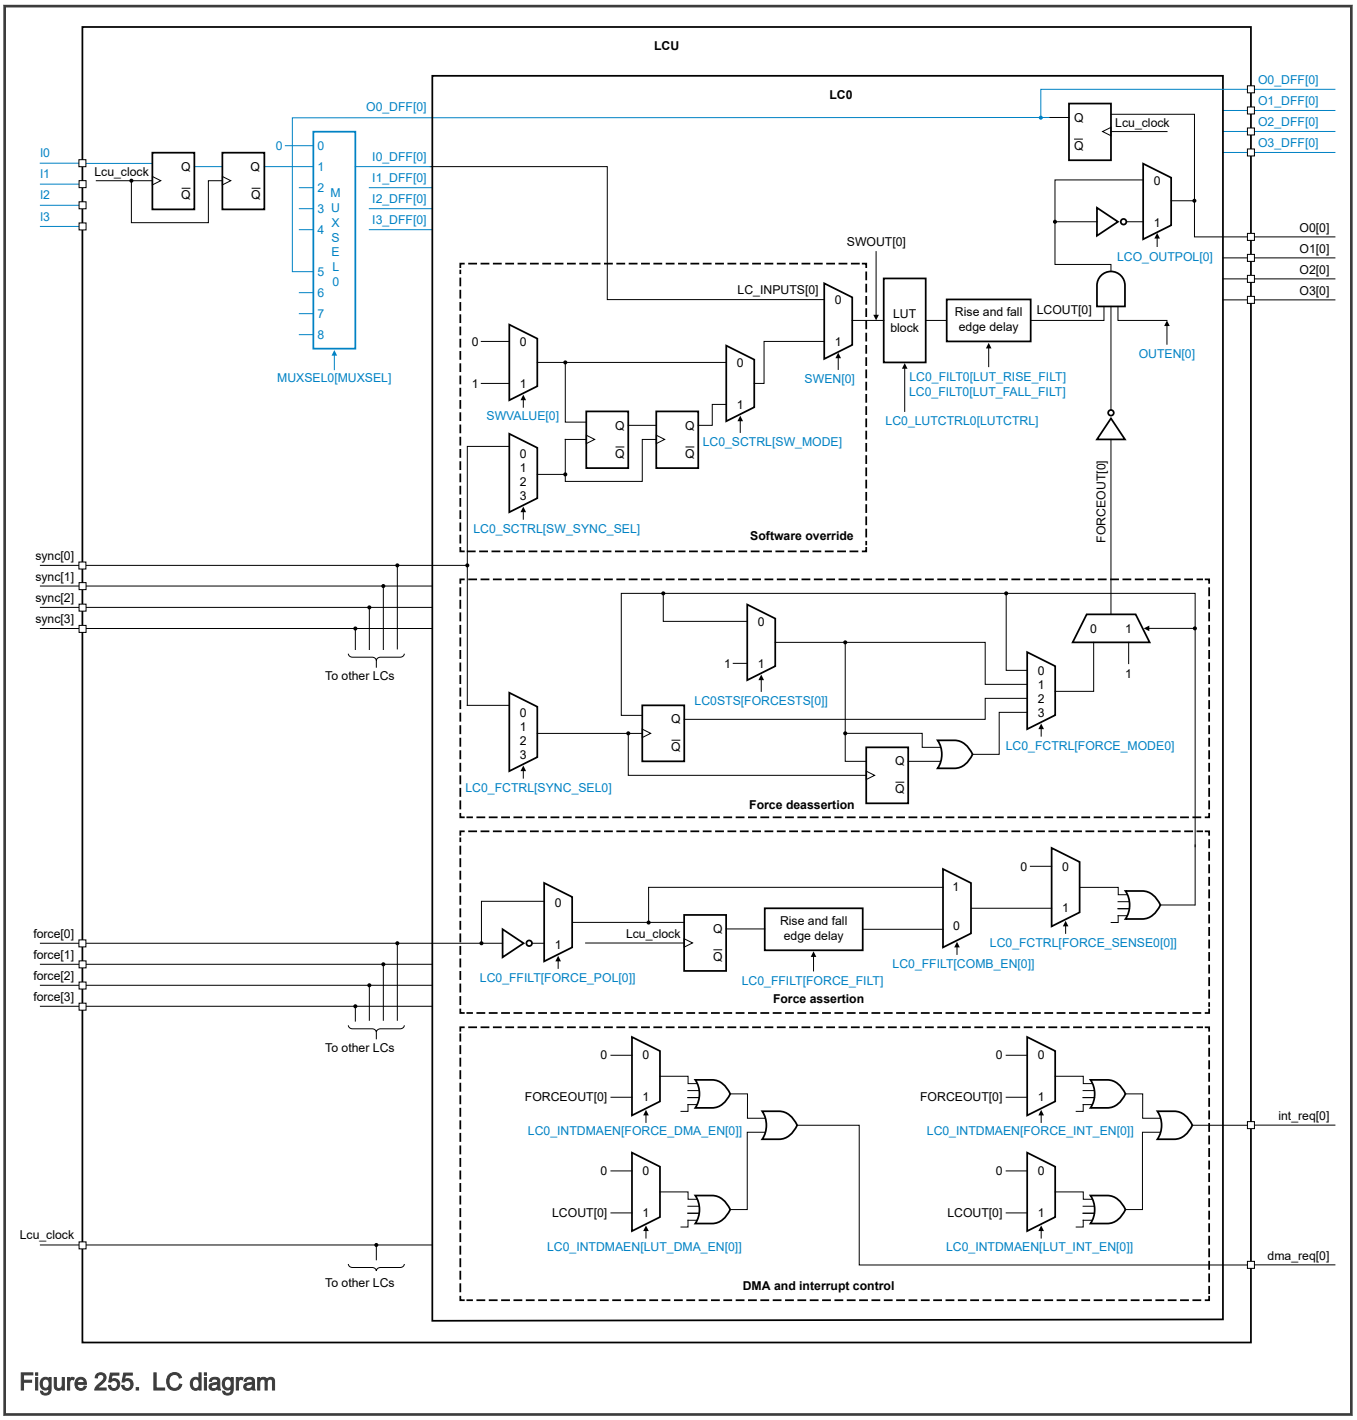

Figure 255. LC diagram

60.5.3 Logic operations

An LC reads its set of inputs (inputs 3, 2, 1, and 0) as a four-bit binary value, with Input 3 as the most-significant bit and Input 0 as the least-significant bit. For example, if:

Input 0 = 0

Input 1 = 1

Input 2 = 0

Input 3 = 1

then the combined input value is 1010b (10 decimal).

Each possible four-bit input value corresponds to a bit position in the LUT Control (LCn_LUTCTRLm[LUTCTRL]), as illustrated in LC LUT. For a given LC output, if the combined LC input value corresponds to a bit position in that output's LUTCTRL value that equals 1, then the LC asserts that output.

For example, if you write 35h to LUTCTRL (shown in the Example column of the LC LUT), then the combined input values 0 (0000b), 2 (0010b), 4 (0100b), and 5 (0101b) cause assertion of the output. All other input values cause deassertion of the output.

LCU processes each look-up table asynchronously.

60.5.4 LC LUT

The LUT maps the combined LC input value to a bit position in LC*n*_LUTCTRL*m*.

Table 297. LC LUT

Input 3	Input 2	Input 1	Input 0	LUTCTRL bit position	Example LUTCTRL value: 35h
0	0	0	0	0	1
0	0	0	1	1	0
0	0	1	0	2	1
0	0	1	1	3	0
0	1	0	0	4	1
0	1	0	1	5	1
0	1	1	0	6	0
0	1	1	1	7	0
1	0	0	0	8	0
1	0	0	1	9	0
1	0	1	0	10	0
1	0	1	1	11	0
1	1	0	0	12	0
1	1	0	1	13	0
1	1	1	0	14	0
1	1	1	1	15	0

60.5.5 LC output filters

Each LC supports two optional digital filters, a Rise Filter (LC*n*_FLIT*m*[LUT_RISE_FILT]) and a Fall Filter (LC*n*_FLIT*m*[LUT_FALL_FILT]), to post-process the LUT output and delay the output signal change.

Each filter starts accumulating clock cycles on the occurrence of the associated LUT event. The Rise Filter counts from an output assertion, and the Fall Filter counts from an output deassertion. When the number of clock cycles reaches the filter threshold (matches the specified filter value), the output flips to the new state. For example, if you specify a Rise Filter value of 100h, and the LUT event triggers an output assertion, the output signal does not assert until the 256th clock cycle after the event.

A filter value of 0 bypasses the filter.

60.6 Behavior in different chip modes of operation

Operation mode	Status of outputs
Normal	• Controlled by LC*n*_LUTCTRL*m* and MUXSEL*n* • Toggled based on the states of the selected inputs
Debug	Inactive or normal operation controlled by Debug Mode Enable (DBGEN)

60.7 Use-case examples

60.7.1 Two-channel multiplexer

60.7.1.1 Overview

A multiplexer (or mux) takes multiple inputs and, based on some control mechanism, passes only one of those inputs to the output. You can implement a two-channel multiplexer controlled by an external signal or a software override using three inputs and one output of a single LC, as illustrated in Logic diagram and Implementation.

This example implementation controls the multiplexer with the SEL input signal and a software override. The software override controls the multiplexer output regardless of the SEL signal state. To use software override, you must enable it for the corresponding output (SWEN[SWEN]). You assert software override by writing 1 to the corresponding bit of the Software Override Value (SWVALUE[SWVALUE]).

60.7.1.7 Waveforms

In this figure, the SWEN and SWVALUE signals represent the states of the software override control registers. Writes to SWEN and SWVALUE have immediate impact on LC outputs, whereas LC inputs require input synchronization to prevent metastability.

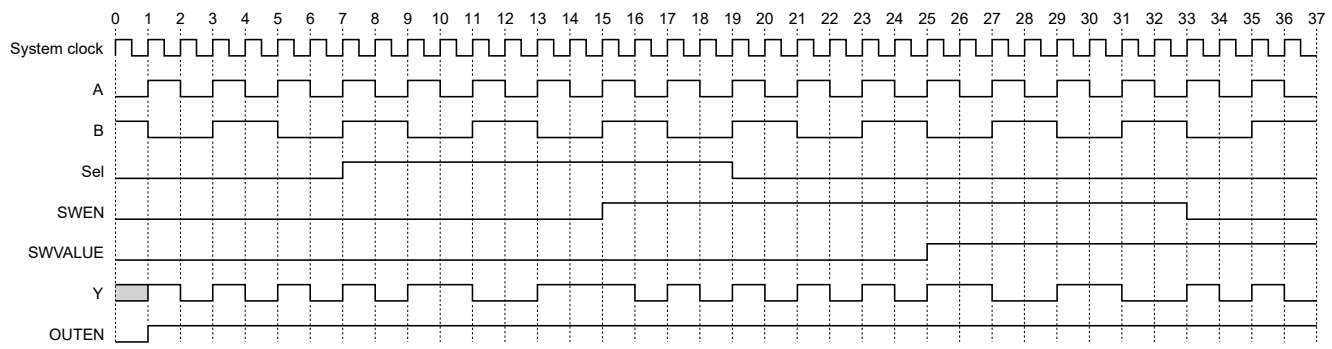

Figure 258. Waveforms

60.7.2 Binary to Gray code converter

60.7.2.1 Overview

Gray code, also known as reflected binary code (RBC), is a non-weighted, minimum change code. In this code, any two adjacent code numbers differ by only one bit. This code solves the problem of physical switch transitions by changing only one switch at a time, so there is never any ambiguity of position.

You can implement binary to Gray code conversion using a single LC, as illustrated in Logic diagram and Implementation.

In this example, the LC also generates a DMA request on each rising edge of output 3, which is bit 0 of the Gray code (G0).

60.7.2.2 Conversion table

Table 301. Conversion table

60.7.2.8 Waveforms

The LC outputs are delayed by two clock cycles because of the two-stage input synchronizers.

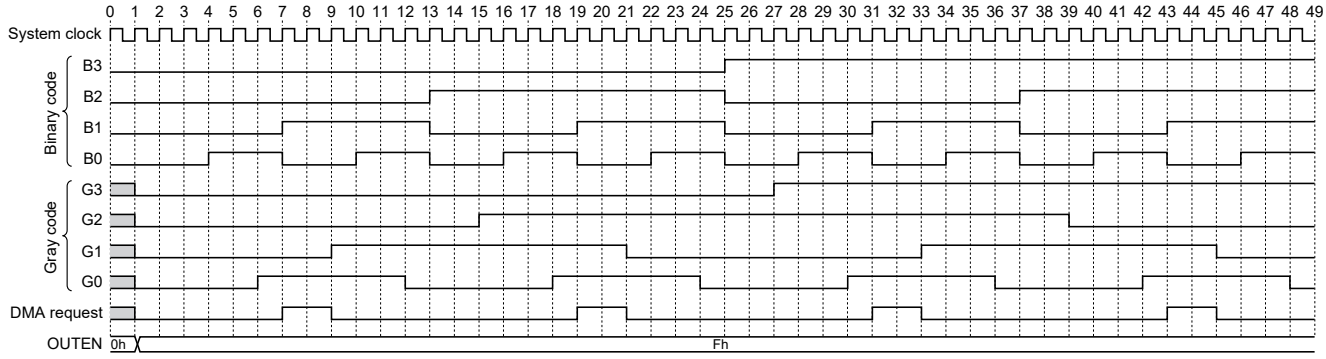

Figure 261. Waveforms

60.7.3 Manchester encoder and decoder

60.7.3.1 Overview

Manchester encoding (also known as phase encoding) is a data-modulation technique for binary data transfer based one of these signals:

- Analog
- RF
- Optical
- High-speed-digital
- Long-distance-digital

The fundamental idea behind Manchester encoding is to use voltage transitions, instead of voltage levels, to represent 1s and 0s. It performs an exclusive OR of data and clock signals to encode and decode data. A high-to-low transition on the falling clock edge indicates 0. A low-to-high transition on the rising clock edge indicates 1.

60.7.3.8 Waveforms for encoder

This figure includes the Manchester-encoded waveform (labeled PE) of the input waveform (labeled "Data in"). The PE waveform is delayed by two clock cycles because of two-stage input synchronization.

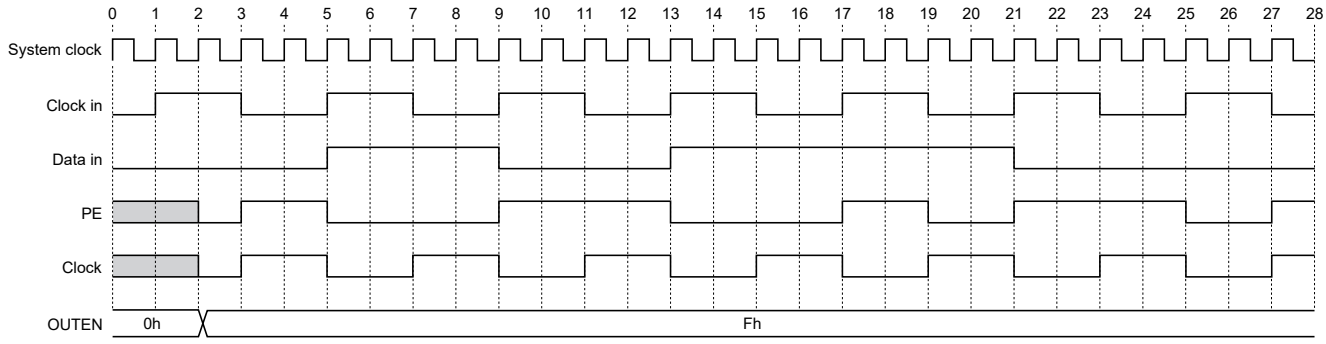

Figure 264. Waveforms for encoder

60.7.3.9 Waveforms for decoder

The output waveform (labeled "Data out") is delayed by four clock cycles from the input waveform (labeled "Data in") because of two-stage input synchronization. In this example, the Manchester encoder also propagates the Clock waveform that the decoder uses to reconstruct the "Data in" waveform from the Manchester-decoded waveform (labeled PE).

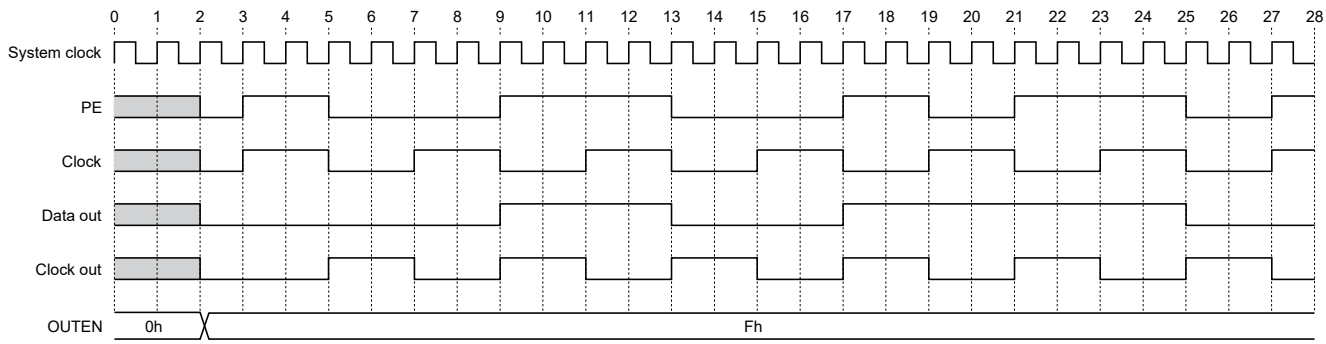

Figure 265. Waveforms for decoder

60.7.4 Adjustable PWM/FM generator

60.7.4.1 Overview

In many cases, it is useful to route an LC output back to one of its inputs, as illustrated in Implementation. In addition, you can delay outputs with a digital filter with different time constants for delaying rising and falling edges. Combining these capabilities, you can use an LC to generate output waveforms with adjustable pulse width and frequency.

In addition to waveform generation, the software-override feature forces the generator output low or high by software. You control the override via Software Override Enable (SWEN) and Software Override Value (SWVALUE).

60.7.4.2 Implementation

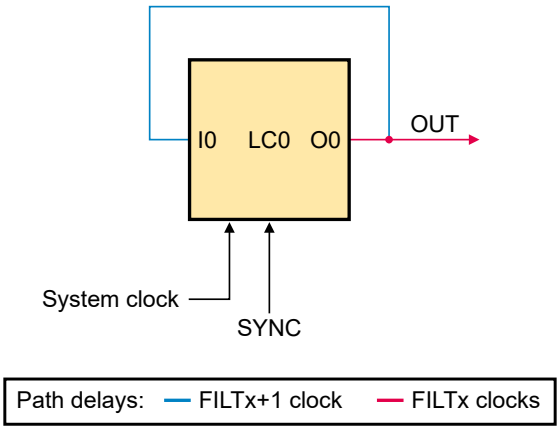

Figure 266. Implementation

60.7.4.3 Connections and controls

Table 309. Connections and controls

Name	Description
I0	Delayed output routed back to LC input
O0 and OUT	Delayed output

SYNC	Software override synchronization signal

60.7.4.4 Truth table

This example generates an adjustable PWM/FM waveform according to the following table. In the table:

- OUT is the LC output signal that is also routed to the LC input using an internal multiplexer.
- TdH is the digital filter value to delay the rising edge of the output signal.
- TdL is the digital filter value to delay the falling edge of the output signal.

Table 310. Truth table

I0	OUT
0	1 delayed by TdH (see Output edge delays)
1	0 delayed by TdL (see Output edge delays)

In this example, software override control is synced with the rising edges of the SYNC waveform.

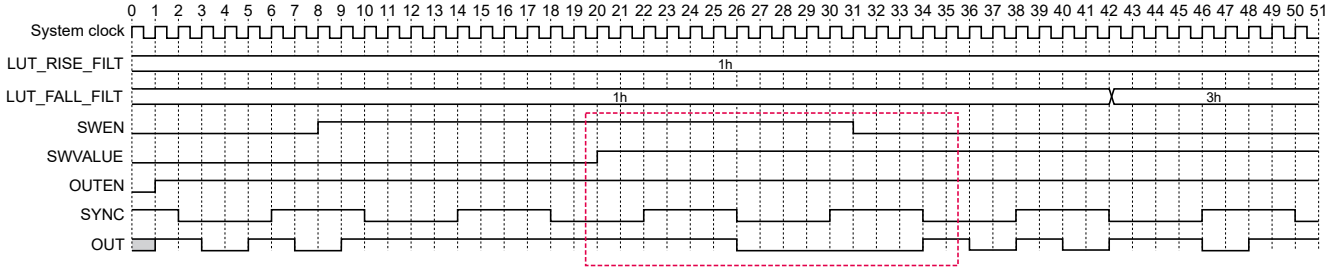

Figure 269. Waveforms for synced software override

60.7.5 SR latch

60.7.5.1 Overview

An SR latch is the simplest bistable device and a fundamental component of data storage.

This example implementation uses one LC that includes an internal feedback path configured by the internal multiplexer, as illustrated in Implementation. Output Q responds to inputs S (set) and R (reset). It changes with a delay of two clock cycles—the time required for the S and R signal inputs to pass through the internal two-stage synchronizers. This example implementation bypasses the Q digital filter; therefore, the loop of Q back to the input experiences a delay of one clock cycle." See Waveforms.

60.7.6 D flip-flop

60.7.6.1 Overview

A D flip-flop stores and outputs whatever logic level is applied to its data terminal at the time its clock input goes high.

You can implement a D flip-flop element using an LC as illustrated in Implementation. On a clock rising edge, the LC either asserts or deasserts the Q output based on the D input.

The Q output and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle. See Waveforms.

60.7.7 JK flip-flop

60.7.7.1 Overview

A JK flip-flop is a gated SR latch (see SR latch) with an added clock input circuit that prevents the illegal or invalid output condition that can occur when both SR-latch inputs (S and R) are asserted.

Truth table for JK flip-flop presents the four possible input combinations for a JK flip-flop. All output changes occur at the clock rising edge.

You can create a JK flip-flop using two LCs, as illustrated in Implementation. The first LC detects rising edges of the CLK clock input (see Truth table for LC0). The second LC processes J and K inputs at every rising clock edge (see Truth table for LC1).

Output Q and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle (see Waveforms).

60.7.7.8 Waveforms

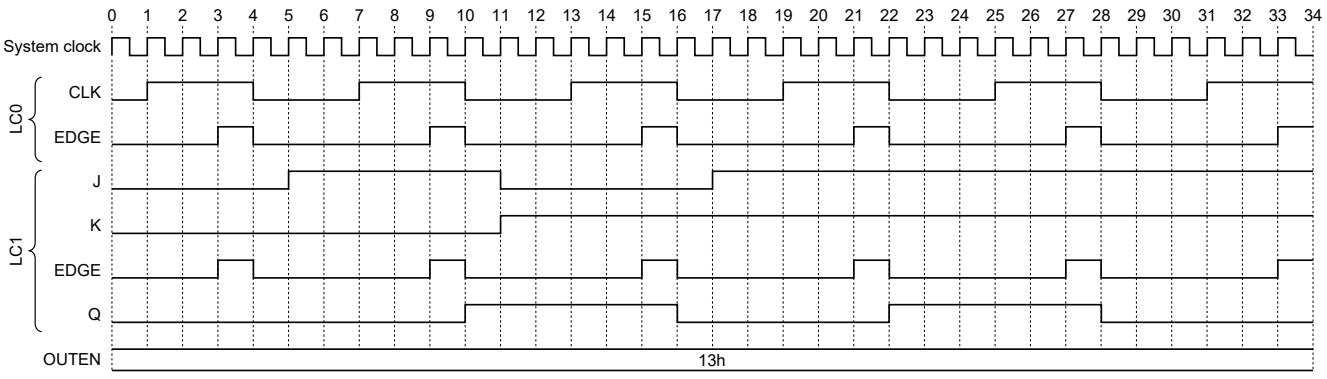

Figure 275. Waveforms

60.7.8 Incremental encoder

60.7.8.1 Overview

An incremental encoder provides A and B pulse outputs in the form of 90-degree shifted waveforms (see Outputs). The decoding circuit processes these waveforms to detect the rotor position and the direction of rotation.

This example implementation requires two LCs (see Implementation):

- LC0 provides pulse streams on CW or CCW output at every A and B signal edge. If the encoder rotation is CW (A signal leading), then pulses appear at the CW output. If the encoder rotation is CCW (B signal leading), then pulses appear at the CCW output. Two pulse counters accumulate these pulse streams to provide the actual absolute encoder position in the respective direction of rotation.
- LC1 then uses the LC0 outputs to detect the direction of the rotation.

60.7.8.8 Waveforms

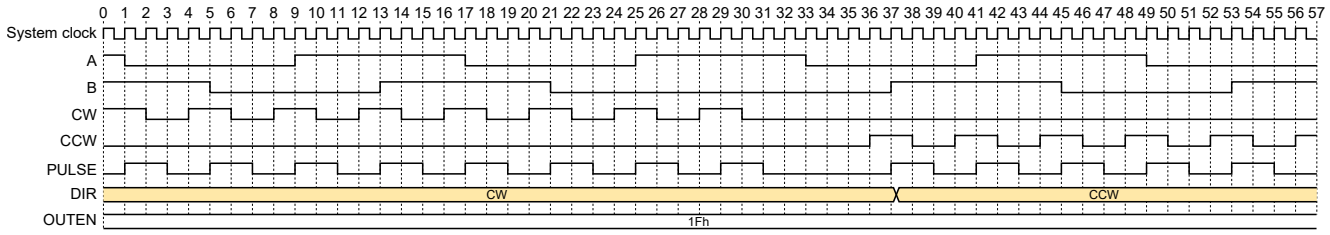

Figure 278. Waveforms

60.7.9 AC motor PWM controller

60.7.9.1 Overview

Driving a three-phase AC motor requires dedicated PWMs to perform:

- Complementary signal generation
- Dead time insertion
- Fault-state assertion
- Manual or automatic fault recovery

LCU enhances basic timer functionality with the necessary complementary features available only on dedicated motor control PWMs.

Implementation for AC motor controller shows all input and output signals of LCU in a typical three-phase motor control application.

TdH is the time delay preceding each rising edge of the complementary PWM output signals. See Truth table for details.

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. Any active fault must immediately change all PWM outputs to the inactive state. Force logic causes PWM outputs to transition to the inactive state upon an external fault event. See Truth table for details.

The dead time is one clock cycle. On a fault event, both PWM outputs transition to the inactive state (logic 0). When the fault event deasserts, both PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion). See Waveforms for force cleared on force deassertion for details.

60.7.9.7 Waveforms for force cleared on force deassertion

This example shows two behaviors, depending on the Force Clearing mode (LC0_FCTRL[FORCE_MODE0]).

00b - Both PWM signals start normal operation when the fault event deasserts. See Waveforms for force cleared on force deassertion for details.

01b - Both PWM signals start normal operation on rising sync after the fault event deasserts. See Waveforms for force cleared on rising sync after force deassertion for details.

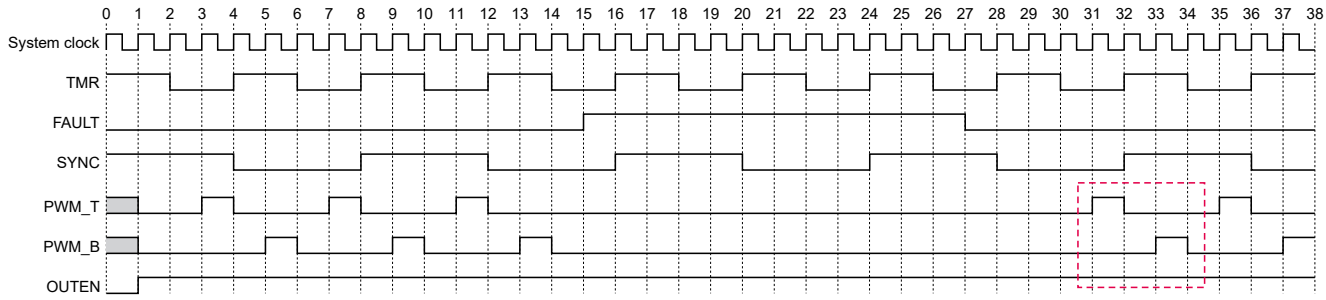

Figure 281. Waveforms for force cleared on force deassertion

60.7.9.8 Waveforms for force cleared on rising sync after force deassertion

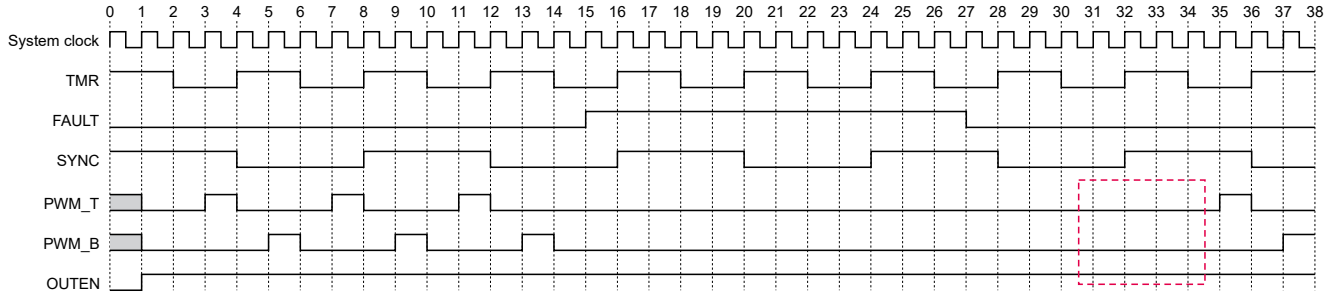

Figure 282. Waveforms for force cleared on rising sync after force deassertion

60.7.10 AC motor double-switching controller

60.7.10.1 Overview

The simplest method of obtaining motor winding currents is to measure the current in each phase by placing a shunt resistor in two or three inverter legs (phases).

This example implementation of an AC motor drive for low-cost and high-volume applications uses a single shunt on the DC bus return path, as illustrated in AC motor power stage schematic. LCU supports double-switching by XORing two timer channel outputs. The implementation uses two LCs arranged to perform double switching, dead time generation, and the processing of three external fault signals.

60.7.10.2 Double-switching

The double-switching technique requires:

- Six synchronized timer pulses
- Three fault signals
- Six PWM outputs for controlling top and bottom power switches
- A sync signal for automatic fault recovery

Waveforms for double-switching technique example applies the PWM switching cycle to an AC motor to reconstruct currents in three phases using a single DC bus shunt resistor (RSH). It applies the non-zero switching vectors 100, 110, and 101 to the power switches, which sample currents IA[0], -IC[0], -IC[1], and IA[1]. Because the durations (T1) of active vectors 110 and 101 are the same, it also applies the zero switching vector (000) with durations T2 and T3 in the middle of the switching cycle to

allow phase current reconstruction. This technique can only be used by PWM modules targeted at motor control and power conversion applications.

60.7.10.3 Fault inputs and deadtime insertion

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. You must program the Combinational Force Path (LCn_FFILT[COMB_EN]) to enable an active fault input to immediately force all PWM outputs to the inactive state.

60.7.10.4 Deadtime insertion

In Waveforms for generation of PWM complementary signals using an LC, the PWMA_T output is generated by XORing timer outputs TMR0 and TMR1. The PWMA_B output is complementary to PWMA_T. Digital filters insert a dead time of one system clock cycle to delay the rising edges of both PWM signals.

60.7.10.5 Fault events

Waveforms for force cleared on force deassertion shows the reaction to the fault event. On a fault event, both the PWM outputs transition to the inactive state (logic 0). When fault event deasserts, both the PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion).

Alternatively, after the fault event deasserts, fault clearing can be performed according to FORCE_MODE = 01 (cleared on rising sync force deassertion). See Waveforms for force cleared on rising sync after force deassertion for details.

60.7.11 Brushless DC (BLDC) motor PWM controller

60.7.11.1 Overview

You can use LCU to replace the mechanical commutator in the BLDC motor control application with Hall-sensor position measurement.

In this example implementation, LC0 receives the direction (DIR) and Hall A, Hall B, and Hall C sensor output states, and from those inputs generates the switching states S1, S2, and S3. LC1 and LC2 convert the switching states to PWM or on-off signals for controlling power switches, as illustrated in Waveforms for BLDC motor control technique.

BLDC motor power stage schematic and BLDC motor electrical arrangement illustrate a three-phase BLDC motor power stage with switching pulses and phase currents controlling motor rotation in the CCW direction. The state of the Hall sensors is 010. As the rotor shaft rotates, Hall sensors track the motor position. You accelerate or decelerate the motor by controlling the width of the PWM signal. You can include one or more faults (force inputs) to force power switches instantaneously into the inactive state if there is an overcurrent.

60.7.11.13 Waveforms for reversing BLDC motor

This figure illustrates the waveforms for controlling a reversing BLDC motor. The DIR input indicates the direction of rotation:

- Logic 0 for CW rotation
- Logic 1 for CCW rotation

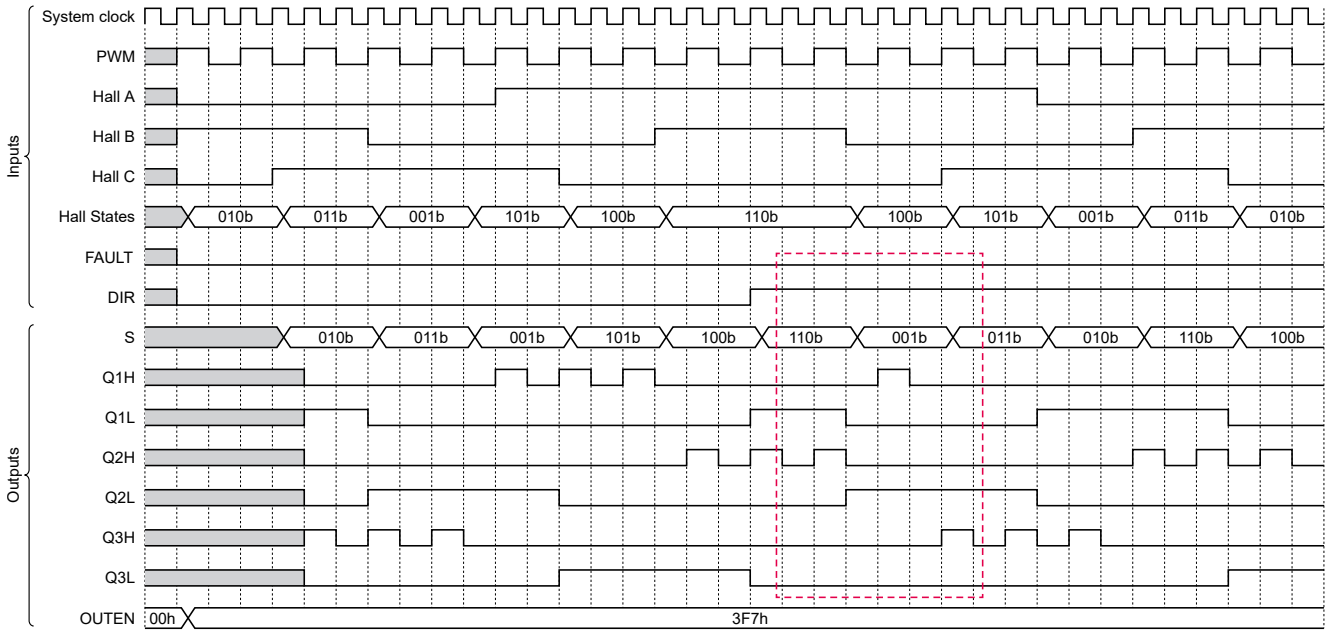

Figure 294. Waveforms for reversing BLDC motor

60.7.11.14 Waveforms for reversing BLDC motor with fault assertion

This figure illustrates the waveforms for the reaction to an external fault in addition to reversing the BLDC motor. On the occurrence of an external fault event, the power switches transition to the inactive state (logic 0). Two clock cycles after external fault deassertion, the power switches start operating normally.

Switching state outputs S1, S2, and S3, generated by LC0, receive an additional delay of one clock cycle on their way to the inputs of other LCs (digital filters bypassed).

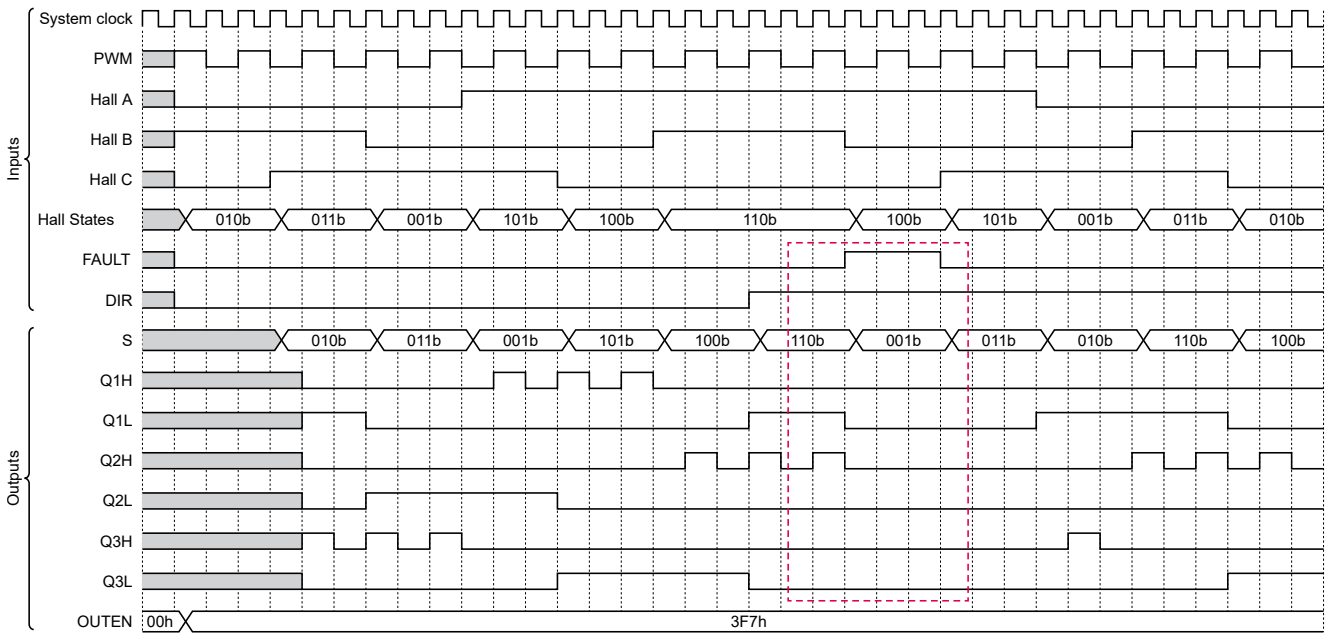

Figure 295. Waveforms for reversing BLDC motor with fault assertion

60.8 Registers

60.8.1 Mapping of 16-bit input, output, and state fields

This table maps inputs, outputs, or states to the bit positions in the following 16-bit fields:

- SWEN[SWEN]
- SWVALUE[SWVALUE]
- OUTEN[OUTEN]
- LCIN[LC_INPUTS]
- SWOUT[SWOUT]
- LCOUT[LCOUT]
- FORCEOUT[FORCEOUT]
- FORCESTS[FORCESTS]
- DBGEN[DBGEN]

60.9.2 LC n Output m LUT Control (LC0_LUTCTRL0 - LC2_LUTCTRL3)

Offset

For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_LUTCTRLm	0h + (n × 40h) + (m × 4h)

Function

See LUTCTRL.

Fields

Field	Function
31-16 —	Reserved
15-0 LUTCTRL	LUT Control Specifies the LUT positions, based on the combined LC input value, that result in assertion of this output. For more information, see Logic operations.

60.9.3 LC n Output m Filter (LC0_FILT0 - LC2_FILT3)

Offset

For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_FILTm	10h + (n × 40h) + (m × 4h)

Function

Specifies the rising- and falling-edge thresholds for the LC output filters.

Diagram

1	29
2	30
3	31

27 —	Reserved

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>26-24
COMB_EN</td><td>Combinational Force Path (CFP) Enable
Enables an active force input to combinationally affect the LC outputs. When CFP is not enabled, force inputs must be synchronized and then optionally filtered. When you enable CFP (write 1 to one of these bits), the corresponding force input bypasses synchronization and filtering and immediately affects the LC output.
The Force Filter (FORCE_FILT) is still in effect. Force inputs that do not meet the pulse width requirements for synchronization and filtering are not registered in Force Status (FORCESTS) and you do not need to write 1 to change the bit to 0.
CFP provides a safety factor when the LC outputs drive a motor and immediate response is required. In some topologies, an oscillation can result if the assertion of the force input causes the LC output to turn off. This situation in turn leads to deassertion of the force input and the output turning back on. In general, you must disable CFP unless the LCU outputs drive a motor or similar safety-critical application, which requires an immediate response without synchronization delays.</td></tr>
<tr><td>23-19
—</td><td>Reserved</td></tr>
<tr><td>18-16
FORCE_POL</td><td>Force Input Polarity
Specifies the polarity of the force inputs to this LC.
For each bit:

60.9.13 Software Override Value (SWVALUE)

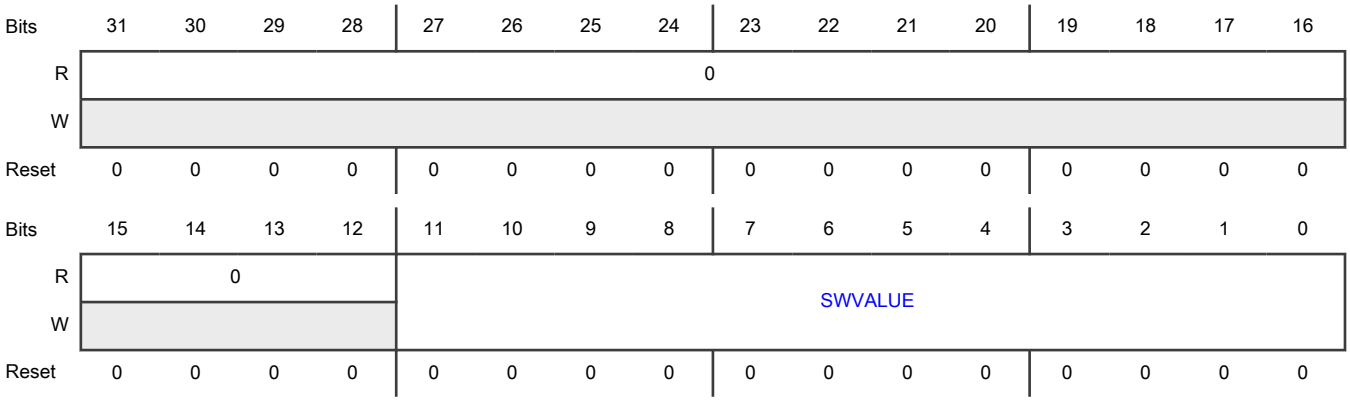
Offset

Register	Offset
SWVALUE	288h

Function

Specifies the software override value for each LC input.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWVALUE	Software Override Value Specifies the software override value for each LC input. For each bit: 0b - 0 1b - 1 Mapping of bits: See Mapping of 16-bit input, output, and state fields.

60.9.14 Output Enable (OUTEN)

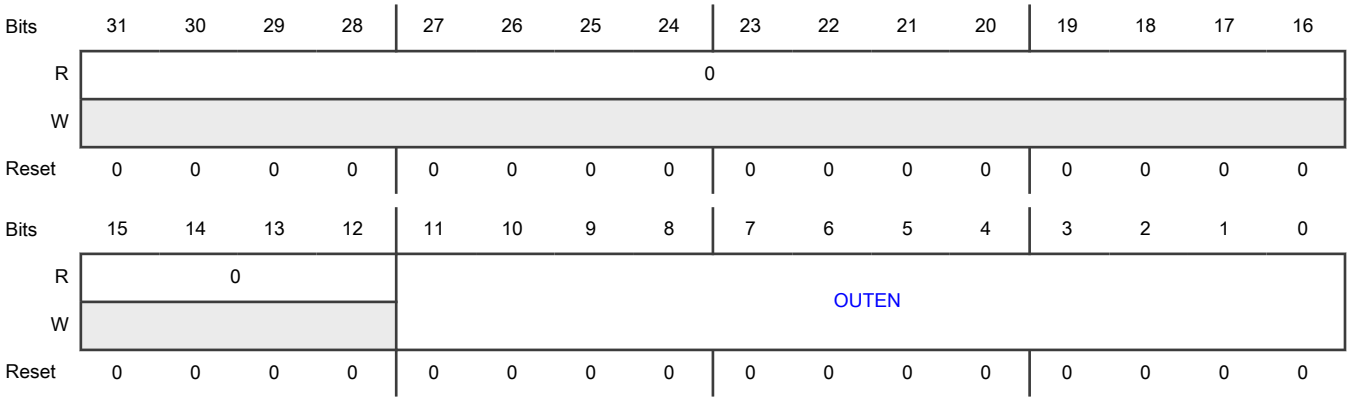
Offset

Register	Offset
OUTEN	28Ch

Function

Enables LC outputs.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 OUTEN	Output Enables Enables LC outputs. For each bit: 0b - Disable 1b - Enable Mapping of bits: See Mapping of 16-bit input, output, and state fields.

60.9.15 Logic Inputs (LCIN)

Offset

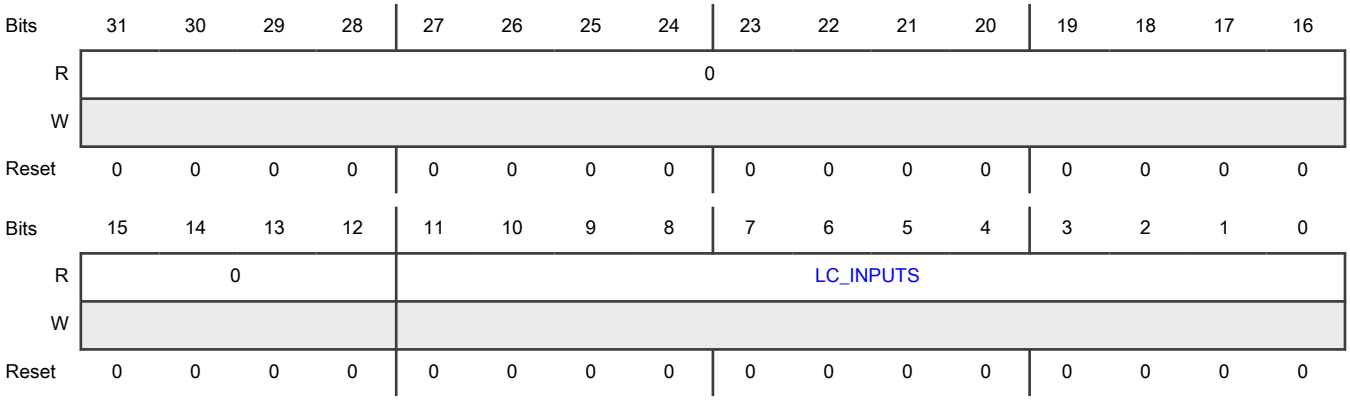
Register	Offset
LCIN	290h

Function

Indicates states of LC inputs.

If you write to this register, LCU generates a bus transfer error.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 LC_INPUTS	Logic Inputs Indicates states of LC inputs. For each bit: 0b - 0 1b - 1 Mapping of bits: See Mapping of 16-bit input, output, and state fields.

60.9.16 Overridden Inputs (SWOUT)

Offset

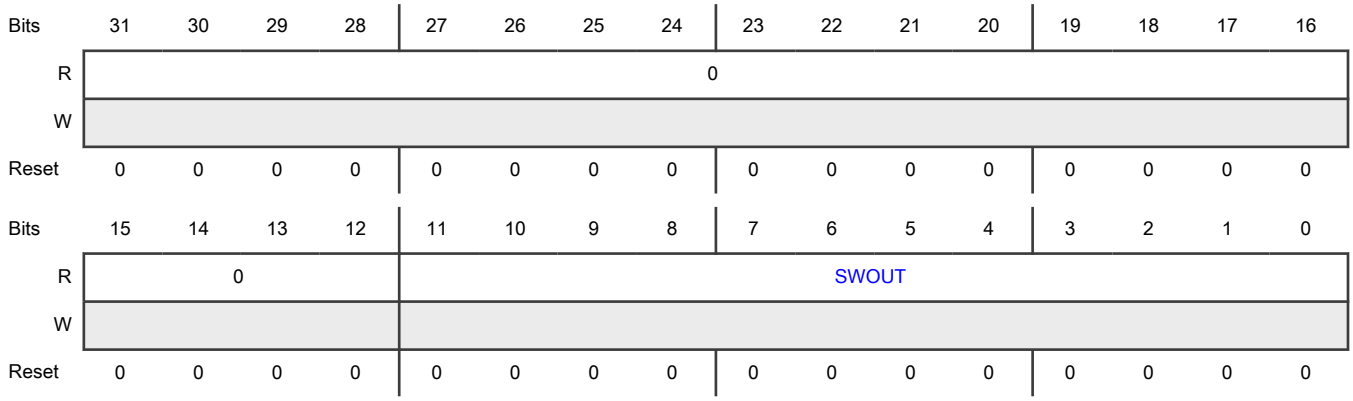
Register	Offset
SWOUT	294h

Function

Indicates states of LC inputs or states of software-overridden inputs, depending upon the state of the corresponding SWEN bit.

If you write to this register, LCU generates a bus transfer error.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWOUT	Overridden Inputs Indicates states of LC inputs or software-overridden inputs. For each bit, when the corresponding SWEN bit is 0: 0b - LC input is 0 1b - LC input is 1 For each bit, when the corresponding SWEN bit is 1: 0b - Software-overridden input is 0 1b - Software-overridden input is 1 Mapping of bits: See Mapping of 16-bit input, output, and state fields.

60.9.17 Logic Outputs (LCOUT)

Offset

Register	Offset
LCOUT	298h

Function

Indicates states of LC outputs.

If you write to this register, LCU generates a bus transfer error.

Chapter 61
Enhanced Modular IO Subsystem (eMIOS)

61.1 Chip-specific eMIOS information

61.1.1 eMIOS configuration

This chip has up to 3 instances of eMIOS that are each configured as shown in the following tables.

Table 340. eMIOS instances

Instance	S32K314/S32K324/S32K344/S32K358	S32K311/S32K312/S32K322/S32K342
eMIOS_0	Yes	Yes
eMIOS_1	Yes	Yes
eMIOS_2	Yes	No

Table 341. eMIOS configuration

Parameter	eMIOS_0	eMIOS_1	eMIOS_2
Timer width	16 bits	16 bits	16 bits
Number of channels	24	24	24
Channels configuration	See EMIOS channel configuration figure below		
Local Channel prescaler width	4	4	4
Number of global counter buses	2	2	2
Number of global prescaler	1	1	1
Global channel prescaler width	8	8	8

NOTE

eMIOS is clocked by CORE_CLK.

61.1.2 Channel types

The eMIOS contain 4 different types of channel, which are listed below.

Table 342. eMIOS channel types

Mode Description	Name	Ch TypeX	Ch TypeY	Ch TypeG	Ch TypeH
General Purpose Input / Output	GPIO	X	X	X	X
Single Action Input Capture	SAIC	X	X	X	X
Single Action Output Compare	SAOC	X	X	X	X

Table continues on the next page...

Table 342. eMIOS channel types (continued)

Mode Description	Name	Ch TypeX	Ch TypeY	Ch TypeG	Ch TypeH
Modulus Counter	MC	X			
Modulus Counter Buffered (Up / Down)	MCB	X		X	
Input Pulse Width Measurement	IPWM			X	X
Input Period Measurement	IPM			X	X
Double Action Output Compare	DAOC			X	X
Output Pulse Width and Frequency Modulation Buffered	OPWFMB	X		X	
Center aligned Output PWM Buffered with dead time	OPWMCB			X	
Output Pulse Width Modulation Buffered	OPWMB	X	X	X	X
Output Pulse Width Modulation Trigger	OPWMT	X	X	X	X
Pulse Edge Counting	PEC			X	

NOTE

ChType X and G has internal counters.

Table 343. eMIOS channel configuration

CH19	Y	Y	Y
CH20	Y	Y	Y
CH21	Y	Y	Y

61.1.3 Channel configuration

The eMIOS channel configuration with respect to Type and Counter_bus is shown below.

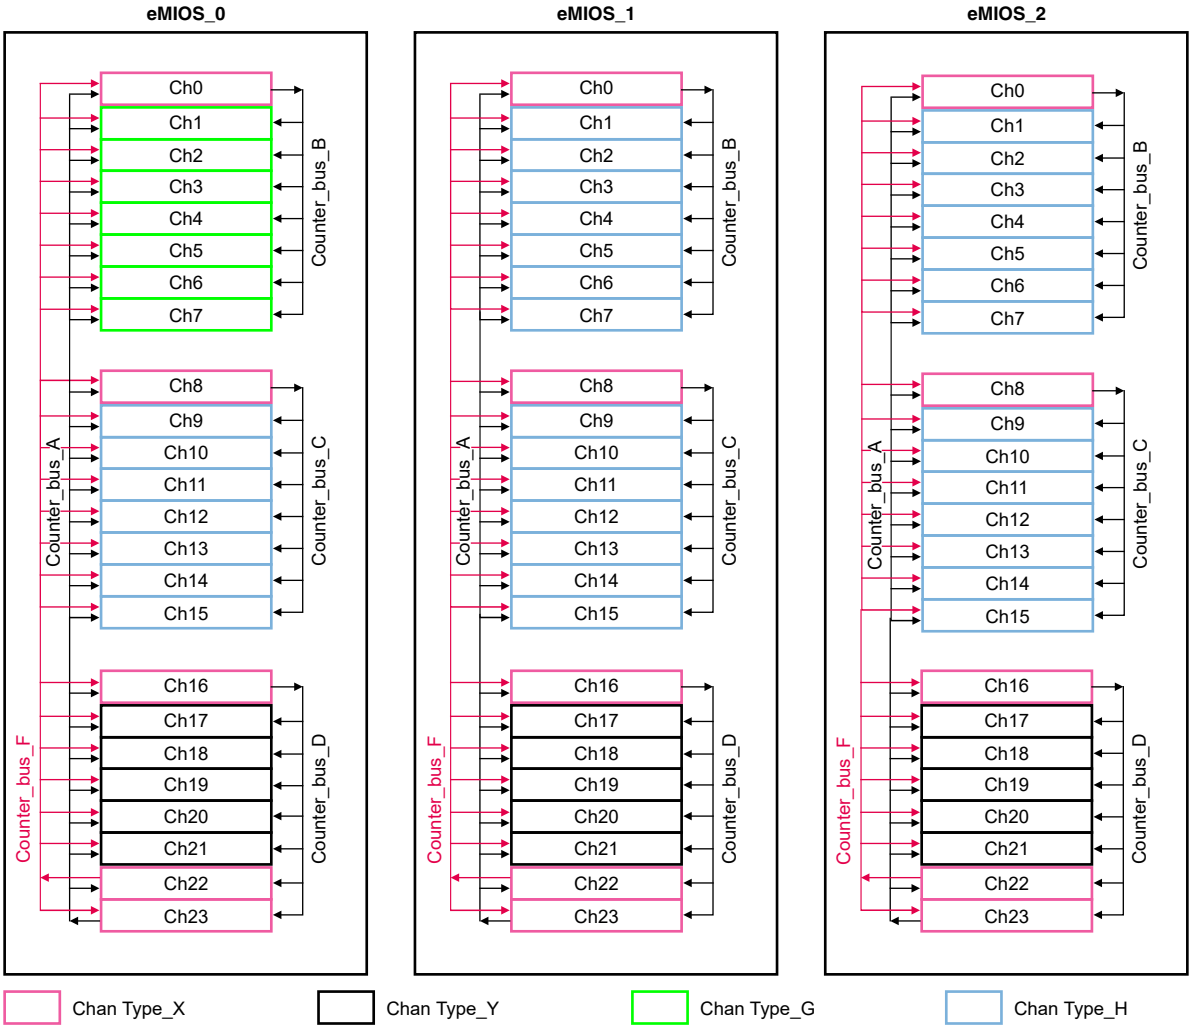

Figure 296. EMIOS channel types

61.1.4 eMIOS disabling

eMIOS can disable it's output using it's disable inputs. Disable inputs[3:0] are driven from the flag out bits[11:8].

Disable inputs	
eMIOS0 Output disable input[3:0]	trgmux_output[31:28]
eMIOS1 Output disable input[3:0]	trgmux_output[31:28]
eMIOS2 Output disable input[3:0]	trgmux_output[31:28]

For details, see the TRGMUX connectivity file attached to this document.

61.1.5 BCTU Interface

Each eMIOS channel, with the exception of the main counterbus channel (ch[23]) is capable of triggering the BCTU. See BCTU chapter for mapping. BCTU allows triggering from as many eMIOS modes as possible.

61.4 Introduction

eMIOS provides independent channels, UCs, that you configure to generate or measure time events for different functions in different chip applications.

eMIOS distributes these channels across a number of global and local counter buses. Each local bus is dedicated to a group of eight contiguous channels. Each channel can generate its own timebase, and each counter bus has its timebase provided by a dedicated channel. For a list of counter buses with their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

61.5 Block diagram

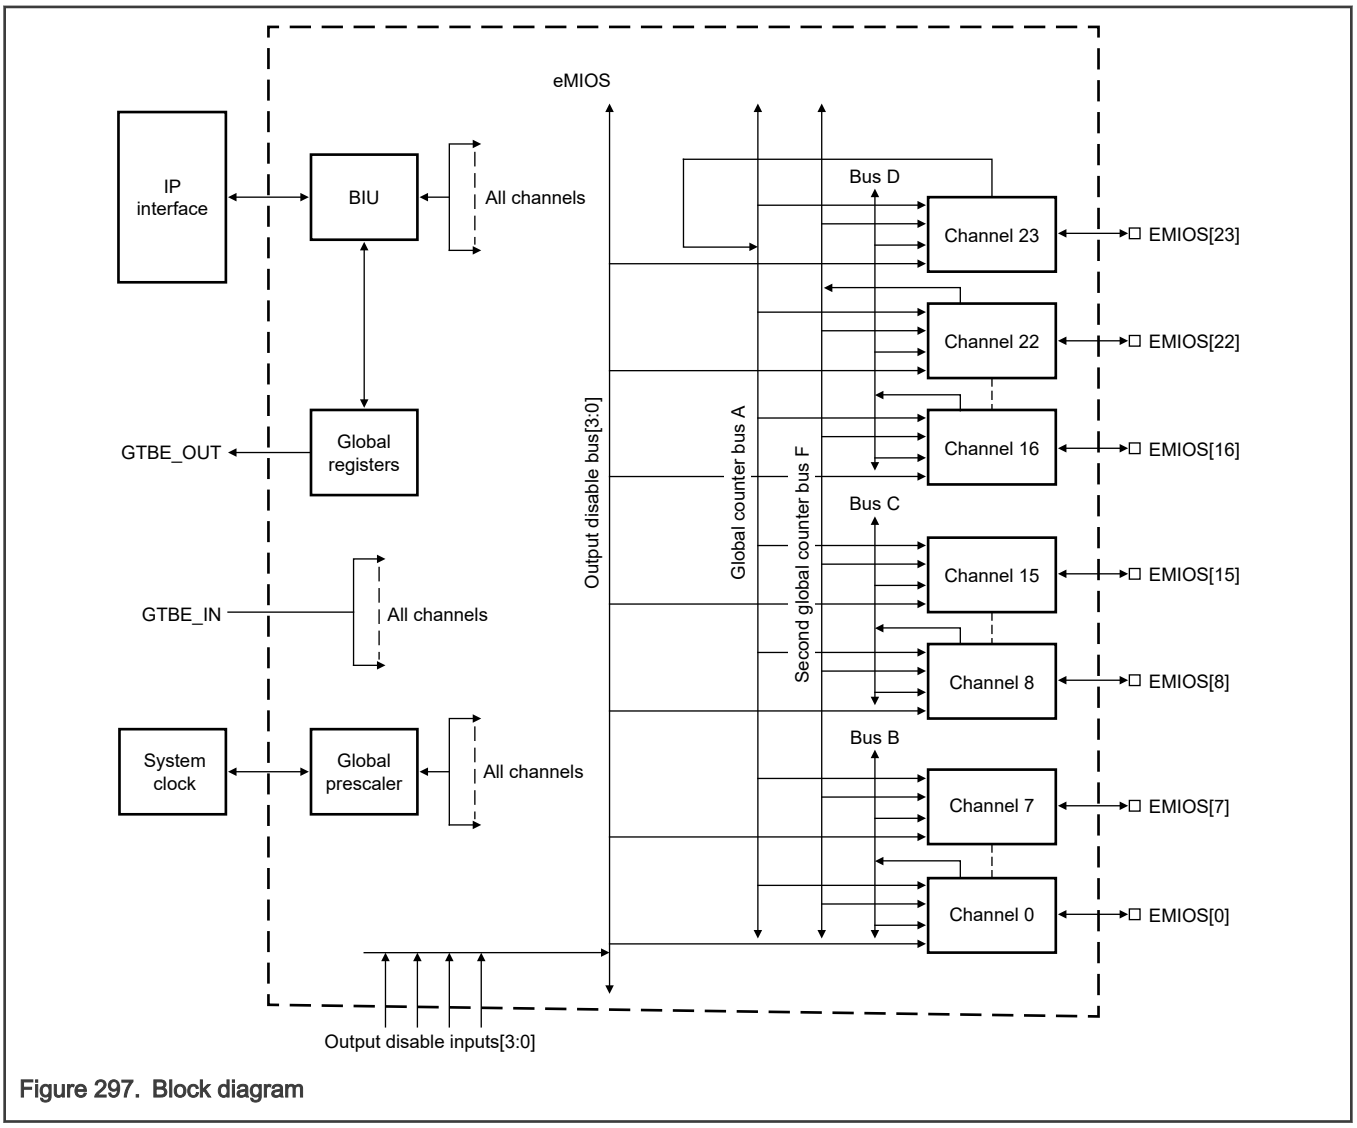

Figure 297. Block diagram

61.6 Features

- 24 UCs distributed across local counter buses as shown in Counter buses, channels, and timebase sources
- Global counter bus A driven by UC23
- Global counter bus F driven by UC22
- Synchronized timebases shared through the counter buses

- Dedicated timebase for each channel, distinct from the counter buses
- Global clock prescaler (GCP)
- One CP per channel
- Dedicated set of control and status registers for each UC
- 16-bit–wide data registers
- Shadow flag register (GFLAG) to access all channel flags with one read access
- Ability to freeze the UC state for debug purposes
- Motor control capability

61.7 Functional description

61.7.1 Reset

eMIOS resets asynchronously. Reset affects all registers.

On reset, UCs enter GPIO input mode.

61.7.2 Counter buses, channels, and timebase sources

Table 344. Counter buses, channels, and timebase sources

Counter bus	Channels	Timebase channel
Global bus A	All UCs	23
Local bus B	• UC0 • UC1 • UC2 • UC3 • UC4 • UC5 • UC6 • UC7	0
Local bus C	• UC8 • UC9 • UC10 • UC11 • UC12 • UC13 • UC14 • UC15	8
Local bus D	• UC16	16

Table continues on the next page...

Table 344. Counter buses, channels, and timebase sources (continued)

Counter bus	Channels	Timebase channel
	• UC17 • UC18 • UC19 • UC10 • UC21 • UC22 • UC23	
Global bus F	All UCs	22

61.7.3 Unified channels (UC)

61.7.3.1 Overview

Each UC contains the following:

- Two double-buffered data registers, A*n* and B*n*, that allow up to two events—input capture, output compare, or both—to occur before software intervention is needed
- Two comparators, A and B, that indicate when the selected counter bus is equal to the value in A*n* and B*n*
- An internal counter (CNT*n*[C]) that runs in all modes except GPIO.

  You can use this counter as a local timebase or to count input events. You can use it as a timebase if CNT*n*[C] is not used in the current mode.
- An output flip-flop that holds the logic level to be applied to the output pin
- A status register, UC Status n (S0 - S23), that flags input capture and match events, indicates flag overruns and overflows, and shows the input and output pin states
- A control register, UC Control n (C0 - C23), that controls UC operation

You control the following operational characteristics for each UC:

- The logic (C*n*[MODE]) that specifies the behavior of the UC (see UC modes)
- The counter bus (C*n*[BSL]) that provides the timebase for all timing functions
- The CP (C*n*[UCPRE] and C2_*n*[UCEXTPRE])
- The minimum input pulse width (C*n*[IF]) for the input filter that determines valid pin transitions
- Which input edges to detect (C*n*[EDSEL])
- Which of four output disable input signals (C*n*[ODISSL]) to use for disabling outputs
- For all output modes except GPIO, whether to disable the output flip-flop (C*n*[ODIS])

UC block diagram illustrates the basic UC architecture.

For a list of counter buses and their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

61.7.3.2 UC block diagram

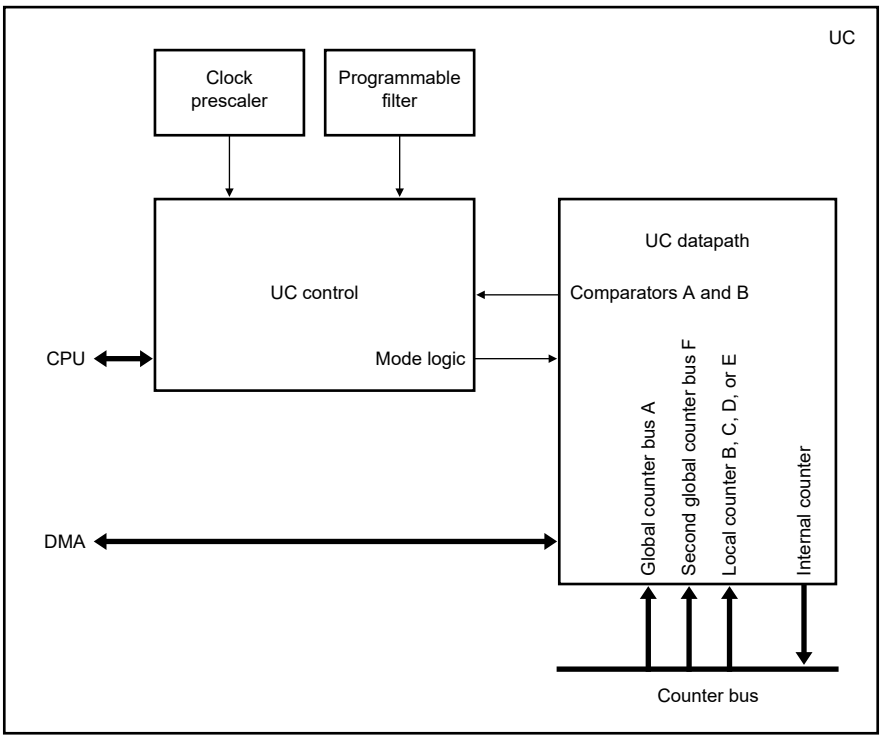

Figure 298. UC block diagram

61.7.3.3 Buffered modes

To provide smooth waveform generation even when A*n*[A] and B*n*[B] are changing, the following modes double buffer the A*n* and B*n* registers:

- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Output PWM Buffered (OPWMB) mode

These modes appear in separate sections because there are several basic differences in UC operation between them and their corresponding nonbuffered modes.

61.7.3.4 UC control and datapath

As illustrated in UC control and datapath diagram, the UC contains control and datapath subblocks.

The control subblock generates signals to control the multiplexers in the datapath subblock. eMIOS implements each UC mode in dedicated logic independent from the other modes. The UC modes share a set of registers allowing the storing of sequential events.

The datapath block contains the channel A and B registers, the internal timebase, and the comparators. Multiplexers receive inputs from the control subblock to configure the datapath for the specific channel modes. This configuration consists of selecting the input of comparators and data for the register inputs. The outputs of the A and B comparators connect to the control block.

61.7.3.5 UC control and datapath diagram

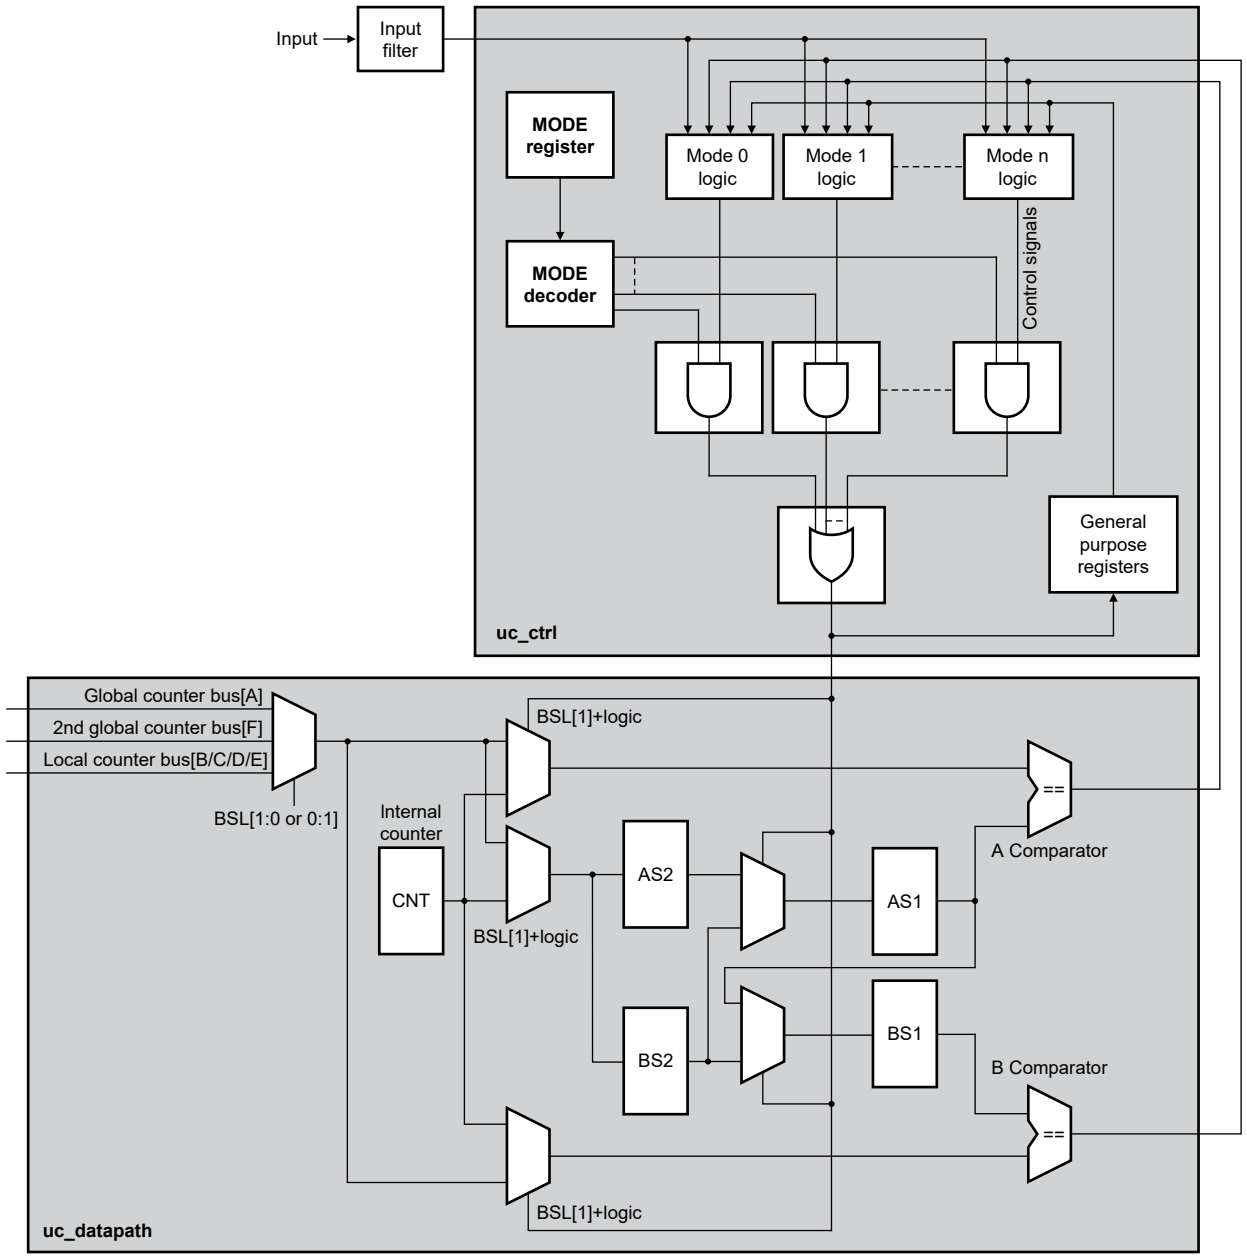

Figure 299. UC control and datapath diagram

61.7.3.6 UC modes

You can configure UCs to operate in the following modes:

- General-Purpose Input and Output (GPIO) mode
- Single Action Input Capture (SAIC) mode
- Single Action Output Capture (SAOC) mode
- Input Pulse Width Measurement (IPWM) mode
- Input Period Measurement (IPM) Mode

- Double Action Output Compare (DAOC) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Output PWM Buffered (OPWMB) mode
- Output PWM with Trigger (OPWMT) mode

Each channel supports a specific subset of these modes. See the chip-configuration information to see which modes each channel supports.

61.7.3.7 General-Purpose Input and Output (GPIO) mode

61.7.3.7.1 Overview

This mode disables all UC input-capture and output-compare functions, and resets and disables the internal counter (C*n*[C]). All control fields remain accessible.

To change the UC from one operation mode to another, you must first change to GPIO mode and then change to the desired final mode. To prepare the UC for a new operation mode, you must configure AS1, BS1, AS2, and BS2 before exiting GPIO mode and entering the desired final mode (see AS1, AS2, BS1, and BS2 shadow registers). Specifically:

- Writing to A*n*[A] stores the same value in AS1 and AS2.
- Writing to B*n*[B] stores the same value in BS1 and BS2.
- Writing to ALTA*n*[ALTA] stores a value only in AS2.

As its name implies, GPIO mode supports both input and output submodes. See Differences for input and output submodes.

61.7.3.7.2 Differences for input and output submodes

Table 345. Differences for input and output submodes

Submode	To enter submode, write this value to C*n*[MODE]	Characteristics
Input	0	• You control the generation of input-capture flags with C*n*[EDPOL] and C*n*[EDSEL]. • You can determine the input pin status by reading S*n*[UCIN].
Output	1	• The UC performs as a single output port pin. • The value of C*n*[EDPOL] permanently drives the output flip-flop.

61.7.3.8 Single Action Input Capture (SAIC) mode

61.7.3.8.1 Overview

In this mode, when a triggering event occurs on the input pin, eMIOS:

- Captures the selected timebase into AS2
- Changes S*n*[FLAG] to 1 to indicate that an input capture has occurred

A*n*[A] returns the value of AS2. As soon as the UC enters SAIC mode after exiting GPIO mode, the channel is ready to capture events.

eMIOS captures the events as soon as they occur. Therefore, reading A*n*[A] always returns the value of the latest captured event. Subsequent capture events occur regardless of whether you read the previous event from A*n*[A]. Each new capture event sets the input capture flag (writes 1 to S*n*[FLAG]).

The input capture is triggered by an edge transition on the input pin as configured by C*n*[EDPOL] and C*n*[EDSEL].

SAIC with rising edge triggering and SAIC with both edges triggering show how to use the UC for input capture.

61.7.3.8.2 SAIC submodes and MODE field values

Table 346. SAIC submodes and MODE field values

Capture behavior	C*n*[MODE] (binary)
The UC only captures the timestamp.	000_0010
• The UC captures a timestamp. • AS2 bit 0 indicates the input signal level.	100_0010

61.7.3.8.3 Effect of C*n*[EDPOL] on edge capturing

Table 347. Effect of C*n*[EDPOL] on edge capturing

C*n*[EDPOL]	Input signal transition	Resulting value of AS2 bit 0
0	0→1	0
	1→0	1
1	0→1	1
	1→0	0

61.7.3.8.4 SAIC with rising edge triggering

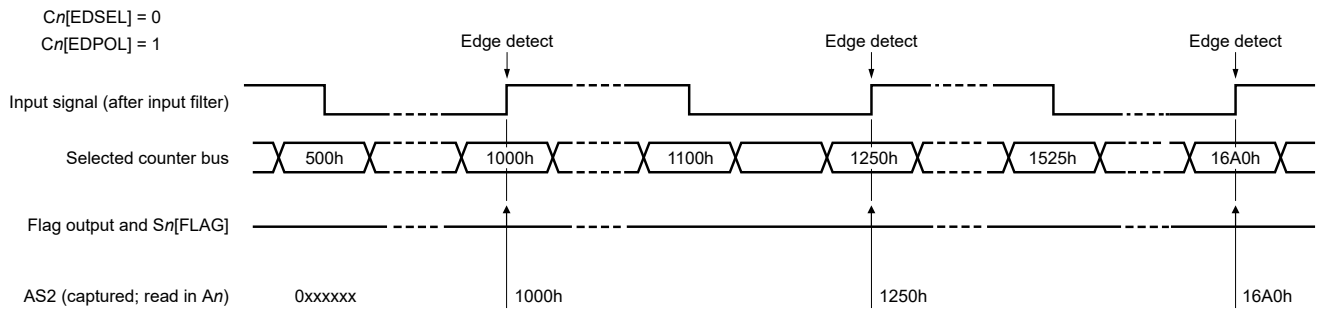

Figure 300. SAIC with rising edge triggering

61.7.3.8.5 SAIC with both edges triggering

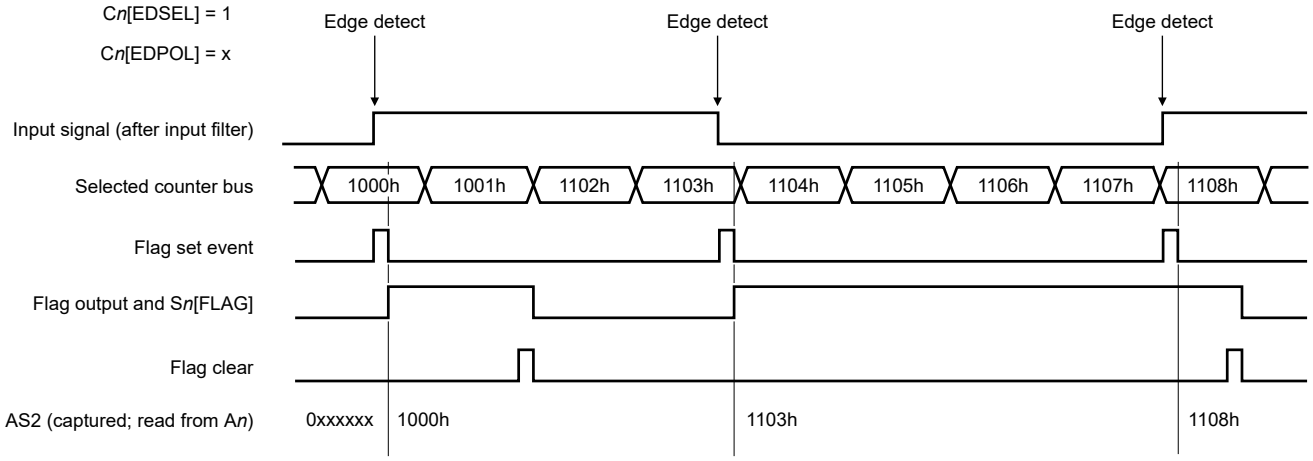

Figure 301. SAIC with both edges triggering

61.7.3.9 Single Action Output Capture (SAOC) mode

61.7.3.9.1 Overview

In this mode, eMIOS loads a match value into AS2 and then immediately transfers it to AS1 for comparison with the selected timebase. When an output-compare match occurs, eMIOS:

- Either toggles the output flip-flop or transfers C*n*[EDPOL] to the output flip-flop, as determined by C*n*[EDSEL].
- Sets the input capture flag (changes S*n*[FLAG] to 1).

Along with the match, S*n*[FLAG] becomes 1 to indicate that the output-compare match has occurred. Writing to A*n*[A] stores the value in AS2, and reading A*n*[A] returns the AS1 value.

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the UC enters SAOC mode.

You can force an output-compare match by writing 1 to C*n*[FORCMA]. A forced output-compare match does not set the input capture flag (S*n*[FLAG]).

When the UC enters SAOC mode after exiting GPIO mode, the output flip-flop value becomes the complement of C*n*[EDPOL].

You select the internal or external counter bus with C*n*[BSL].

SAOC with C*n*[EDPOL] transferred to the output flip-flop shows how to perform a single output compare and transfer C*n*[EDPOL] to the output flip-flop.

SAOC toggling the output flip-flop shows how to perform a single output compare and toggle the output flip-flop at each match.

61.7.3.9.2 Preload the desired match value

eMIOS enables matches immediately after the UC enters SAOC mode. Therefore, you must write the desired match value to AS1 before the UC enters SAOC mode. You can update AS1 at any time. This modifies the match value reflected in the channel-generated output signal. Subsequent capture events occur regardless of whether you write to A*n*[A] again. Each new capture event sets the input capture flag (S*n*[FLAG]). See SAOC with flag behavior.

61.7.3.9.3 SAOC with C*n*[EDPOL] transferred to the output flip-flop

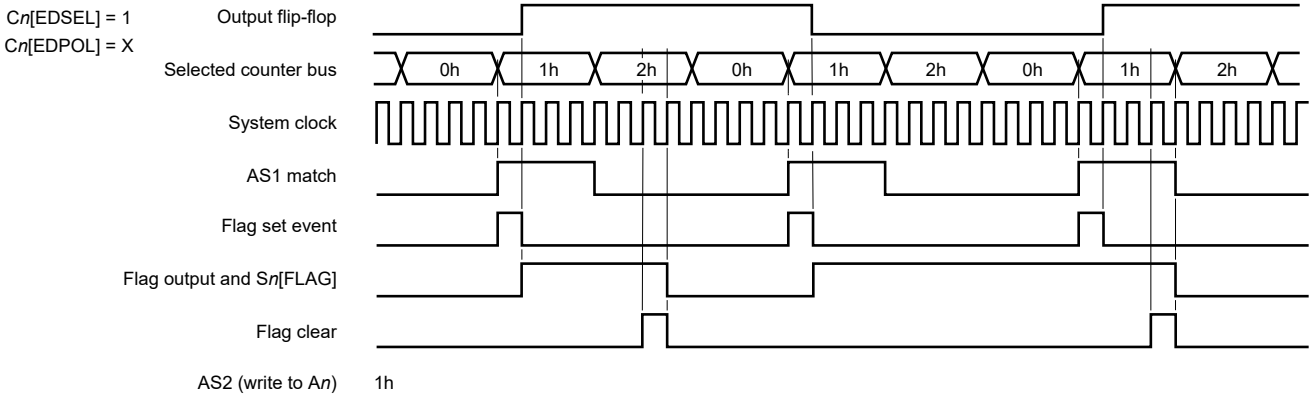

Figure 304. SAOC with flag behavior

61.7.3.10 Input Pulse Width Measurement (IPWM) mode

61.7.3.10.1 Overview

This mode allows you to measure the width of a positive or negative pulse. Select whether to measure from the rising or falling edge with Edge Polarity (Cn[EDPOL]).

The first leading edge:

- Triggers the first input capture, which latches the count value of the selected timebase into BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Does not set the input-capture flag (Sn[FLAG])
- Enables AS2 capture

The next trailing edge:

- Latches the selected timebase into AS2
- Sets the input-capture flag (Sn[FLAG])
- Transfers BS2 to BS1 and AS1

eMIOS captures successive values on consecutive edges of opposite polarity. If you initiate subsequent input capture events while the input-capture flag (Sn[FLAG]) is set, eMIOS updates AS2, BS1, and AS1 with the latest captured values and keeps the flag set.

61.7.3.10.2 Coherency

Reading A*n*[A] updates BS1 with AS1. It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading Bn updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next trailing edge capture.

Because transfers from BS2 to AS1 are never blocked, to guarantee data coherency you must read An, then read Bn.

If you do not require coherent data, you should read Bn before you read An, although doing so requires a second read of Bn to unblock BS1 updates.

61.7.3.10.3 Timing example: measure pulse width

This figure shows how to measure the input pulse width by subtracting BS1 from AS2.

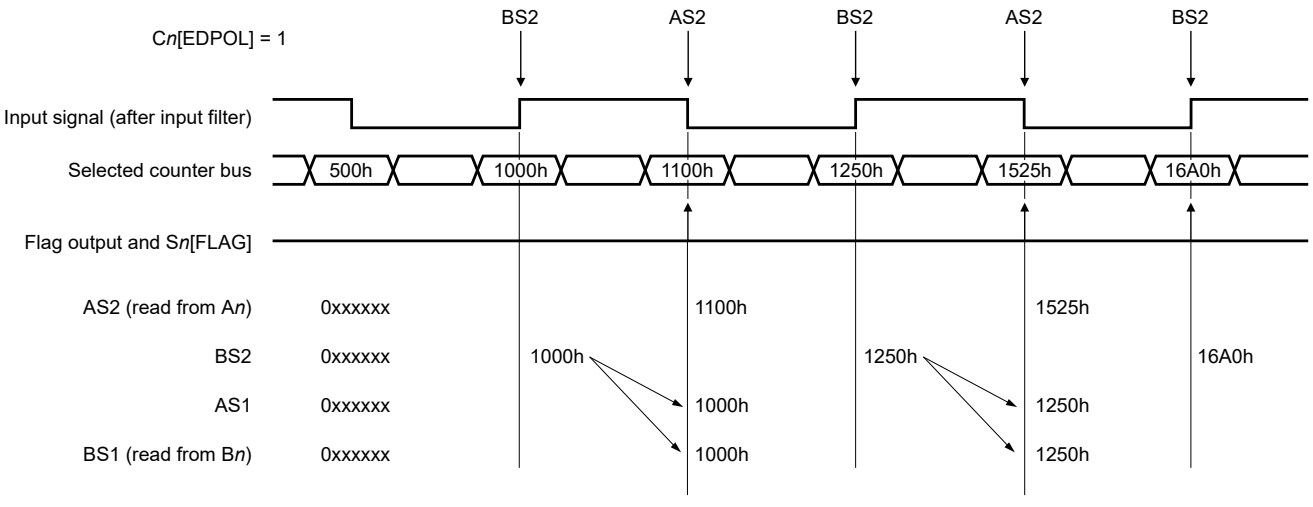

Figure 305. Timing example: measure pulse width

61.7.3.10.4 Timing example: AS1 and BS1 updates on channel reads

This example illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B]. AS1 always has coherent data related to AS2 (see Coherency).

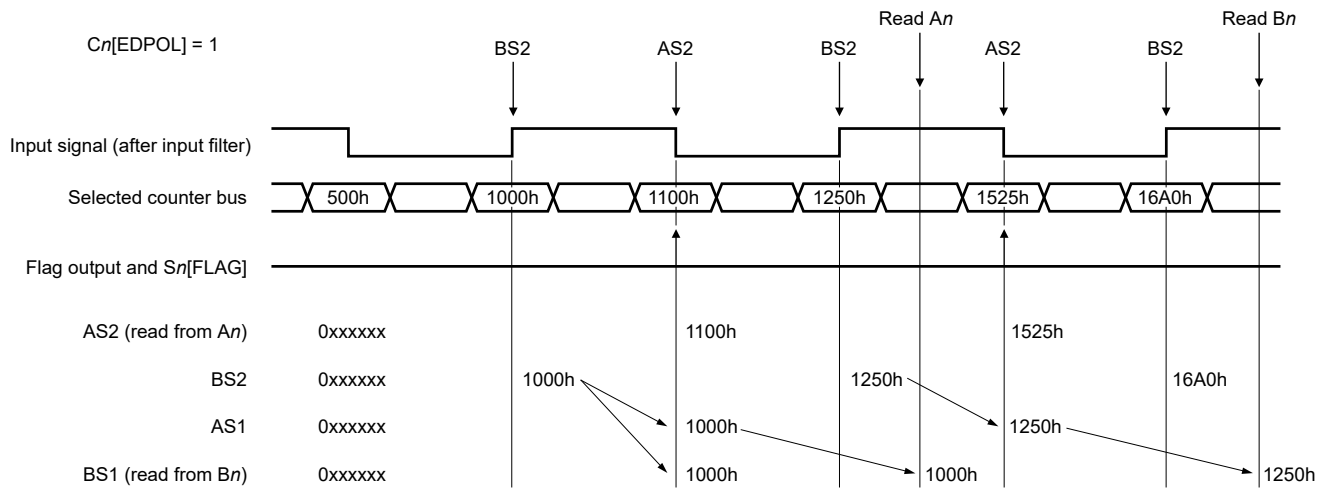

Figure 306. Timing example: BS1 and AS1 updates on channel reads

61.7.3.11 Input Period Measurement (IPM) Mode

61.7.3.11.1 Overview

This mode allows you to measure the period of an input signal. Select whether to measure from the rising or falling edges with Edge Polarity (C*n*[EDPOL]).

The first edge of selected polarity:

- Latches the selected timebase into AS2 and BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Transfers BS2 to BS1
- Does not set the input-capture flag (S*n*[FLAG])

The second edge of the same polarity:

- Latches the counter bus value into AS2 and BS2
- Transfers BS2 to BS1 and AS1
- Sets the input-capture flag (S*n*[FLAG])

eMIOS repeats this process for each subsequent capture.

eMIOS captures successive values on two consecutive edges of the same polarity. The measured input signal must have a period of at least four system clock cycles to be properly captured by the synchronization logic at the channel input, even if the input filter is in bypass mode.

61.7.3.11.2 Coherency

Reading A*n*[A] updates BS1 with AS1, which provides coherent data in AS2 and BS1 (see Timing example: AS1 and BS1 updates on channel reads). It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading B*n*[B] updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next edge capture.

61.7.3.11.3 Timing example: measure input period

This example illustrates how to measure the input period by subtracting BS1 from AS2.

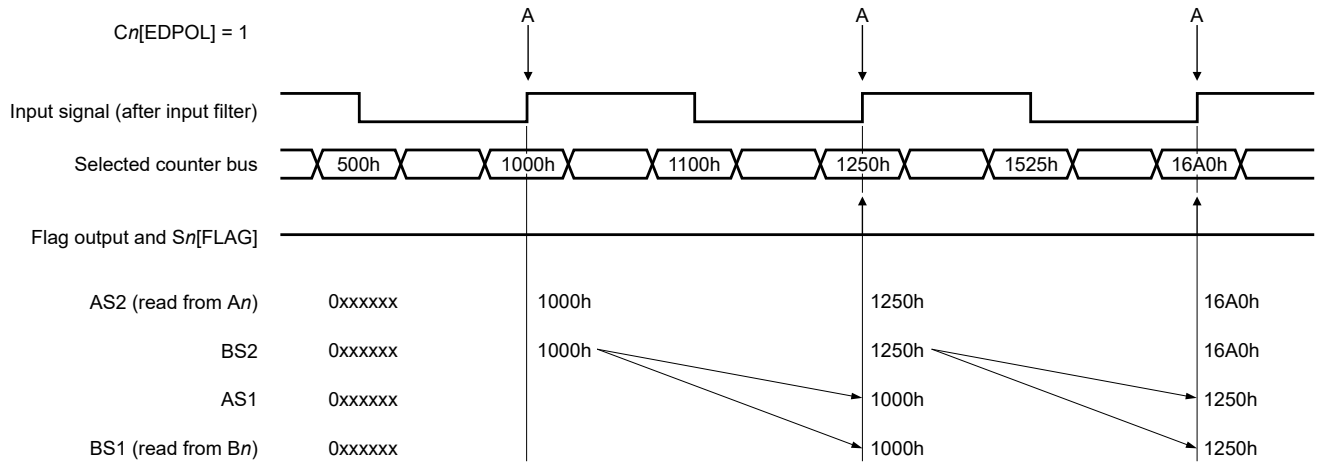

Figure 307. Timing example: measure input period

61.7.3.11.4 Timing example: AS1 and BS1 updates on channel reads

This diagram illustrates AS1 and BS1 updates when you read An[A] and Bn[B].

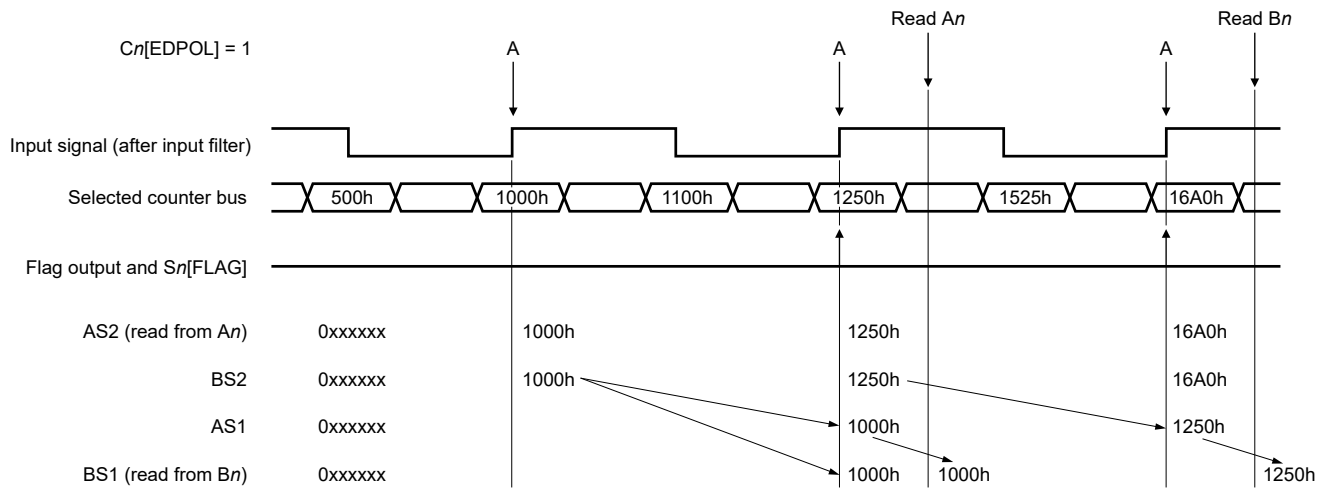

Figure 308. Timing example: AS1 and BS1 updates on channel reads

61.7.3.12 Double Action Output Compare (DAOC) mode

61.7.3.12.1 Overview

In this mode, matches on comparators A and B cause the UC to generate the leading and trailing edges of the variable pulse width output. See DAOC submodes and MODE field values. There is no restriction on the order in which A and B matches occur.

When the UC enters DAOC mode from GPIO mode, eMIOS disables both comparators and drives the complement of Edge Polarity (Cn[EDPOL]) onto the output flip-flop.

61.7.3.12.2 DAOC submodes and MODE field values

Table 348. DAOC submodes and MODE field values

When set flag event occurs	C*n*[MODE] (binary)
Only on B matches	000_0110
On A or B matches	000_0111

61.7.3.12.3 Data transfer and compare

If you enable output (write 0 to OUDIS[OU*n*]), on the next clock cycle the UC transfers AS2 and BS2 to AS1 and BS1 respectively (see Timing example: leading dead time insertion). If you disable output (write 1 to OUDIS[OU*n*]), no transfer occurs.

eMIOS enables and disables the A and B comparators independently. It enables comparator A only after the transfer to AS1 completes, and disables comparator A on the next A match. Similarly, eMIOS enables comparator B only after the transfer to BS1 completes, and disables comparator B on the next B match.

When a match occurs on comparator A, the output flip-flop acquires the value of Edge Polarity (C*n*[EDPOL]). When a match occurs on comparator B, the output flip-flop acquires the complement of Edge Polarity (C*n*[EDPOL]).

61.7.3.12.4 Differences between flag on A match and flag on A and B matches

In the flag on B match submode (see DAOC submodes and MODE field values), the UC sets the input-capture flag (S*n*[FLAG]) only for matches on the B comparator. In the flag on both A and B matches submode, it sets the flag for matches on either comparator.

If subsequent enabled output compares occur on AS1 or BS1, the UC continues generating pulses regardless of the flag state.

If you load both AS1 and BS1 with the same value, the B match takes precedence and the UC drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

61.7.3.12.5 Forced operation by Cn[FORCMA] and Cn[FORCMB]

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to the comparator, Edge Polarity (C*n*[EDPOL]) for an A match, or the complement of Edge Polarity for a B match. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

61.7.3.12.6 Timing example: flag on both matches

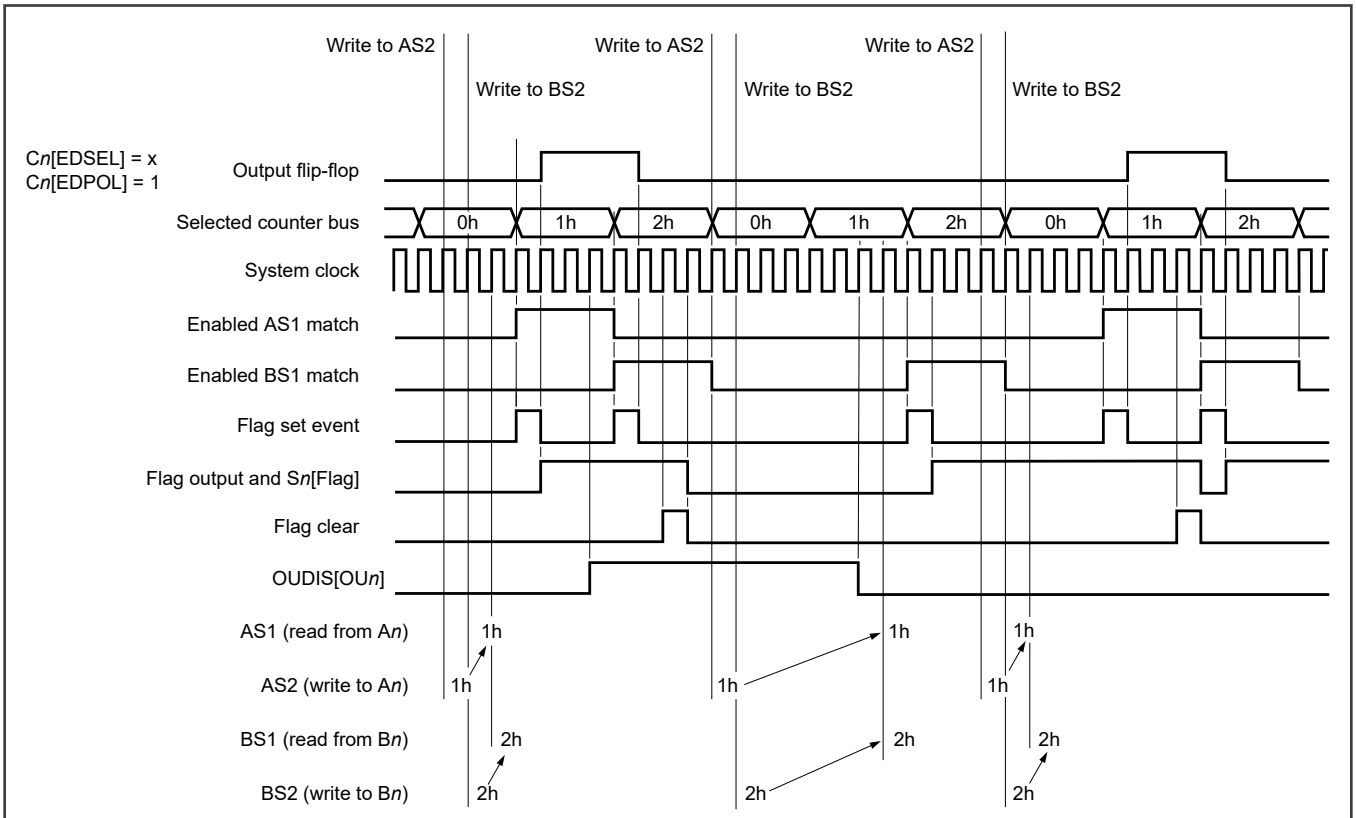

Figure 311. Timing example: transfer disabling

61.7.3.13 Pulse Edge Counting (PEC) mode

61.7.3.13.1 Overview

This mode counts the number of pulses or edges detected on the input for a desired time window. C*n*[EDSEL] and C*n*[EDPOL] determine which edges the UC counts.

Specify the window start time in AS1 and the end time in BS1. After you write to AS1, when the selected timebase matches comparator A, eMIOS resets the internal counter and starts counting input events. When the timebase matches comparator B, eMIOS:

- Disables the internal counter.
- Transfers the counter's content to AS2.
- Sets the input-capture flag (changes S*n*[FLAG] to 1).

You obtain the number of detected pulses by reading C*n*[C] or AS2.

Timing example continuous and Timing example single-shot show how to use the UC in continuous or single-shot operation.

61.7.3.13.2 PEC submodes and MODE field values

Table 349. PEC submodes and MODE field values

Operation	C*n*[MODE] (binary)
Continuous; the next match between comparator A and the selected timebase resets the internal counter and enables counting again. To guarantee coherent measurements when you read C*n*[C] after S*n*[FLAG] becomes 1, you must check if the timebase value is out of the time interval defined by AS1 and BS1. Alternately, AS2 (available in ALTA*n*[ALTA]) always holds the latest available measurement, providing coherent data at any time after the first set-flag event.	000_1010
Single-shot; The next match between comparator A and the selected timebase has no effect until you write to A*n*[A]. eMIOS also transfers the C*n*[C] value to AS2 when a match in the B comparator occurs.	000_1011

61.7.3.13.4 Timing example single-shot

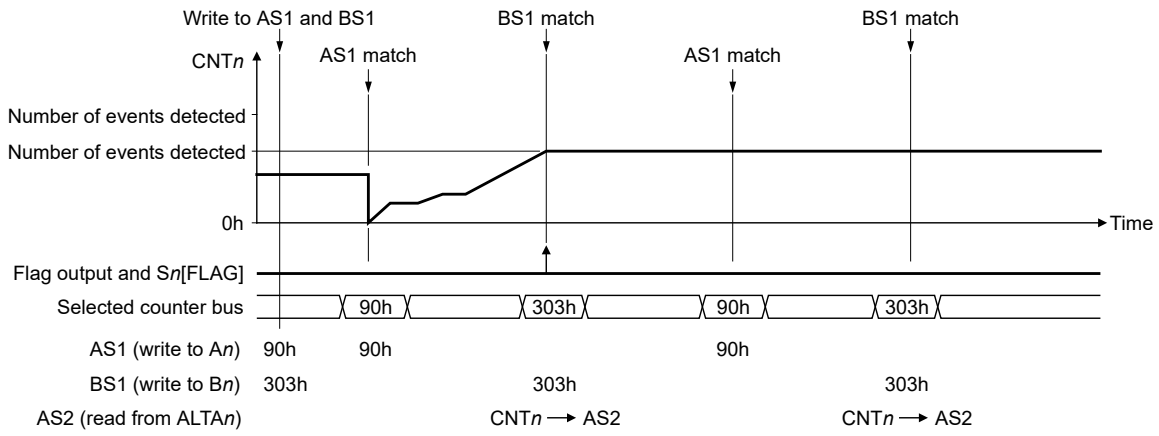

Figure 313. Timing example single-shot

61.7.3.14 Modulus Counter (MC) mode

61.7.3.14.1 Overview

In this mode, the UC produces a timebase for a counter bus or as a general purpose timer. The internal counter (C*n*[C]) counts up from the current value until it matches AS1.

Selecting external clock source (see MC submodes and MODE field values) causes the UC to uses the input signal pin as the source. You select the triggering polarity edge using Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must write only non-zero values to A*n*[A]. Writing to A*n*[A] or the internal counter may cause a match to be missed and the counter to roll over and resume operation in the next cycle. The channel writes 0 to BS1, which is not accessible by the MCU. You can read and write BS2, but it is not used in this mode.

61.7.3.14.2 MC submodes and MODE field values

Table 350. MC submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	001_0pp0[1]
External clock source	001_0pp1[1]
Internal counter reset on match start	001_0p0p[1]
Internal counter reset on match end	001_0p1p[1]
Up Count	001_00pp[1]
Up Count-Down Count	001_01pp[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

61.7.3.14.3 Up Count submode

Table 351. Up Count submode operation

Counter reset timing[1]	C*n*[MODE]		
	Bit 1	External clock (Bit 0 = 1)	Internal clock (Bit 0 = 0)
Reset on match start	0	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Increments the internal counter at the next input event, resulting in a short zero count.	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Maintains the internal counter at 0 on the next prescaler tick after the match. • Resumes counting on the next prescaler tick.
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match start and internal clock.	
Clear on match end	1	When the next input event after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).	When the next internal counter tick after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match end.	

1. If you select internal clock source and a prescaler value of 1 for the internal counter, the behavior is the same for both submodes.

See Timing example: Up Count submode.

61.7.3.14.4 Timing example: Up Count submode

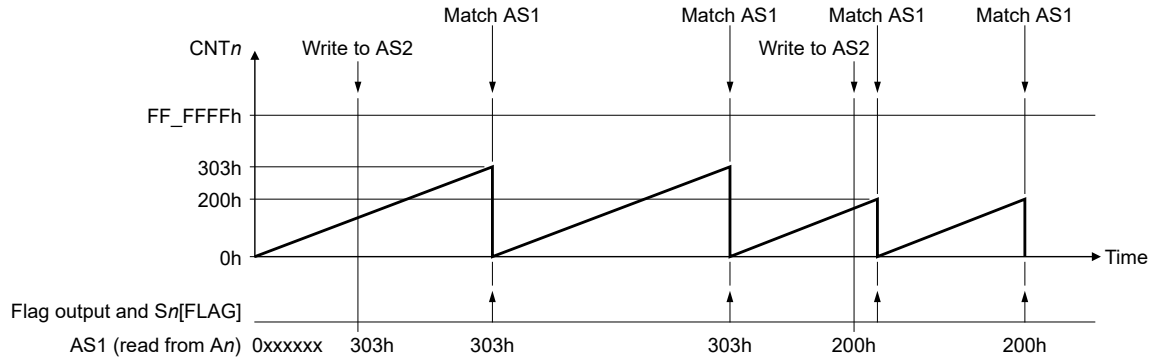

Figure 314. Timing example: Up Count submode

61.7.3.14.5 Up Count-Down Count submode operation

In Up Count-Down Count submode:

- When the internal counter matches AS1, the counter begins decrementing and the UC sets the input-capture flag (S*n*[FLAG]).
- When the internal counter matches BS1, the counter begins incrementing and, if in clear on match end operation (C*n*[1] = 1), the UC sets the input-capture flag (S*n*[FLAG]).

See Timing example: Up Count-Down Count submode.

61.7.3.14.6 Timing example: Up Count-Down Count submode

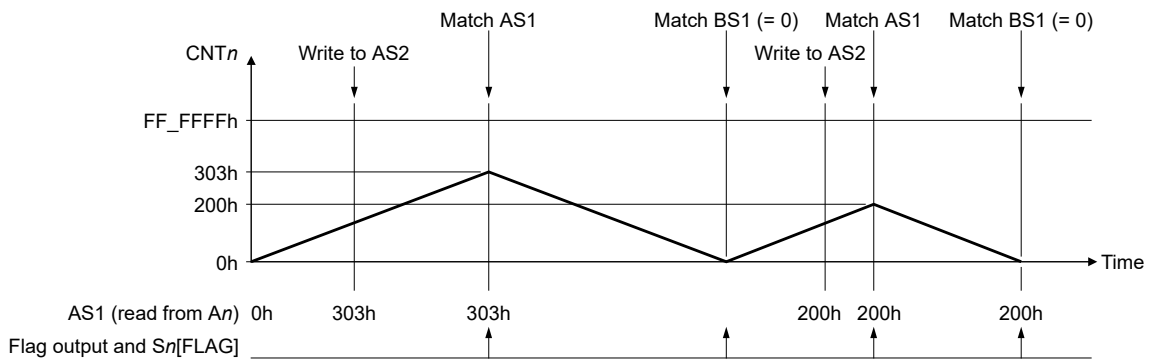

Figure 315. Timing example: Up Count-Down Count submode

61.7.3.14.7 Up Count with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or BS1 in the Up Count-Down Count submode, the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2*n*[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

61.7.3.14.8 Timing example: Up Count mode with delayed reload

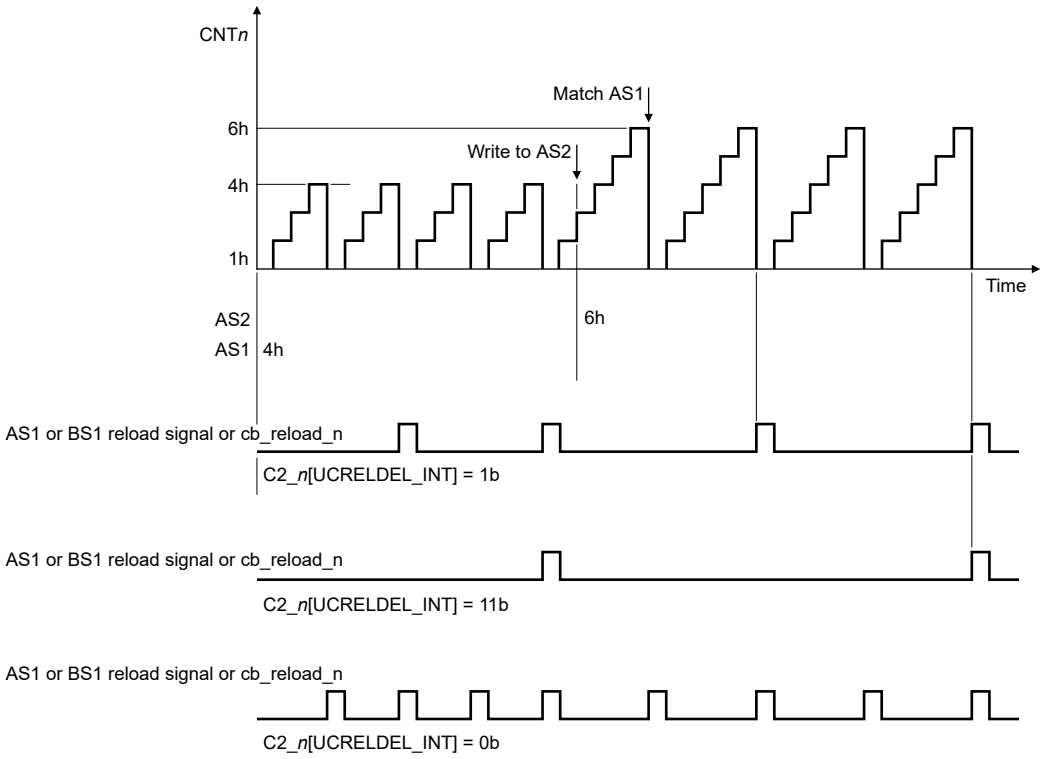

Figure 316. Timing example: Up Count mode with delayed reload

61.7.3.15 Modulus Counter Buffered (MCB) mode

61.7.3.15.1 Overview

In this mode, the UC generates a timebase that can be shared with other channels through the internal counter buses. AS1 is double-buffered, so you can change AS2 at any time with smooth transitions. The UC updates AS1 at the counter period boundary, which is when the internal counter (CNT*n*[C]) transitions to 1h.

Selecting external clock (see MCB submodes and MODE field values) causes the UC to use the input signal as the source. You select the triggering edge with Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must ensure the internal counter is in the range from 1h to the AS1 value; otherwise, the A*n*[A] match does not occur and this causes the internal counter to wrap at the maximum counter value (FFFFh for a 16-bit counter). After a counter wrap occurs, the UC resets the counter to 1h and resumes normal operation.

NOTE

Do not write 1h to the internal counter when the UC is in Freeze state. Doing so can cause the match to be missed and the counter to overflow.

61.7.3.15.2 MCB submodes and MODE field values

Table 352. MCB submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	101_0pp0b[1]

Table continues on the next page...

Table 352. MCB submodes and MODE field values (continued)

Submode or function	C*n*[MODE] (binary)
External clock source	101_0pp1b[1]
Up Count	101_000p[1]
Reserved	101_001p[1]
Up Count-Down Count	101_01pp[1]
Flag set only on match start	101_010p[1]
Flags also set at counter period boundary	101_011p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

61.7.3.15.3 Up Count submode

In the Up Count submode:

- The internal counter (CNT*n*[C]) starts counting up (incrementing) from its current value.
- When the internal counter matches AS1 and a clock tick occurs (either prescaled clock or input pin event), the UC resets the internal counter to 1h.
- The UC sets the input-capture flag (S*n*[FLAG]) one system clock cycle after the match occurs.

You must write only values greater than 1h to AS1.

The boundary between counter period *n* and period *n*+1 occurs when the UC changes the internal counter from the AS1 value in period *n* to 1h in period *n*+1. AS1 defines the counter period.

The UC asserts the AS1 load signal (which has a duration of one system clock cycle) at the last system clock cycle of a counter period. This causes the UC to update AS1 with AS2 at the period boundary, at the same time that it resets the counter to 1h. Therefore, any value you write to AS2 during period *n* updates AS1 at the next period boundary and the UC uses it in period *n*+1. See Timing example: Up Count submode.

You can use Output Update Disable (OUDIS) to delay the update of AS1 for synchronization.

The UC sets the input-capture flag (S*n*[FLAG]) at the period boundary. See Timing example: Up Count submode flag assertion.

61.7.3.15.4 Timing example: Up Count submode

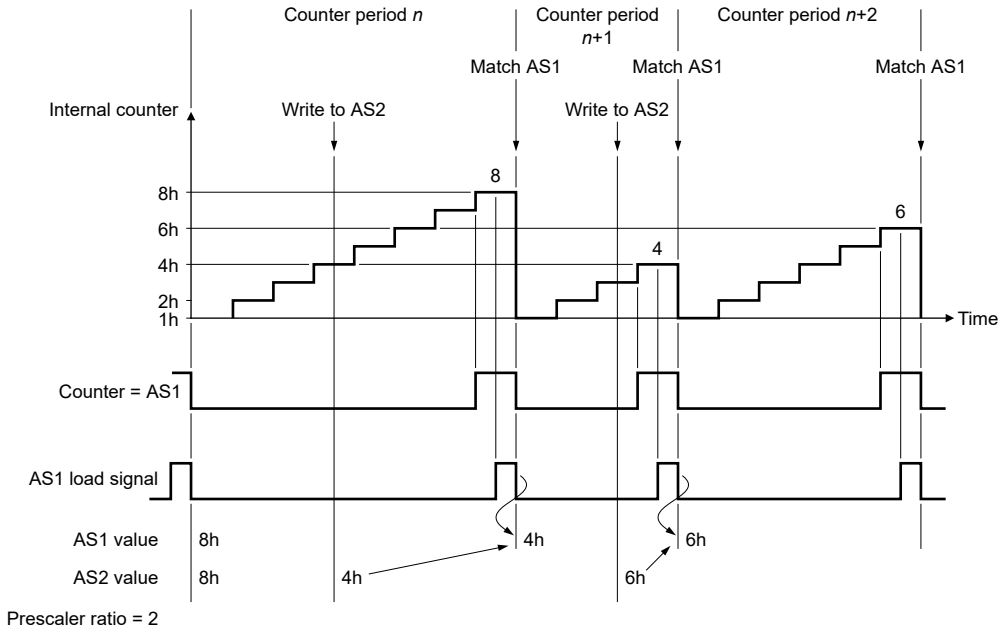

Figure 317. Timing example: Up Count submode

61.7.3.15.5 Timing example: Up Count submode flag assertion

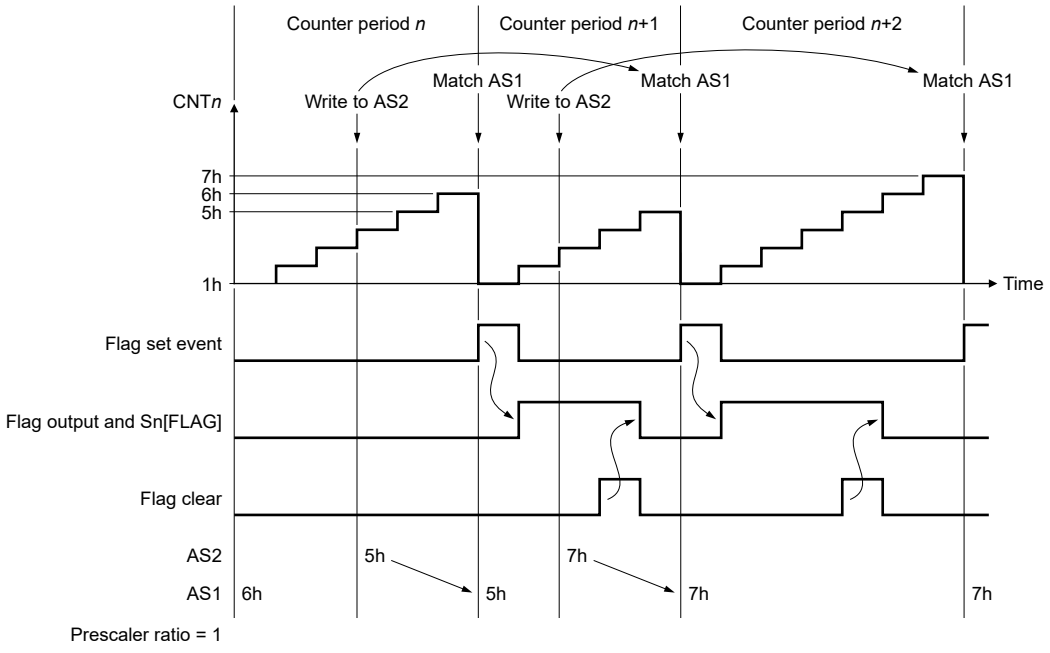

Figure 318. Timing example: Up Count submode flag assertion

61.7.3.15.6 Up Count-Down Count submode

In Up Count-Down Count submode:

- The counter period is: (2 x AS1) – 2. The counter changes direction at AS1 match and counts down (decrements) until it reaches 1h, then counts up (increments) again.
- BS1 generates a match to start the internal counter incrementing, and BS1 cannot be changed in this submode.

The UC updates AS1 at the counter period boundary. If you write AS2 (write A*n*[A]) during period *n*, the UC uses this new value in period *n*+1 for AS1 match. You can disable updates of AS1 (OUDIS[OU*n*]). See Timing example: Up Count-Down Count submode.

The UC sets the input-capture flag (S*n*[FLAG]) at AS1 match start, and may also do so at the period boundary. See Overview and Timing example: Up Count-Down Count submode flag assertion.

61.7.3.15.7 Timing example: Up Count-Down Count submode

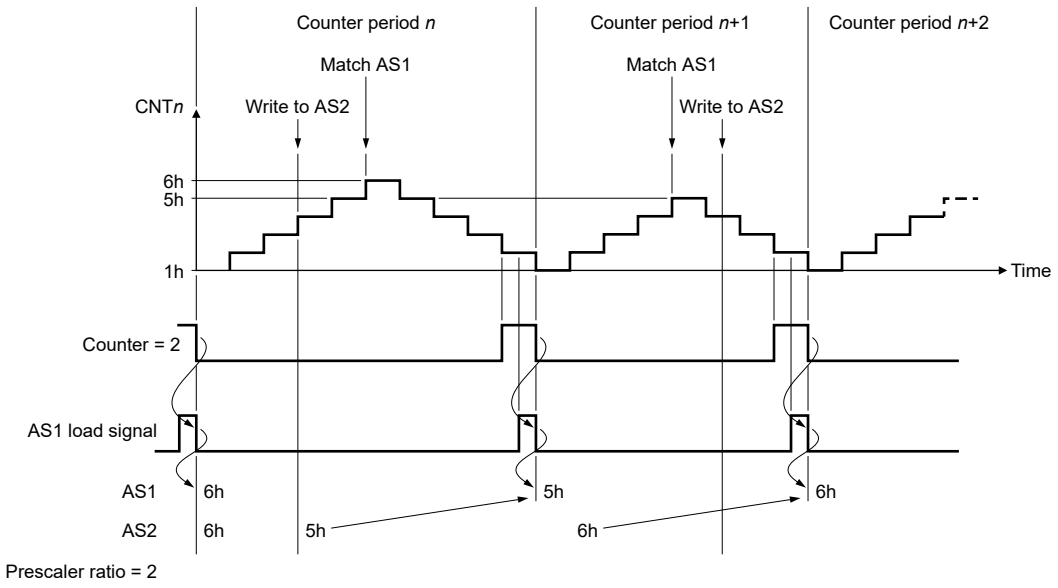

Figure 319. Timing example: Up Count-Down Count submode

61.7.3.15.8 Timing example: Up Count-Down Count submode flag assertion

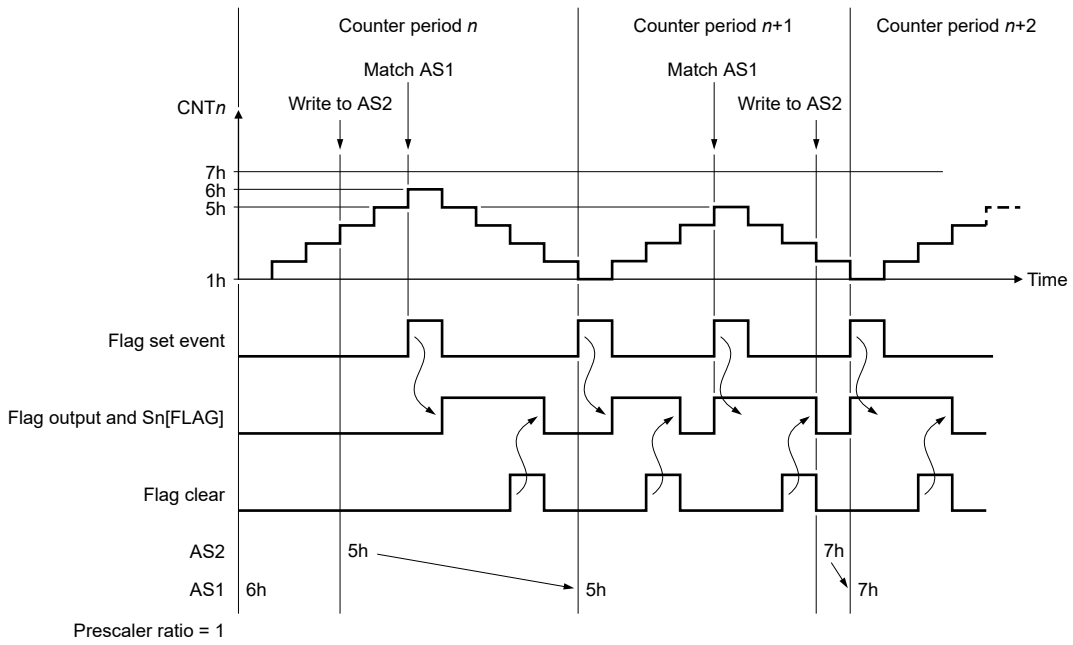

Figure 320. Timing example: Up Count-Down Count submode flag assertion

61.7.3.15.9 Up Count mode with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or 1h in the Up Count-Down Count submode (see MCB submodes and MODE field values), the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

61.7.3.15.10 Timing example: Up Count mode with delayed reload

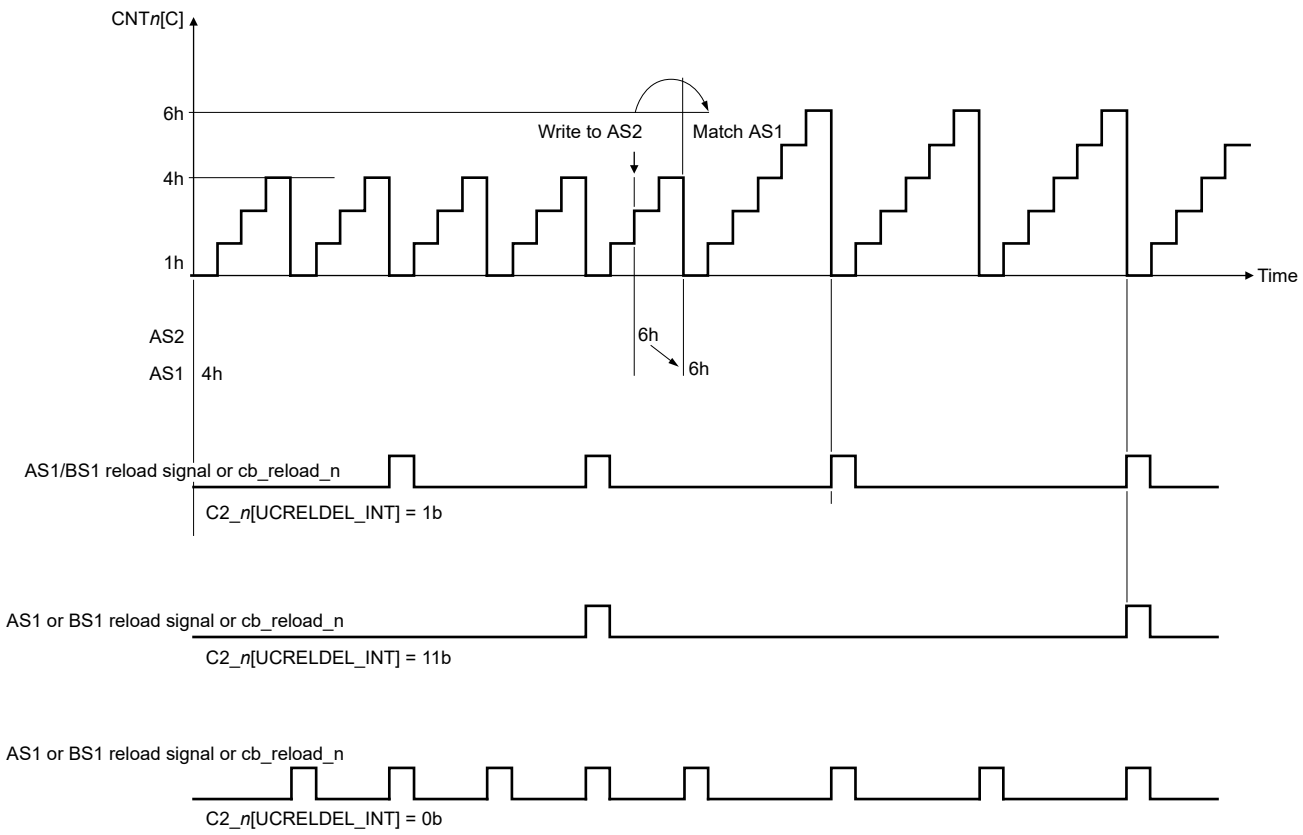

Figure 321. Timing example: Up Count mode with delayed reload

61.7.3.16 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode

61.7.3.16.1 Overview

In this mode, the UC produces an output signal that has:

- A duty cycle determined by AS1.
- A period of BS1.

The double-buffered AS1 and BS1 registers produce smooth duty-cycle and period transitions when you change AS1 and BS1 during runtime.

See Table 359 for the values that you must write to C*n*[MODE] to enter this mode.

To provide smooth and consistent channel operation:

- AS1 and BS1 are both double-buffered to allow smooth signal generation when changing the register values.
- There is a delay from the AS1 match to the output pin transition (see AS1 and BS1 match timing).
- The internal counter ranges from 1h to BS1. When you write to BS1, you must write only values greater than 1h. Writing 0h or 1h leads to unpredictable results.

When a match on comparator A occurs, the UC drives C*n*[EDPOL] onto the output flip-flop. When a match on comparator B occurs, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop. A BS1 match also causes the internal counter to transition to 1h, thus restarting the counter cycle.

The UC automatically selects the internal channel counter as the timebase when you select this mode. The mode supports duty cycles ranging from 0% to 100%.

61.7.3.16.2 OPWFMB submodes and MODE field values

Table 353. OPWFMB submodes and MODE field values

Match behavior	C*n*[MODE] (binary)
When BS1 matches the selected counter	101_1000
When AS1 or BS1 match the selected counter	101_1010

61.7.3.16.3 Avoid counter wrapping

When the UC enters OPWFMB mode, the output flip-flop acquires the value of C*n*[EDPOL]. If the UC transitions from GPIO to OPWFMB mode when the internal counter value is not within the range 1h–BS1, then the B match never occurs. Because the match never occurs, the internal counter wraps at the maximum counter value—FFFFh for a 16-bit counter. When the counter wrap occurs, the counter returns to 1h and normal OPWFMB operation resumes. Therefore, to avoid this counter wrapping, ensure that the counter value is within the range 1h–BS1 before the UC enters OPWFMB mode.

61.7.3.16.4 AS1 and BS1 match timing

As illustrated in Timing example: AS1 and BS1 match, the output pin transition occurs when the AS1 or BS1 match signal deasserts, as indicated by the AS1 match negative-edge detection signal. If you write 4h to AS1, the output pin transitions 4 counter increments plus one system clock cycle after the counter period starts.

61.7.3.16.5 Timing example: AS1 and BS1 match

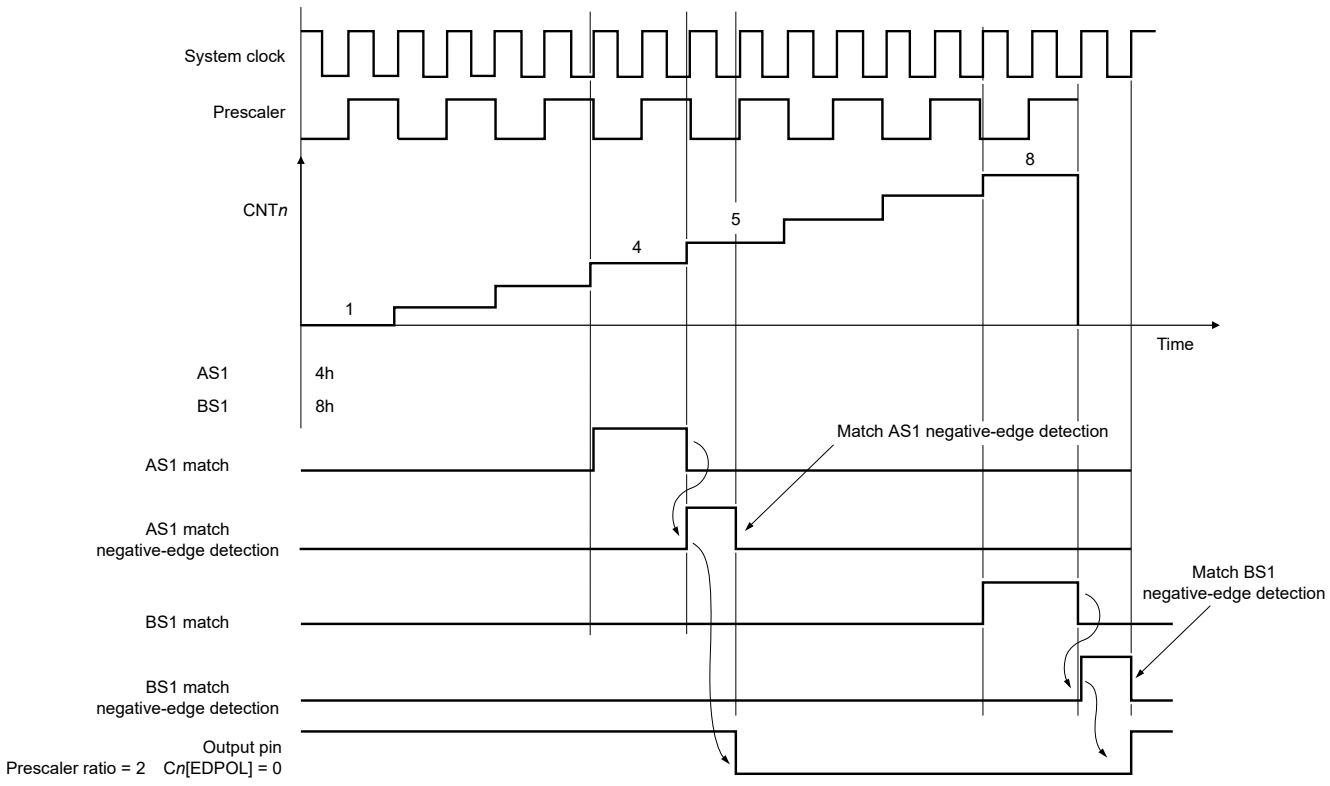

Figure 322. Timing example: AS1 and BS1 match

61.7.3.16.6 0% duty cycle

Timing example: AS1 = 0 illustrates the generated output signal when AS1 = 0, which results in a 0% duty cycle.

Because the internal counter never reaches zero in this situation, the UC infers a match as if AS1 = 1h. However, it is the positive edge of the match signal that triggers the output pin transition instead of the negative edge, which is what happens when AS1 = 1h. The AS1 positive-edge match signal from period *n*+1 occurs at the same time as the BS1 negative-edge match signal from period *n*. This timing allows the AS1 positive-edge match to mask the BS1 negative-edge match when they occur at the same time. As a result, no transition occurs on the output flip-flop and the UC generates a 0% duty cycle.

61.7.3.16.7 Timing example: AS1 = 0

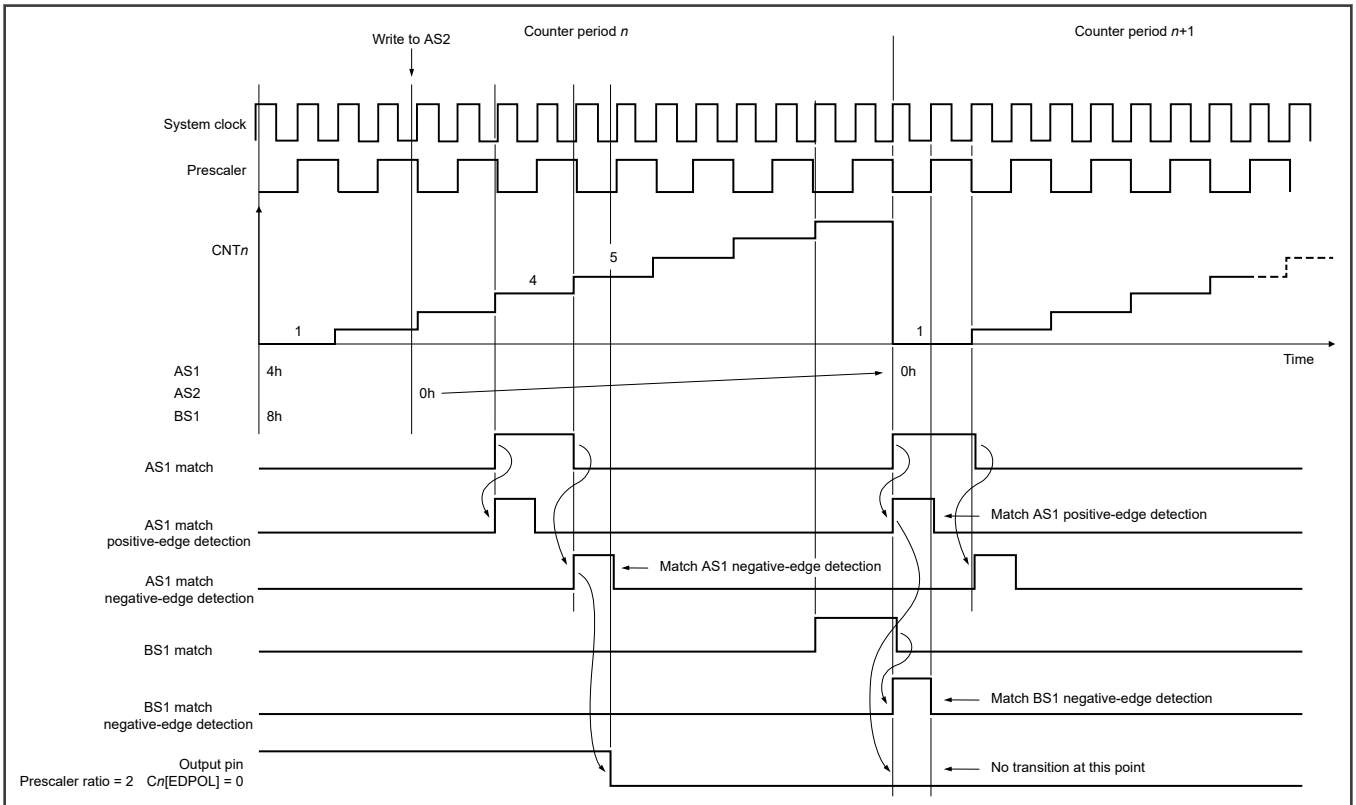

Figure 323. Timing example: AS1 = 0

61.7.3.16.8 Loading AS1 and BS1

As illustrated in Timing example: AS1 and BS1 update and FLAGs, AS1 and BS1 both use the same signal, generated at the last system clock cycle of a counter period. Therefore, eMIOS updates AS1 and BS1 with AS2 and BS2 values, respectively, at the same time that it changes the internal counter (CNT*n*[C]) to 1h. This event is the counter period boundary. The load signal pulse lasts for one system clock cycle. If you write AS2 and BS2 within counter period *n*, their values are available in AS1 and BS1, respectively, at the first clock cycle of counter period *n*+1. The UC then uses these new values for matches at counter period *n*+1. You can use Output Update Disable (OUDIS) to delay updating AS1 and BS1 for synchronization purposes.

61.7.3.16.9 Timing example: AS1 and BS1 update and FLAGs

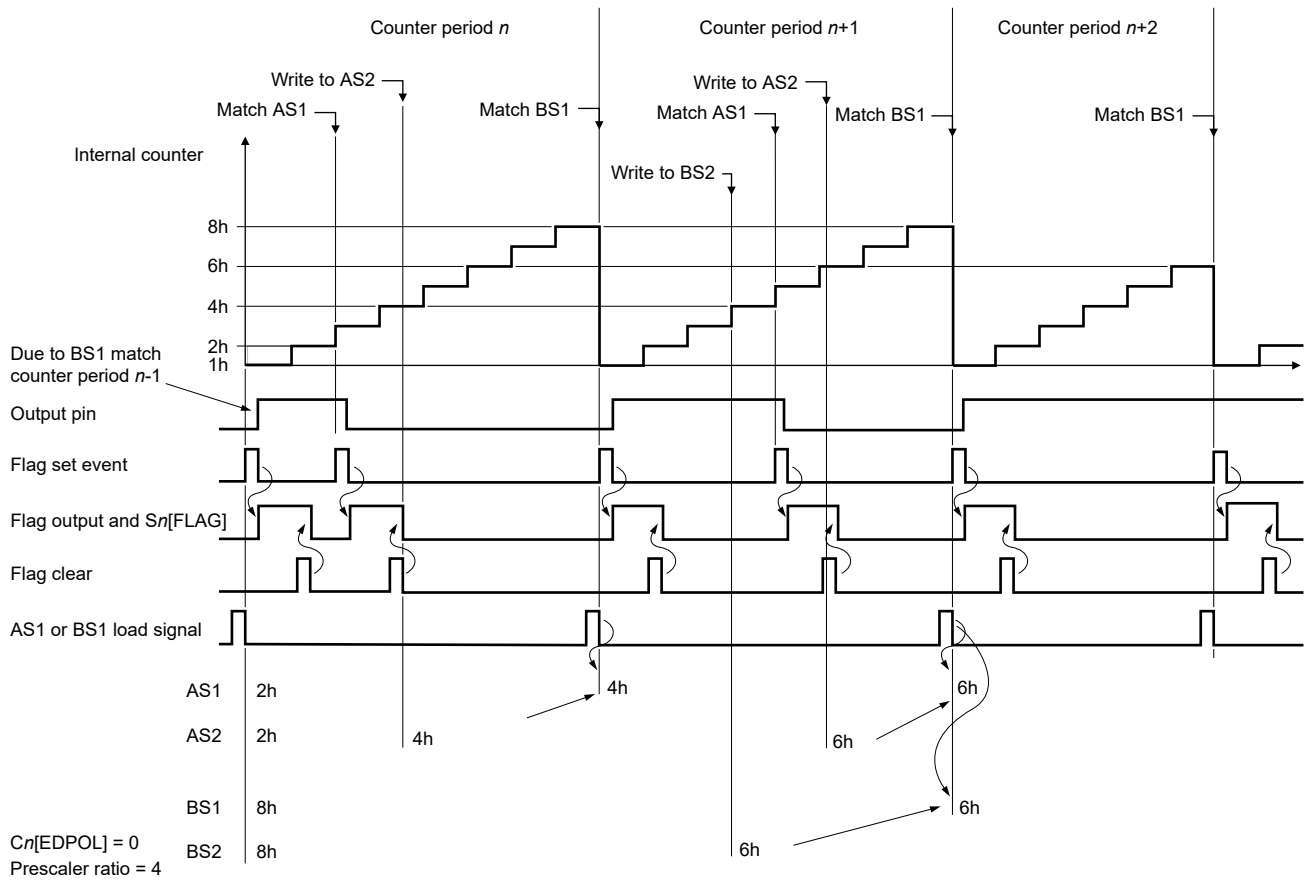

Figure 324. Timing example: AS1 and BS1 update and FLAGs

61.7.3.16.10 Flag generation

Timing example: AS1 and BS1 update and FLAGs assumes that both the channel and global prescalers are 1h (divide ratio of 2), causing the internal counter to transition every four system clock cycles. You can configure flags to be generated only on BS1 matches when bit 1 of C*n*[MODE] is 0, or on both AS1 and BS1 matches when that bit is 1. Because the BS1 flag occurs at the period boundary, you can use this flag to indicate that the AS2 or BS2 data written in period *n* has been loaded to AS1 or BS1, respectively, thereby generating matches in period *n*+1. Flag operation is synchronous, which means the flag sets one system clock cycle after the set-flag event.

61.7.3.16.11 Output disable

As illustrated in Timing example: active output disabled, the output-disable feature in OPWFMB mode forces the channel output flip-flop to the value of C*n*[EDPOL]. This functionality supports applications that use active-high signals and a high-to-low transition at an AS1 match. In this case, you must write 0 to C*n*[EDPOL]. You also must configure the internal counter to transition on every system clock cycle (write 0 to both GCP and CP).

The output-disable feature operates synchronously, meaning that the assertion of the Output Disable input signal causes the channel output flip-flop to transition to C*n*[EDPOL] at the next system clock cycle. If the Output Disable input pin deasserts, the output-signal transition occurs at the next AS1 or BS1 match.

Timing example: active output disabled assumes that the Output Disable input is enabled (using C*n*[ODIS]) and selected (using C*n*[ODISSL]). See UC Control n (C0 - C23) for a detailed description of the ODIS and ODISSL fields that enable and select the Output Disable inputs, respectively.

61.7.3.16.12 Timing example: active output disabled

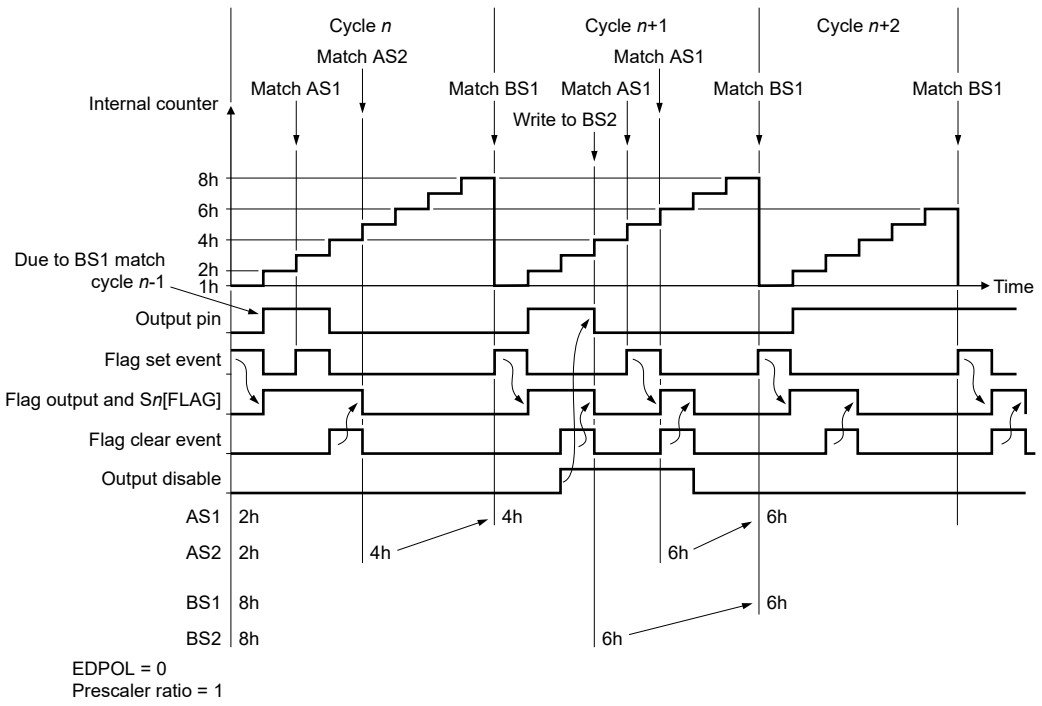

Figure 325. Timing example: active output disabled

61.7.3.16.13 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

61.7.3.16.14 100% and 0% duty cycles

Timing example: from 100% to 0% duty cycle illustrates the generation of 100% and 0% duty-cycle signals. Initially, AS1 = 8h and BS1 = 8h. In this case, a BS1 match has precedence over an AS1 match—therefore, the output flip-flop acquires the complement of C*n*[EDPOL]. This configuration corresponds to a 100% duty-cycle signal. The same output signal can be generated for any AS1 value greater than or equal to BS1.

If AS1 is 0, the UC generates a 0% duty-cycle signal. In this case, the BS1 = 8h match from period 8 occurs at the same time as the AS1 = 0h match from period 9. See Timing example: AS1 = 0 for AS1 and BS1 match generation. In this case, an AS1 match has precedence over a BS1 match, and the output signal transitions to C*n*[EDPOL].

61.7.3.16.15 Timing example: from 100% to 0% duty cycle

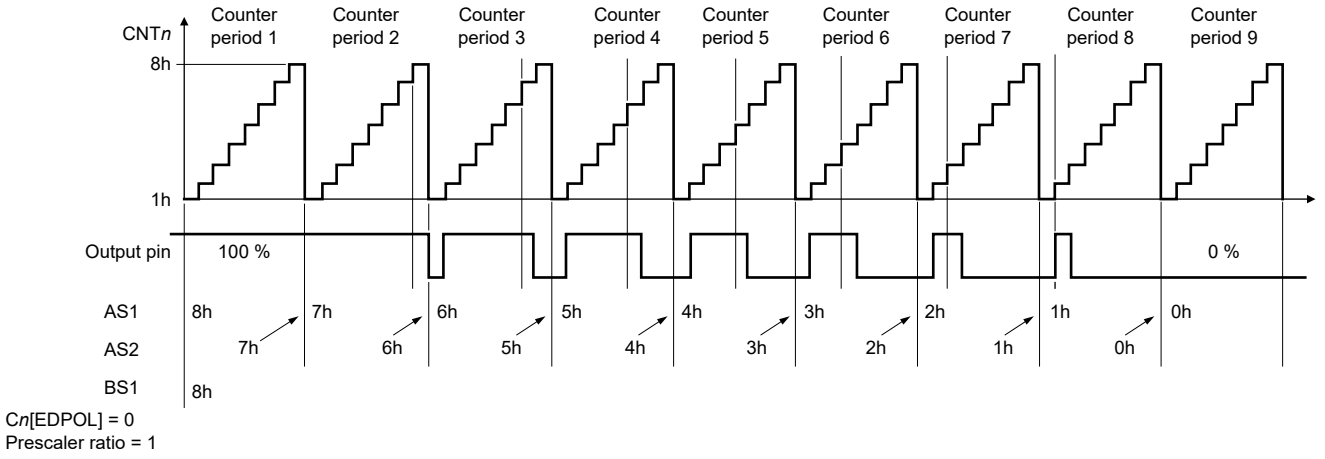

Figure 326. Timing example: from 100% to 0% duty cycle

61.7.3.17 Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

61.7.3.17.1 Overview

In this mode, the UC generates a center-aligned PWM pulse with dead time insertion in the leading or trailing edge. See OPWMCB functions and MODE field values. AS1 and BS1 are double-buffered to allow smooth output signal generation when you change the AS2 or BS2 values.

When the UC enters OPWMCB mode from GPIO mode:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Select the timebase using Bus Select (C*n*[BSL]). The timebase you select must be running in Up Count-Down Count mode. See Timing example: Up Count submode flag assertion. You must start the MCB timebase after the UC enters OPWMCB mode to avoid missing a match on the first duty cycle.
- Store the ideal duty cycle for the PWM signal in AS1 (write to A*n*[A]), which the UC compares with the selected timebase.
- Store the dead time value in BS1 (write to B*n*[B]), which the UC compares with the internal counter (CNT*n*[C]).

The internal counter may use the internal prescaler ratio, while the selected timebase may use a different prescaler ratio. The UC always resets the internal counter to 1h when an AS1 match occurs.

As in OPWMB and OPWFMB modes, the UC generates the match signal which compares the selected timebase with AS1 or BS1. When the UC deasserts the channel's combinational comparator output signal, it uses the match signal to assert or negate the channel's output flip-flop. See Timing example: AS1 and BS1 match for an illustration of the delay from match to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB mode with respect to match behavior and output pin transition.

See Entering OPWMCB mode.

61.7.3.17.2 OPWMCB functions and MODE field values

Table 354. OPWMCB functions and mode field values

Function	C*n*[MODE] (binary)
Insert trailing edge dead time with duty cycle determined by BS1 + AS1	101_11p0[1]

Table continues on the next page...

Table 354. OPWMCB functions and mode field values (continued)

Function	C*n*[MODE] (binary)
Insert leading edge dead time with duty cycle determined by BS1 – AS1	101_11p1[1]
Assert the input capture flag (Sn[FLAG]) on the trailing edge of the output PWM signal	101_110p[1]
Assert the input capture flag (Sn[FLAG]) on both edges of the output PWM signal	101_111p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

61.7.3.17.3 Entering OPWMCB mode

To enter OPWMCB mode (this procedure assumes the channel is initially in GPIO mode):

1. Disable the GCP (write 0 to MCR[GPREN]).
2. For the timebase (MCB) channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the internal counter (write 1h to CNT*n*[C]).
   c. Initialize the A data (write appropriate value to A*n*[A]).
   d. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   e. Select the CP ratio (C*n*[UCPRE]).
   f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For the OPWMCB channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the A data (write appropriate value to A*n*[A]).
   c. Initialize the B data (write appropriate value to B*n*[B]).
   d. Select the timebase input (C*n*[BSL]).
   e. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   f. Select the CP ratio (C*n*[UCPRE]).
   g. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).

61.7.3.17.4 Timing example: AS1 and BS1 load

When the selected counter bus transitions from 2h to 1h:

- The UC loads AS1 and BS1 as shown in the following figure.
- This event defines the counter period boundary.

The UC loads the values you write to AS2 or BS2 within period *n* into AS1 or BS1, respectively, and uses them to generate matches in period *n*+1.

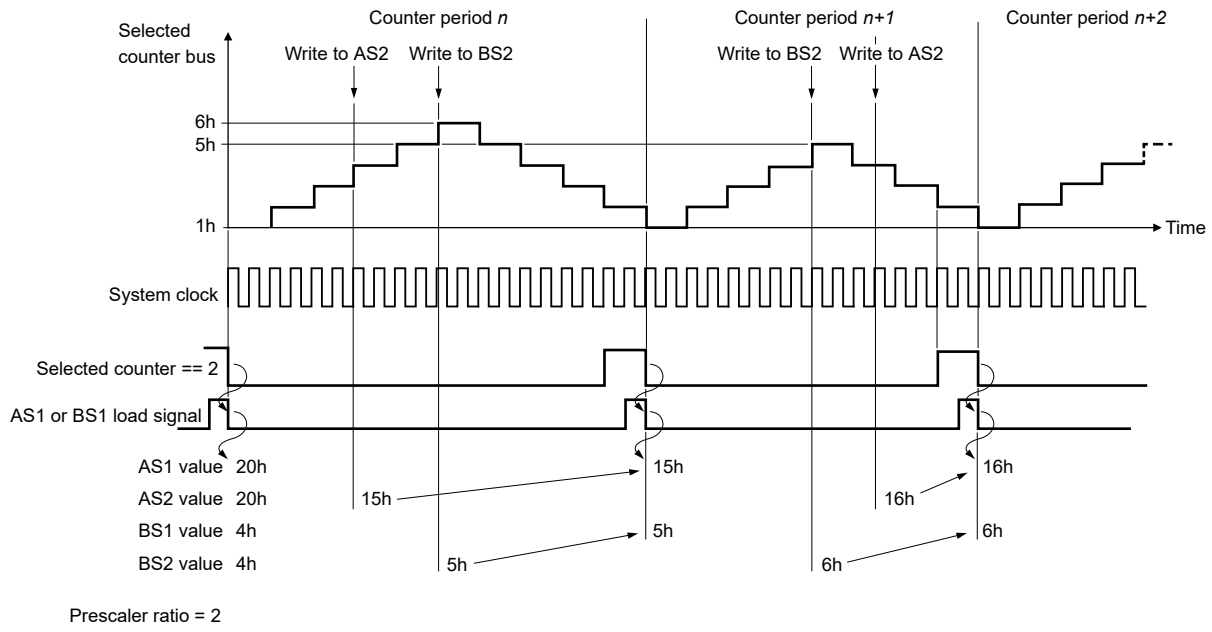

Figure 327. Timing example: AS1 and BS1 load

61.7.3.17.5 Operation sequence with leading edge dead time insertion

When operating with leading edge dead time insertion:

1. When the first AS1 match occurs, the UC writes 1h to the internal counter.
2. When a match between BS1 and the internal timebase occurs, the UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
3. When the next match between AS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats the above sequence continuously.

You must not allow the internal counter to reach 0h as the result of a rollover. To avoid this, you must not write a value greater than

2 x ((external Count Up limit) – A*n*[A])

into B*n*[B].

See Timing example: leading dead time insertion.

61.7.3.17.6 Timing example: leading dead time insertion

This example illustrates two cycles of a center-aligned PWM signal. AS1 and BS1 values change within the same period, which allows you to change the duty cycle and dead time values at the same time.

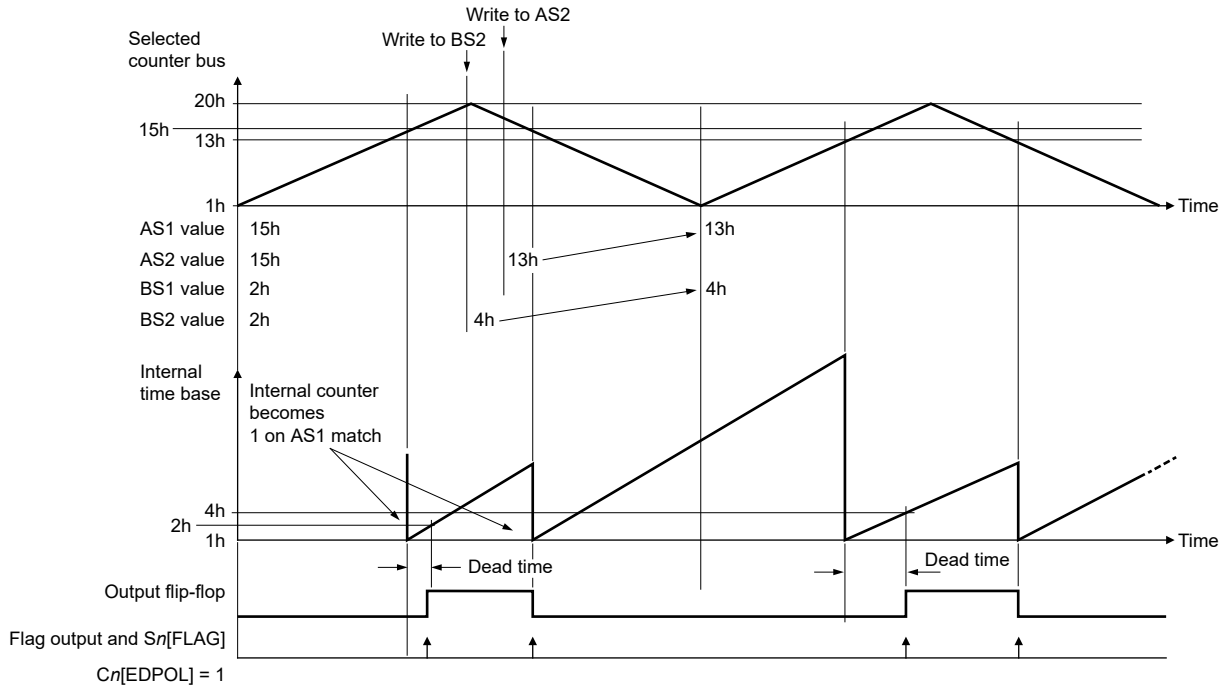

Figure 328. Timing example: leading dead time insertion

61.7.3.17.7 Operation sequence with trailing edge dead time insertion

When operating with trailing edge dead time insertion:

1. When the first match between AS1 and the selected timebase occurs, the UC:
   a. Drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
   b. Writes the internal counter (CNT*n*[C]) to 1h.
2. When the second match between AS1 and the selected timebase occurs, the UC:
   a. Writes the internal counter to 1h.
   b. Enables BS1 matches.
3. When a match between BS1 and the selected timebase occurs, the UC drives the the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats this sequence continuously.

61.7.3.17.8 Timing example: trailing dead time insertion

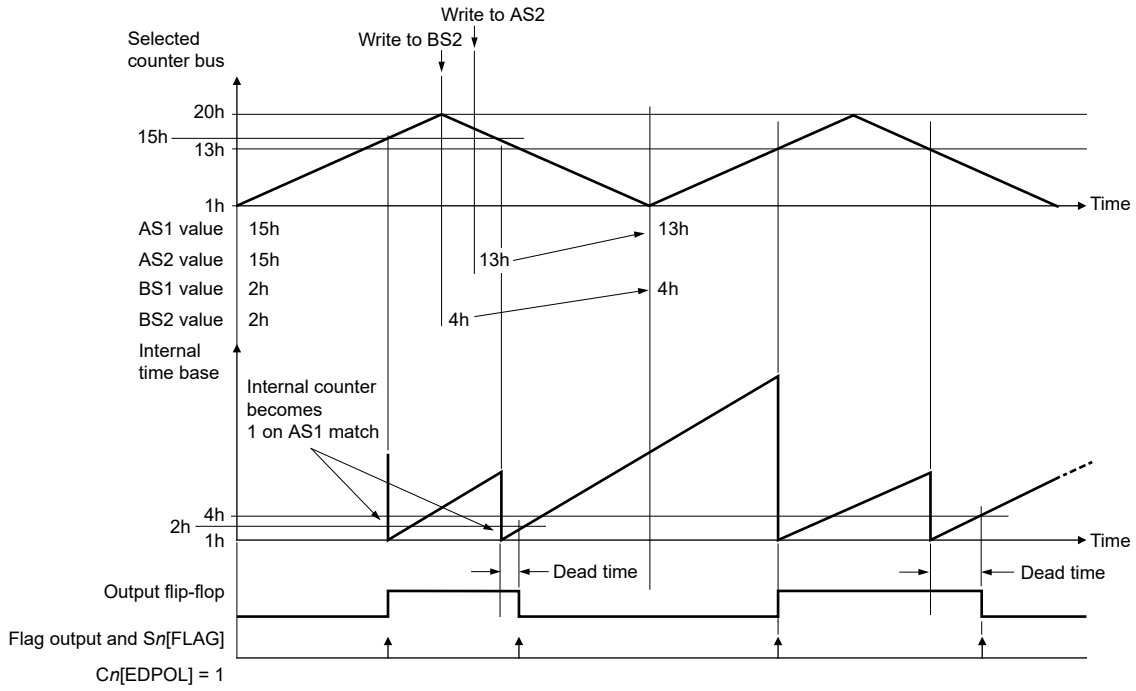

Figure 329. Timing example: trailing dead time insertion

61.7.3.17.9 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

When you select leading edge dead time insertion:

- Force Match A drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

When you select trailing edge dead time insertion:

- Force Match A drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

Force Match operation does not write 1h to the internal timebase.

Force Match operation does not set the input-capture flag.

When you assert Force Match A and Force Match B at the same time, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop. This is the equivalent of saying that Force Match A has precedence over Force Match B when you select leading edge dead time insertion, and Force Match B has precedence over Force Match A when you select trailing edge dead time insertion.

Force Match A and Force Match B have the same output transition behavior in both Freeze state and unfrozen state.

61.7.3.17.10 Duty cycle

You generate a duty cycle from 0% to 100% by writing appropriate values to AS1 and BS1 relative to the period of the external timebase.

To generate a 100% duty cycle waveform:

- Select trailing edge dead time insertion (see OPWMCB functions and MODE field values).
- Write 1h to Edge Polarity (C*n*[EDPOL]).
- The BS1 match must occur on or after the counter period boundary (external counter = 1).

You can also generate a 100% duty cycle waveform by writing 1h to AS1. However, if you do this before the UC enters OPWMCB mode, a 100% duty cycle may not occur in the first PWM period depending upon the pin state at mode entry.

To generate a 0% duty cycle waveform:

- AS1 must be greater than the maximum value of the selected counter period.
- The pin must start the current period with the complement value of Edge Polarity (C*n*[EDPOL]). If starting at 100% duty cycle, you can change Edge Polarity (C*n*[EDPOL]) to its complement by forcing the pin (see Force match).

You must write only non-zero values to AS1. If you write the maximum value of the external counter given by

(external counter period)/2

to AS1, the UC constantly drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

UC logic prevents matches from one period propagating to the next period. In trailing edge dead time insertion, the UC masks out BS1 matches that occur late in period *n*, so matches in period *n*+1 are unaffected and the output flip-flop does not transition.

61.7.3.17.11 Timing example: duty cycle

To generate a 100% duty cycle output waveform, write 4h to AS1 and 3h to BS1, as illustrated in this diagram. In this case, the trailing edge is at the boundary of counter period *n*+1, which actually belongs to period *n*+2 and therefore does not cause the output flip-flip to transition.

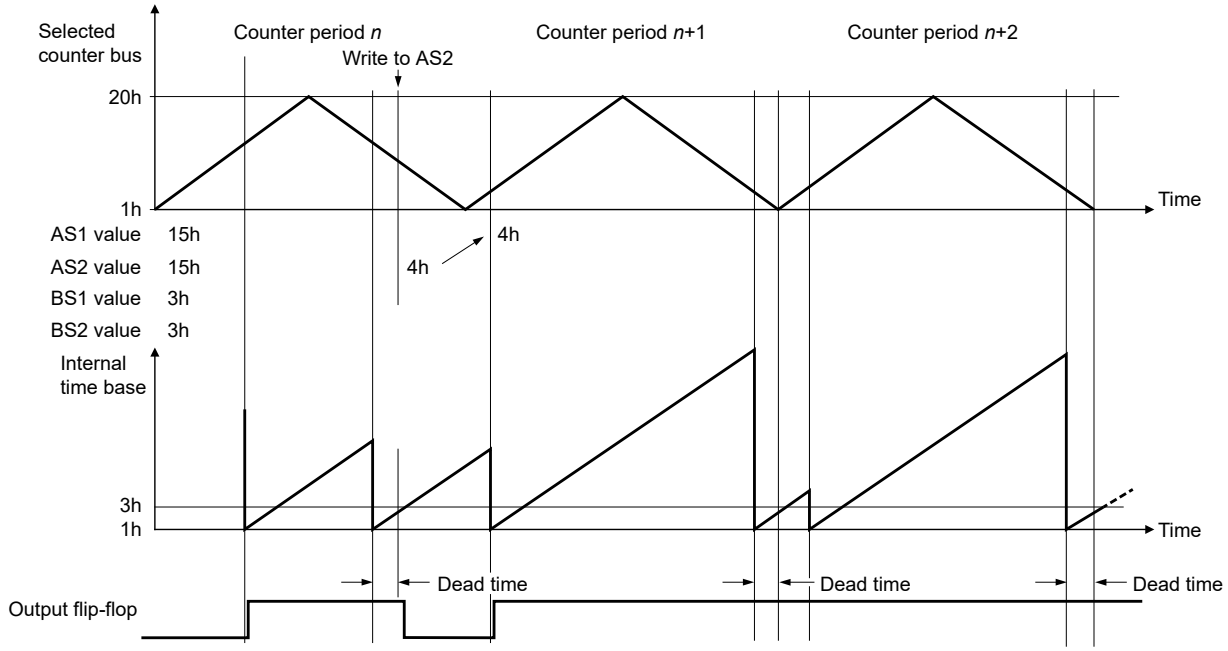

Figure 330. Timing example: duty cycle

61.7.3.17.12 Output disable

You can use Output Update Disable (write 0 to OUDIS[OU*n*]) to disable AS1 and BS1 updates. This allows you to update AS1 and BS1 in the same counter period and synchronize the loading of these registers with the loading of AS1 or BS1 in other channels.

Asserting Output Update Disable drives the complement of Edge Polarity (C*n*[EDPOL]) on output flip-flop. The internal channel matches continue to occur, and therefore the UC continues to set flags.

When you deassert Output Update Disable, the output flip-flop is again controlled by AS1 and BS1 matches. The UC transitions the output flip-flop only on system clock edges.

61.7.3.18 Output PWM Buffered (OPWMB) mode

61.7.3.18.1 Overview

In this mode, the UC produces PWM pulses with programmable leading and trailing edge placement. You must select an external counter driven in MCB Up mode from one of the counter buses. AS1 and BS1 define the first and second edges, respectively. C*n*[EDPOL] defines the output signal polarity. If C*n*[EDPOL] = 0, a negative edge occurs when AS1 matches the selected counter bus and a positive edge occurs when BS1 matches the selected counter bus.

See OPWMB submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

AS1 and BS1 are double-buffered and updated from AS2 and BS2, respectively, at the cycle boundary. The load operation is similar to the one that occurs in OPWFMB mode. See Timing example: AS1 and BS1 update and FLAGs for more information about AS1 and BS1 updates.

When the UC enters OPWMB mode, the UC drives C*n*[EDPOL] on the output flip-flop.

These rules apply to OPWMB mode:

- If the AS1 and BS1 matches occur at the same time within the same counter period, the BS1 match has precedence over the AS1 match.
- An AS1 = 0 match in period *n* has precedence over a BS1 match in period *n*-1.
- The UC masks out AS1 matches if they occur after a BS1 match within the same period.
- The UC loads any value that you write to AS2 or BS2 in period *n* into AS1 and BS1 at the following period boundary (assuming that the corresponding OU*n* field of Output Update Disable (OUDIS) is 0). Therefore, the UC uses the new values for AS1 and BS1 matches in period *n*+1.

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 is programmed to the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the flag output transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

61.7.3.18.2 OPWMB submodes and MODE field values

Table 355. OPWMB submodes and MODE field values

When FLAG generation occurs	C*n*[MODE] (binary)
At a BS1 match	110_0000
At an AS1 or BS1 match	110_0010

61.7.3.18.3 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

61.7.3.18.4 Matches and flag operation

Timing example: matches and flags illustrates the operation of OPWMB mode with an emphasis on AS1 and BS1 matches and the transition of the channel output pin. The output pin transitions are based on the negative edges of the AS1 and BS1 match signals. AS1 becomes zero in period *n*+1. In this case, the UC uses the match positive edge instead of the negative edge to transition the output flip-flop.

61.7.3.18.5 Timing example: matches and flags

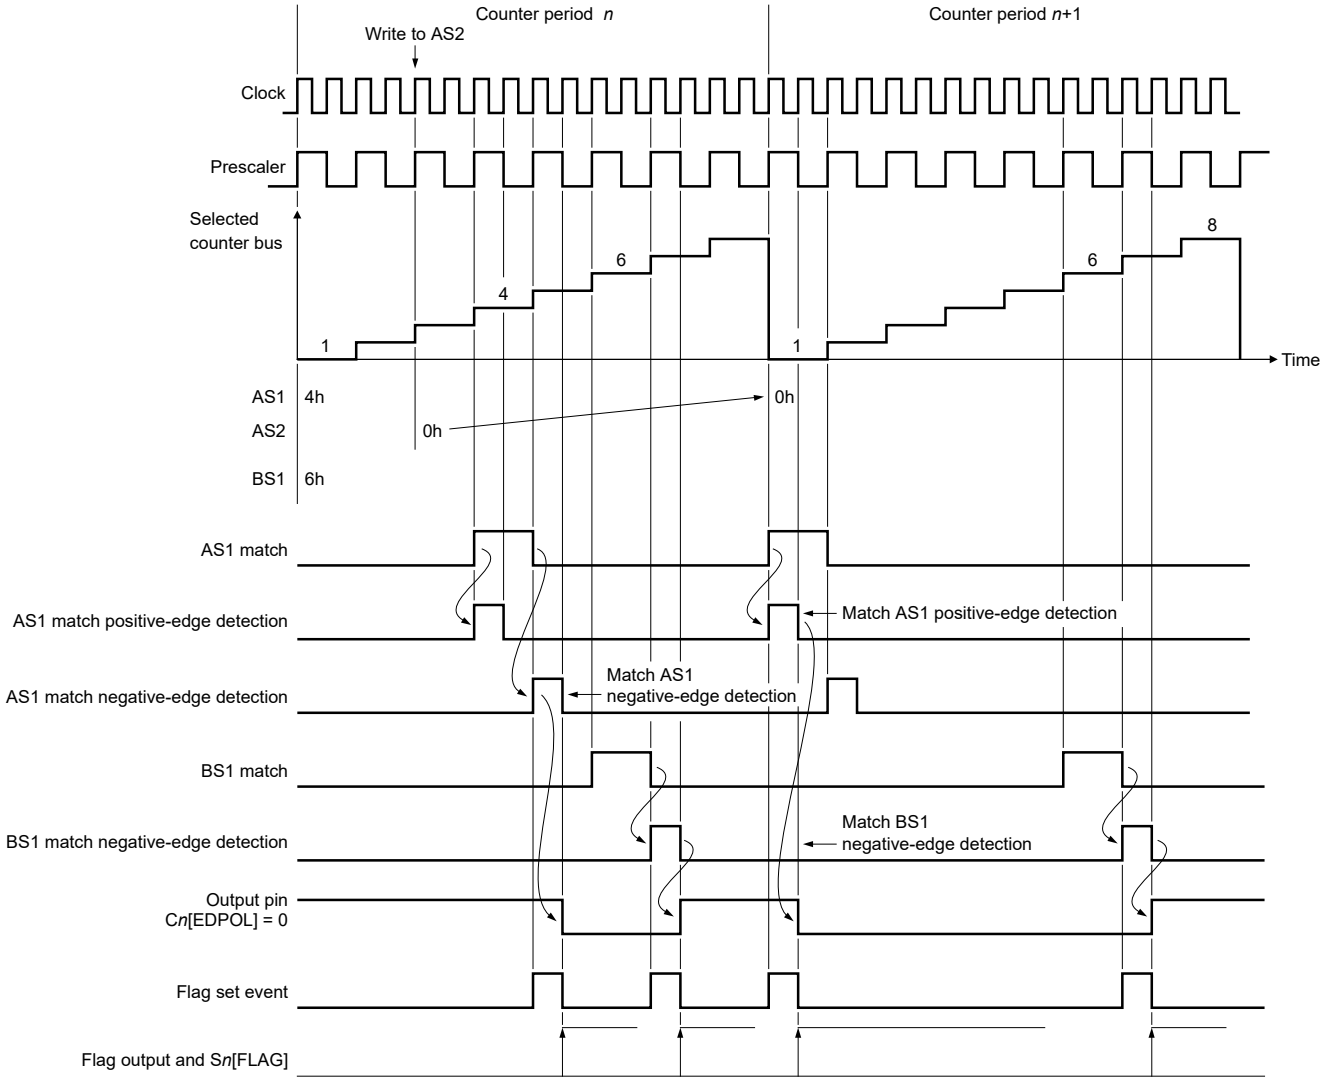

Figure 331. Timing example: matches and flags

61.7.3.18.6 0% duty cycle

Timing example: 0% duty cycle illustrates the channel operation for a 0% duty cycle. The AS1 match positive-edge signal occurs at the same time as the BS1 = 8h negative-edge signal. In this case, the AS1 match has precedence over the BS1 match, causing the output pin to remain at the value of C*n*[EDPOL] and generating a 0% duty-cycle signal.

61.7.3.18.7 Timing example: 0% duty cycle

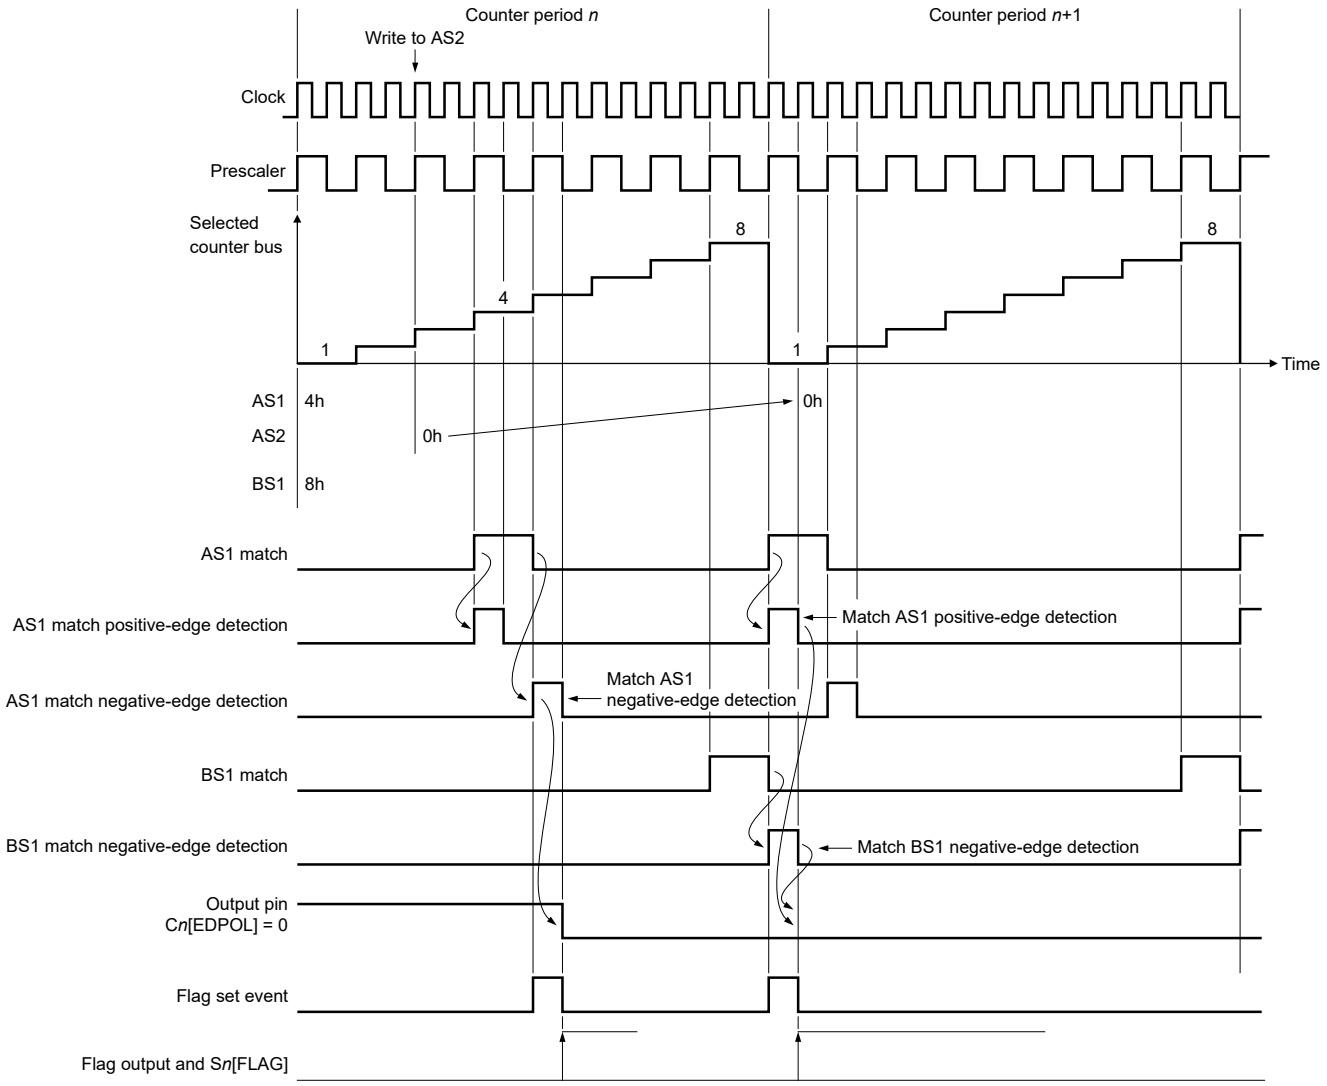

Figure 332. Timing example: 0% duty cycle

61.7.3.18.8 Active output disabled

Timing example: active output disabled illustrates the operation of the OPWMB mode with an emphasis on the assertion of the output-disable signal. The output disable forces a transition in the output pin to the value of C*n*[EDPOL]. The deassertion of the output-disable signal allows the output pin to transition at the following AS1 or BS1 match. The output disable does not modify the behavior of S*n*[FLAG]. A delay of one system clock cycle exists between the assertion of the output-disable signal and the transition of the output pin to C*n*[EDPOL].

61.7.3.18.9 Timing example: active output disabled

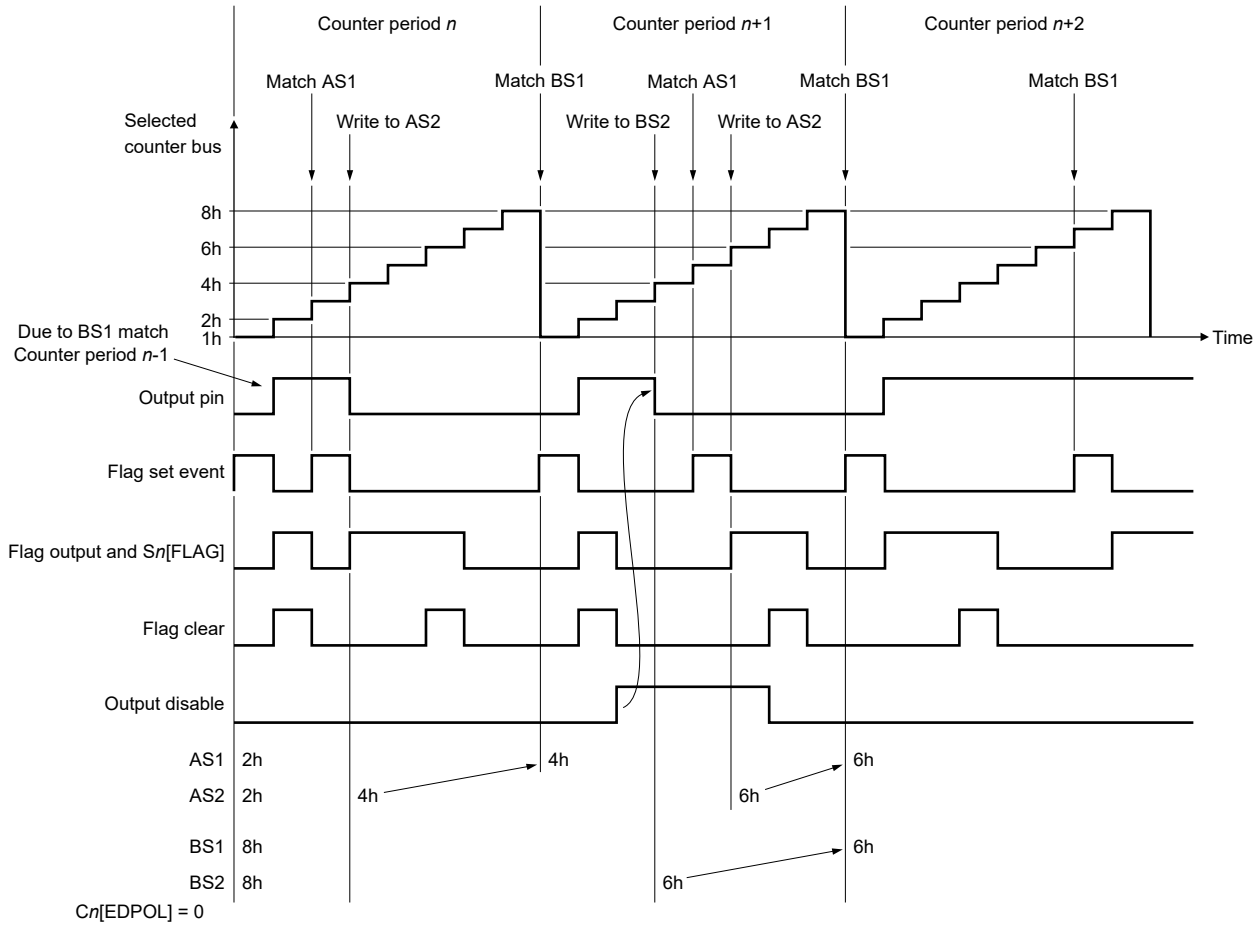

Figure 333. Timing example: active output disabled

61.7.3.18.10 Changing from 100% to 0% duty cycle

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 has the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the output pin transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

61.7.3.18.11 Timing example: 100% to 0% duty cycle

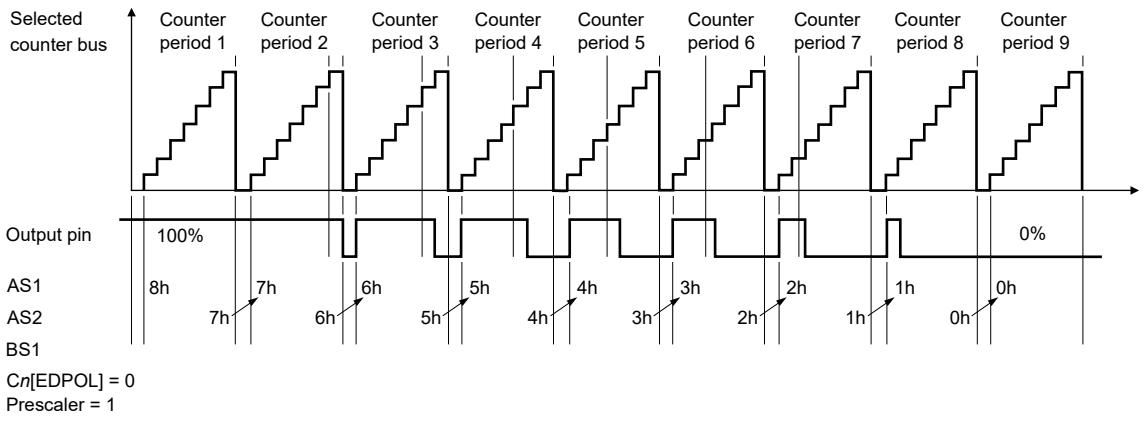

Figure 334. Timing example: 100% to 0% duty cycle

61.7.3.19 Output PWM with Trigger (OPWMT) mode

61.7.3.19.1 Overview

In this mode, the UC generates PWM pulses where the period does not change while the UC outputs the signal, but the duty cycle changes. When the duty cycle changes, it must not create glitches. The mode supports multiple UCs executing in the same mode and sharing a common timebase. Each UC can have a fixed PWM leading-edge position with respect to the other UCs. It can also generate a trigger signal at any point in the period. eMIOS can output this trigger signal to initiate activity in other parts of the chip—for example, to start ADC conversions.

You must select an external counter, driven in either MC Up or MCB Up mode (see Modulus Counter Buffered (MCB) mode), from one of the counter buses.

AS1 in OPWMT mode, AS2 in OPWMT mode, and BS1 and BS2 in OPWMT mode describe the configuration and behavior of the individual shadow registers in this mode.

To account for the shift in the AS1-defined leading edge of the waveform, the BS1-defined trailing edge may roll over into the next period. This means that a match against BS1 does not have to be qualified by a match in AS1. This also means that if you incorrectly write a value less than AS1 to BS1, the output persists over a period boundary until the UC encounters the BS1 value.

This mode provides a buffered update of the trailing edge by updating BS1 with BS2 contents only at a match of AS1.

The positive edges of the AS1, BS1, and AS2 match signals drive the output pin and flag transitions. See Timing example: matches and flags for details on positive-edge matches.

The UC sets the input capture flag (S*n*[FLAG]) only at an AS2 match. An AS1, BS1, or BS2 match has no effect on the flag.

When the UC enters OPWMT mode, it drives the complement of C*n*[EDPOL] on the output flip-flop.

Timing example: OPWMT illustrates the UC running in OPWMT mode with trigger-event generation and duty-cycle update after the next-period update.

61.7.3.19.2 Timing example: OPWMT

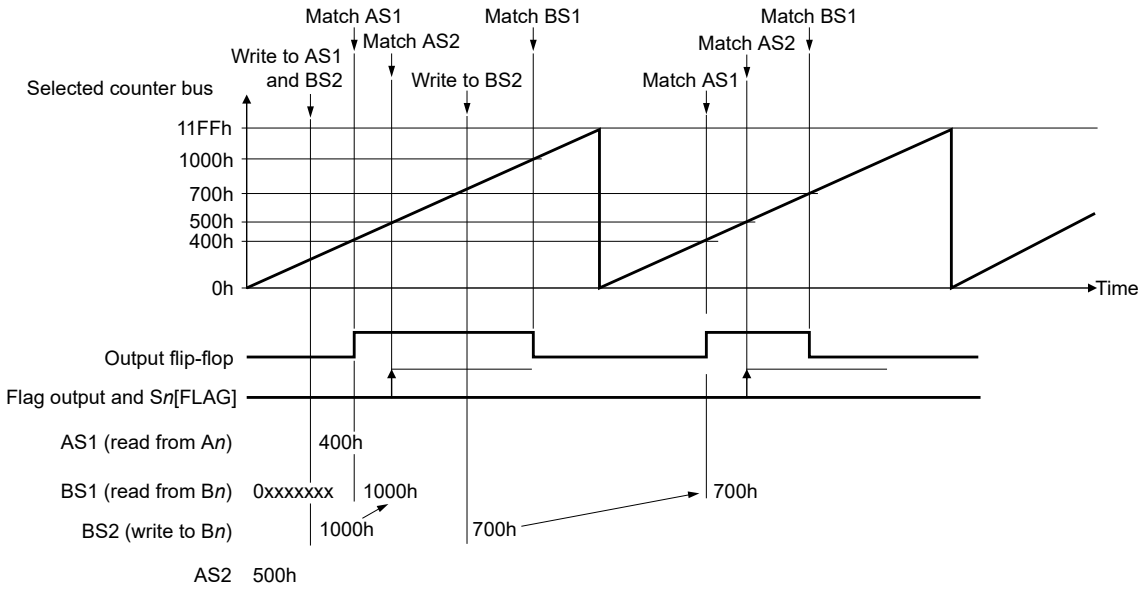

Figure 335. Timing example: OPWMT

61.7.3.19.3 AS1 in OPWMT mode

AS1 defines the leading edge of the PWM pulse output, and therefore the beginning of the PWM period. Using this fact, you can ensure that, when using a shared timebase, the leading edges of multiple UCs in OPWMT mode occur at specific times with respect to the other UCs. You can also introduce a fixed offset for each UC, which is particularly useful in the generation of lighting control signals. For this application, to reduce or eliminate noise generation, you can shift the PWM pulse of each UC with respect to the selected timebase by adjusting the AS1 value for each channel. The value you write to AS1 must be within the range of the selected timebase. Shadow registers (AS1, AS2, BS1, and BS2) loaded with 0h do not produce matches if the channel driving the timebase is in MCB mode.

AS1 is not buffered, because the shift of a PWM channel must not change while the UC generates the PWM signal. If you modify AS1, it updates immediately and one PWM pulse could be lost.

The UC compares AS1 to the selected timebase. When a match on AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop. When a match occurs on comparator B, the UC drives the complement of C*n*[EDPOL] on the output flip-flop.

61.7.3.19.4 AS2 in OPWMT mode

AS2 defines the generation of a trigger event within the PWM period. The value you write to AS2 must be within the range of the selected timebase—otherwise the UC does not generate a trigger. A match on the comparator asserts the input-capture flag, but the match has no effect on the PWM output signal generation. The typical setup to obtain a trigger with a flag is to enable DMA and drive the DMA acknowledgement or DMA completion input high.

AS2 is not buffered, and therefore the UC updates it immediately. If the UC is running when you make a change, this could cause either of the following:

- The loss of one trigger event
- The generation of two trigger events within the same period

You access AS2 by reading or writing ALTA*n*[ALTA].

61.7.3.19.5 BS1 and BS2 in OPWMT mode

You access BS1 and BS2 using B*n*[B]:

- When you read B*n*[B], you read BS1.
- When you write to B*n*[B], you write to BS2.

BS1 defines the trailing edge of the PWM pulse output, and therefore the duty cycle of the PWM signal. To synchronize the BS1 update with the PWM signal and to ensure a correct output pulse generation, the BS2→BS1 transfer occurs at every AS1 match. This behavior is the same as in OPWM mode with next-period update.

Output Update Disable (OUDIS) affects transfers between BS2 and BS1 only.

61.7.3.19.6 Force match

At any time, Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on AS1 or BS1, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]). Any match resulting from writing 1 to FORCMA or FORCMB has priority over any simultaneous match regarding output pin transitions. BS2→BS1 transfer at an A match is not inhibited by writing 1 simultaneously to both FORCMA or FORCMB. If you write 1 to both FORCMA and FORCMB simultaneously, the output pin acquires the complement of C*n*[EDPOL], as if AS1 and BS1 had the same value. FORCMA assertion causes the UC to process the BS2→BS1 transfer as a regular A match comparison and not due to FORCMA assertion, regardless of FORCMB assertion. If subsequent matches occur on comparators AS1 and B, the UC continues to generate PWM pulses, regardless of the state of S*n*[FLAG].

61.7.3.19.7 Duty cycle

To achieve 0% duty cycle, you must write the same value to AS1 and BS2. When a simultaneous match on comparators A and B occurs, the UC drives the complement of C*n*[EDPOL] on the output flip-flop at every period.

To achieve 100% duty cycle, you must write a value to BS1 that is greater than the maximum value of the selected timebase. The maximum counter value for the timebase is FF_FFFEh for a 24-bit counter and FFFEh for a 16-bit counter. When a match on comparator AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop at every period. The match at comparator A still triggers the BS2→BS1 transfer.

Timing example: 0% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 0% duty cycle.

Timing example: 100% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 100% duty cycle.

61.7.3.19.8 Timing example: 0% duty cycle

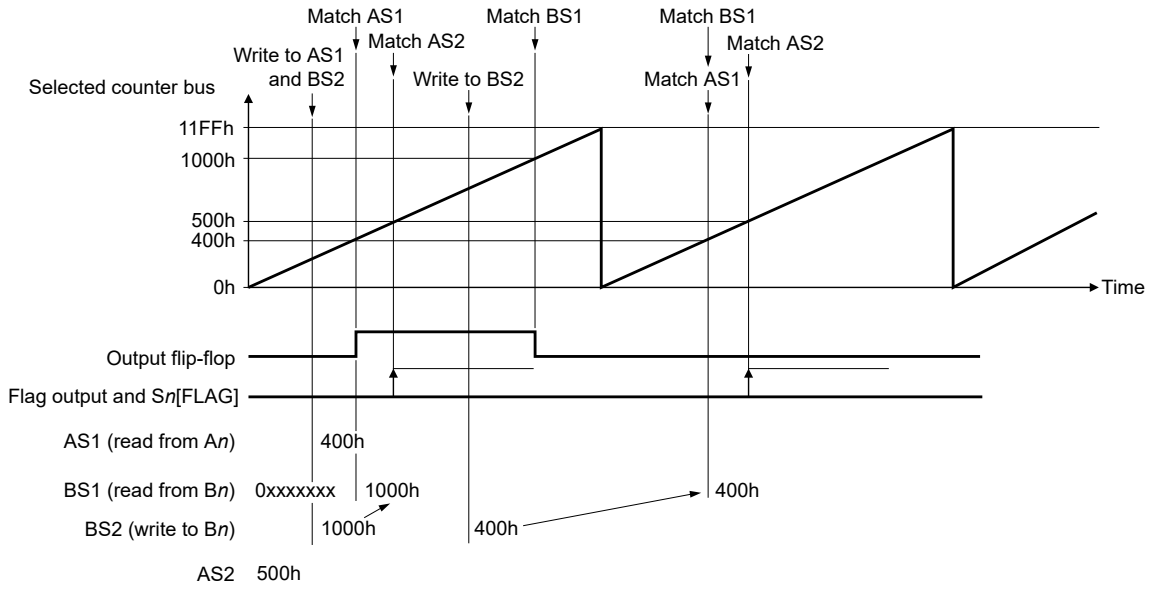

Figure 336. Timing example: 0% duty cycle

61.7.3.19.9 Timing example: 100% duty cycle

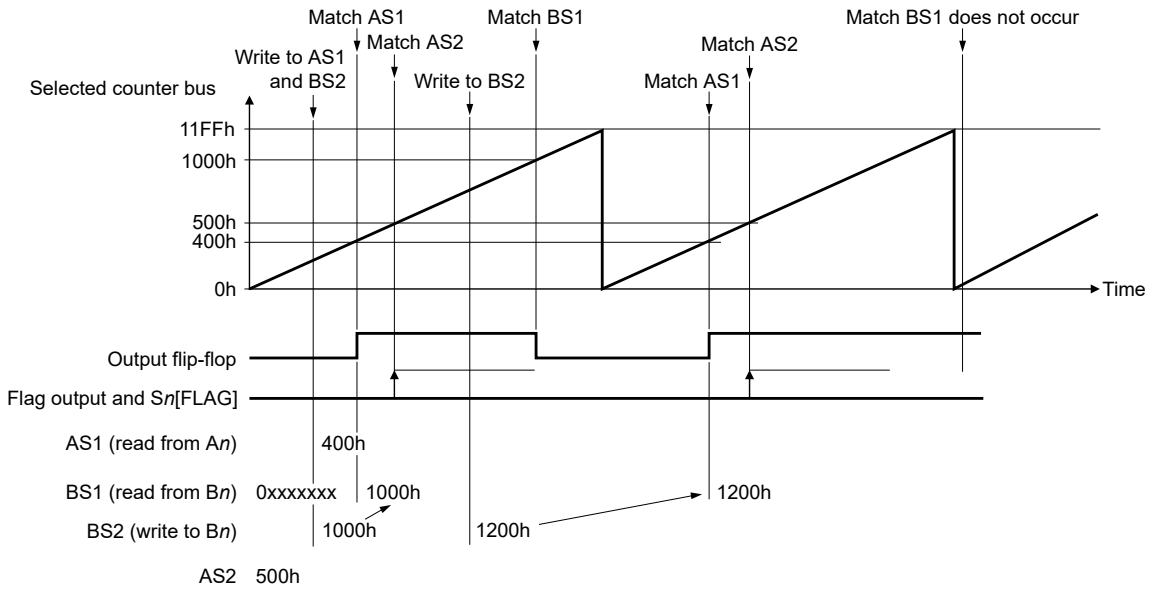

Figure 337. Timing example: 100% duty cycle

61.7.3.19.10 Output disable

As with other UC modes, OPWMT mode implements the output-disable function. When C*n*[ODIS] = 1, assertion of the output-disable input causes the UC to drive C*n*[EDPOL] on the output. Other than the fixed output, the UC continues to operate normally. When the output-disable signal deasserts, the UC returns to full normal operation.

61.7.3.20 Programmable input filter (PIF)

61.7.3.20.1 Overview

The PIF specifies the minimum input pulse width, in clock cycles, that can pass through the filter. It supports bypass operation (C*n*[IF]), with the input signal synchronized before arriving at the digital filter, or from 2 to 16 clock cycles in powers of 2.

61.7.3.20.2 Counter

The PIF is a 5-bit programmable up counter. The selected clock source increments the up counter after the number of clock cycles specified by the input filter (C*n*[IF]0.

The system clock synchronizes the input signal. When this signal changes state, the counter begins incrementing. As long as the new signal state is stable, the counter continues incrementing. If the counter overflows, eMIOS validates the new signal value. In this case, it transmits the value as a pulse edge to the edge detector. If the opposite edge appears on the signal before validation (overflow), eMIOS resets the counter. At the next transition, the counter starts incrementing again. A glitch does not occur on the edge detector for any pulse shorter than the full range of the masked counter.

Neither Freeze state nor deasserted GTBE disables the filter.

61.7.3.20.3 UC PIF logic

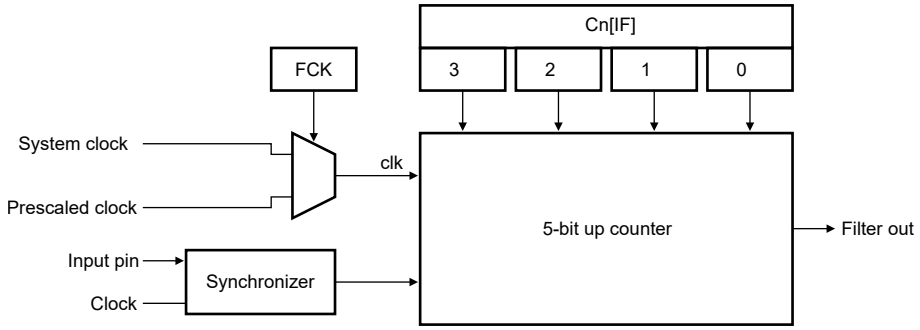

Figure 338. UC PIF logic

61.7.3.20.4 Timing example: UC PIF at 4 cycles

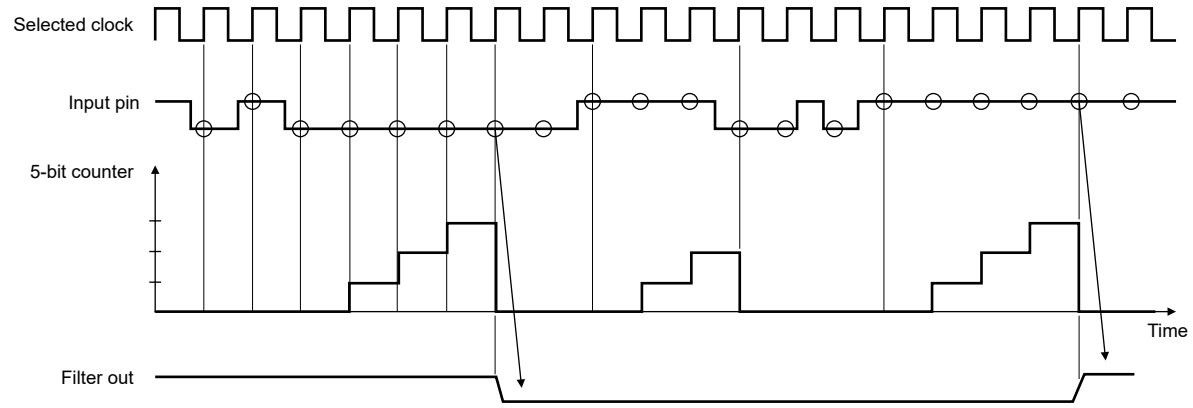

Figure 339. Timing example: UC PIF at 4 cycles

61.7.3.21 UC clock prescaler (CP)

eMIOS divides the GCP output signal by the UC CP (C*n*[UCPRE] + 1) to generate a clock enable for the UC internal counter. See Global clock prescaler (GCP). You enable the UC CP by writing 1 to C*n*[UCPREN]. If you disable the CP (write 0 to the same field), eMIOS stops the UC internal counter.

To ensure safe operation and avoid glitches, you must perform the following steps to change the UC CP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Disable the UC CP (write 0 to C*n*[UCPREN]).
3. Specify the new prescaler value (write CP – 1 to C*n*[GPRE].
4. Enable the UC CP (write 1 to C*n*[UCPREN]).
5. Enable the GCP (write 1 to MCR[GPREN]).

61.7.4 Peripheral bus interface unit (BIU)

The BIU provides the interface between the IIB and the peripheral bus, which allows communication among all submodules and the IP interface. The BIU supports 8-, 16-, and 32-bit accesses performed over a 32-bit data bus in a single clock cycle.

61.7.5 Global clock prescaler (GCP)

eMIOS divides the system clock by the GCP (MCR[GPRE] + 1) and routes the resulting prescaled clock output to the channel CPs. You enable the GCP by writing 1 to MCR[GPREN]. If you disable the GCP (write 0 to the same field), eMIOS clears the prescaler counter and stops the prescaler clock.

To ensure safe operation and avoid glitches, you must perform the following steps to change the GCP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Specify the new prescaler value (write GCP – 1 to MCR[GPRE].
3. Enable the GCP (write 1 to MCR[GPREN]).

61.7.6 Freeze and chip Debug mode

61.7.6.1 Enter and exit Freeze state

When the chip is in Debug mode (the chip Debug signal is asserted), you can freeze individual UCs. For the effects of Freeze state on eMIOS functions, see Freeze effects.

To put a channel in Freeze state, you must meet all of the following conditions:

- The chip must assert Debug.
- Prepare eMIOS for the Freeze state (write 1 to MCR[FRZ]).
- Enable Freeze for each channel you want to freeze:
  - Write 1 to C*n*[FREN].

A channel exits Freeze state when any of the following conditions occur:

- The chip deasserts Debug.
- You take eMIOS out of the Freeze state (write 0 to MCR[FRZ]).
- You disable Freeze for the channel:
  - write 0 to C*n*[FREN].

61.7.6.2 Freeze effects

Function	Effects of freeze
GCP	No effect
UC	• Halts counter, capture, and compare operation. • Freezes UC in its current state. • Makes all registers accessible. • In output modes, force match remains operational, allowing software to force the output to the desired level. • In input modes, the UC ignores input events. • When eMIOS exits Freeze state then UC operations resume, but they may be inconsistent until the UC reenters GPIO mode.
STAC	No effect
BIU	No effect

61.8 Initialization information

When initializing eMIOS, take the following considerations into account.

For eMIOS behavior on reset, see Reset.

Before changing the UC operating mode, you must:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Write the correct values for the next operating mode to A*n* and B*n*.
3. Put the UC in the new operating mode (write the appropriate value to C*n*[MODE]).

If you change a UC from one mode to another without performing this procedure, the first operation cycle of the selected timebase can be random; that is, matches can occur in random time because you did not update A*n* and B*n* with correct values before the timebase matches the previous contents of either register.

When you enable interrupts, any interrupt service routine must clear the flag before exiting.

61.9 Application information

61.9.1 Overview

All output operation modes can generate correlated output signals. You can disable updates of the output signals for each UC (OUDIS).

To guarantee that incrementing of the internal counters of correlated channels occurs in the same clock cycle, you must configure the internal CPs before enabling the GCP. If you configure the internal CPs after enabling the GCP, the internal counters may increment in the same ratio, but at different clock cycles.

You should drive the Output Disable Input signals with the flag signals of some UCs running in SAIC mode. When an output disable condition happens, the interrupt service routine must process the output channels before processing the channels running SAIC. This sequence avoids glitches in the output pins.

61.9.2 Timebase generation

In the MC and OPWFM modes with internal clock sources, you can modify the internal counter rate by configuring the CP ratio. Timebase with the fastest prescaler ratio illustrates a timebase with a prescaler ratio of one.

NOTE

The buffered modes, MCB and OPWFMB, behave differently.

If the prescaler ratio is greater than one or you select an external clock, the internal counter behaves in one of four different ways depending on the channel mode:

- In MC mode with Clear on Match Start and External Clock: Timebase generation with clear on match start and external clock.
- In MC mode with Clear on Match Start and Internal Clock source: Timebase generation with clear on match start and internal clock.
- In MC mode with Clear on Match End: Timebase generation with clear on match end.
- In OPWFM mode: Timebase generation with clear on match start and internal clock. The internal counter clears at the start of the match signal, skips the next prescaled clock edge, and then increments in the subsequent prescaled clock edge.

61.9.3 Timebase with the fastest prescaler ratio

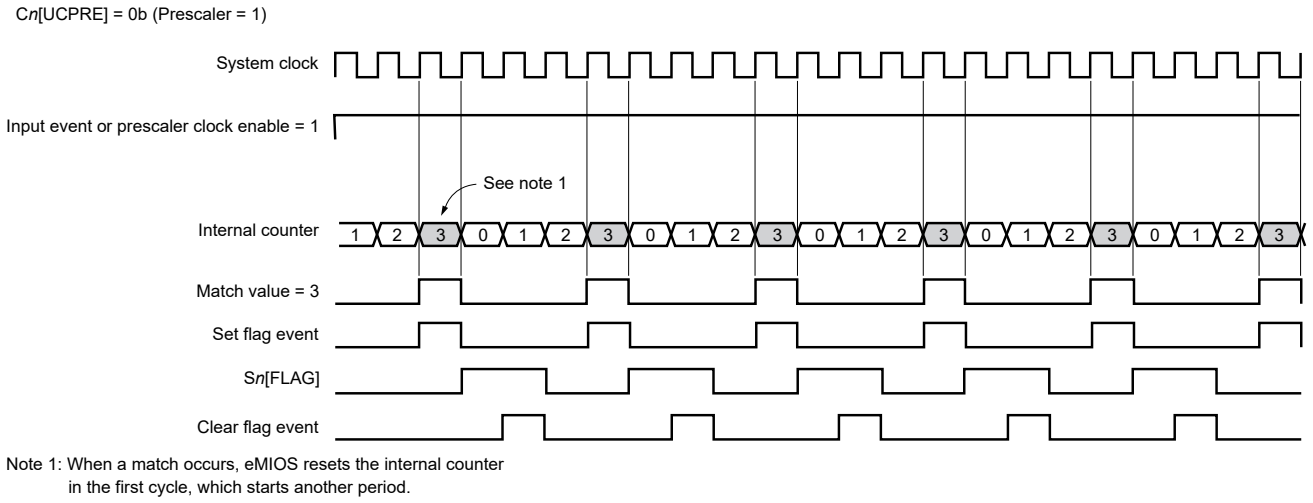

Figure 340. Timebase with fastest prescaler ratio

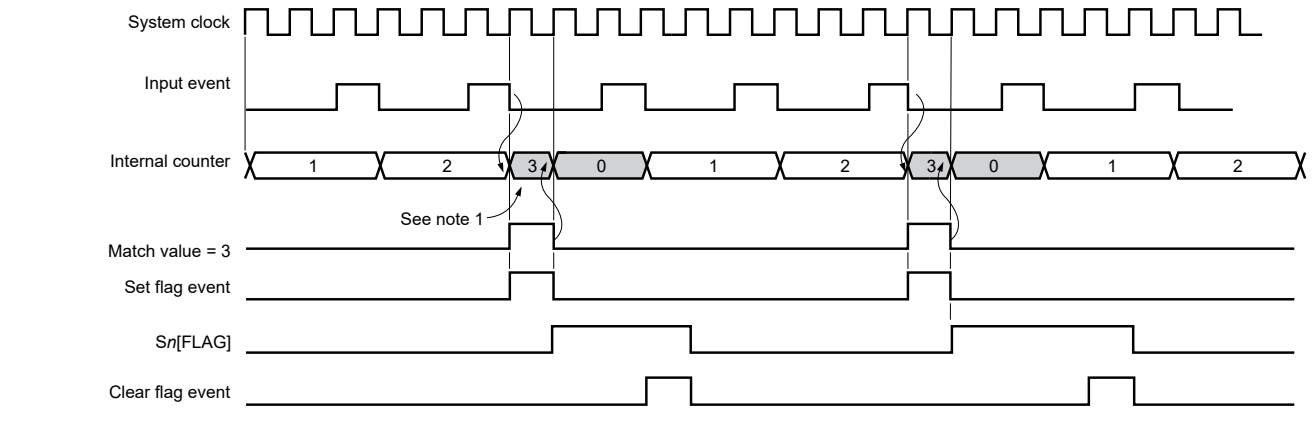
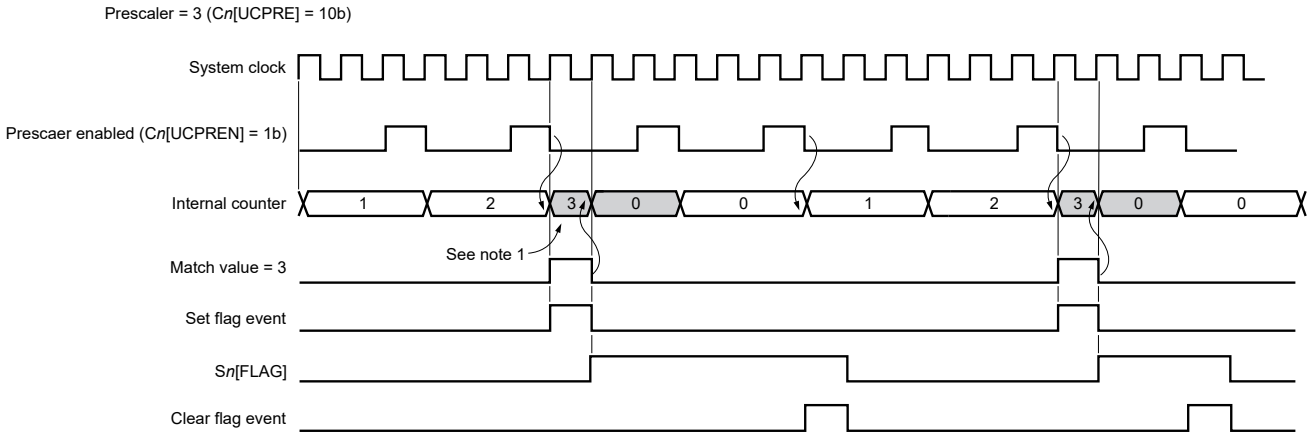
61.9.4 Timebase generation with clear on match start and external clock



Note 1: When a match occurs, eMIOS resets the internal counter in the first clock cycle.
The counter starts counting at the next edge of the prescaler clock enable.

Figure 341. Timebase generation with clear on match start and external clock

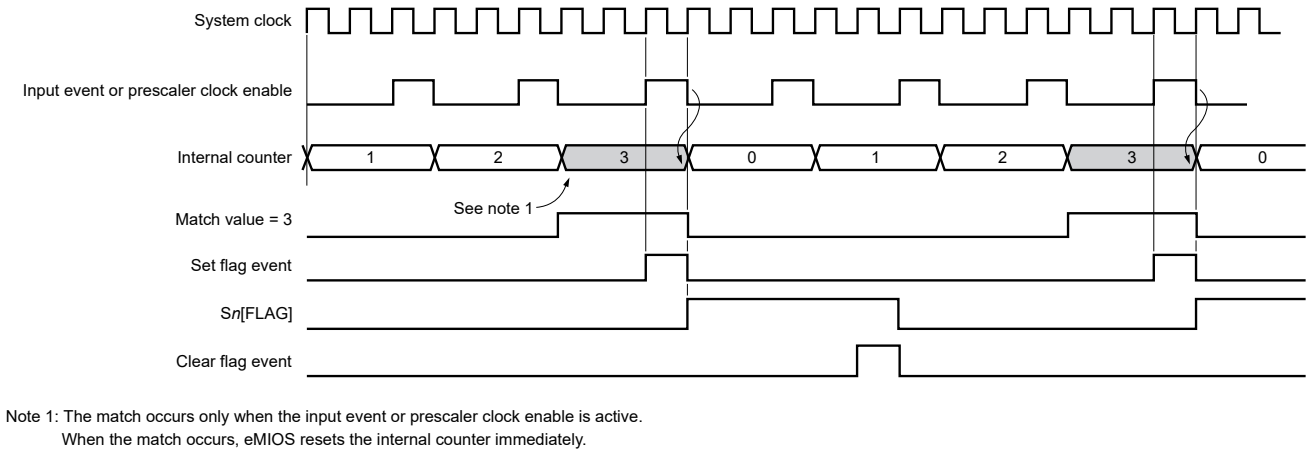
61.9.5 Timebase generation with clear on match start and internal clock



Note 1: When a match occurs, eMIOS clears the internal counter in the first clock cycle.
The counter starts counting again only after the second edge of the prescaled clock.

Figure 342. Timebase generation with clear on match start and internal clock

61.9.6 Timebase generation with clear on match end



Note 1: The match occurs only when the input event or prescaler clock enable is active.
When the match occurs, eMIOS resets the internal counter immediately.

Figure 343. Timebase generation with clear on match end

61.9.7 Coherent accesses

Reading A*n*[A] again in the same period as the last read of B*n*[B] results in incoherent results if the last read of B*n*[B] occurred after a disabled BS2→BS1 transfer.

61.9.8 Initializing channels and modes

Perform the following basic steps for output mode startup. This procedure assumes the channels are initially in GPIO mode:

1. Disable the GPC (write 0 to MCR[GPREN]).
2. For each timebase UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write an initial value to the internal counter (CNT*n*[C]).
    c. Write initial values to A*n*[A] and B*n*[B].
    d. Configure the UC for MC or MCB Up mode (write the appropriate value to C*n*[MODE]).
    e. Select the CP ratio (C*n*[UCPRE]).
    f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For each output UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write initial values to A*n*[A] and B*n*[B].
    c. Select the timebase input (C*n*[BSL]).
    d. Specify the output mode (write the appropriate value to C*n*[MODE]).
    e. Select the same CP ratio as the timebase UC (C*n*[UCPRE]).
    f. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).
5. Enable GBTE (write 1 to MCR[GBTE]).

The timebase channel and the output channel may be the same for some applications such as in OPWFM or OPWFMB mode, or whenever the output channel drives the timebase itself.

You may configure flags at any time.

61.10 Memory maps and registers

61.10.1 Overall address map organization

All address locations not explicitly mentioned in this table are reserved. When you access an absent register, absent channel, or reserved address space, the transfer terminates with an error.

Table 356. Overall address map organization

Base address (hex)	Description
0	Module Configuration (MCR)
4	Global Flag (GFLAG)
8	Output Update Disable (OUDIS)
C	Disable Channel (UCDIS)
20	Channels 0–7
120	Channels 8–15
220	Channels 16–23

61.10.2 UC memory overview

Table 357. UC memory overview

Offset from UC *n* base address (hex)	Description
0	UC A n (A0 - A23)
4	UC B n (B0 - B23)
8	UC Counter n (CNT0 - CNT23)
C	UC Control n (C0 - C23)
10	UC Status n (S0 - S23)
14	Alternate Address n (ALTA0 - ALTA23)
18	UC Control 2 n (C2_0 - C2_23)
1C–1F	Reserved

61.10.3 AS1, AS2, BS1, and BS2 shadow registers

When you use eMIOS UC modes, you rely heavily on four shadow registers:

- AS1
- AS2
- BS1
- BS2

You use A*n*[A], B*n*[B], and ALTA*n*[ALTA] to access these shadow registers:

- Each instance of A*n*[A] has a separate associated instance of AS1 and AS2. In some UC modes, you also use ALTA*n*[ALTA] to access AS2.
- Each instance of B*n*[B] has a separate associated instance of BS1 and BS2.

See Relationship between A*n*, B*n*, ALTA*n*, and shadow registers.

Each UC mode uses the AS1-AS2 and BS1-BS2 shadow register pairs for various match and capture functions, as described in Unified channels (UC).

A reset clears all shadow registers.

Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] describes how you write to and read from the shadow registers for all operation modes. Values not listed are reserved. For more information, see Unified channels (UC).

61.10.4 Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

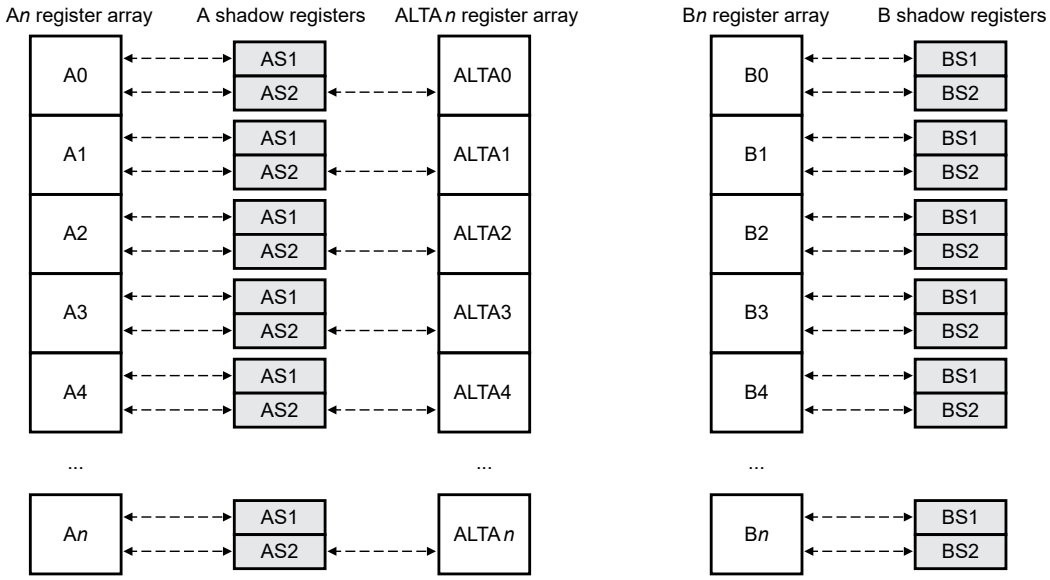


Figure 344. Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

61.10.5 Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

This table describes how you write to and read from the following registers for all operation modes:

- UC A n (A0 - A23)
- UC B n (B0 - B23)
- Alternate Address n (ALTA0 - ALTA23)

Values not listed are reserved. For more information, see Unified channels (UC).

Table 358. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
GPIO	AS1 and AS2[1]	AS1	BS1 and BS2[2]	BS1	AS2	AS2

Table continues on the next page...

Table 358. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] (continued)

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
SAIC[3]	—	AS2	BS2	BS2	—	—
SAOC[3]	AS2	AS1	BS2	BS2	—	—
IPWM	—	AS2	—	BS1	—	—
IPM	—	AS2	—	BS1	—	—
DAOC	AS2	AS1	BS2	BS1	—	—
PEA	AS1	AS2	—	BS1	—	—
PEC[3]	AS1	AS1	BS1	BS1	—	AS2
WPTA	AS1	AS1	BS1	BS1	—	AS2
MC[3]	AS2	AS1	BS2	BS2	—	—
OPWFM	AS2	AS1	BS2	BS1	—	—
OPWMC	AS2	AS1	BS2	BS1	—	—
OPWM	AS2	AS1	BS2	BS1	—	—
OPWMT	AS1	AS1	BS2	BS1	AS2	AS2
MCB[3]	AS2	AS1	BS2	BS1	—	—
OPWFMB	AS2	AS1	BS2	BS1	—	—
OPWMCB	AS2	AS1	BS2	BS1	—	—
OPWMB	AS2	AS1	BS2	BS1	—	—

1. This operation writes the same value to AS1 and AS2.
2. This operation writes the same value to BS1 and BS2.
3. These modes do not require UC B n (B0 - B23), but you can still use it to access BS2.

61.10.6 eMIOS register descriptions

All control registers are 32 bits wide. Data fields are 16 bits wide. There are 24 UCs, as mapped in Counter buses, channels, and timebase sources.

61.10.6.1 eMIOS memory map

eMIOS_0 base address: 4008_8000h

eMIOS_1 base address: 4008_C000h

eMIOS_2 base address: 4009_0000h

61.10.6.2 Module Configuration (MCR)

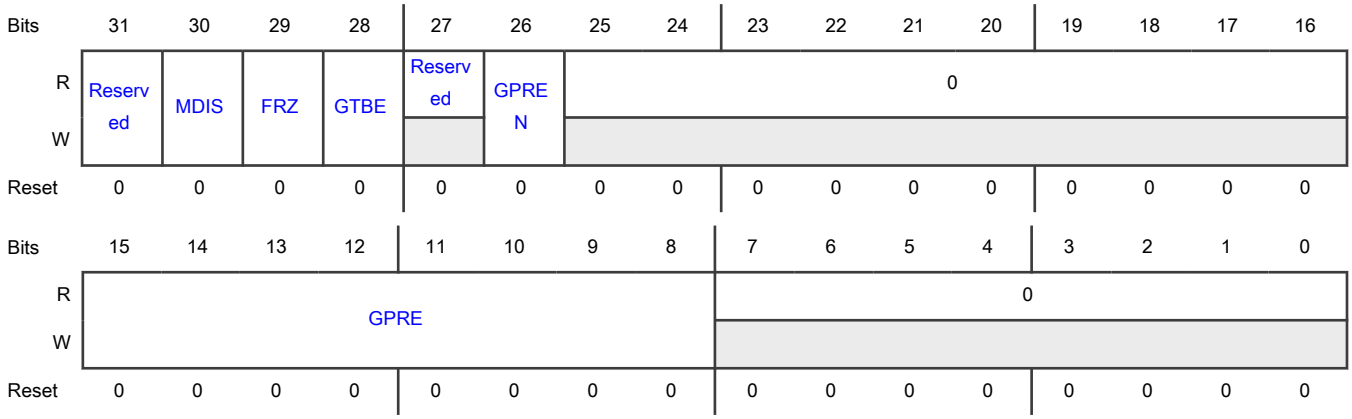
Offset

Register	Offset
MCR	0h

Function

Configures eMIOS operation.

Diagram



Fields

Field	Function
31 —	Reserved Write only the reset value to this field.
30 MDIS	Module Disable Disables eMIOS by stopping the clock. When you disable eMIOS, its clock stops, it consumes less power, and you can access only the following registers: • Module Configuration (MCR) • Output Update Disable (OUDIS) • Disable Channel (UCDIS) 0b - Enable 1b - Disable
29 FRZ	Freeze Prepares eMIOS to enter Freeze state (see Freeze and chip Debug mode). eMIOS does not enter Freeze state until both of the following conditions occur: • The chip asserts Debug mode. • You enable Freeze for each UC (write 1 to C*n*[FREN]). A channel remains frozen until one or more of the following occur: • You force eMIOS to exit the Freeze state (write 0 to FRZ). • The chip deasserts Debug mode. • You disable Freeze for that UC (write 0 to C*n*[FREN]). 0b - Exit Freeze state 1b - Enter Freeze state
28	Global Timebase Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
GTBE	Asserts the GTBE_OUT signal. If GTBE_OUT is connected to the GTBE_IN input of one or more eMIOS instances, asserting the signal turns on the internal counters of those eMIOS instances simultaneously. **NOTE** The GTBE_IN input enables (asserted) or disables (deasserted) the internal counters. 0b - Deassert GTBE_OUT 1b - Assert GTBE_OUT
27 —	Reserved
26 GPREN	Global Prescaler Enable Enables the global prescaler counter. Disabling the global prescaler clears the prescaler counter and stops the prescaler clock. 0b - Disable 1b - Enable
25-16 —	Reserved
15-8 GPRE	Global Prescaler Specifies the global clock prescaler. Write the desired clock divide ratio minus 1. For example, for a divide ratio of 8, write 111b. The prescaler can range from 1 (0b) to 256 (11111111b).
7-0 —	Reserved

61.10.6.3 Global Flag (GFLAG)

Offset

Register	Offset
GFLAG	4h

Function

Groups the flag fields from all channels into one register to improve interrupt handling.

For UCs, each field mirrors the corresponding channel flag (S*n*[FLAG]).

Diagram

61.10.6.4 Output Update Disable (OUDIS)

Offset

Register	Offset
OUDIS	8h

Function

Disables transfers from AS2 to AS1 and BS2 to BS1 on a per-channel basis. This applies to any channel operating in MC, MCB, or any output mode that writes to AS2 and BS2.

When a field is 0, transfers on that channel occur immediately or in the next period, depending on the operation mode. Unless that mode's description states otherwise, the transfer occurs immediately.

61.10.6.6 UC A n (A0 - A23)

Offset

For n = 0 to 23:

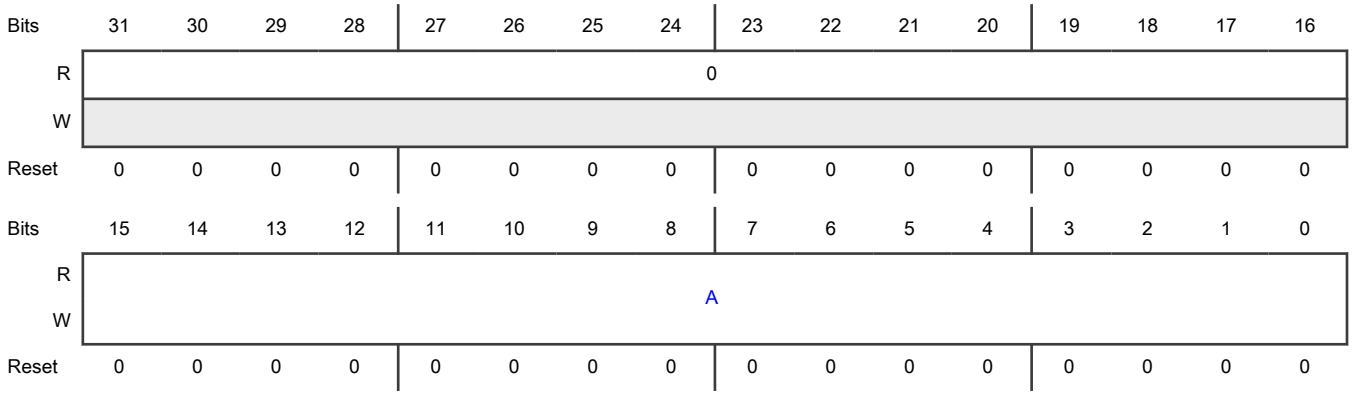
Register	Offset
An	20h + (n × 20h)

Function

Accesses the AS1 and AS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 A	A See the register description.

61.10.6.7 UC B n (B0 - B23)

Offset

For n = 0 to 23:

Register	Offset
Bn	24h + (n × 20h)

Function

Accesses the BS1 and BS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

15-0 B	B See the register description.

61.10.6.8 UC Counter n (CNT0 - CNT23)

Offset

Register	Offset
CNT0	28h
CNT1	48h
CNT2	68h
CNT3	88h
CNT4	A8h
CNT5	C8h
CNT6	E8h
CNT7	108h
CNT8	128h
CNT16	228h
CNT22	2E8h
CNT23	308h

Function

Indicates the value of the UC internal counter.

When eMIOS is in GPIO mode or the UC is frozen, this register is read-write. For all other modes, this register is read-only. When entering some UC modes, eMIOS automatically clears this register. See Unified channels (UC) for details.

The following modes use the UC counter:

- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode

All other modes not in this list do not use the internal counter.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
eMIOS_0	CNT0–CNT8 CNT16 CNT22–CNT23	—
eMIOS_1	CNT0 CNT8 CNT16 CNT22–CNT23	CNT1–CNT7
eMIOS_2	CNT0 CNT8 CNT16 CNT22–CNT23	CNT1–CNT7

OPWMCB (with leading edge dead time)	101_11p1[1]
OPWMB	110_00p0[1]
Reserved	110_0001–111_1111

1. p = Adjust parameters for the mode of operation. See Unified channels (UC) for details.

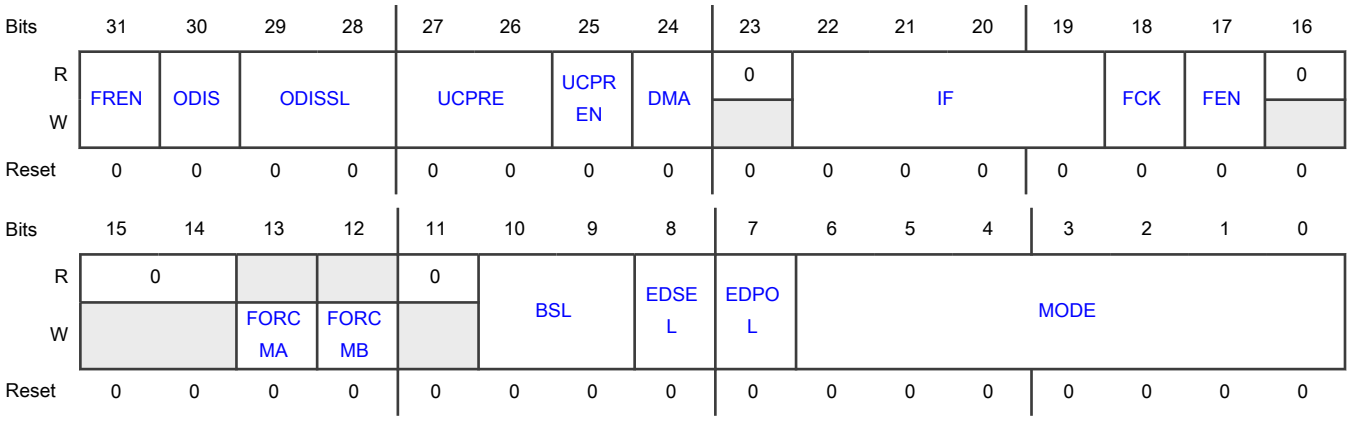
Table 360. Edge Polarity (EDPOL) settings

For these modes:	EDPOL does this:	and EDPOL values mean:
Input	Selects which edge triggers the internal counter, an input capture, or the input capture flag. If EDPOL does not appear in the UC mode description, it has no effect on UC operation.	0b - Trigger on a falling edge 1b - Trigger on a rising edge
Output	Selects the logic level on the output pin.	0b - A match on comparator A deasserts the output flip-flop, while a match on comparator B sets it 1b - A match on comparator A asserts the output flip-flop, while a match on comparator B clears it

Table 361. Edge Select (EDSEL) settings

For these modes:	EDSEL does this:	and EDSEL values mean:
Input	Selects whether the internal counter is triggered by both edges of a pulse or by a single edge as defined by EDPOL. If EDSEL does not appear in the UC mode description, it has no effect on UC operation.	0b - Single-edge triggering on edge specified in EDPOL 1b - Both-edges triggering
GPIO in	Selects whether an edge asserts the input capture flag (S*n*[FLAG]).	0b - Sets S*n*[FLAG] on the edge specified in EDPOL 1b - Does not set S*n*[FLAG]
SAOC	Selects the behavior of the output flip-flop at each match.	0b - Drive the EDPOL value on the output flip-flop 1b - Toggle output flip-flop

Diagram



Fields

Field	Function
31 FREN	Freeze Enable Enables putting the UC in Freeze state. See Freeze and chip Debug mode. 0b - Disable 1b - Enable
30 ODIS	Output Disable Disables the output pin when running any of the output modes except GPIO. When you assert ODIS: • If the selected Output Disable Input signal asserts, the output pin reflects: — For OPWFMB and OPWMB modes, EDPOL (see Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode and Output PWM Buffered (OPWMB) mode).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— For all other modes, the complement of EDPOL, but the UC continues to operate normally—it continues to generate flags and matches. • If the selected Output Disable Input signal deasserts, the output pin operates normally. 0b - Enables output pin (the output pin operates normally) 1b - Disables output pin
29-28 ODISSL	Output Disable Select Selects one of four output disable input signals. 00b - 0 01b - 1 10b - 2 11b - 3
27-26 UCPRE	Prescaler Selects the clock divider value for the UC internal prescaler. **NOTE** The two least-significant bits of C2_*n*[UCEXTPRE] mirror UCPRE. Any write to UCPRE also affects UCEXTPRE. 00b - 1 01b - 2 10b - 3 11b - 4
25 UCPREN	Prescaler Enable Enables the prescaler counter. 0b - Disable (no clock) 1b - Enable
24 DMA	Direct Memory Access Selects whether the input capture flag (S*n*[FLAG]) or overrun (S*n*[OVR]) triggers an interrupt or DMA request. 0b - Interrupt request 1b - DMA request
23 —	Reserved
22-19	Input Filter

Table continues on the next page...

Table continued from the previous page...

Field	Function
IF	Selects the minimum input pulse width, in filter clock cycles, that can pass through the input filter. This field does not apply to output modes. The filter latency—the difference in time between the input and the response—is three clock edges. 0000b - Bypassed; the input signal is synchronized before arriving at the digital filter 0001b - 2 cycles 0010b - 4 cycles 0100b - 8 cycles 1000b - 16 cycles All other values are reserved.
18 FCK	Filter Clock Select Selects the clock source for the programmable input filter. 0b - Prescaled clock 1b - eMIOS module clock
17 FEN	Flag Enable Enables the input capture flag (S*n*[FLAG]) to generate an interrupt request or a DMA request, as selected in DMA. 0b - Disable 1b - Enable
16-14 —	Reserved
13 FORCMA	Force Match A For output modes, asserting Force Match A causes the comparator to report a successful comparison on comparator A regardless of whether a comparison actually occurred. It does not set the input capture flag (S*n*[FLAG]). This field always reads 0. This bit is meaningful for every output operation mode that uses comparator A. Otherwise it has no effect. 0b - No effect 1b - Force a match at comparator A
12 FORCMB	Force Match B For output modes, asserting Force Match B causes the comparator to report a successful comparison on comparator B regardless of whether a comparison actually occurred. It does not set the input capture flag (S*n*[FLAG] does not become 1). This field always reads 0. This field applies only if the UC is in one of the following output modes. • Single Action Output Capture (SAOC) mode • Double Action Output Compare (DAOC) mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode • Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode • Output PWM Buffered (OPWMB) mode • Output PWM with Trigger (OPWMT) mode This field has no effect in all other modes. 0b - No effect 1b - Force a match at comparator B
11 —	Reserved
10-9 BSL	Bus Select Selects one of the counter buses or the internal counter for the UC. Not all chips support all counter buses. See the chip-specific eMIOS information for details. 00b - • Channels 0-22: counter bus A • Channel 23: reserved 01b - • Channels 1-7: counter bus B • Channels 9-15: counter bus C • Channels 17-23: counter bus D • Channels 25-31: counter bus E • Channels 0, 8, 16, 24: reserved 10b - • Channels 0-21, 23: counter bus F • Channel 22: reserved 11b - Internal counter for all channels
8 EDSEL	Edge Selection Controls several functions as shown in Table 361.
7 EDPOL	Edge Polarity Controls several functions as shown in Table 360.
6-0 MODE	Mode Selection Selects the UC mode as shown in Table 359.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If you write a reserved value to this field, the results are unpredictable. When you change the value of MODE, you must first enter GPIO mode to reset the UC's internal functions. Failure to do this can result in invalid and unexpected output compare or input capture results or incorrectly set input capture flags (S*n*[FLAG]).

61.10.6.10 UC Status n (S0 - S23)

Offset

For n = 0 to 23:

Register	Offset
Sn	30h + (n × 20h)

Function

Indicates the status of the UC input-output signals and the overflow condition of the internal counter.

Diagram

2 UCIN	UC Input Pin Indicates the input pin state after the input pin has been filtered and synchronized. 0b - Negated 1b - Asserted
1 UCOUT	UC Output Pin Indicates the output pin state. 0b - Negated 1b - Asserted
0 FLAG	Flag Indicates that an input capture or a match event in the comparators has occurred. **NOTE** This field behaves differently for read and write operations. When reading 0b - No event 1b - Event has occurred When writing 0b - No event 1b - Clear the flag (FLAG returns to 0)

61.10.6.11 Alternate Address n (ALTA0 - ALTA23)

Offset

For n = 0 to 23:

Register	Offset
ALTAn	34h + (n × 20h)

Function

Provides an alternate address to access AS2 shadow registers in these restricted modes:

- General-Purpose Input and Output (GPIO) mode

- Pulse Edge Counting (PEC) mode
- Output PWM with Trigger (OPWMT) mode

In these modes, you can use A*n*[A] together with with ALTA*n*[ALTA] to access both AS1 and AS2. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] summarizes the ALTA*n* writing and reading accesses for all ALTA*n* operation modes.

In modes that do not require this register, any write access is ignored and any read access returns unspecified data.

NOTE

You must clear triggers to BCTU after TRGMUX programming using TRGCFG_n[TRG_FLAG] bit.

62.2 Introduction

BCTU accepts ADC conversion-request trigger inputs and routes those requests to one or more ADCs.

BCTU accepts the following trigger sources:

- Hardware triggers (outputs from on-chip timer modules)
- Software triggers through the SFTRGRn register

BCTU maps each trigger input to a Trigger Configuration (TRGCFG_0 - TRGCFG_71) register, which specifies the target ADC channel and other control data for the requested conversion.

You can configure a list of ADC channels, the CL, that processes a sequence of conversions in response to a single trigger input. See the Conversion list (CL) section.

BCTU stores each ADC conversion result for CPU access or routing to memory through DMA.

If the same ADC is targeted by multiple triggers, priority logic selects the next trigger to process from all active trigger inputs. See Priority of simultaneous triggers.

BCTU inputs are active-high signals. That is, a logic 1 asserts the trigger input.

62.3 Features

BCTU supports:

- 72 trigger inputs, configured with the Trigger Configuration (TRGCFG_0 - TRGCFG_71) registers
- Trigger outputs to 3 ADCs
- One priority selection logic block per ADC
- Selection multiplexers to select one trigger at a time for each ADC
- A CL of 32 ADC channels
- A trigger grouping block to latch the hardware triggers. BCTU clears these triggers when the ADC sends an acknowledgement for conversion completion.

62.4 Block diagram

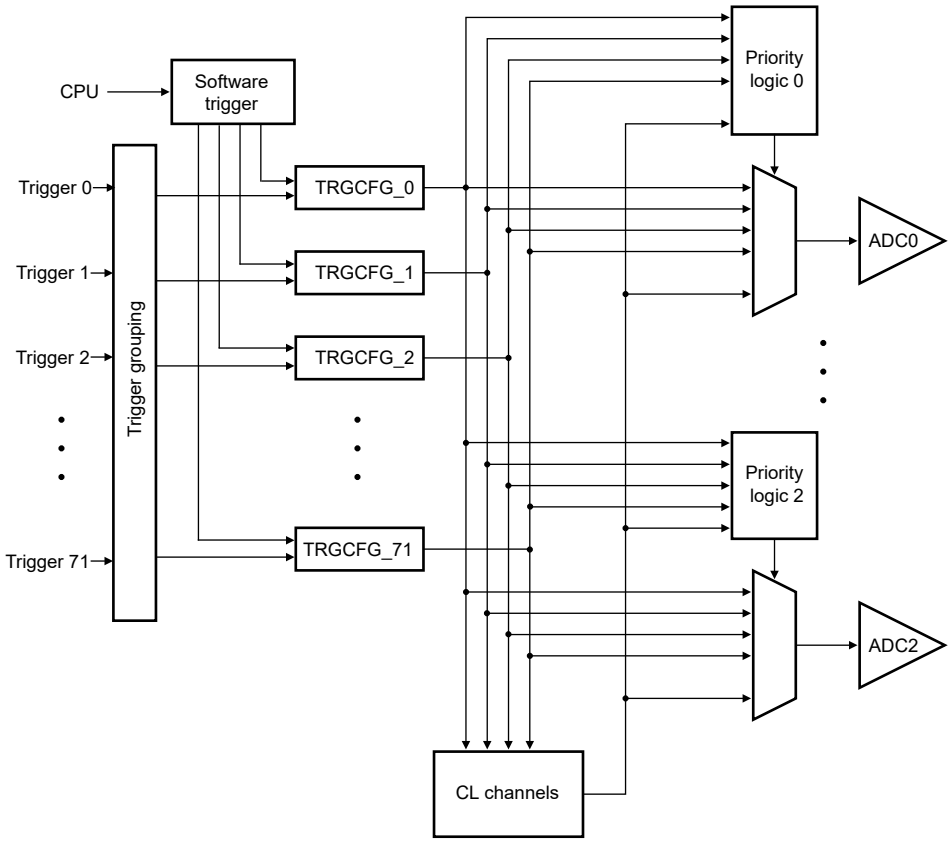

Figure 345. BCTU block diagram

62.5 Interaction with other peripherals

BCTU works together with timer and ADC modules on the chip. Use the Trigger Configuration registers (TRGCFG_*n*) to map BCTU triggers to ADC inputs. When a timer output asserts a BCTU trigger, BCTU passes the trigger to an ADC input and stores the trigger assertion until the corresponding ADC begins the requested conversion. When the ADC completes the conversion, BCTU asserts a trigger clear signal to clear both the internally stored trigger and the external trigger source if they are still asserted. Implementation illustrates the modules that interact with BCTU.

NOTE

A timer trigger can remain active until the corresponding ADC initiates conversion. Therefore, another match may occur in the timer before the ADC conversion begins. BCTU does not detect this trigger overrun. Your application must look for and respond to such conditions.

62.6 Implementation

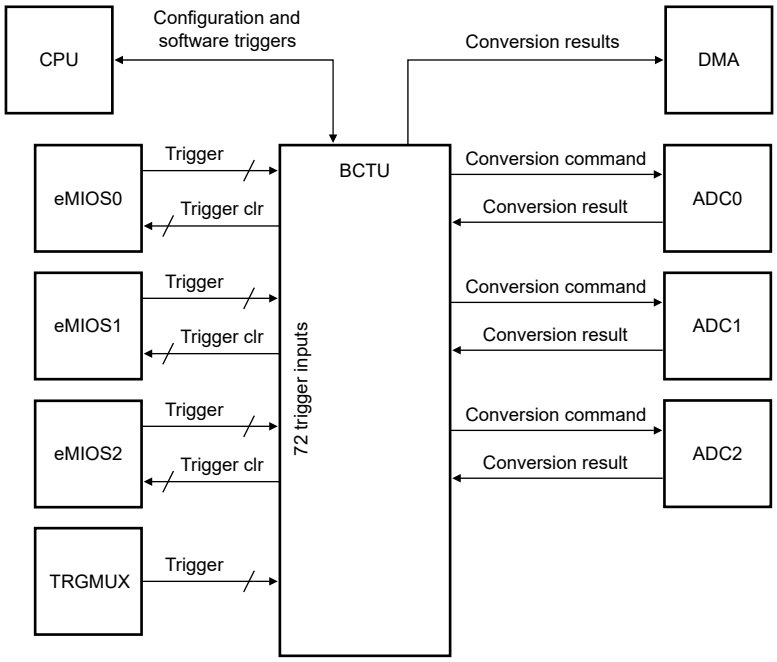

Figure 346. Implementation

62.7 Module Disable (Low Power state)

Module Disable (MCR[MDIS]) stops the BCTU clock, resulting in reduced power consumption.

When you disable BCTU (write 1 to MDIS), it:

- Waits for the completion of any in-progress conversions before stopping the clock.
- Ignores all trigger inputs.
- Does not trigger any ADC conversion requests.
- Maintains any asserted trigger inputs, which you can clear if necessary.

When you re-enable BCTU (write 0 to MDIS) and Global Triggers are enabled (MCR[GTRGEN]), BCTU processes all active asserted trigger inputs and sends conversion requests to ADCs according to the priority scheme.

62.8 Software reset

You can reinitialize all BCTU registers to their reset values with Software Reset (MCR[Software_Reset]).

Software reset does not clear any active trigger inputs, but it does put the ADC interface into the Reset state. Therefore, to avoid data incoherency, you must terminate any BCTU-triggered conversions or wait until they are complete before asserting software reset.

62.9 Triggers

62.9.1 Overview

BCTU prioritizes ADC trigger inputs based on the input number: the lower the number, the higher the priority associated with it. Therefore, trigger 0 is the highest priority trigger and trigger 71 is the lowest priority. The trigger input priority scheme determines

which trigger takes precedence when more than one trigger occurs at the same time, or when the triggered ADC is busy with a conversion. Therefore, there are two possible scenarios for the trigger priority selection:

- When there are no ongoing conversions
- When a triggered ADC is executing a conversion

BCTU supports two types of trigger sources:

- Hardware triggers from timer modules
- Software triggers (SFTRGR*n*)

62.9.2 Hardware triggers

To request an ADC conversion through the BCTU, a timer module such as eMIOS asserts its output signal, which is connected to a BCTU trigger input. When BCTU detects the asserted trigger, it routes that request to the ADCs selected in the corresponding Trigger Configuration (TRGCFG_*n*[ADC_SEL*m*]). The trigger remains asserted until the requested conversion begins, at which time BCTU clears the trigger. If the timer asserts the trigger input when the trigger is already set, BCTU ignores the new trigger. If BCTU receives a new trigger input at the same time it is clearing the trigger, then the trigger remains asserted and BCTU initiates a new conversion.

If you configure the trigger for CL, trigger assertion begins a sequence of conversions controlled by the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers. In this event, BCTU clears the trigger when the last conversion in the CL begins.

NOTE

Any new trigger input participates in the trigger priority selection scheme and therefore may not trigger the next conversion.

62.9.3 Software triggers

You assert a software trigger by writing 1 to the corresponding field of the appropriate Software Trigger (SFTRGR*n*) register. Similar to the hardware triggers, BCTU changes the software trigger field to 0 when the requested conversion begins. If you write 1 to the software trigger field while the conversion is still in progress, BCTU ignores the request. If you write 1 to the field at the same time BCTU is attempting to clear the trigger (change the field to 0), the trigger remains asserted and BCTU triggers a new conversion following the trigger priority criteria.

62.9.4 Configure all triggers

Global Trigger Enable (MCR[GTRGEN]) allows you to configure the BCTU trigger inputs and then activate them all at one time.

To configure and then activate all BCTU triggers:

1. Clear any currently active and asserted trigger inputs (write 0 to TRGFG_*n*[TRG_FLAG]), which also causes BCTU to assert trigger clear to the trigger sources.
2. Disable Global Triggers (MCR[GTRGEN]). This action deactivates all trigger inputs and prevents BCTU from generating any ADC conversion requests.
3. Configure the individual trigger inputs (see Configure individual triggers).
4. Enable Global Triggers (MCR[GTRGEN]). This action activates all individually enabled triggers at the same time.

62.9.5 Configure individual triggers

Using Trigger Configuration (TRGCFG_0 - TRGCFG_71), for each trigger:

- Enable the trigger (TRIGEN).
- Specify the target ADC (ADC_SEL*n*).
- Specify the ADC channel (CHANNEL_VALUE_OR_LADDR).
- Specify whether the trigger initiates a single conversion or a CL (TRS).

- For a CL trigger, specify a pointer to the CL element (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]).

62.9.6 Reconfigure triggers on-the-fly

NOTE

Reconfigure BCTU triggers only when the individual trigger is not active (TRG_FLAG). If TRG_FLAG is 1, the requested conversion is still in progress and it is not safe to modify the trigger configuration.

To reconfigure a trigger on-the-fly (while BCTU is in full operation):

1. Disable the trigger (TRIGEN) to prevent it from requesting a new conversion.
2. Check the current state of the trigger (TRG_FLAG) to be sure no conversion or CL is in progress.
3. When any in-progress conversion or CL completes (TRG_FLAG == 0), clear the trigger source by writing 1 to TRG_FLAG. This action ensures that only trigger inputs that assert after you reconfigure and re-enable the trigger are able to request a new conversion or CL.
4. Reconfigure the trigger (see Configure individual triggers).
5. Enable the trigger (TRIGEN).

62.9.7 Enable software triggers

To allow software triggers (SFTRGR*n*[SFTRG*m*]) to request conversions, you must enable Global Trigger Enable (MCR[GTRGEN]). If you disable Global Trigger Enable, software triggers do not initiate a conversion but asserted triggers remain asserted. However, when you enable Global Trigger Enable, any asserted software triggers initiate conversions following the priority scheme of lowest to highest trigger number.

Software triggers operate regardless of individual Trigger Enable (TRGCFG_x[TRIGEN]). That is, writing 1 to any Software Trigger (SFTRGR*n*[SFTRG*m*]) initiates a conversion (following the priority scheme) regardless of the value of Trigger Enable. This software trigger independence supports the elimination of conflict between software and hardware triggers.

62.9.8 Trigger timing

There are four clock cycles from assertion of a BCTU trigger input to assertion of the trigger output to the ADC. For single conversions, BCTU asserts Trigger Clear back to the trigger source simultaneous to asserting the trigger to the ADC.

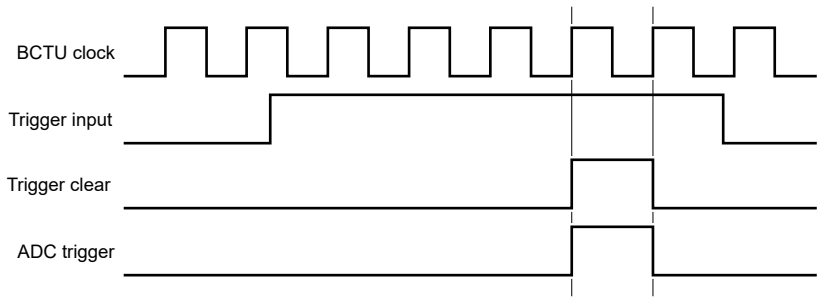

Figure 347. Trigger timing

62.9.9 Priority of simultaneous triggers

When more than one trigger input asserts a conversion request to the same ADC at the same time—that is, in the same BCTU clock cycle—BCTU employs a priority scheme to determine which asserted trigger to process next. BCTU prioritizes trigger inputs based on the trigger number. The lowest number, trigger 0, has the highest priority, and the highest number, trigger 71, has the lowest priority.

If two triggers assert in the same clock cycle, BCTU gives priority to the lower numbered trigger. For example, if trigger 0 and trigger 1 both assert in the same cycle, BCTU selects trigger 0 for trigger generation. Trigger 1 remains active (pending) until the conversion requested by trigger 0 completes. See Simultaneous trigger priority management.

If trigger 0 asserts again before the next trigger selection opportunity at the end of the current conversion, then BCTU selects it again and trigger 1 remains asserted (pending) during the next ADC conversion time frame.

As illustrated in Trigger timing, BCTU requires four clock cycles to transmit a conversion request to an ADC if that ADC is not already executing a conversion. However, if the ADC is busy at the time of trigger assertion, BCTU requires only three clock cycles to generate the conversion request for a subsequent conversion.

Triggers that assert in the same clock cycle but target different ADCs are not in conflict, and BCTU processes both triggers at the same time.

62.9.10 Simultaneous trigger priority management

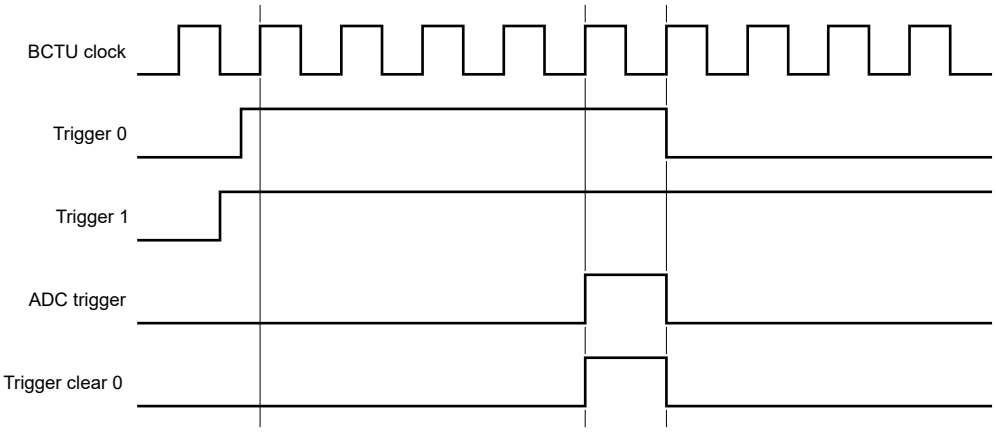

Figure 348. Simultaneous trigger priority management

62.9.11 Trigger management when ADC is busy

When a trigger input asserts a conversion request to an ADC that is already processing a conversion requested by a different trigger, the new trigger remains active (pending) until the conversion in progress completes. This behavior is the same as if the two triggers had been simultaneous (occurred in the same clock cycle). When the in-progress conversion completes, the pending trigger then competes for priority with any other active trigger for that ADC.

62.10 Conversion list (CL)

62.10.1 CL overview

A CL executes a sequence of conversions on one or more target ADCs. See CL architecture and operation. It also stores information from the last conversion executed in a sequence except for the target ADC, which is stored in ADC Select n (TRGCFG_*m*[ADC_SEL*n*]).

If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) points to a CL element containing one or more entries:

1. The trigger initiates a sequence of conversions starting with the target CL element.
2. The sequence executes until the LAST channel (LISTCHR_*n*[LAST_y] is 1), and stops after that channel is converted.

When you configure the CL element for Next Channel Wait For Trigger (write 1 to LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y]):

1. BCTU clears the trigger source.

2. CL execution pauses after the current conversion is completed.
3. CL execution resumes when the same trigger asserts again.

BCTU determines trigger priority before executing any CL. See Priority of simultaneous triggers.

62.10.2 CL architecture and operation

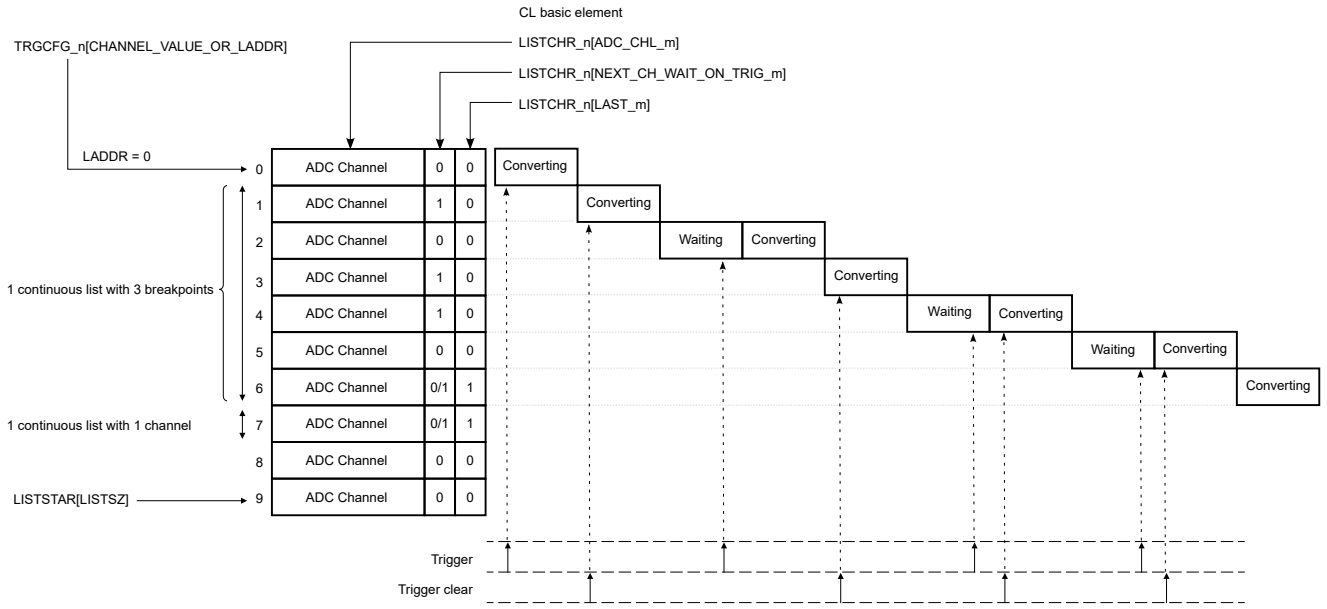

Figure 349. CL architecture and operation

62.10.3 CL channel rules

CL conversion obeys the following rules:

- The sequence of conversions executes until the Last Channel (LISTCHR_*n*[LAST_y] is 1).
- A CL conversion sequence precludes other conversions on the same ADC. If the CL is waiting (LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y] is 1), BCTU cannot route a non-CL conversion to that ADC (although that ADC remains available for normal and injected conversions).
- Two or more triggers for different ADCs may point to the same CL. This CL can drive parallel execution on the selected ADCs.
- If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) does not point to a valid list address, BCTU uses address 0 by default.
- When the CL pointer reaches the last available list address (LISTSTAR[LISTSZ] minus 1), the pointer wraps to list address 0.
- You can select more than one ADC per trigger using the ADC Select n (TRGCFG_x[ADC_SELn]) fields, but selecting more than one ADC is valid only for multiple parallel CL operation. If you select more than one ADC for a single-conversion trigger, BCTU ignores the trigger.

62.11 ADC conversion results access

62.11.1 Overview

The value of DATA_DEST determines access to ADC results.

- DATA_DEST = 000: ADC results are available in the ADC data registers.

- DATA_DEST = 001: ADC results are available in FIFO 1 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.
- DATA_DEST = 010: ADC results are available in FIFO 2 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.

You can access ADC results using flags and interrupt requests (see Access on interrupt request) or DMA (see Access on DMA request). Interrupt requests are based on Module Status (MSR) flags. ADC*n*DR provides the following information, with one register used for each ADC:

- The conversion results
- The channel that was used for the conversion
- The trigger input that initiated the conversion
- Whether a CL element generated the conversion
- Whether the data was the last conversion of a CL

62.11.2 Access on interrupt request

If interrupts are enabled for ADC*n* Result Data (MCR[IEN*n*] is 1) and DMAs are disabled for ADC*n* Result Data (MCR[DMA*n*] is 0), BCTU generates an interrupt request for each available conversion data in ADC*n*DR. Because BCTU executes conversions on different ADCs in parallel, conversion results may be available on multiple ADCs at the same time. New Data (MSR[NDATAn] is 1) indicates that new conversion data is available in the corresponding ADC Data Result (ADC*n*DR). To clear the New Data flag, write 1 to MSR[NDATAn_CLR].

62.11.3 Access on DMA request

If you enable DMA requests (MCR[DMA*n*]):

- You must select one channel for DMA per ADC.
- New conversion result data (ADC*n*DR) generates a DMA request.
- The DMA controller deasserts the DMA request and writes 1 to MSR[NDATAn_CLR] to clear the flag.

When an ADC generates New Data (MSR[NDATAn]), BCTU processes the DMA request. See Clear a DMA request.

62.11.4 Clear an interrupt request

BCTU clears an interrupt request when:

- The number of valid entries is less than or equal to the FIFOn Watermark Level (FIFOWM[WM_FIFO*n*]).
- You write 1 to FIFO Watermark Interrupt Status (FIFOERR[WM_INT_FIFO*n*]).

62.11.5 Clear a DMA request

BCTU clears a DMA request when:

- The number of valid entries is less than or equal to the FIFOn Watermark Level (FIFOWM[WM_FIFO*n*]).
- The DMA controller sends acknowledgment to BCTU.

62.11.6 Clear an error-generated interrupt request

Clear an interrupt generated because of an error condition by writing 1 to the appropriate error flag:

- FIFOERR[OVR_ERR_FIFO1]
- FIFOERR[UNDR_ERR_FIFO1]
- FIFOERR[OVR_ERR_FIFO2]

- FIFOERR[UNDR_ERR_FIFO2]

62.11.7 Conversion data overrun

If new ADC conversion data becomes available before you read the previous data (ADC*n*DR), then BCTU indicates a data overrun (MSR[DATAOVRn] is 1).

If you enable interrupts for the ADC (MCR[IEN*n*]), a data overrun also generates an interrupt request, regardless of the DMA request configuration.

To clear a data overrun (MSR[DATAOVRn]), write 1 to Data Overrun Clear (MSR[DATAOVRn_CLR]). See Clear an error-generated interrupt request.

62.11.8 Route conversion data to FIFO

BCTU allows you to route multiple ADC conversion results to one of 2 internal data FIFOs. Any trigger source can route results to an available FIFO based on the trigger index. Each FIFO has a dedicated counter (FIFOCNTR[CNTR_FIFO*n*]) to indicate the number of entries in the FIFO.

Each FIFO also has its own result data register (FIFO*n*DR) that contains the following information about the last conversion result routed to the FIFO.

- ADC result data
- Trigger source index
- ADC number
- ADC channel number

62.11.9 Read ADC result from FIFO

Each FIFO has DMA and interrupt interfaces. The DMA interface reads data. The interrupt interface indicates watermark and error conditions:

- An overrun error (FIFOERR[OVR_ERR_FIFO*n*]) occurs when you attempt to write data to an already full FIFO.
- An underrun error (FIFOERR[UNDR_ERR_FIFO*n*]) occurs when you attempt to read data from an empty FIFO.
- BCTU asserts a Watermark interrupt request if the number of valid FIFO entries exceeds the watermark level (FIFOWM[WM_FIFO*n*]).

You can read a FIFO:

- by enabling DMA requests (FIFOCR[DMA_EN_FIFO*n*])
- by polling the FIFO Full status (FIFOSR[FULL_FIFO*n*])

See Configuration of DMA and interrupt behavior.

62.11.10 Configuration of DMA and interrupt behavior

Table 365. Configuration of DMA and interrupt behavior

FIFOCR[DMA_EN_FIFO*n*]	FIFOCR[IEN_FIFO*n*]	Condition
0	0	No DMA request; no interrupt request
0	1	Interrupt request when FIFO exceeds watermark level; interrupt request on error
1	0	DMA request when FIFO exceeds watermark level
1	1	DMA request when FIFO exceeds watermark level; interrupt request on error

62.12 Multiple parallel conversions (MPC)

62.12.1 Overview

The MPC mechanism allows you to execute a series of simultaneous ADC conversions by selecting more than one ADC for any CL-configured trigger.

62.12.2 Configure MPC

To configure a CL to perform MPC:

1. Select CL for the trigger resolution (write 1 to TRGCFG_*m*[TRS]).
2. Select more than one ADC for the trigger (TRGCFG_*m*[ADC_SEL*n*]).
3. Specify the CL address for the first CL element (TRGCFG_*m*[CHANNEL_VALUE_OR_LADDR]).

62.12.3 CL address selection for MPC

When the trigger input for the CL asserts, BCTU uses the Channel or List Address (CHANNEL_VALUE_OR_LADDR) as an index into the CL for the lowest numbered ADC selected (ADC_SEL*n*), and each subsequent element of the CL for each remaining selected ADC. The set of selected ADC channels perform their conversions in parallel. When that set of conversions is complete, the next set of CL elements determine the next set of ADC channels to perform parallel conversions, as illustrated in:

- Example: MPC with two ADCs
- Example: MPC with three ADCs

62.12.4 Example: MPC with two ADCs

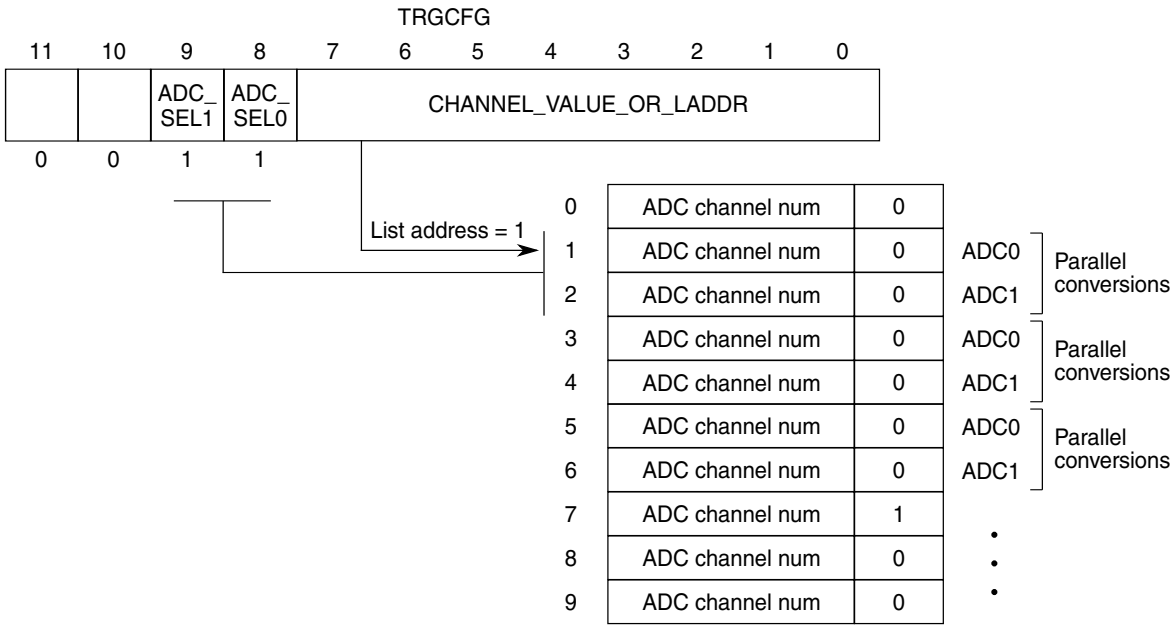

Figure 350. Example: MPC with two ADCs

62.12.5 Example: MPC with three ADCs

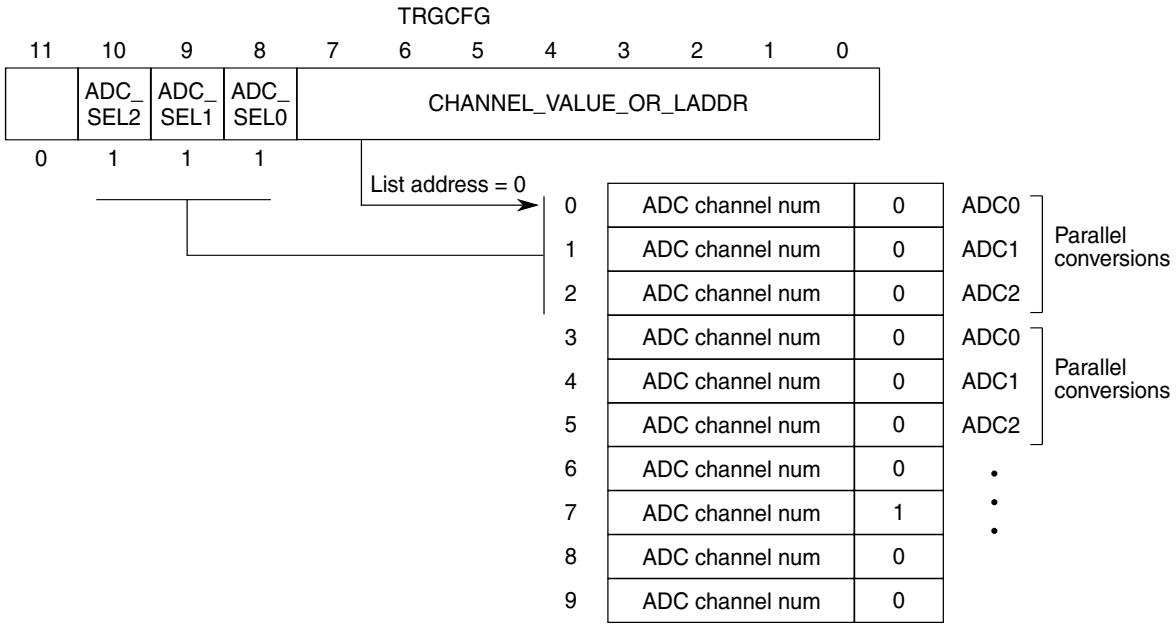

Figure 351. Example: MPC with three ADCs

62.12.6 MPC priority rules

MPC follows the same priority rules as for single conversions, which is based on the trigger input number: the lower the trigger, the higher the priority. However, MPC cannot start until all ADCs selected for the CL are available; that is, they are not currenlty engaged in conversion. For example, if a trigger input asserts for a CL using ADC0 and ADC1, BCTU does not initiate the CL until ADC0 and ADC1 are both available.

Also, if ADC0 is available but there is a higher priority trigger for ADC1, the MPC does not start. If trigger inputs assert for two MPCs that have at least one ADC in common, the lower trigger number has higher priority. A priority conflict occurs only when separate requested CLs have at least one ADC in common. If the MPCs use different ADCs, there is no conflict and the MPCs execute at the same time.

62.13 Interrupts and DMA requests

Table 366. Interrupts and DMA requests

Event	Enable interrupt	Enable DMA request	Description
Trigger Flag	MCR[TRGEN]	—	Interrupt request on assertion of Trigger Flag (MSR[TRGF])
ADC Data Ready	MCR[IEN*n*]	MCR[DMA*n*]	Interrupt or DMA request when ADC result data is available (ADC*n*DR)
CL Last	MCR[LIST_IEN]	—	Interrupt request when the last conversion of any CL executes
FIFO Watermark	FIFOCR[IEN_FIFO*n*]	FIFOCR[DMA_EN_FIFO*n*]	Interrupt or DMA request when the number of valid FIFO entries exceeds the FIFO

62.14 BCTU register descriptions

All BCTU registers are 32 bits wide. 8-bit write operations are allowed. The BCTU module does not include any coherence mechanism, so application software must ensure coherency.

NOTE

- You must always write 0 to reserved writable registers and fields. Read accesses of reserved registers and fields do not return meaningful data.
- For registers with write protection, if protection is active and you attempt to write to those registers, register content is unaffected and BCTU issues a transfer error.

62.14.1 BCTU memory map

BCTU base address: 4008_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration (MCR)	32	RW	0000_0000h
8h	Module Status (MSR)	32	WORZ	0000_0000h
18h - 134h	Trigger Configuration (TRGCFG_0 - TRGCFG_71)	32	RW	0000_0000h
228h	Write Protection (WRPROT)	32	RW	0000_0000h
22Ch	Software Trigger 1 (SFTRGR1)	32	RW	0000_0000h
230h	Software Trigger 2 (SFTRGR2)	32	RW	0000_0000h
234h	Software Trigger 3 (SFTRGR3)	32	RW	0000_0000h
23Ch - 244h	ADCn Result Data (ADC0DR - ADC2DR)	32	RO	0000_0000h
24Ch	CL Size Status (LISTSTAR)	32	RO	0000_0020h
250h - 28Ch	CL Channel Address (LISTCHR_0 - LISTCHR_15)	32	RW	0000_0000h
450h - 454h	FIFO Result Data (FIFO1DR - FIFO2DR)	32	RO	0000_0000h
460h	FIFO Control (FIFOCR)	32	RW	0000_0000h
464h	FIFO Watermark Configuration (FIFOWM)	32	RW	0000_0000h
468h	FIFO Error/Status (FIFOERR)	32	W1C	0000_0000h
46Ch	FIFO Status (FIFOSR)	32	RO	0000_0000h
470h	FIFO Counter (FIFOCNTR)	32	RO	0000_0000h

62.14.2 Module Configuration (MCR)

Offset

Register	Offset
MCR	0h

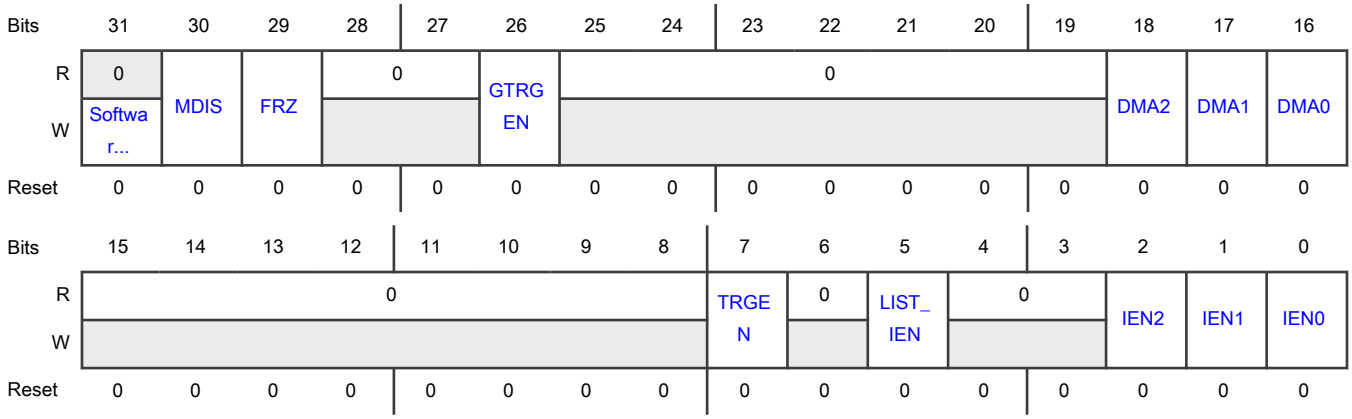
Function

Configures the following aspects of BCTU behavior:

- Low power
- Debug
- Trigger control
- DMA control
- Interrupt control

Access: User read/write

Diagram



Fields

Field	Function
31 Software_Reset	Software Reset Asserts soft reset, which initializes all BCTU registers and internal state machines to their reset values. 0b - Deasserts 1b - Asserts
30 MDIS	Module Disable Disables BCTU by putting it in Low Power state (see Module Disable (Low Power state)). 0b - Enable (normal operation) 1b - Disable (low-power operation)
29 FRZ	Debug Freeze Disables all hardware trigger inputs but leaves the software trigger enabled. Debug Freeze isolates BCTU from external triggers and allows you to manually trigger a conversion and read the conversion result. 0b - Disables 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
28-27 —	Reserved
26 GTRGEN	Global Trigger Enable Enables all individually enabled trigger inputs at the same time. For any given input trigger to be active, you must both enable the individual trigger (TRGCFG_*n*[TRIGEN]) and Global Trigger Enable. See Configure all triggers. 0b - Disable 1b - Enable
25-19 —	Reserved
18-16 DMAn	Enable ADCnDR DMA Enables DMA operation when new data is available in ADC*n*DR. 0b - Disable 1b - Enable
15-8 —	Reserved
7 TRGEN	Trigger Interrupt Request Enable Enables an interrupt request on a Trigger Flag (MSR[TRGF]). 0b - Disable 1b - Enable
6 —	Reserved
5 LIST_IEN	CL Interrupt Enable Enables an interrupt request for the last conversion in a CL (both ADC*n*DR[LIST] and ADC*n*DR[LAST] are 1). 0b - Disable 1b - Enable
4-3 —	Reserved
2-0 IENn	Interrupt Enable For ADCnDR

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables an interrupt request when BCTU writes a new conversion result to ADC Data (ADC*n*DR). Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]]. Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled. 0b - Disable 1b - Enable

62.14.3 Module Status (MSR)

Offset

Register	Offset
MSR	8h

Function

Indicates the status of various BCTU functions, including:

- Whether conversion data is available for each ADC
- CL operation, such as the last conversion command executed in a CL
- Whether BCTU triggered any of the ADCs

All flag fields become 0 upon assertion of a low-power (software) or clock-stop (hardware) request. You can turn off individual flags by writing 1 to the field.

Access: User read/write

18-16 NDATAn_CLR	New Data Clear Changes New Data *n* (NDATA*n*) to 0. 0b - No action 1b - Changes to 0
15 TRGF	Trigger Flag Indicates at least one ADC was triggered. 0b - No ADC triggered 1b - An ADC was triggered
14-11 —	Reserved
10-8 LISTn_Last	CL n Last Conversion Indicates that ADCn has executed the last conversion in a CL.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Last conversion not complete 1b - Last conversion complete
7 —	Reserved
6-4 DATAOVRn	Data Overrun n Indicates that the data in ADCn has been overwritten with new data. 0b - Data not overwritten 1b - Data overwritten
3 —	Reserved
2-0 NDATAn	New Data n Indicates that new conversion data is available for ADCn. 0b - Not available 1b - Available

62.14.4 Trigger Configuration (TRGCFG_0 - TRGCFG_71)

Offset

For a = 0 to 71:

Register	Offset
TRGCFG_a	18h + (a × 4h)

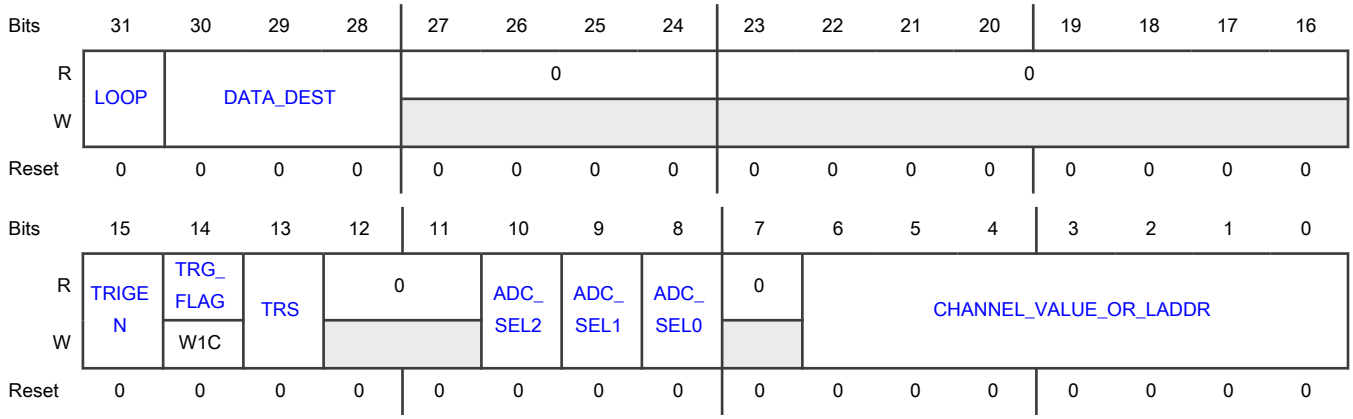
Function

Configures the corresponding trigger:

- Specifies the target ADC and ADC channel to use for conversion.
- Specifies whether to use a CL or a single ADC conversion command.

Access: User read/write

Diagram



Fields

Field	Function
31 LOOP	Loop Specifies that the current trigger executes in a loop; that is, the triggered conversion repeats until you disable Loop. Each loop-triggered conversion wins the priority evaluation among all pending triggers, and executes only if it is the highest-priority triggered conversion at the moment the conversion starts. 0b - Disable 1b - Enable
30-28 DATA_DEST	Data Destination Specifies the destination for storing the conversion results. You can route each ADC's conversion result to either of the following: • ADC-specific data registers • One of the available FIFOs BCTU routes conversion results to different destinations based on the trigger index that requested the conversion. You cannot duplicate the same data in more than one destination. 000b - ADC-specific data registers 001b - FIFO1 010b - FIFO2 011b - Reserved All other values are reserved.
27-24 —	Reserved
23-16 —	Reserved
15	Trigger Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRIGEN	Enables hardware input triggers to initiate ADC conversions. This field does not affect software triggers. 0b - Disable 1b - Enable
14 TRG_FLAG	Trigger Flag Indicates the trigger input is asserted and an ADC conversion is in progress. When the conversion completes, BCTU changes this field to 0. Writing 1 to this field causes the input trigger event to clear when the in-progress conversion completes, and prevents this trigger from initiating a new ADC conversion until the input trigger is asserted again. **NOTE** This field behaves differently for read and write operations. When reading 0b - No ongoing ADC conversion initiated 1b - Ongoing ADC conversion initiated When writing 0b - No action 1b - Changes to 0
13 TRS	Trigger Resolution Selects single conversion or CL conversions. 0b - Single conversion 1b - CL conversions
12-11 —	Reserved
10-8 ADC_SELn	ADC Select n Selects ADC *n* for conversion. 0b - Deselects 1b - Selects
7 —	Reserved
6-0 CHANNEL_VALUE_OR_LADDR	Channel or CL Address Depending on the value of TRS: • 0: Specifies the ADC channel for conversion • 1: Specifies the address of the first CL position to execute

62.14.5 Write Protection (WRPROT)

Offset

Register	Offset
WRPROT	228h

Function

Enables write protection at reset exit. To allow writes to protected registers, you must write a special code into PROTEC_CODE. There are two codes to remove protection: one that permanently disables the protection; one that disables protection during one write cycle to a protected register, after which the protection code returns to the initial (protected) value of 0000b.

Access: User read/write

Fields

Field	Function
31-4 —	Reserved
3-0 PROTEC_CODE	Protection Code Controls the protection of write-protected registers. **NOTE** You can write this field only in Normal mode (MCR[MDIS] is 0). 0000b - Enable protection 1001b - Disable protection for one write cycle 1010b - Disable protection permanently

62.14.6 Software Trigger 1 (SFTRGR1)

Offset

Register	Offset
SFTRGR1	22Ch

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_x[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

62.14.7 Software Trigger 2 (SFTRGR2)

Offset

Register	Offset
SFTRGR2	230h

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_*n*[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

62.14.9 ADCn Result Data (ADC0DR - ADC2DR)

Offset

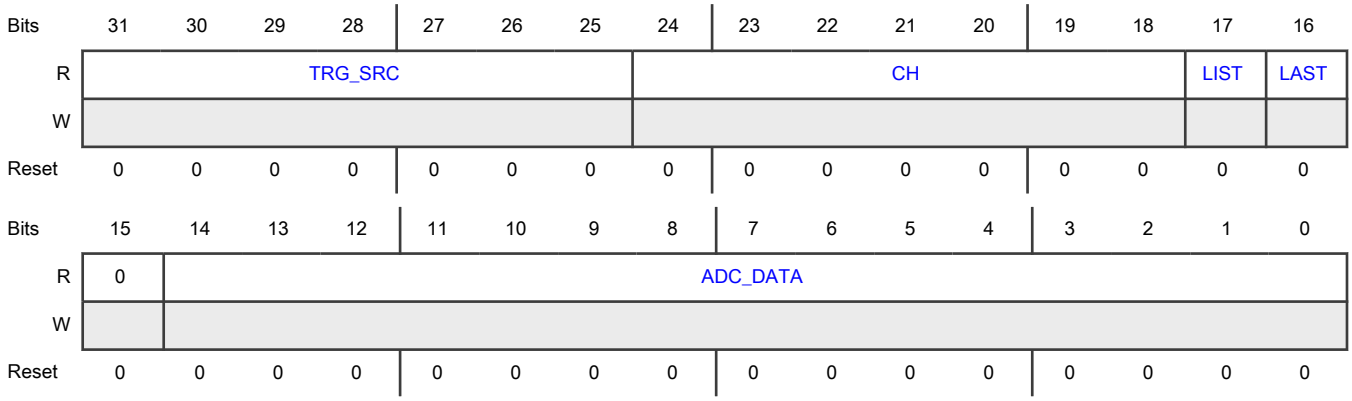
Register	Offset
ADC0DR	23Ch
ADC1DR	240h
ADC2DR	244h

Function

Provides ADC conversion result data. Also indicates the ADC channel used in that conversion, the trigger source that initiated it, and whether conversion was initiated from a CL.

Access: User read

Diagram



Fields

Field	Function
31-25 TRG_SRC	Trigger Source Contains the trigger number used to trigger the conversion.
24-18 CH	Channel Contains the ADC channel used for the conversion.
17 LIST	List Indicates whether the conversion was part of a CL or a single conversion trigger. 0b - Single conversion 1b - CL
16 LAST	Last For CL conversions, indicates this conversion result is the last conversion of the CL. 0b - Not the last conversion of a CL, or not a CL conversion 1b - Last conversion of a CL
15 —	Reserved
14-0 ADC_DATA	ADC Data Contains the data from the conversion.

62.14.10 CL Size Status (LISTSTAR)

Offset

Register	Offset
LISTSTAR	24Ch

Function

Indicates the size of the CL. Each element of the CL contains the channel number used in one conversion.

Access: User read

Diagram

7-0 LISTSZ	CL Size Indicates the size of the CL in number of elements.

62.14.11 CL Channel Address (LISTCHR_0 - LISTCHR_15)

Offset

For m = 0 to 15:

Register	Offset
LISTCHR_m	250h + (m × 4h)

Function

Configures these attributes for two CL elements:

- ADC channel number to use for conversion
- Whether the element is the last element of a CL

Access: User read/write

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
	0b - Not next-to-last 1b - Next-to-last channel in CL
14 NEXT_CH_WAIT_ON_TRIG_y_plus_1	Next Channel Wait For Trigger Plus 1 Instructs CL execution to stop after executing the current ADC channel. Execution begins again when the same trigger, which started the CL, reoccurs. **NOTE** If this is the last channel in the CL (LAST_y_plus_1), you must write 0 to this field. 0b - CL executes continuously 1b - CL stops executing
13-12 —	Reserved
11-8 —	Reserved
7 —	Reserved
6-0 ADC_CHL_y_plus_1	ADC Channel Selection Plus 1 Specifies the ADC channel to use for the (*y* + 1) element of the CL, where *y* equals (2 x *m*).

62.14.12 FIFO Result Data (FIFO1DR - FIFO2DR)

Offset

Register	Offset
FIFO1DR	450h
FIFO2DR	454h

Function

Contains the ADC conversion result and information about the conversion:

- ADC channel
- Trigger source
- ADC number

Access: User read

Diagram

3-0 WM_FIFO1	FIFO1 Watermark Level Specifies the watermark level for FIFO1.

62.14.15 FIFO Error/Status (FIFOERR)

Offset

Register	Offset
FIFOERR	468h

Function

Allows you to clear FIFO error and status flags. Each FIFO has its own error and status flags that can be configured to generate an interrupt. FIFO Status (FIFOSR) maintains the status of these flags. BCTU writes a 1 to these flags, and you must then clear them using FIFOERR.

Access: User read/write

Diagram

62.15 Glossary

CL Conversion list. The set of ADC channels, configured through the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers, used for performing multiple sequential conversions initiated by a single trigger.

MPC Multiple parallel conversions

PSI Parallel side interface

RWB Read/write bus

WDATA Write Data bus

Chapter 63
Trigger MUX (TRGMUX)

63.1 Chip-specific TRGMUX information

63.1.1 TRGMUX input output configuration and instances

This chip has 1 instance of TRGMUX module.

Table 367. TRGMUX instance

Instance	S32K311/S32K312/S32K322/S32K342/S32K314/S32K324/S32K344/S32K358
TRGMUX	Yes

The device supports the triggering scheme between peripherals. For the supported trigger sources and destination, see the TRGMUX connectivity file attached to this document.

This device has 16 pads (SIUL2) mapped from TRGMUX inputs and TRGMUX outputs are mapped to the eMIOS channels, hence two timers channels can use a single pin of the device to do input capture.

While using TRGMUX, below points need to be taken care:

- User must ensure the minimum pulse of 100 ns on SIUL2 pads when using them as trigger source on TRGMUX.
- Pulses which are visible on pads depends on the pad type. Different pad supports different frequencies. For more details on pad types and their respective bandwidth, see section "IO signal table" in "Signal Multiplexing" chapter.
- End of conversion (EOC) signals of ADC modules are mapped on TRGMUX inputs as trigger sources. The EOC signal is asserted after ADC conversion regardless whether conversion is signaled by polling flags, interrupt or DMA transfer. The signal shall not be used to start injected conversion on same ADC channel as it will overwrite current result register.
- The minimum pulse length requirement is 1.5X of destination clock, so that it gets properly sampled at the destination IP connected to TRGMUX outputs, otherwise there are chances of missing the triggers generated from source. For example, the trigger generated from PAD for ADC conversion should be kept high/low for at least 1.5X of ADC clock so that it gets sampled in ADC clock domain. To ensure this, pulse strechers have been placed before some of the hardware modules mapped on TRGMUX outputs.
- Some PADS are being shared by both ADC and TRGMUX. It is recommended that trigger initiated from such PADS should not be used to trigger a conversion on the ADC channel mapped on same PAD. Failing to do this will cause congestion on same PAD.
- Out of all the pads mapped on TRGMUX, first four pads have glitch filters. For details, see the TRGMUX connectivity file attached to this document. The trigger pulse width should honour the pulse width requirement as per Glitch Filter specifications. The same signal can be observed at output pin if the pulse width of the input data signal is more than 400ns and no output signal should be observed if the pulse width of the input data signal is less than 20ns. A signal with a pulse width that is between 20ns and 400 ns should not be applied as the behavior is not guaranteed.
- Trigger outputs are grouped peripheral-wise and have a common lock bit based on TRGMUX REGx. For instance, normal_trigger, injected_trigger and external_sync of ADC_0 are grouped onto TRGMUX_REG0 and have a common lock bit.

63.1.2 Pulse strechers in TRGMUX

TRGMUX has some hardware modules on its input side running at faster clock than some of the IPs present on output side. For instance, eMIOS reload outputs running at 160 MHz can trigger LPI2C trigger input clocked at 40 MHz, in that case there is a high chance that trigger from eMIOS will be missed. Following Pulse strechers are added for the IPs on output side of TRGMUX.

Table 368. Pulse strechers in TRGMUX

Evaluation Parameter	ADC_0/1/2 external trigger to sync the start pulse	BCTU trigger 23/47/71	FlexIO trigger input_0/1/2/3[1]	LPI2C_0 Trigger input	LPSPI_0/1/2 Trigger input	CM7_0/1/2 RXEV
IP expects	Synchronized single cycle pulse	Synchronized pulse	IP requirement is to have 2 cycle pulse of flexio_clk	IP requirement is to have 2 cycle pulse of lpi2c_clk	IP requirement is to have 2 cycle pulse of lpspi_clk	Single cycle pulse
Frequency	CORE_CLK	CORE_CLK	CORE_CLK	AIPS_SLOW_CLK	LPSPI_0 - PLAT_AIPS_CLK LPSPI_1/2/3 - AIPS_SLOW_CLK	CORE_CLK
Inside IP	Used as combo signal	Flopped inside IP and clear after ADC conversion completed	Synchronized inside IP	Synchronized inside IP	Synchronized inside IP	-
At SoC	Since it an ASYNC signal and IP required synchronized single cycle pulse, so a pulse stretcher is added to convert pulse from any frequency domain into a signle cycle pulse of CORE_CLK	Since slow IP such as LPCMP or from PAD can also trigger BCTU and BCTU wants that trigger should clear after the ADC conversion. So a pulse stretcher is added which convert any size of pulse to a single cycle pulse of BCTU clock (CORE_CLK)	Pulse stretcher is added to convert any pulse into a two cyle pulse of FLEXIO_CLK	Pulse stretcher is added to convert any pulse into a two cyle pulse of LPI2C_CLK	Pulse stretcher is added to convert any pulse into a two cyle pulse of LPSPI_CLK	Pulse stretcher is added to convert any pulse into a single cyle pulse of CORE_CLK
Output slot at which pulse stretcher is added	2, 6, 10	24, 25, 26	64, 65, 66, 67	84	88, 92, 96	156, 157, 158[2]

1. These pulse stretchers are available in S32K314, S32K324 and S32K344 variants only.
2. CM7_2 is applicable for S32K358 only.

NOTE

The trigger outputs which have pulse stretcher before them, there should be atleast a gap of 5 cycle of destination clock for back to back trigger.

63.1.3 Trigger monitor

A trigger monitor is added before the TRGMUX inputs ADC12_0_EOC, ADC12_1_EOC and ADC12_2_EOC. You can configure the UDR registers in SIUL2 to select which trigger needs to propagate to the above TRGMUX inputs. By default after coming out of reset, all the enables are 0. Hence no trigger will be coming to these 3 TRGMUX inputs.

NOTE

Trigger monitor is not present in S32K314, S32K324 and S32K344.

63.2 Introduction

The trigger multiplexer (TRGMUX) module allows software to configure the trigger inputs for various peripherals.

63.3 Features

The TRGMUX module allows software to select the trigger source for peripherals. The block diagram below shows the trigger selection logic of the TRGMUX module.

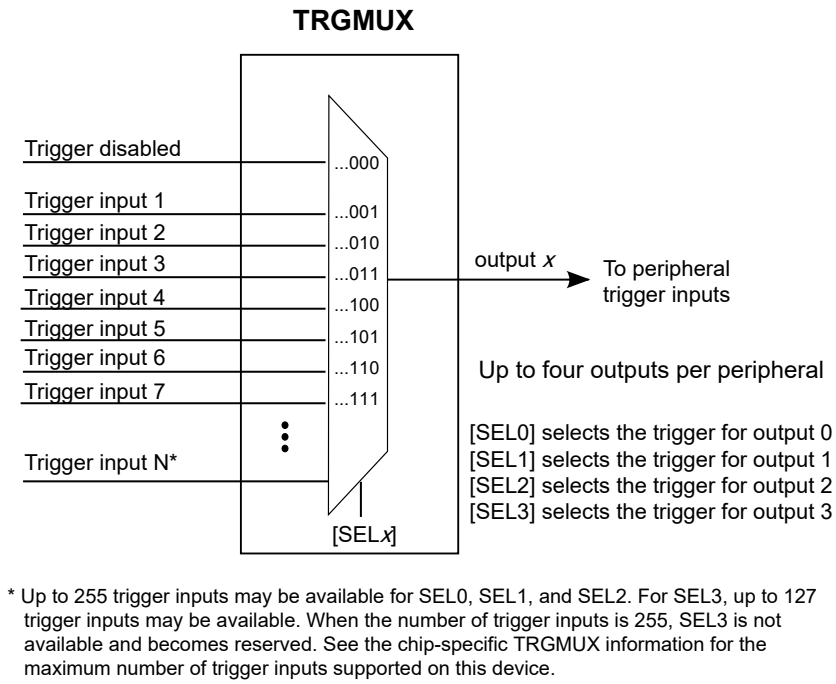

Figure 352. TRGMUX block diagram

Each peripheral has its own dedicated TRGMUX register. See each peripheral's TRGMUX register for details.

63.4 Memory map and register definition

The TRGMUX registers contain fields for selecting trigger sources for peripheral modules.

TRGMUX registers can be written only in supervisor mode.

63.4.1 TRGMUX register descriptions

63.4.1.1 TRGMUX memory map

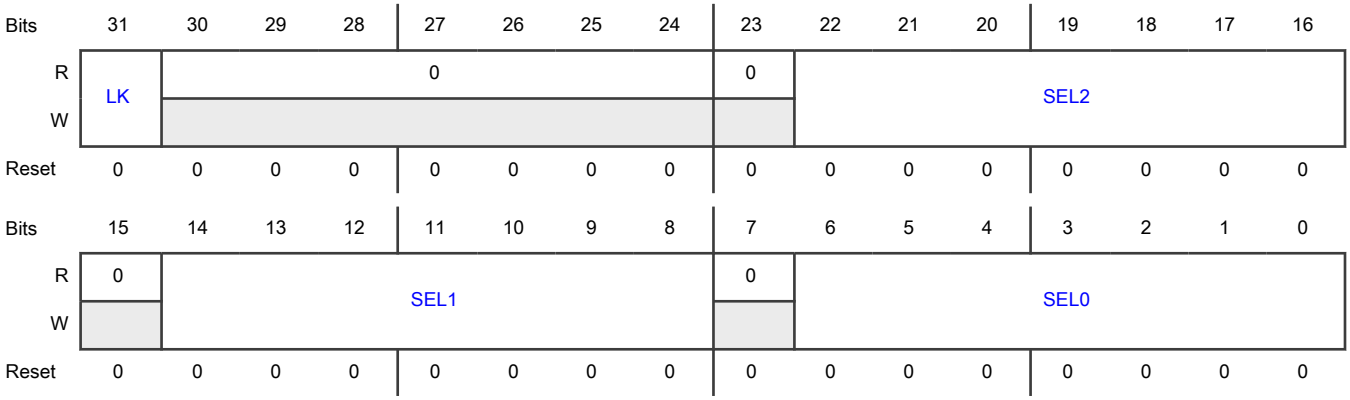
Offset

Register	Offset
ADC12_0	0h

Function

This register is for the ADC12_0 module.

Diagram



Fields

Field	Function
31	TRGMUX register lock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
LK	This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30-24 —	This read-only bit field is reserved and always has the value 0.
23 —	This read-only bit field is reserved and always has the value 0.
22-16 SEL2	Trigger MUX Input 2 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 2. For the field setting definitions, see Memory map and register definition.
15 —	This read-only bit field is reserved and always has the value 0.
14-8 SEL1	Trigger MUX Input 1 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 1. For the field setting definitions, see Memory map and register definition.
7 —	This read-only bit field is reserved and always has the value 0.
6-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

63.4.1.3 TRGMUX ADC12_1 Register (ADC12_1)

Offset

Register	Offset
ADC12_1	4h

Function

This register is for the ADC12_1 module.

Diagram

Chapter 64
Software Watchdog Timer (SWT)

64.1 Chip-specific SWT information

64.1.1 SWT instances and configuration

This chip supports up to three instances of SWT, one for each Cortex-M7 core.

Table 370. SWT instances

Instance	S32K358	S32K322/S32K324	S32K311/S32K312/S32K314/S32K342/S32K344
SWT_0	Yes	Yes	Yes
SWT_1	Yes	Yes	No
SWT_2	Yes	No	No

Table 371. SWT configuration

Instance	Core	Reset type	Clock Source	SWT_MIN_TO (100µs)	SWT_TO_RST (25ms)
SWT_0[1]	Cortex-M7_0	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_1	Cortex-M7_1	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_2	Cortex-M7_2	Functional Reset - RAM retention	SIRC (32K)	3	320h

1. SWT_0 supports operation in STANDBY mode.

NOTE

When using SWT as a wakeup source from standby, software should ensure proper value of timeout such that SWT timeout doesn't get expired again (after wakeup till standby exit is completed). The timeout should be programmed to a value greater than the time till standby exit is complete (sum of standby exit time and the time till software disables padkeeping).

NOTE

The "Reset only the SWT" feature using SWT_RRR[RRF] is supported only when SWT reset reaction is demoted to interrupt within MC_RGM.

Protect SWT from service by non-core masters

You must program protection for the SWT registers so that only core masters can service SWT.

When an SWT timeout takes place, the logic generating a reset to the system runs off the slow internal RC oscillator (32KHz). It could therefore take the SWT almost 31.25µs to reset the system, after timeout, leaving more time for runaway code to execute. The register interface clock of SWT is running from AIPS_SLOW_CLK, see Clocking chapter for more details. The register interface clock is responsible for generating the abort for invalid access while the counter clock is responsible for generating the SWT reset request. Since there is a synchronization happening between the register interface clock and counter clock domains before generating the SWT reset request, thus the generation of the reset request can take a number of register interface clock cycles after an invalid access is done.

Clock source

SWT is clocked by SIRC only.

64.2 Introduction

The Software Watchdog Timer (SWT) is a 32-bit window watchdog timer that enables the system to recover from situations such as:

- Software trapped in a loop
- A bus transaction failing to terminate

In regular operation, SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified timeout period. If this servicing action does not occur before the timer expires, SWT generates an interrupt or a hardware reset request.

You can configure SWT to generate a reset request or an interrupt on the initial timeout. SWT always generates a reset request on a second consecutive timeout.

64.3 Features

SWT has the following features:

- 32-bit countdown timer
- Selection of regular or window servicing
- Selection of reset request or interrupt on an initial timeout
- Selection of fixed or keyed service sequence
- Master access protection
- Hard and soft configuration lock bits

64.4 Initialize the SWT

To initialize the SWT, you must do the following:

- Select the clock source (if there are more than one possible sources).
- Set the timeout period.
- Control timeout behavior. There are two options:
  - Select reset request on timeout, or
  - Select interrupt on initial timeout.

You must initialize all registers before enabling SWT (CR[WEN]). You can initialize the registers in any sequence.

64.4.1 Select the clock source

See the chip-specific SWT information to find the clock source that drives the countdown timer.

64.4.2 Set the timeout period

When you enable SWT, it loads the greater of the specified watchdog timeout period or the minimum timeout period into an internal 32-bit countdown timer every time you perform a valid service operation.

To set the watchdog timeout period:

- Write the desired timeout period to TO[WTO].

The minimum timeout period is 3 clock cycles.

64.4.3 Control timeout behavior

SWT can respond to a timeout in one of two ways:

- Generate an immediate reset request on any timeout.
- Generate an interrupt and load the countdown timer on an initial timeout, then generate a reset request on a subsequent timeout.

64.4.3.1 Select reset request on timeout

To configure SWT to generate an immediate reset request on any timeout:

- Write 0 to CR[ITR].

64.4.3.2 Select interrupt on initial timeout

To configure SWT to generate an interrupt on an initial timeout:

- Write 1 to CR[ITR].

In this configuration, on the initial timeout:

- SWT loads the countdown timer with the timeout period (TO[WTO]).
- SWT indicates the interrupt with the timeout interrupt flag (IR[TIF]).
- If a second consecutive timeout occurs before writing the service sequence for the first timeout, SWT generates a reset request.

You clear the interrupt flag by writing 1 to IR[TIF].

64.4.4 Configure locking and unlocking

You can lock the SWT configuration with either a hard lock or a soft lock. When either lock is in effect, CR, TO, WN, and SK are read-only.

64.4.4.1 Enable the hard lock

To enable the hard lock:

- Write 1 to CR[HLK].

Hard lock is disabled only by a reset.

64.4.4.2 Enable the soft lock

To enable the soft lock:

- Write 1 to CR[SLK].

64.4.4.3 Unlock the soft lock

To unlock the soft lock:

1. Write C520h to SR[WSC].
2. Write D928h to SR[WSC].

This unlock sequence:

- Ignores service sequence writes.
- Recognizes the unlock sequence regardless of previous writes.
- Recognizes the unlock sequence regardless of the time between writes.
- Does not require CR[WEN] to be 1.

You can write this unlock sequence at any time.

NOTE

It is possible for a keyed service sequence to unlock soft lock. See Avoid soft unlock for the procedure to handle this situation.

64.4.4.4 Avoid soft unlock

When SWT operates in keyed sequence service, the sequence of service keys generated by the pseudorandom generator includes the unlock keys for soft lock. If one or more service routines use both unlock keys in the proper order, 0xC520 followed at any future time by 0xD928, SWT unlocks soft lock (CR[SLK] = 0). The unlock sequence logic ignores any service keys other than the unlock keys, so the unlock keys don't have to be inserted consecutively. If the second unlock key is also the second key of a service operation, unlock occurs before the service operation completes.

To avoid unlock:

If the service routine writes a key value of C520h to SR[WSC] as a key of the service operation, then do the following:

1. Complete the service operation.
2. Complete the unlock sequence by writing the second unlock key, D928h, to SR[WSC].
3. Reinitiate the soft lock (CR[SLK] = 1).

64.4.5 Select behavior on an invalid access

SWT can respond to an invalid access one of two ways:

- Generate a bus error.
- Generate a bus error and, if SWT is enabled, a reset request.

To select how SWT responds to an invalid access:

- Write the appropriate value to CR[RIA].

64.5 Enable the SWT

To enable the SWT:

- Write 1 to CR[WEN].

64.6 Initiate service operations

When enabled, SWT requires periodic execution of a servicing operation.

SWT can operate in one of the following service sequence modes:

- Fixed service sequence
- Keyed service sequence

64.6.1 Initiate a fixed service sequence

To initiate the fixed service sequence:

1. Select the fixed servicing mode (write 00b to CR[SMD]).
2. Write A602h to SR[WSC].
3. Write B480h to SR[WSC].

There is no timing requirement between the two writes. The service sequence logic ignores unlock-sequence writes.

64.6.2 Initiate a keyed service sequence

To initiate the keyed service sequence:

1. Select the keyed servicing mode (write 01b to CR[SMD]).
2. Read the initial service key from SK[SK].
3. Calculate the next service key using the provided equation.
4. Write that service key to SR[WSC].
5. Repeat steps 2 through 4 one time.

See Service key generation for information about service keys.

64.6.3 Select window service mode

In window service mode, you must write the service sequence only when the watchdog timer is less than the window start value (WN[WST]). If you write the service sequence outside of this window, the access is invalid and generates a bus error or reset request depending on the Reset on Invalid Access setting (CR[RIA]).

For example, if the timeout period is 5000 and the window start value is 1000, you must write the service sequence during the last 20% of the timeout period.

Synchronization logic in SWT causes a slight delay in the opening of the window. This delay can be up to three system clock cycles plus four counter clock cycles.

To select window service mode:

- Write 1 to (CR[WND].

64.7 Reset only the SWT

When a timeout triggers a reset request and the application does not require a system reset, you can make the SWT instance reset itself rather than the whole system.

To make a timeout reset request trigger only an SWT reset (rather than the whole system), write 1 to the Reset Request Flag (RRR[RRF]).

This action causes SWT to:

- Clear the reset request.
- If an interrupt request also occurred, clear the interrupt request (IR[TIF]).
- Reset and restart the SWT.

For systems with multiple SWT instances, this feature allows you to reset an individual SWT instance, avoiding the widespread impact of a system reset.

64.8 Test SWT operation

When you disable SWT, it loads the current countdown timer into CO[CNT]. When you enable SWT, it clears this register. You can use CO[CNT] to perform a software self-test of SWT.

To test SWT operation:

1. Enable the SWT (CR[WEN] = 1).
2. Do not service SWT for a fixed period of time that is less than the timeout value.
3. Disable the SWT (CR[WEN] = 0).
4. Read the value in CO[CNT] to determine whether the internal countdown timer is working properly.

NOTE

The value shown in CO[CNT] can lag behind the actual internal timer up to six system clock cycles plus eight counter clock cycles.

64.9 Functional description

64.9.1 Behavior in different chip and core modes

SWT supports the core modes of operation as follows:

Core mode	SWT behavior
Normal	When SWT is enabled (CR[WEN] = 1), the SWT timer counts down continuously.
Debug	If CR[FRZ] = 1, SWT stops the timer; otherwise, the timer continues to run.
Stop or Standby	If CR[STP] = 1, SWT stops the timer; otherwise, the timer continues to run.

64.9.2 Register access latency

Accesses to SWT registers occur with no peripheral bus wait states. The peripheral bus bridge may add 1 or more system wait states. However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system clock cycles plus seven counter clock cycles.

64.9.3 Service key generation

SWT generates service keys with the pseudorandom key generator defined by the following equation.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 353. Pseudorandom key generator

This algorithm generates a sequence of 2^{16} different key values before repeating. In keyed service sequence mode, each time you write a valid key to SR[WSC], SWT updates SK[SK] with the next key.

For example, if the previous service key (SK[SK]) is 100h, then the next service sequence keys are 1103h followed by 2136h.

64.10 SWT register descriptions

The SWT programming model allows only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- Non-32-bit accesses
- Writes to read-only registers
- Writes of incorrect values to SR when SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

You control how SWT responds to an invalid access with CR[RIA].

64.10.1 SWT memory map

SWT_0 base address: 4027_0000h

Chapter 65
System Timer Module (STM)

65.1 Chip-specific STM information

65.1.1 STM instances and configuration

This chip has up to three instances of STM, one for each Cortex-M7 core. The STM counter increments at the STM module clock frequency divided by a pre-scaled value.

Table 372. STM instances

Instance	S32K358	S32K322/S32K342/S32K314/S32K324/ S32K344	S32K311/S32K312

STM_1	Yes	Yes	No
STM_2	Yes	No	No

Table 373. STM configuration

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM_0	Intended for Cortex-M7_0 core	4	14
STM_1	Intended for Cortex-M7_1 core	4	14
STM_2	Intended for Cortex-M7_2 core	4	14

65.2 Overview

STM supports commonly required system and application software timing functions. STM includes a 32-bit count-up timer and four 32-bit compare channels with a separate interrupt source for each channel. The timer is driven by the STM module clock divided by an 8-bit prescale value (1 to 256).

65.2.1 Block diagram

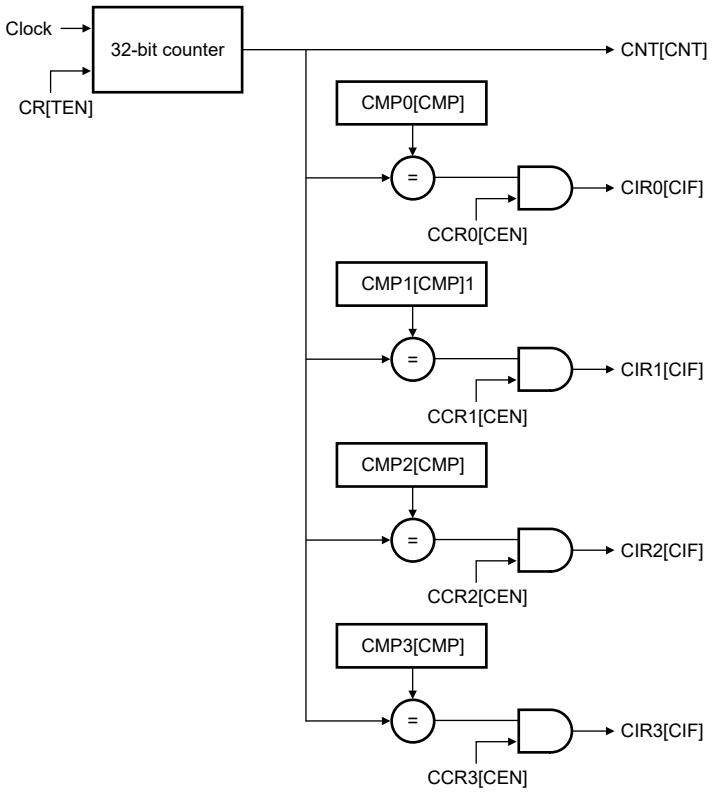

Figure 354. Block diagram

65.2.2 Features

STM has the following features:

- One 32-bit count-up timer with an 8-bit prescaler
- Four 32-bit compare channels
- An independent interrupt source for each channel
- Ability to stop the timer in Debug mode

65.3 Functional description

65.3.1 Count-up timer

STM has one 32-bit count-up timer that serves as the time base for four compare channels. When enabled, the counter increments at the module clock frequency divided by a prescaler value in the range from 1 to 256. When enabled in Normal mode, the timer increments continuously. The counter rolls over at FFFF_FFFFh to 0000_0000h with no restrictions at this boundary.

65.3.2 Compare channels

STM has four identical compare channels. Each channel includes a channel control register (CCR*n*), a channel interrupt register (CCR*n*), and a channel compare register (CMP*n*). When the channel is enabled and its channel compare value matches the timer count, STM sets the channel interrupt flag and generates an IRQ on that channel.

65.3.3 Behavior in different chip modes

STM supports the chip modes of operation as follows:

Chip mode	STM behavior
Normal	When the timer is enabled (CR[TEN] = 1), the timer counts up continuously.
Debug	If CR[FRZ] = 1, STM stops the timer. Otherwise, when the timer is enabled (CR[TEN] = 1), the timer counts up continuously.

65.3.4 Clocking

This module has no clocking considerations.

65.3.5 Interrupts

STM can generate a channel interrupt. For information, see:

- Compare channels
- Respond to compare channel events
- Channel Interrupt (CIR0 - CIR3)

65.4 External signals

This module has no external signals.

65.5 Initialization

This module does not require initialization.

65.6 Application information

65.6.1 Configure the timer

1. Set the initial timer count (CNT[CNT]).
2. Specify STM behavior in chip Debug mode (CNT[FRZ]).
3. Set the counter prescaler (CR[CPS]).
4. Start the timer (CR[TEN]).

65.6.2 Configure the compare channels

For each compare channel:

1. Set the channel compare value (CMP*n*[CMP]).
2. Enable the compare channel (CCR*n*[CEN]).

65.6.3 Respond to compare channel events

For each compare channel:

1. Check the channel interrupt flag (CIR*n*[CIF]).
2. If the channel interrupt flag is set, respond to the interrupt request.
3. When the channel interrupt has been handled, clear the channel interrupt flag (CIR*n*[CIF]).

65.7 STM register descriptions

The STM programming model allows only 32-bit (word) accesses. An attempted reference using a different size or to a reserved address generates a bus error termination.

65.7.1 STM memory map

STM_0 base address: 4027_4000h

65.8 Glossary

IRQ Interrupt request

Chapter 66
Periodic Interrupt Timer (PIT)

66.1 Chip-specific PIT information

66.1.1 PIT instances and configuration

This chip has up to 3 instances of the PIT each with 4 PIT timers/channels, each channel being 32 bits in length.

Table 374. PIT instances

Instance	K358/K3x4/K342	K312	K311
PIT_0	Yes	Yes	Yes
PIT_1	Yes	Yes	Yes
PIT_2	Yes	No	No

Table 375. PIT instances and features

Feature	PIT_0	PIT_1	PIT_2
Real time interrupt (RTI)	Yes (32-bit)[1]	No	No
Lifetime Timer	Yes	No	No
Timer chaining to create a 64-bit timer	Yes	No	No
Number of 32-bit timer channels	4	4	4
Timer value unchanged by a non-destructive reset	No	No	No

1. The RTI on PIT_0 supports operation in STANDBY mode

The RTI shall be possible to set the timer resolution to 1us independently to other timers. The interrupt can be generated by programming LDVAL0, LDVAL1, LDVAL2 and LDVAL3 to 48 in case of 48 MHz FIRC as system clock and 40 in case of 40 MHz system clock to generate an interrupt after 1us.

66.1.2 Input Output

All the PIT instances are capable of generating periodic triggers. PIT triggers are routed to motor control IPs such as eMIOS, LCU, BCTU, ADC etc. via TRGMUX. See the TRGMUX connectivity file attached to this document for details.

66.2 Introduction

PIT includes an array of timers that can be used to raise interrupts and trigger DMA channels. It also includes a dedicated RTI timer, which runs on a separate oscillator clock and can be used for system wakeup. Some of the registers listed in PIT register descriptions are used to configure these timers, and after the expiry of a timer, the respective registers indicate a timeout status, which can be used to raise interrupts and triggers.

66.2.1 Block diagram

The following figure shows the block diagram of PIT_RTI module.

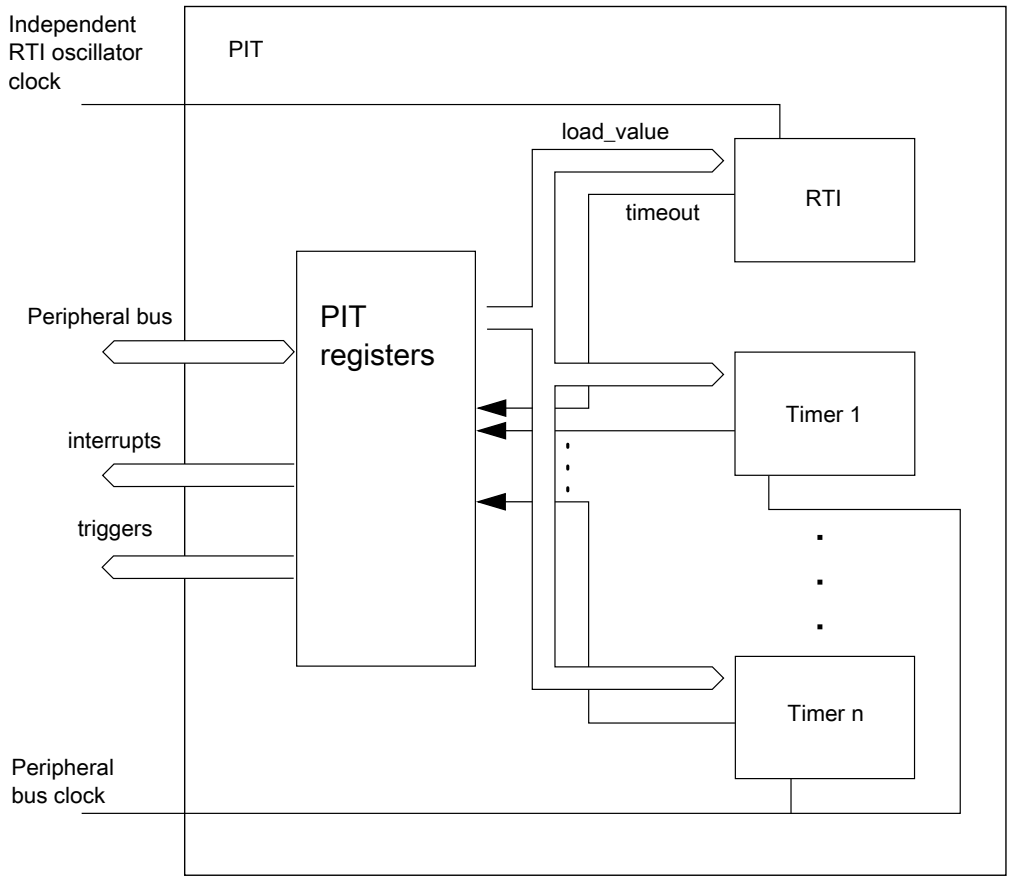

Figure 355. Block diagram of PIT_RTI

66.2.2 Features

The key features of the module are:

- One RTI timer to wakeup the CPU
- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Option to raise RTI interrupt, even when the bus clock is switched off
- Power saving with a separate input clock for the RTI timer. All other timers share a common core clock.
- Independent timeout periods for each timer
- All the timers use a downcounter

66.3 Modes of operation

This subsection briefly describes all operating modes supported by PIT.

- Run mode

  All functional parts of the PIT are running during normal Run mode.

- Debug mode

  Timers are running or stopped according to MCR[FRZ] in Debug mode.

66.4 Functional description

This section provides the functional description of the module.

66.4.1 General operation

This section provides detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts, and each interrupt is available on a separate interrupt line. Additionally, the RTI timer can be used to wake up the processor.

66.4.1.1 Timers/RTI

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start values again. Each time a timer reaches 0, it generates a trigger pulse and sets the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared. Because in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 must be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted by first disabling and then enabling the timer with TCTRLn[TEN]. See the following figure.

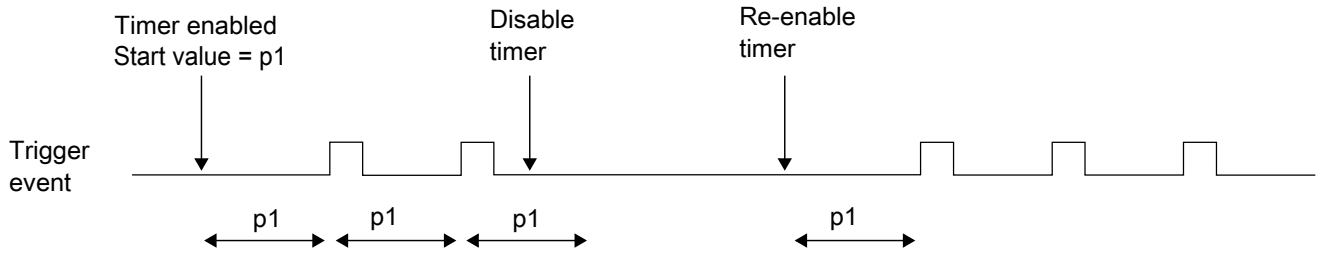

Figure 356. Stopping and starting a timer

The counter period of a running timer can be modified by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

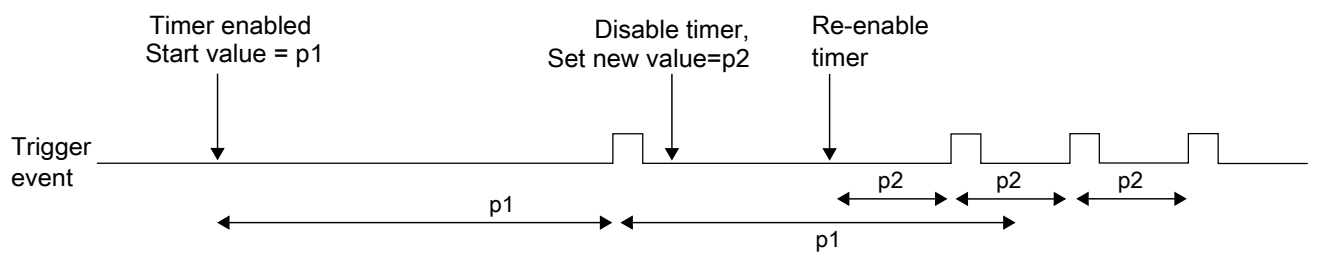

Figure 357. Modifying running timer period

It is also possible to change the counter period without restarting the timer, by writing LDVAL with the new load value. This value then loads after the next trigger event. See the following figure.

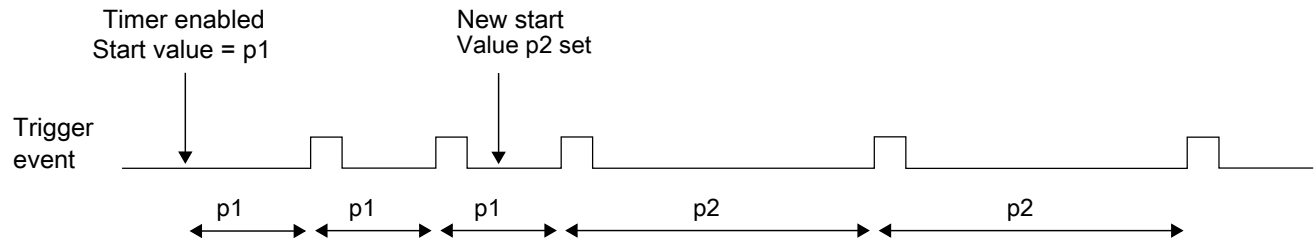

Figure 358. Dynamically setting a new load value

NOTE

- If MCR[FRZ] is written as 1 and when the timer is nearing 0 (CVALn =0x0), the debug mode command may not make it to the IP before the timer expires and generates a trigger.
- Debug Mode will be ignored if CVALn =0x0, but the trigger will remain asserted until the mode is removed. The user is recommended to exit Debug mode and then clear the interrupt TFLGn[TIF].
- If the timers are to be frozen for debug, sufficient time must be ensured for the IP to react.

66.4.1.2 Debug mode

In the Debug mode, the timers are frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

66.4.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well.

Timer interrupts can be enabled by setting TCTRLn[TIE].

TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

The PIT_RTI generates an RTI when the selected interrupt time period elapses. The RTI is disabled locally by setting TCTCRLn[TIE] to zero. The real-time interrupt flag (TIF) is set to 1 when a timeout occurs, and is cleared by writing a 1 to the corresponding TFLGn[TIF]. The flag is set regardless of whether the interrupt is enabled.

The RTI can be used for periodic wakeup from a STANDBY mode. It can also be used to generate a general-purpose interrupt.

66.4.3 Chained timers

When a timer has chain mode enabled, it counts after the previous timer has expired. So if timer n-1 counts down to 0, counter n decrements the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer. The same applies to RTI. See Example configuration for chained timers for details.

66.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5,000,000 cycles. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means RTI LDVAL is written with 004C4B3F hex; LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F, respectively.

To generate the wakeup interrupt, the interrupt line must be enabled by writing 1 to the RTI TIE bit in the TCTRL register. To start the RTI, the TEN in the RTI TCTRL register must also be set.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. But, TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN; // start RTI
```

```
// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

66.6 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt is raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

66.7 Example configuration for the Lifetime Timer

To configure the Lifetime Timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the Lifetime Timer, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

66.8 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT_RTI module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- The RTI registers should be programmed only when the RTI clock is running.

66.8.1 PIT memory map

Diagram

Fields

Field	Function
31-0 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

66.8.4 PIT Lower Lifetime Timer Register (LTMR64L)

Offset

Register	Offset
LTMR64L	E4h

Function

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. The value for the LTMR64H register is set to CVAL1 register at the time of the first access and the value of the LTMR64L register is set to CVAL0 register at first access. Therefore, the application is not affected by the carry-over effects of the running counter.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

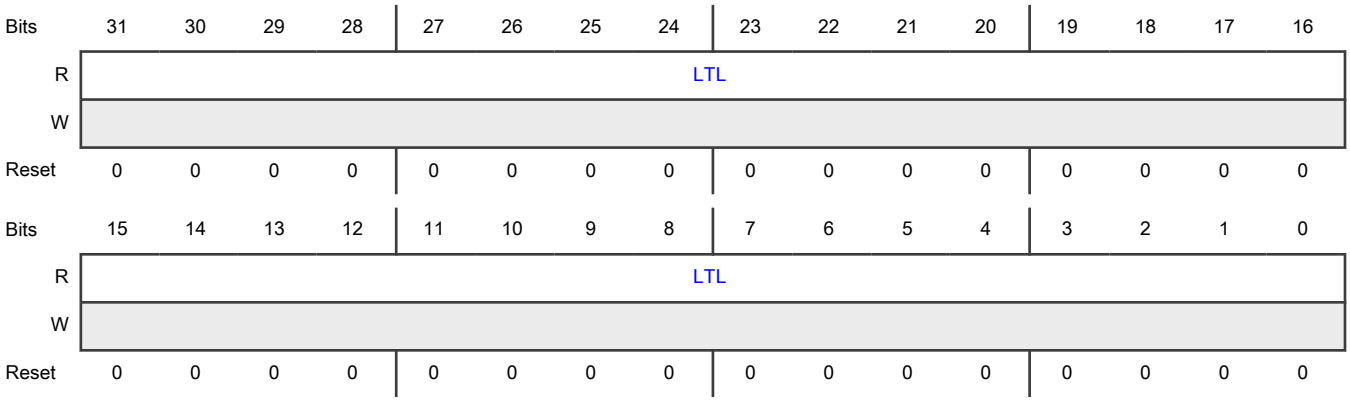
PIT_1	—	LTMR64L
PIT_2	—	LTMR64L

Diagram



Fields

Field	Function
31-0 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

66.8.5 RTI Timer Load Value Sync Status Register (RTI_LDVAL_STAT)

Offset

Register	Offset
RTI_LDVAL_STAT	ECh

Function

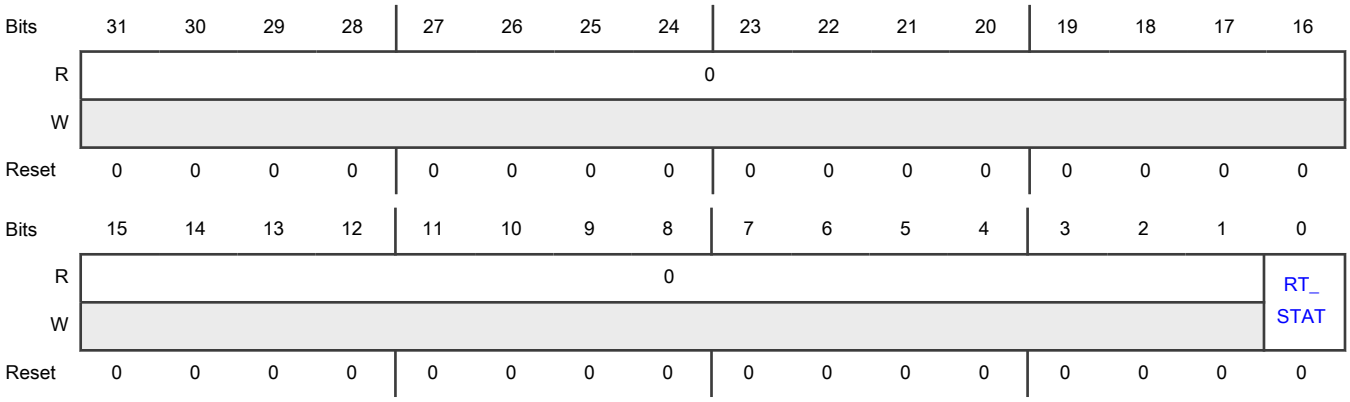
These registers gives the RTI timer load synchronization status. In the case of the RTI timer load, it will take several cycles until this value is synchronized into the RTI clock domain. This register gives the status of the new value loaded in the RTI timer load register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL_STAT	—
PIT_1	—	RTI_LDVAL_STAT
PIT_2	—	RTI_LDVAL_STAT

Diagram



Fields

Field	Function
31-1 —	Reserved
0 RT_STAT	RTI Timer Load Value Sync Status RTI timer load value loaded in RTI_LDVAL register. **NOTE** Any attempt to write will clear this field. 0b - RTI_LDVAL register not loaded. 1b - RTI_LDVAL register updated with new value.

66.8.6 Timer Load Value Register (RTI_LDVAL)

Offset

Register	Offset
RTI_LDVAL	F0h

Function

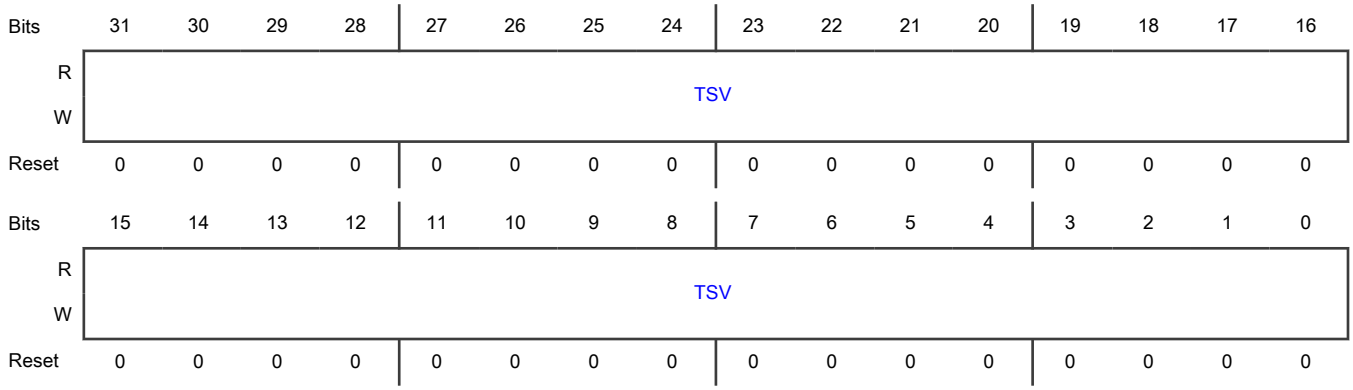
These registers select the timeout period for the timer interrupts. In the case of the RTI, it will take several cycles until this value is synchronized into the RTI clock domain. For all other timers, the value change is visible immediately. The synchronization mechanism allows 0 wait states in this case.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL	—
PIT_1	—	RTI_LDVAL
PIT_2	—	RTI_LDVAL

Diagram



Fields

Field	Function
31-0 TSV	Timer Start Value Sets the timer start value. The timer counts till it reaches 0; then it generates an interrupt and loads the register value again. Writing a new value to this register does not restart the timer; instead the value loads after the timer expires. To abort the current cycle and start a timer period with a new value, the timer must be disabled and enabled again. **NOTE** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply; however, there are practical limits because the processor requires several cycles to service an interrupt.

66.8.7 Current Timer Value Register (RTI_CVAL)

Offset

Register	Offset
RTI_CVAL	F4h

Function

These registers indicate the current timer position. For the RTI timers, they show a value that is several cycles old because it originates from a potentially different clock domain.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_CVAL	—
PIT_1	—	RTI_CVAL
PIT_2	—	RTI_CVAL

66.9 Glossary

RTI Real-time interrupt

Chapter 67
Real Time Clock (RTC)

67.1 Chip-specific RTC information

67.1.1 RTC instances and configuration

The chip contains one instance of RTC (Real Time Clock) timer and API (Autonomous Periodic Interrupt) timer, where both can perform 32-bit comparisons.

The RTC is present in always ON domain, hence available in RUN mode as well as in STANDBY mode. Both RTC and API timers can generate interrupts as well as wakeup from low power modes.

RTC supports a resolution of 1µs with high speed internal oscillator clock (1/48MHz (FIRC) * 48 (RTC counter) = 1µs)

This chip supports seamless RTC operation across functional reset with the clock sources SIRC and SXOSC.

NOTE

SXOSC is not present in K311, thus RTC will run from SIRC clock.

API has the capability to change the Timer compare value (APIVAL) independently without stopping the timer.

API can also be used in conjunction with the Comparator module. In STANDBY mode configuration, the API is configured to generate a START / NEXT type signal to inform the Comparator module that a 'compare' must be carried out.

Table 376. RTC instances

Module	S32K311/S32K312/S32K322/S32K342/S32K314/S32K324/S32K344/S32K358
RTC	Yes

67.4 Introduction

The Real-Time Clock (RTC) is a free-running counter used for time keeping applications. The RTC can be configured to generate an interrupt at a pre-defined interval independent of the mode of operation (run mode or low power mode). If in a low power mode, the RTC interval is reached, the RTC first generates a wakeup and then asserts the interrupt request. The RTC also supports an API function used to generate a periodic wakeup request to exit a low-power mode or an interrupt request.

67.4.1 Features

RTC features include:

- 32-bit counter
- Selectable counter clock sources (IRCs and OSCs)
  - Clock source 0
  - Clock source 1
  - Clock source 2
  - Clock source 3
- Optional 512 prescaler and optional 32 prescaler to run the 32 bit counter.
- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC counter is reset when the counter is disabled by software and by reset to RTC block.
- Autonomous periodic interrupt support includes:

— 32-bit compare value to support range of wakeup intervals/interrupts

— API logic has a separate enable to support changing compare value while RTC is running

— API interrupt with interrupt enable

— Operates in all modes

— API compare value can be modified while RTC is running

- Optional interrupt for RTC match, API match, and RTC rollover.

67.4.2 Block diagram

The following figure shows Clock gating for RTC clocks.

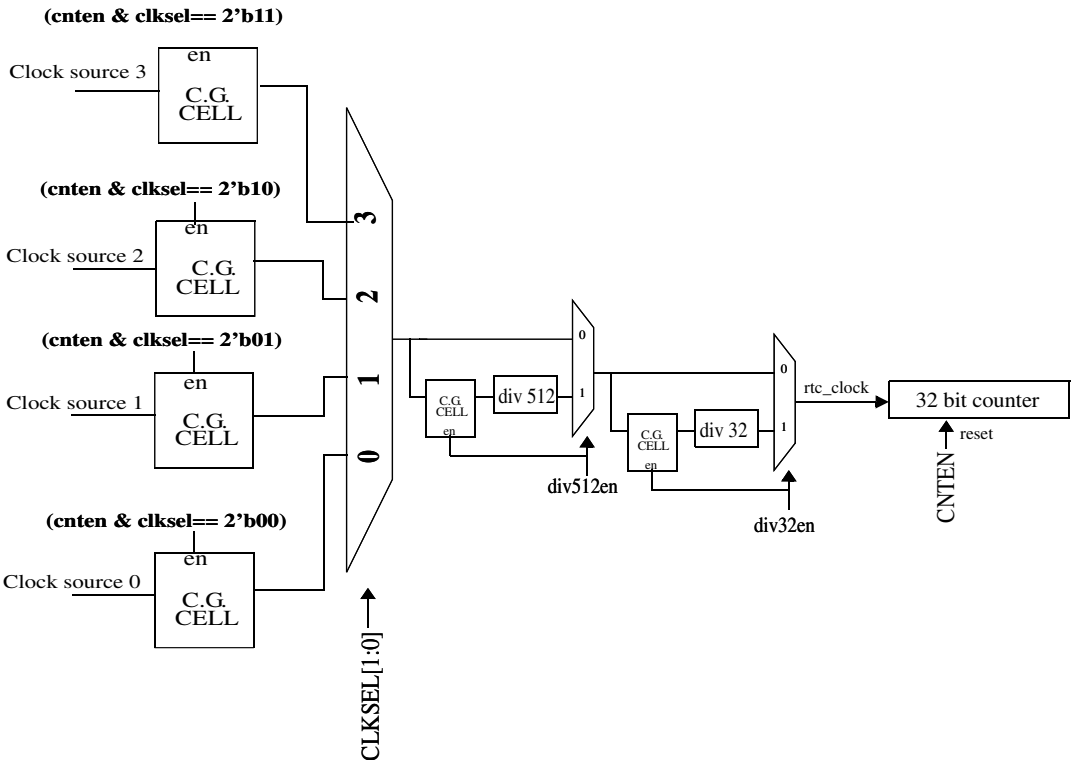

Figure 359. Clock gating for RTC clocks

The following figure shows the block diagram of RTC.

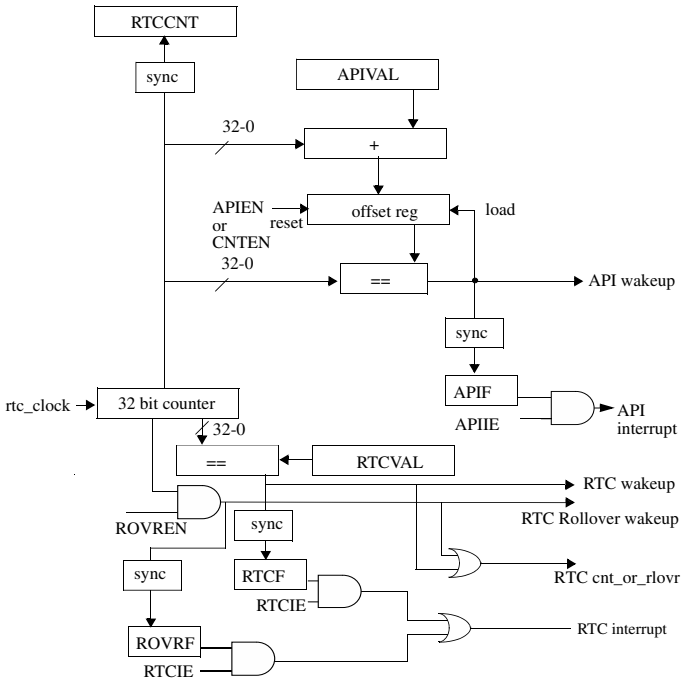

Figure 360. Block diagram

67.4.3 Modes of operation

67.4.3.1 Functional mode

There are two functional modes of operation for RTC: normal operation and low-power mode. In normal operation, all RTC registers can be read or written . The RTC/API and associated interrupts are optionally enabled. In low-power mode, the bus interface is disabled. The RTC/API is enabled (if enabled prior to entry into low-power mode).

67.4.3.2 Debug mode

On entering into the debug mode, the RTC counter freezes on the last valid count if the FRZEN is set. On exit from debug mode, counter continues from the frozen value.

67.5 Functional description

67.5.1 RTC

The RTC consists of a 32-bit free running counter enabled with the CNTEN bit (CNTEN, when negated, asynchronously resets the counter and synchronously enables the counter when enabled). After disabling CNTEN, RTCVAL, APIVAL, needs to be written again for desired functionality. The value of the counter may be read via the RTC Counter register (RTCCNT) register. Note that because of clock synchronization, the RTC Counter register (RTCCNT) value may represent a previous counter value. The difference between the counter and the read value depends on the ratio of counter clock and bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the CLKSEL field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be on these:Clock source 0, Clock source 1, Clock source 2, and Clock source 3. The output of the clock mux can be optionally divided by a combination of 512 and 32 to give various count periods for different clock sources. Note that the CNTEN bit should be disabled when the RTC/API clock source is switched.

When the RTC Counter register (RTCCNT) counter value for counter bits 31-0 match the 32-bit value in the RTCVAL field, then the RTCF interrupt flag bit is set (after proper clock synchronization). If the RTCIE interrupt enable bit is set, then the RTC interrupt request is generated. RTC Compare value register (RTCVAL) register can be written only when INV_RTC bit is clear. Initially INV_RTC=0, and hence RTC Compare value register (RTCVAL) can be written once and hence INV_RTC gets set. This bit can now be cleared only by enabling the RTC counter. After the counter is enabled, RTC Compare value register (RTCVAL) can be written anytime, until RTC is disabled again. RTC Compare value register (RTCVAL) is first synchronized to the RTC clock domain, therefore, if RTC Compare value register (RTCVAL) is updated at the point where a counter match is due to happen in the next 2-3 RTC clocks because of previous RTC Compare value register (RTCVAL), the RTCF flag is set. However, if the RTC Compare value register (RTCVAL) is updated at the point where no counter match is due as per the previous RTC Compare value register (RTCVAL), the RTCF flag is set when the counter matches the new RTC Compare value register (RTCVAL). If there is a match when in the low-power mode, then the RTC first generates a wakeup request to force a wakeup to run mode,and then the RTCF flag is set.

If RTC Compare value register (RTCVAL) is updated just after counter match, new RTC Compare value register (RTCVAL) value should not be within next 6 RTC counter values.

A rollover wakeup and/or interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the ROVREN bit. If RTCIE is enabled, an interrupt request is generated for an RTC counter rollover. If system is in low power mode, RTC counter rollover with this bit causes a wakeup from the low-power mode.

Both rollover wakeup and RTC wakeup gets asynchronously de-asserted with disabling of CNTEN.

All the flags and counter values are synchronized with the Bus clock. It is assumed that the Bus clock and RTC clock selected through CLKSEL follows the below relation:

Bus clock >= (1.5 * RTC clock)/(div_factor)

- if both DIV32EN and DIV512EN bits are disabled, div_factor = 1
- if DIV32EN=1 and DIV512EN=0, div_factor = 32
- if DIV32EN=0 and DIV512EN=1, div_factor = 512
- if both DIV32EN and DIV512EN bits are enabled, div_factor = 512*32 = 16384

In case, RTC wakeup's are used as a wakeup source, Bus clock should be disabled after enabling the required wakeup and ensuring sufficient time gap (few Bus clock or RTC clock cycles, whichever is slower) between Bus clock disabling and wakeup event.

67.5.2 API functional description

Setting APIEN bit enables the autonomous interrupt function. The 32-bit APIVAL field selects the time interval for triggering an interrupt and/or wakeup event. Because the RTC is a free-running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, an interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN bits are asserted and APIVAL is non-zero. Also, APIVAL can be updated anytime. After APIVAL is updated, the first API interrupt is generated according to the previous value. From the second interrupt onwards, the API interrupt is generated with the new APIVAL. When a compare is reached, the APIF interrupt flag bit is set (after proper clock synchronization). If the APIIE interrupt enable bit is set, then the API interrupt request is generated. If there is a match while being in the low-power mode, then the API first generates a wakeup request to force a wakeup into normal operation, and then the APIF flag is set.

When the CNTEN is de-asserted, the API function is reset , though wakeup API is not asynchronously de-asserted with CNTEN. If APIEN is disabled when counter matches the offset, APIF can be missed.

67.6 Recommended programming flow

1. Program RTCVAL register with the value greater than 4 if RTCF related functionality is required.
2. Program APIVAL register with the value greater than 4 if API functionality is required.
3. Program all fields (as required) of RTC Control register (RTCC) register with CNTEN=1. After setting CNTEN field, counter starts running and RTC/API functionality will be active as per the configurations.

4. If RTCVAL or APIVAL needs to be updated during run, check corresponding INV_RTC or INV_API bit is cleared before writing and do meet all the restrictions of the corresponding register.
5. If CLKSEL or DIV32EN or DIV512EN needs to be updated, first update RTC Control register (RTCC) register with CNTEN=0 (when all INV_RTC or INV_API are 0) keeping other field values same. Wait for minimum 3 RTC clock cycles so that CNTEN will be synchronized to RTC clock domain. Then write the RTC Control register (RTCC) register with new configuration required with CNTEN=1.

67.7 RTC register descriptions

The RTC registers are listed in this section.

NOTE

Address offset - 0x18h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at this offset.

NOTE

XFR error will be generated when RTCSUPV is accessed in user mode, any other register is accessed in user mode when SUPV bit is set, write attempt is made for RTCCNT register and any register accessed out of address range.

67.7.1 RTC memory map

RTC base address: 4028_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	RTC Supervisor control register (RTCSUPV)	32	RW	8000_0000h
4h	RTC Control register (RTCC)	32	RW	0000_0000h
8h	RTC Status register (RTCS)	32	W1C	0000_0000h
Ch	RTC Counter register (RTCCNT)	32	RO	0000_0000h
10h	API Compare value register (APIVAL)	32	RW	0000_0000h
14h	RTC Compare value register (RTCVAL)	32	RW	0000_0000h

67.7.2 RTC Supervisor control register (RTCSUPV)

Offset

Register	Offset
RTCSUPV	0h

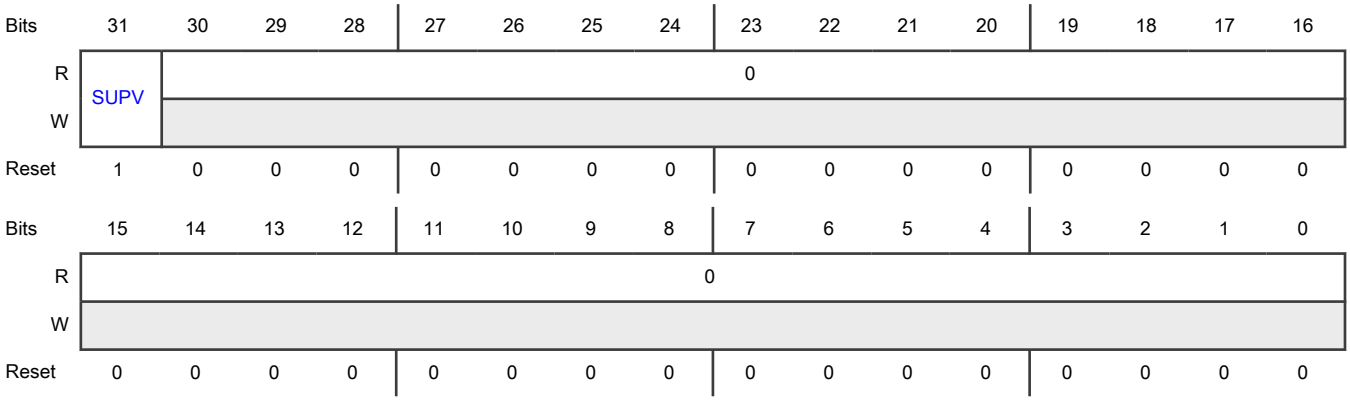
Function

The RTCSUPV register contains the SUPV bit that determines whether other registers are accessible in supervisor mode or user mode.

NOTE

You can access this register only in Supervisor mode, and you must write a value only to the SUPV field of the register.

Diagram



Fields

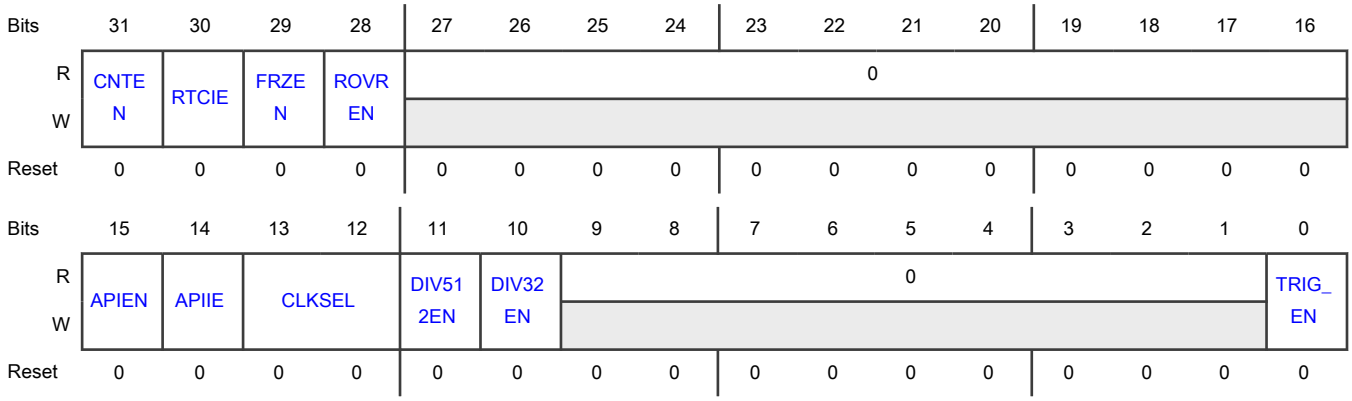
Field	Function
31 SUPV	RTC Supervisor Bit. 0b - All registers are accessible in both user as well as supervisor mode. 1b - All other registers are accessible in the supervisor mode only.
30-0 —	Reserved

67.7.3 RTC Control register (RTCC)

Offset

Register	Offset
RTCC	4h

Diagram



Fields

Field	Function
31 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Setting CNTEN bit to 0b has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic. This allows RTC configuration and clock source selection to be updated without causing synchronization issues. **NOTE** CNTEN should be disabled when INV_RTC, INV_API are cleared. 0b - Counter disabled 1b - Counter enabled
30 RTCIE	RTC Interrupt Enable. The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0b - RTC interrupts disabled. 1b - RTC interrupts enabled.
29 FRZEN	Freeze Enable Bit The counter freezes on entering the debug mode on the last valid count value if the FRZEN bit is set. After passing of the debug mode counter starts from the frozen value. This bit should not be changed when debug mode is enabled. 0b - Counter does not freeze in debug mode. 1b - Counter freezes in debug mode.
28 ROVREN	Counter Roll Over wakeup/Interrupt Enable. The ROVREN bit enables wakeup and interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0b - RTC rollover wakeup/interrupt disabled 1b - RTC rollover wakeup/interrupt enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-16 —	Reserved
15 APIEN	Autonomous Periodic Interrupt Enable. The APIEN bit enables the autonomous periodic interrupt function. Setting this bit to 0b, asynchronously disables API wakeup output of RTC as well. 0b - API disabled. 1b - API enabled.
14 APIIE	API Interrupt Enable. The APIIE bit enables interrupts requests to the system if APIF is asserted. 0b - API interrupts disabled. 1b - API interrupts enabled.
13-12 CLKSEL	Clock select The CLKSEL[1:0] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. **NOTE** Refer the RTC clocking section in the Clocking chapter of this document. 00b - Clock source 0 01b - Clock source 1 10b - Clock source 2 11b - Clock source 3
11 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0b - Divide by 512 is disabled. 1b - Divide by 512 is enabled.
10 DIV32EN	Divide by 32 enable. The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0b - Divide by 32 is disabled 1b - Divide by 32 is enabled
9-1 —	Reserved
0 TRIG_EN	Trigger enable for Analog Comparator

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit (TRIG_EN) when set will de-assert the wakeup_api on the next RTC clock (required for ACMP when bus clock is disabled). **NOTE** If API wakeup is asserted with TRIG_EN set, and bus clock enabled, setting of RTCS[APIF] may be missed.

67.7.4 RTC Status register (RTCS)

Offset

Register	Offset
RTCS	8h

Function

NOTE

W1C has priority over setting of the RTCF, APIF and ROVRF bits, in case both clearing and setting occurs at the same time.

Fields

Field	Function
31-0 RTCCNT	RTC Counter Value Because of clock synchronization, the RTCCNT value may represent a previous counter value.

67.7.6 API Compare value register (APIVAL)

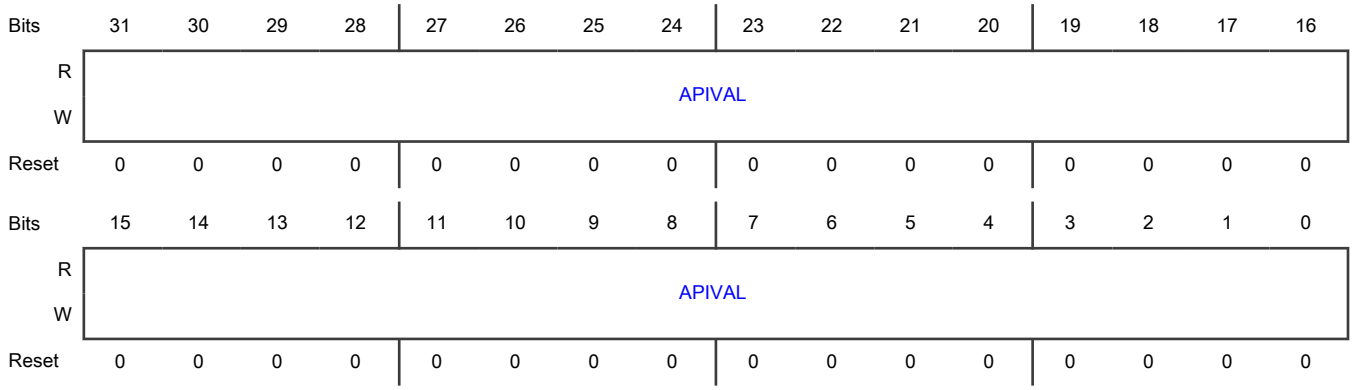
Offset

Register	Offset
APIVAL	10h

Function

The APIVAL offset bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted.

Diagram



Fields

Field	Function
31-0 APIVAL	API Compare Value. APIVAL bits are added to the current count to calculate an offset. The APIVAL offset bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted. **NOTE** API functionality is active only when APIVAL is non zero. The first API interrupt takes two more cycles because of synchronization of APIVAL to RTC clock. After that, interrupts are periodic in nature and it takes APIVAL+1 cycles. The Minimum supported value of APIVAL is 4. This is because of synchronization.

67.7.7 RTC Compare value register (RTCVAL)

Offset

Register	Offset
RTCVAL	14h

Function

The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set. The minimum value of RTCVAL should be 4.

LPSPI5	4x32 bit	4x32 bit	4

- S32K314, S32K324, S32K344, S32K322, and S32K342 supports data rate up to 20 Mbps, S32K312 and S32K311 supports data rate up to 15 Mbps. Only one LPSPI instance support 20 MHz in loopback mode that is LPSPI0
- All LPSPIs supports a minimum a 10 MHz data rate on standard plus pads and 7.5 MHz on standard pads.
- Low leakage and Wait modes are not supported in this device.

The number of chip selects that each LPSPI instance supports varies. Because of that, in the Configuration Register 1 (CFGR1), the Peripheral Chip Select (PCS) field and the Peripheral Chip Select Polarity (PCSPOL) field also vary. See the next 2 tables.

68.1.2 LPSPI HREQ considerations for S32K314, S32K324 and S32K344

It is recommended that the HREQ pin (when PCS[1] is used as HREQ) should get de-asserted before the completion of frame transfer. In case if the HREQ state is still asserted and LPSPI returns to idle state after frame transfer completion, the HREQ state is internally latched and the next data is written to the transmit FIFO without waiting for the next HREQ assertion.

This limitation is present only while using PCS[1] as HREQ and HREQ remains asserted throughout frame transfer. In case of using trigger input as HREQ, there is no issue.

68.2 Overview

LPSPI provides an efficient interface to a SPI bus, either as a master or slave. A SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

68.2.1 Block diagram

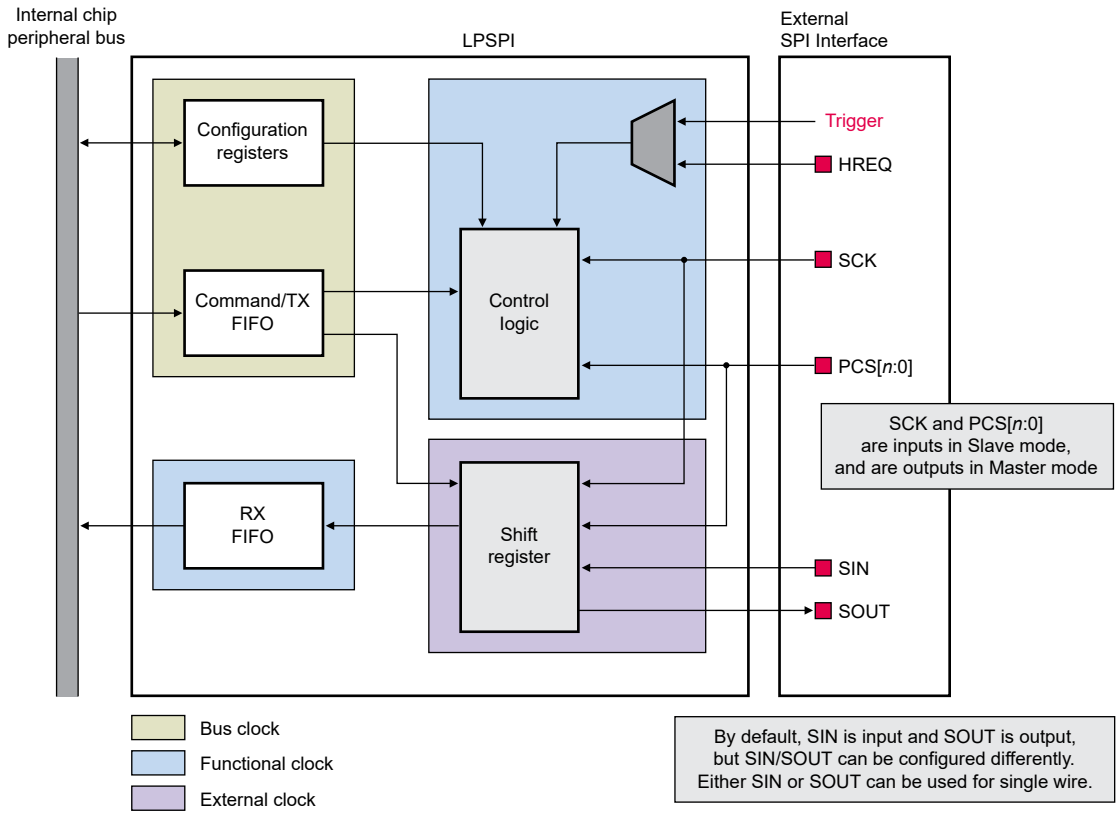

Figure 361. Block diagram

68.2.2 Features

- Requires minimal CPU overhead, with DMA offloading of FIFO register accesses
- Supports DMA accesses and generates DMA requests
- 32-bit word size
- Configurable clock polarity and phase
- Master mode—supports 8 peripheral chip selects
- Slave mode
- 4-word transmit and command FIFO
- 4-word receive FIFO
- Flexible timing parameters in Master mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers support 1-bit transmit and receive on each clock edge
- Half-duplex transfers support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge

— 8-bit transmit or receive on each clock edge

- Can use host request to control the start of a SPI bus transfer

68.3 Functional description

68.3.1 Master mode

68.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- You store transmit data words to the transmit and command FIFO, by writing to Transmit Data (TDR).
- You store command words to the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend upon whether the LPSPI module is busy or between frames. See TCR[CONT] and TCR[CONTC].

Table 381. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle	The command word is pulled from the FIFO, and that command word controls all subsequent transfers.
LPSPI is busy and the Continuing Command field (TCR[CONTC]) is 0	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy, the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the FRAMESZ value), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

About TCR[CONT] and TCR[CONTC]:

- TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.
- TCR[CONTC] = 1 specifies that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least 3 LPSPI functional clock cycles for TCR to update after TCR is written (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing the TCR does not initiate a SPI bus transfer, unless the TCR[TXMSK] = 1. When the TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the TCR[FRAMESZ] value); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Master mode, the LPSPI command word in TCR controls SPI attributes based on selections in register fields.

Table 382. Command word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and either TXMSK or RXMSK must also be 1. • 8-bit half-duplex transfers are useful for interfacing to OctelSPI memory devices, and at least one of TXMSK or RXMSK must also be 1.	Y

Table continues on the next page...

Table 382. Command word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.	Y

68.3.1.1.1 SPI bus transfers

LPSPI initiates a SPI bus transfer when all of the following conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and uses the timing parameters in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the FRAMESZ value have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

68.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags do not update. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO while Circular FIFO mode is enabled.

68.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO.

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of two words in DMR0 and DMR1, or against a masked data word. The received data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the TCR[RXMSK] field cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.
- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to the CFGR0[RDMO] field, then write 0 to SR[DMF].

68.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the TCR[PRESCALE] selection. Although you cannot change Clock Configuration (CCR) when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers using Transmit Command (TCR).

NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 383. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external slave	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 383. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
		requires a large delay between different words of an SPI bus transfer.		
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

This figure shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

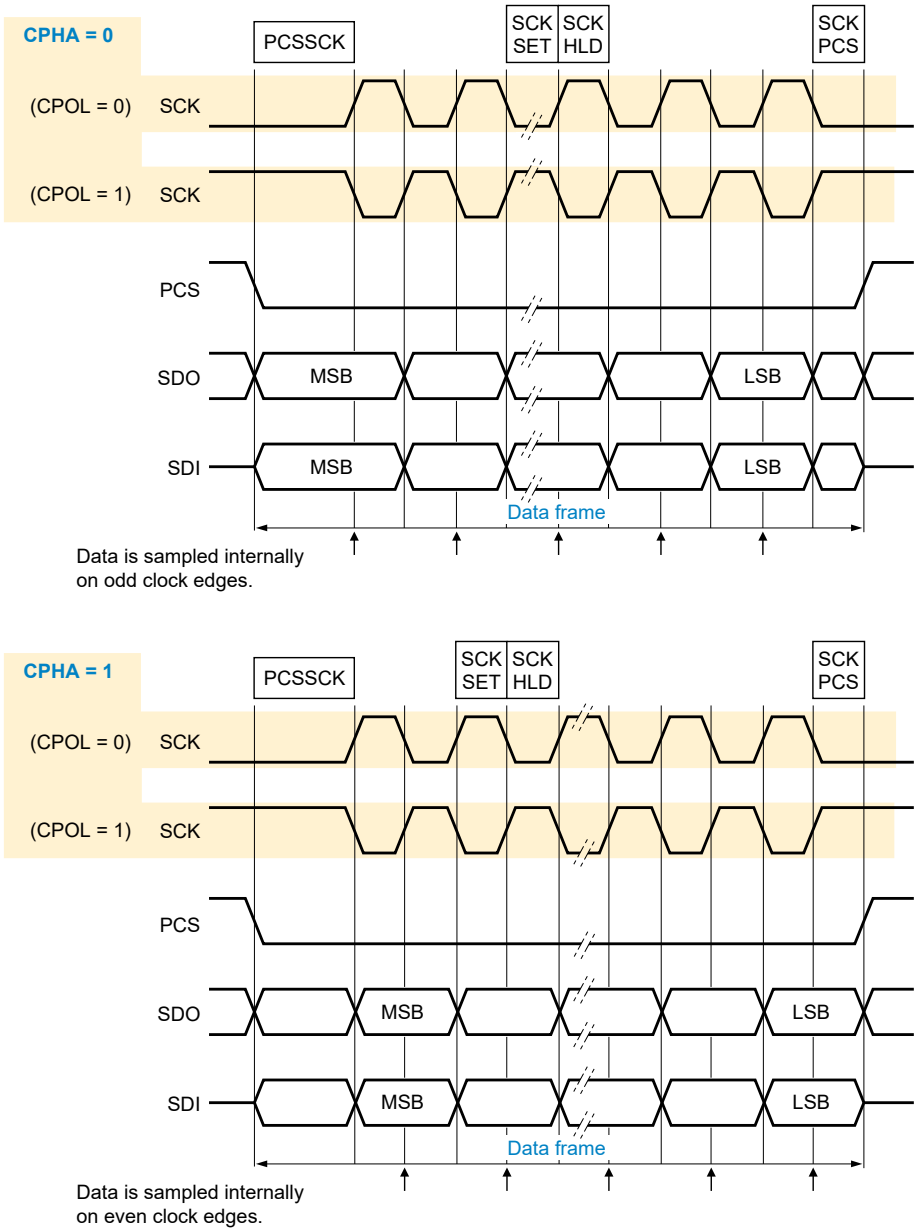

Figure 362. Clock phase (TCR[CPHA]) timing diagram example

68.3.1.4 Pin configuration

- To swap directions or support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring for half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can set CFGR1[PCSCFG] to any value.
- When performing half-duplex 4-bit transfers, you must set CFGR1[PCSCFG] to 1h.

68.3.1.5 Clock loopback

Configure the LPSPI master to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK can improve the setup time of the input data from the slave.

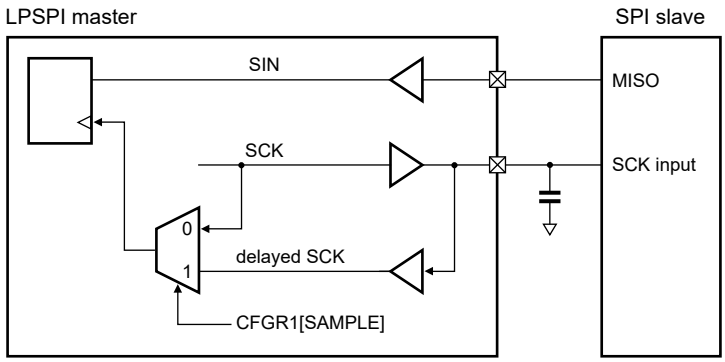

Figure 363. Clock loopback

See the chip data sheet for the specific input setup time in Master Loopback mode.

68.3.2 Slave mode

LPSPI slave mode:

- Uses the same shift register and logic that master mode uses.
- Does not use Clock Configuration Register (CCR).
- Requires that Transmit Command (TCR) remain static (unchanging) during SPI bus transfers.

68.3.2.1 Transmit and command FIFO commands

Before enabling LPSPI in Slave mode, initialize Transmit Command (TCR), although TCR does not update until after LPSPI is enabled. After LSPI is enabled, only change TCR when LPSPI is idle. In Slave mode, the LPSPI command word in TCR controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 384. Command word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.

Table continues on the next page...

Table 384. Command word in Slave mode (continued)

Transmit Command (TCR)		Description
Field	Name	
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Slave mode, after the number of bits indicated by FRAMESZ are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data as if there were a 32-bit shift register.
CONTC	Continuing command	When continuing command is enabled in Slave mode, after the number of bits indicated by FRAMESZ are transferred, then RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one of TCR[TXMSK] or TCR[RXMSK] must be 1. • 8-bit half-duplex transfers are useful for interfacing to OctelSPI memory devices, and at least one of Transmit Data Mask (TCR[TXMSK] or Receive Data Mask TCR[RXMSK]) must also be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits, or 16 bits for an 8-bit parallel transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

68.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words in the DMR0 and DMR1 registers or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the CFGR0[RDMO] bit, then clear the SR[DMF] bit.

68.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register has shifted in a partial word, the receive shift register can be configured to either discard the partial word or to store it in the receive FIFO. You specify this using CFGR1[PARTIAL].

A partial word is defined as less than FRAMESZ bits (when FRAMESZ is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when FRAMESZ is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is fine, but a partial received frame of 1 bit is not supported.

68.3.2.4 Clocked interface

LPSPI supports interfacing to external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOLn] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1), CFGR1[PCSPOL*n*] could be used to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the TCR[PRESCALE] selection) is required between the last SCK edge of one word and the first SCK edge of the next word.

68.3.3 Low-power modes

Table 385. Low-power modes

Chip mode	LPSPI operation
Run	Normal operation

68.3.4 Debug mode

Table 386. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug/ Halted mode)	Can continue operating in Debug mode, if the CR[DBGEN] = 1.

68.3.5 Interrupts and DMA requests

The following table lists the Slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit and receive DMA requests.

Table 387. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Data can be written to transmit FIFO, as configured by the transmit FIFO watermark FCR[TXWATER]	Y	TX	Y
RDF	Receive data flag	Data can be read from the receive FIFO, as configured by the receive FIFO watermark FCR[RXWATER]	Y	RX	Y
WCF	Word complete flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame complete flag	Frame is complete, and PCS has deasserted	Y	N	Y
TCF	Transfer complete flag	Transfer is complete, PCS has deasserted, and the transmit and command FIFO is empty	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), the Transmit Error Flag cannot set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), the Receive Error Flag cannot set.	Y	N	Y
DMF	Data match flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module busy flag	LPSPI is busy performing a SPI bus transfer	N	N	N

68.3.6 Clocks

Table 388. LPSPI clocks

LPSPI functional clock	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups, in both Master and Slave modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (SCK).
External clock	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends upon the mode (Master or Slave):

Table continues on the next page...

Table 388. LPSPI clocks (continued)

	— In Master mode: the SCK clock is generated internally. — In Slave mode: the SCK clock is supplied externally.
Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

For chip-specific clocking information, see the Clocking chapter.

68.3.7 Resets

Table 389. Resets

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	• Resets the LPSPI logic and registers to their default state, except for the Control Register. • The LPSPI software reset is controlled using CR[RST].
FIFO resets	• Resets the transmit and command FIFO and the receive FIFO. • The Reset Transmit FIFO field, CR[RTF], and the Reset Receive FIFO field, CR[RRF], are write only. • After being reset, a FIFO is empty.

68.3.8 Peripheral triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

Table 390. Peripheral triggers

Trigger	Description	Notes
Frame output trigger	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts) • Remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output trigger	The word output trigger: • Asserts at the end of each received word • Remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	
Input trigger	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input. • The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected.	

Table continues on the next page...

Table 390. Peripheral triggers (continued)

Trigger	Description	Notes
	• When the LPSPI module is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • Both HREQ and the LPSPI input trigger are ignored when the module is busy. They are used to start a new transfer when the module is idle.	

68.4 Signals

Table 391. Signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Slave mode • Output in Master mode	I/O
PCS[0]	Peripheral chip select	• Input in Slave mode • Output in Master mode	I/O
PCS[1] / HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0 • Input in either Slave mode or when used as master host request • Output in either Master mode or when used as slave host request	I/O
PCS[2] / DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3] / DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[4] / DATA[4]	Peripheral chip select or data pin 4 during parallel data transfers	When CFGR1[PCSCFG] = 0:	I/O

Table continues on the next page...

Table 391. Signals (continued)

Signal	Name	Description	I/O
		• Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	
PCS[5] / DATA[5]	Peripheral chip select or data pin 5 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[6] / DATA[6]	Peripheral chip select or data pin 6 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[7] / DATA[7]	Peripheral chip select or data pin 7 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT / DATA[0]	Serial data output	Can be configured as serial data input signal • Used as data pin 0 in half-duplex parallel data transfers	I/O
SIN / DATA[1]	Serial data input	Can be configured as serial data output signal	I/O

Table continues on the next page...

Table 391. Signals (continued)

Signal	Name	Description	I/O
		• Used as data pin 1 in half-duplex parallel data transfers	

68.5 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

68.5.1 LPSPI register descriptions

68.5.1.1 LPSPI memory map

LPSPI_0 base address: 4035_8000h

LPSPI_1 base address: 4035_C000h

68.5.1.2 Version ID (VERID)

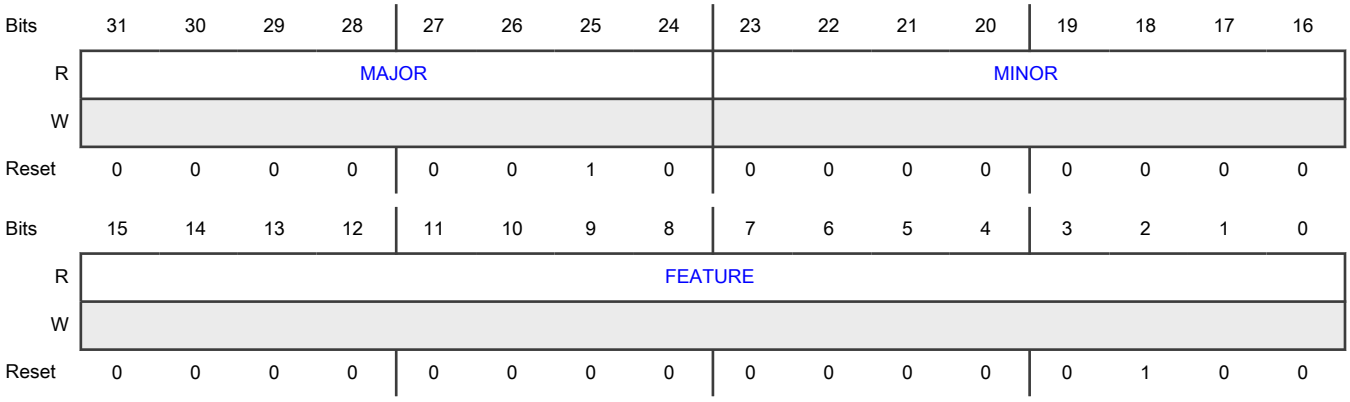
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number for the module specification.
15-0 FEATURE	Module Identification Number Indicates the feature set number. 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register. All other values are reserved.

68.5.1.3 Parameter (PARAM)

Offset

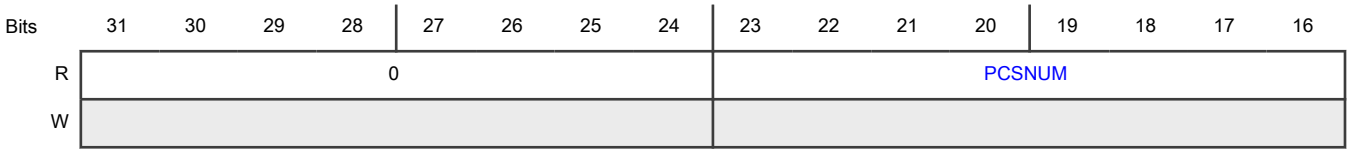
Register	Offset
PARAM	4h

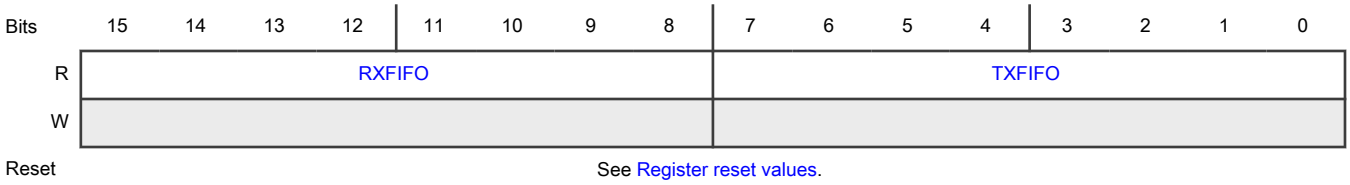
Function

Contains:

- Number of PCS pins
- Receive FIFO size
- Transmit FIFO size

Diagram





Register reset values

Register	Reset value
PARAM	LPSPI_0: 0008_0202h LPSPI_1: 0006_0202h LPSPI_2–LPSPI_5: 0004_0202h

Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Indicates the number of PCS pins supported.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO. The maximum number of words is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO. The maximum number of words is 2^{TXFIFO}.

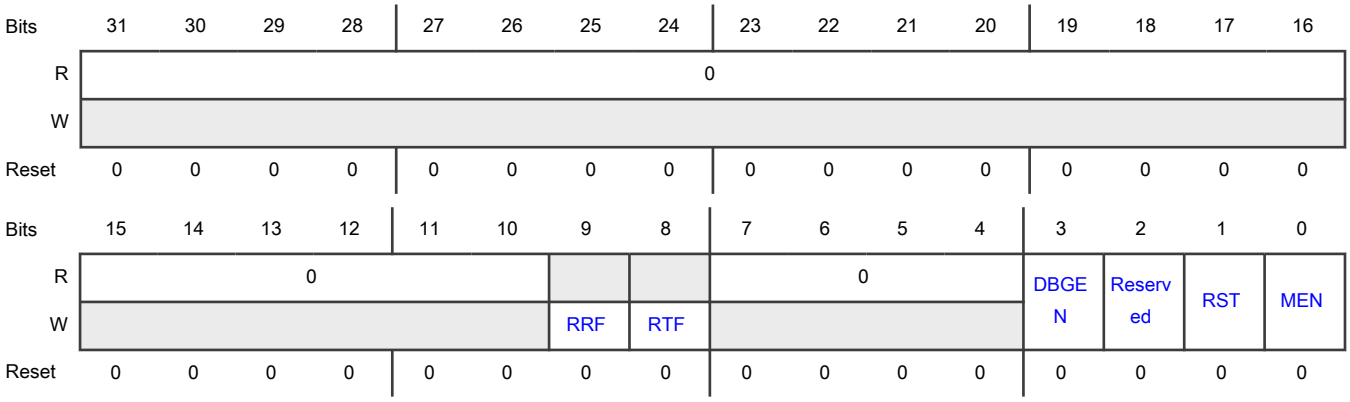
68.5.1.4 Control (CR)

Offset

Register	Offset
CR	10h

Function
Contains fields that control module operation.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Deletes all entries in the receive FIFO. This field always reads zero. 0b - No effect 1b - Reset
8 RTF	Reset Transmit FIFO Deletes all entries in the transmit FIFO. This field always reads 0. 0b - No effect 1b - Reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables LPSPI in when the CPU is in Debug mode. When this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR). Update this field only when the LPSPI module is disabled (MEN = 0). 0b - Disable 1b - Enable
2 —	Reserved
1 RST	Software Reset Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0. 0b - Not reset 1b - Reset
0 MEN	Module Enable 0b - Disable 1b - Enable

68.5.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function

Contains data flow status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag In Master mode, indicates that there is data to transmit and LPSPI is able to transmit (for example, HREQ is asserted). It deasserts after the PCS pin deasserts and the LPSPI master has waited half the CCR[DBT] time with no new data to transmit. Slave mode asserts this flag when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag Indicates that received data matches DMR0[MATCH0] and/or DMR1[MATCH1] (as configured by CFGR1[MATCFG]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No match 1b - Match
12 REF	Receive Error Flag Indicates a receive FIFO overflow error. When this flag is set: 1. End the transfer. 2. Empty the Receive FIFO. 3. Clear this flag. 4. Restart the transfer from the beginning. 0b - No overflow 1b - Overflow
11 TEF	Transmit Error Flag Indicates a Transmit FIFO underrun error. When this flag is set: 1. End the transfer. 2. Clear this flag. 3. Restart the transfer from the beginning. 0b - No underrun 1b - Underrun
10 TCF	Transfer Complete Flag In Master mode, indicates that all transfers have completed and that LPSPI has returned to Idle state and the transmit FIFO is empty. 0b - Not complete 1b - Complete
9 FCF	Frame Complete Flag Indicates that a frame transfer has completed, when the PCS deasserts. 0b - Not complete 1b - Complete
8 WCF	Word Complete Flag Indicates that the last bit of a received word is sampled. 0b - Not complete 1b - Complete
7-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 RDF	Receive Data Flag Indicates that the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive data not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag Indicates that the number of words in the transmit FIFO is equal to or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data is requested

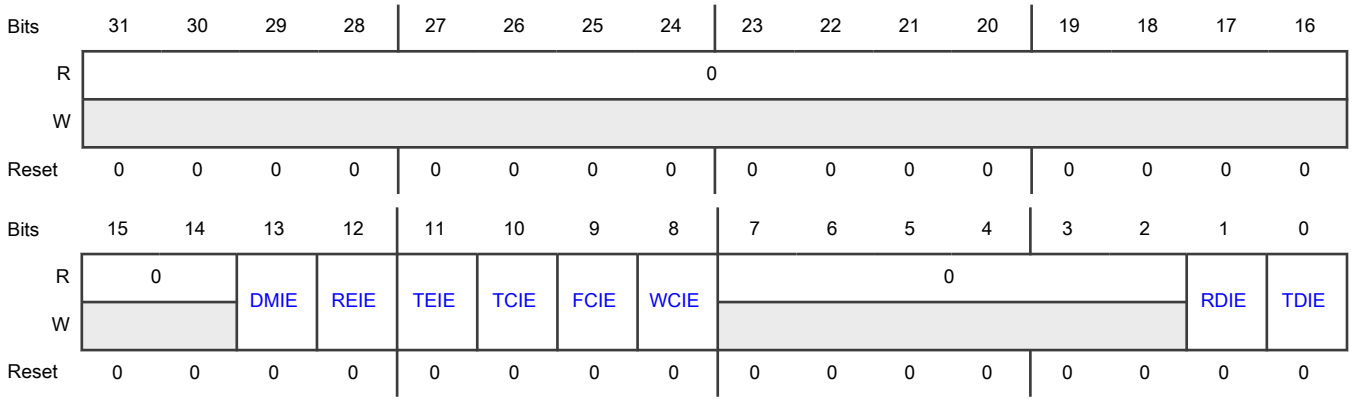
68.5.1.6 Interrupt Enable (IER)

Offset

Register	Offset
IER	18h

Function
Enables interrupts based on data flow and errors.

Diagram



Fields

Field	Function
31-14 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 DMIE	Data Match Interrupt Enable 0b - Disable 1b - Enable
12 REIE	Receive Error Interrupt Enable 0b - Disable 1b - Enable
11 TEIE	Transmit Error Interrupt Enable 0b - Disable 1b - Enable
10 TCIE	Transfer Complete Interrupt Enable 0b - Disable 1b - Enable
9 FCIE	Frame Complete Interrupt Enable 0b - Disable 1b - Enable
8 WCIE	Word Complete Interrupt Enable 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable 0b - Disable 1b - Enable

68.5.1.7 DMA Enable (DER)

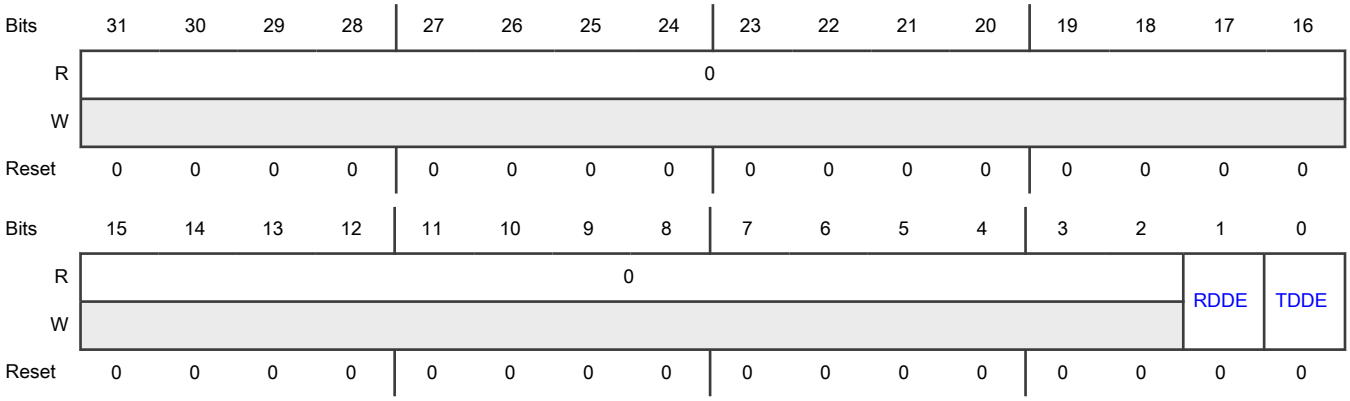
Offset

Register	Offset
DER	1Ch

Function

Enables DMA data flow.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable 0b - Disable 1b - Enable

68.5.1.8 Configuration 0 (CFGR0)

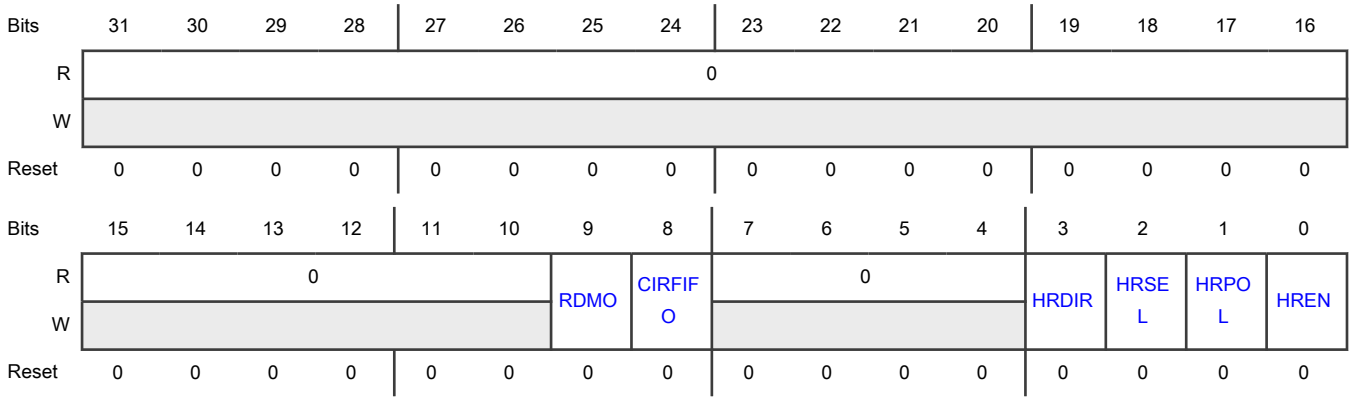
Offset

Register	Offset
CFGR0	20h

Function

Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to assert is discarded. • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. Only configure the HREQ pin as an output when LPSPI is in Slave mode. The HREQ pin direction must be an input for Master mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger. 0b - Active high 1b - Active low
0 HREN	Host Request Enable In Master mode, allows LPSPI to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Slave mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

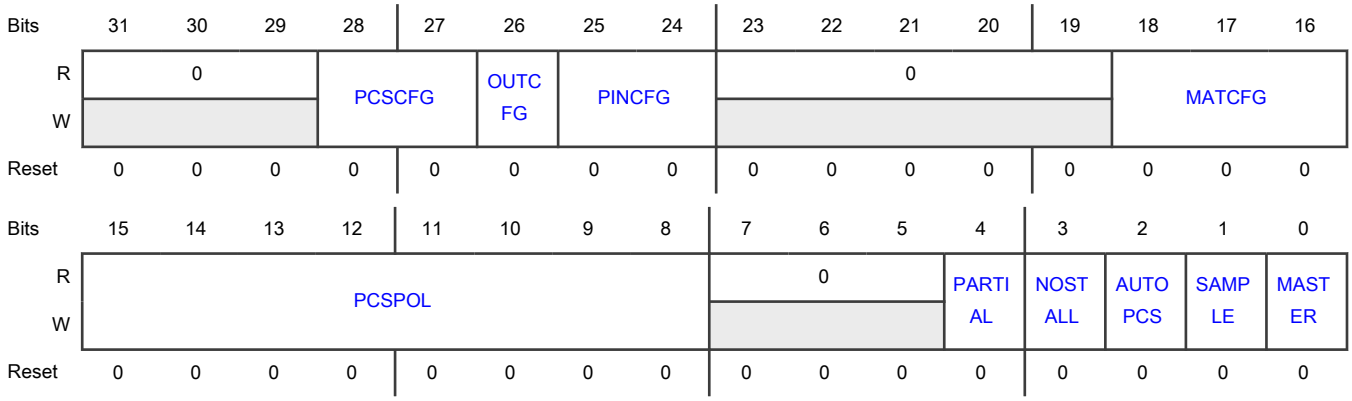
68.5.1.9 Configuration 1 (CFGR1)

Offset

Register	Offset
CFGR1	24h

Function
Includes fields to configure LPSPI. Write to this register only when LPSPI is disabled.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-27 PCSCFG	Peripheral Chip Select Configuration Specifies the PCS pin configuration. When performing parallel transfers, this field must be configured to enable the desired transfer. **NOTE** This field is not supported in every instance. The following table includes only supported registers. 00b - PCS[7:2] are configured for chip select function 01b - PCS[3:2] are configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2]) 11b - PCS[7:2] are configured for half-duplex 4-bit and 8-bit transfers (PCS[7:2] = DATA[7:2])
26 OUTCFG	Output Configuration Specifies whether the output data is 3-stated between accesses (when PCS is deasserted). When performing half-duplex transfers, this field must be 1.

Instance	Field supported in	Field not supported in
LPSPI_0	CFGR1	—
LPSPI_1	CFGR1[27]	CFGR1[28]
LPSPI_2	CFGR1[27]	CFGR1[28]
LPSPI_3	CFGR1[27]	CFGR1[28]
LPSPI_4	CFGR1[27]	CFGR1[28]
LPSPI_5	CFGR1[27]	CFGR1[28]

Table continues on the next page...

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4 PARTIAL	Partial Enable Specifies whether LSPI, when in Slave mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. 0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LSPI, when in Master mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Slave mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least 4 LPSPI functional clock cycles, divided by the prescaler selected (see TCR[PRESCALE]) between each word, to ensure correct operation. This field is ignored in Master mode. 0b - Disable 1b - Enable
1 SAMPLE	Sample Point Specifies the SCK clock edge on which LSPI, when in Master mode, samples input data. Writing 1 to this field causes LSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration. The input data setup time in Master mode is equal to the input data setup time in Slave mode. In Slave mode, this field is ignored. 0b - SCK edge 1b - Delayed SCK edge
0 MASTER	Master Mode Specifies the LPSPI operating mode—either Master or Slave. This field directly controls the direction of the SCK and PCS pins. 0b - Slave mode 1b - Master mode

68.5.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

Function

Specifies match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR0[RDMO] = 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 MATCH0	Match 0 Value MATCH0 value to be compared against received data.

68.5.1.11 Data Match 1 (DMR1)

Offset

Register	Offset
DMR1	34h

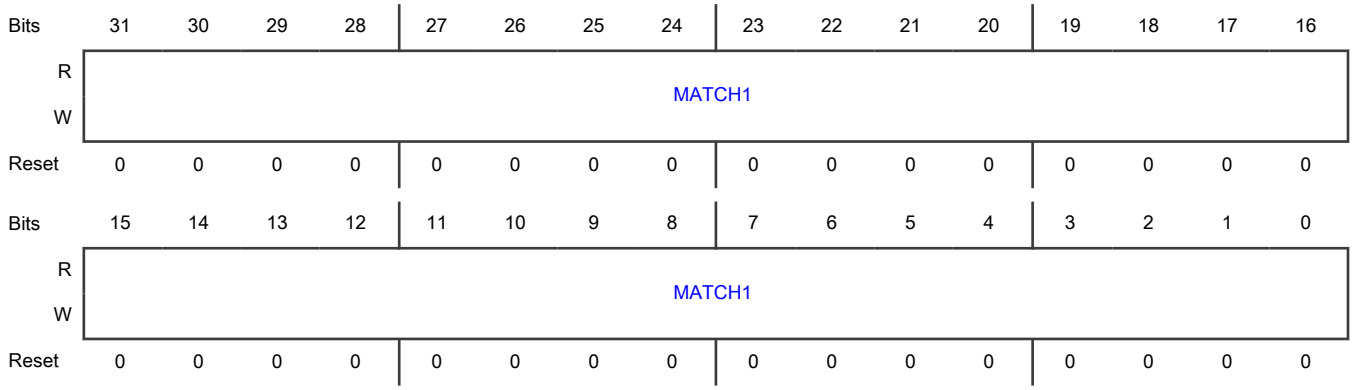
Function

Specifies match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR0[RDMO] = 1.

Diagram



Fields

Field	Function
31-0 MATCH1	Match 1 Value MATCH1 value to be compared against received data.

68.5.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields. These fields are only used in Master mode and you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1:

- Either write all 4 CCR register fields simultaneously and only once in a 32-bit data.
- Or to modify SCKPCS and/or PCSSCK values, write only these 2 upper bytes in a 16-bit data or one of them in an 8-bit data.
- Or to modify CCR1[PCSPCS] and CCR1[SCKSCK] fields only or CCR1[SCKSET] and CCR1[SCKHLD] fields only, write respectively CCR[DBT] or CCR[SCKDIV] in 8-bit data

Diagram

Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay In Master mode: configures the delay from the last SCK edge to the PCS negation. • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 362.
23-16 PCSSCK	PCS-to-SCK Delay In Master mode: configures the delay from the PCS assertion to the first SCK edge. • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 362.
15-8 DBT	Delay Between Transfers Writing this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].
7-0 SCKDIV	SCK Divider Writing this field updates the contents of CCR1[SCKSET] and CCR1[SCKHLD].

68.5.1.13 Clock Configuration 1 (CCR1)

Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields. These fields are only used in Master mode and you can only change them when LPSPI is disabled (CR[MEN] = 0).

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay In Master mode: • Configures the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. **NOTE** For backward compatibility, writing CCR[DBT] updates CCR1[SCKSCK] with the value written.
23-16 PCSPCS	PCS to PCS delay In Master mode: • Configures the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 2 cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the prescaler selected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE For backward compatibility, writing CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8 SCKHLD	SCK Hold In Master mode, this field configures the hold phase of the SCK pin. • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • This is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. This is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. Configure both fields to the same value for 50/50 duty cycle. See Figure 362. **NOTE** For backward compatibility, writing CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup In Master mode, the SCK Setup configures the setup phase of the SCK pin. • The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • This is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. This is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD, configure both fields to the same value for 50/50 duty cycle. See Figure 362. **NOTE** For backward compatibility, writing CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

68.5.1.14 FIFO Control (FCR)

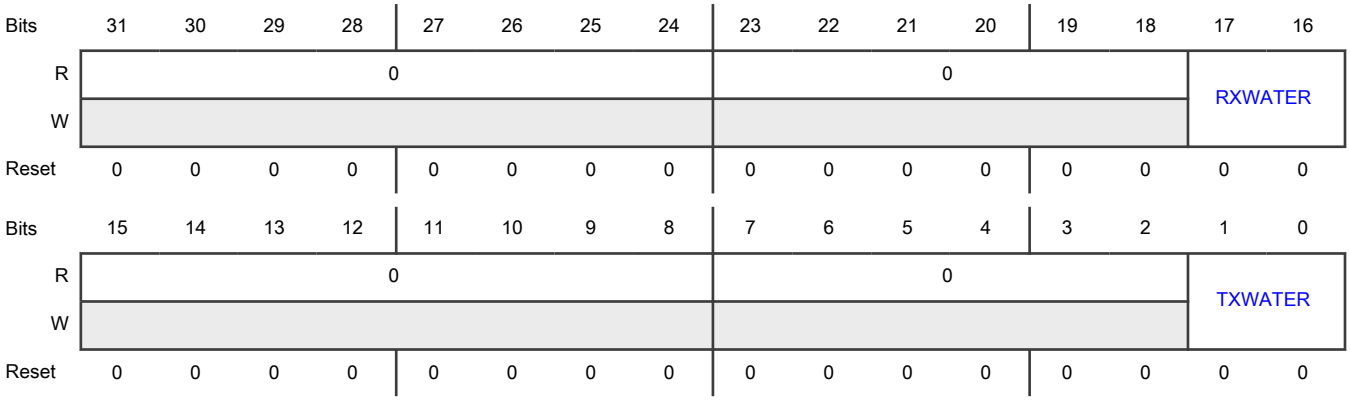
Offset

Register	Offset
FCR	58h

Function

Contains the receive FIFO and transmit FIFO watermark values.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-18 —	Reserved
17-16 RXWATER	Receive FIFO Watermark Causes LPSPI to set the Receive Data Flag (SR[RDF]) when the number of words in the receive FIFO is greater than RXWATER. Writing a value equal or greater than the FIFO size truncates the written value.
15-8 —	Reserved
7-2 —	Reserved
1-0 TXWATER	Transmit FIFO Watermark Causes LPSPI to set the Transmit Data Flag (SR[TDF]) when the number of words in the transmit FIFO is equal or less than TXWATER. Writing a value equal or greater than the FIFO size truncates the written value.

68.5.1.15 FIFO Status (FSR)

Offset

Register	Offset
FSR	5Ch

Function

Contains fields that indicate the number of words currently stored in the receive FIFO and transmit FIFO.

2-0 TXCOUNT	Transmit FIFO Count Indicates the number of words currently stored in the transmit FIFO.

68.5.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Writes to either this register or Transmit Data (TDR) push the data into the transmit FIFO, in the order written. Only write to this register using 32-bit writes. Writes are tagged and cause the command register to update, after that entry reaches the top of the FIFO and the LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, the writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word.

- **In Master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when the PCS deasserts.
- **In Master mode,** if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word then updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- **In Slave mode,** the command word should be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the Transmit FIFO after writing to the Transmit Command Register, wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading the Transmit Command Register returns the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended to:

- Read the Transmit Command Register when the transmit FIFO is empty,
- Read the Transmit Command Register more than once and then compare the returned values.

	<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>LPSPI_0</td><td>TCR</td><td>—</td></tr><tr><td>LPSPI_1</td><td>TCR</td><td>—</td></tr><tr><td>LPSPI_2</td><td>TCR[25–24]</td><td>TCR[26]</td></tr><tr><td>LPSPI_3</td><td>TCR[25–24]</td><td>TCR[26]</td></tr><tr><td>LPSPI_4</td><td>TCR[25–24]</td><td>TCR[26]</td></tr><tr><td>LPSPI_5</td><td>TCR[25–24]</td><td>TCR[26]</td></tr></table> 000b - Transfer using PCS[0] 001b - Transfer using PCS[1] 010b - Transfer using PCS[2] 011b - Transfer using PCS[3] 100b - Transfer using PCS[4] 101b - Transfer using PCS[5] 110b - Transfer using PCS[6] 111b - Transfer using PCS[7]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disabled 1b - Enabled
21 CONT	Continuous Transfer • In Master mode, CONT keeps the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In Slave mode, when CONT is enabled, LPSPI only transmits the first FRAMESZ bits; after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 CONTC	Continuing Command In Master mode, this field enables the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. In Slave mode, the Continuing Command bit modifies the internal RXMSK/TXMSK configuration after the first FRAMESZ bits and until the PCS negation. • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1 this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits, this allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask Masks receive data (receive data is not stored in receive FIFO). 0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from transmit FIFO and the output pin is 3-stated). In Master mode, TXMSK initiates a new transfer which cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be 1. **NOTE** The descriptions of the field settings vary by module instance.

FRAMESZ</td><td>Frame Size
Configures the frame size in number of bits equal to (FRAMESZ + 1).
• The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer
• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

68.5.1.17 Transmit Data (TDR)

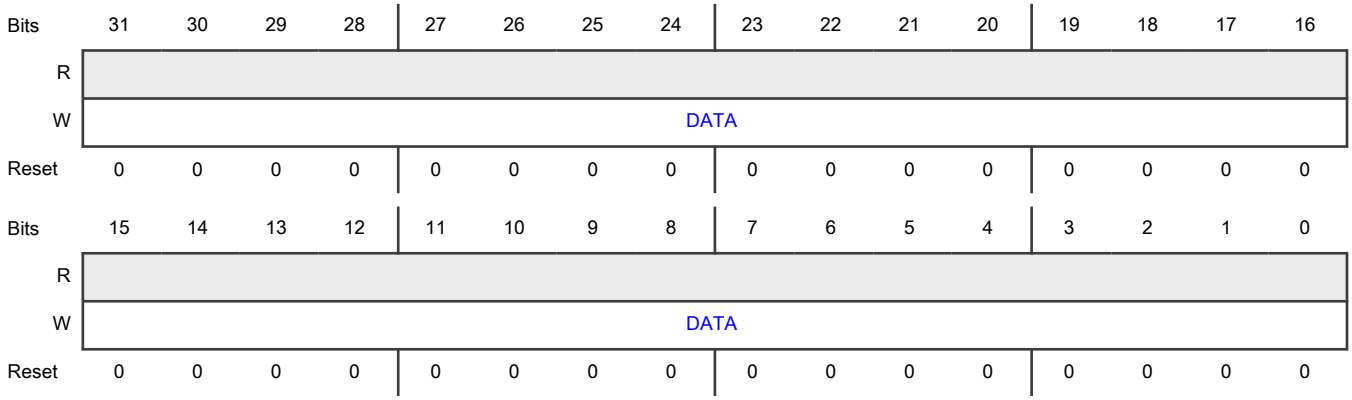
Offset

Register	Offset
TDR	64h

Function

Writes to either Transmit Command (TCR) or this register push the data into the transmit FIFO, in the order that the data is written. You can write to TDR using 32-, 16-, or 8-bit writes, but each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram



Fields

Field	Function
31-0 DATA	Transmit Data Both 8- and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8- and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

68.5.1.18 Receive Status (RSR)

Offset

Register	Offset
RSR	70h

Function

Contains data flow status fields for receive FIFO.

Instances	TX FIFO Size	RX FIFO Size	SMBus[1]	Slave Mode Enable
LPI2C_0	4x11 bit	4x8 bit	Yes	Yes
LPI2C_1	4x11 bit	4x8 bit	Yes	Yes

1. System Management Bus

- LPI2C slave mode operation supports up to high speed mode = 3.4MHz (3.4 Mbps data rate; effective data rate reduces according to I2C protocol).
- LPI2C master mode operation supports up to fast Mode = 400KHz (400 kbps data rate; effective data rate reduces according to I2C protocol).
- The LPI2C module includes SMBus (System Management Bus) support and DMA support.
- LPI2C RX FIFO is 8-bit and TX FIFO is 11-bit (8bit data + 3bit command)
- LPI2C supports fast data communication as per I2C standard v3.0.

69.2 Overview

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I^2C bus as a master and/or as a slave.

- Implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- Uses little CPU overhead, with DMA offloading of FIFO register accesses.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

NOTE

The I^2C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

69.2.1 Block diagram

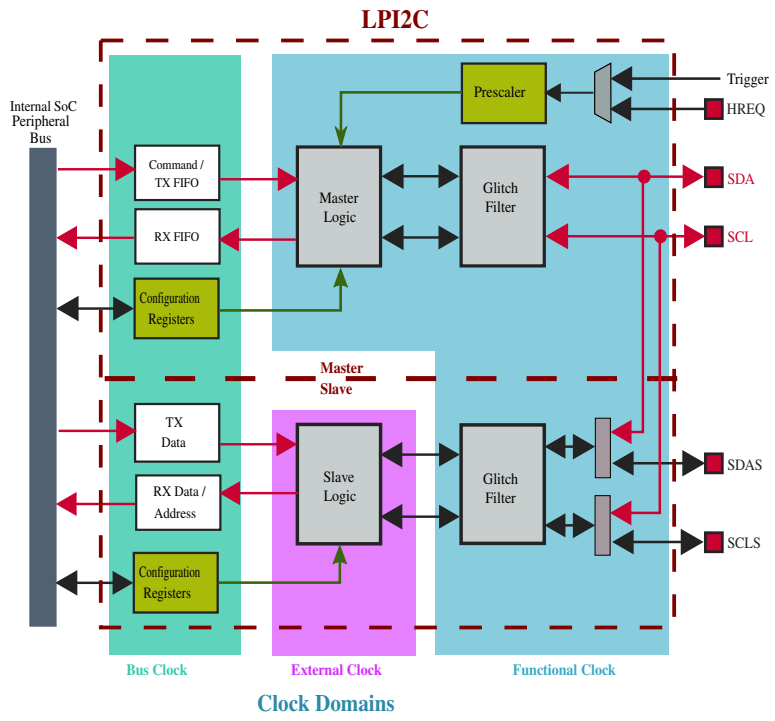

Figure 364. LPI2C block diagram

69.2.2 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- High speed mode (HS) in slave mode
- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.
  - When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism.
  - When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4 words (8-bit transmit data + 3-bit command).
- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers

- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

69.3 Functional description

69.3.1 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP condition; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master automatically transmits a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example,HS-mode master code) must be followed by a STOP or (repeated) START condition.

Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout

is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, if the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master initiates a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
- Transmit a START condition and address byte using the timing configuration in Master Clock Configuration 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C continues to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C generates a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this results in SCL pulled low continuously on the first bit of a byte, until the following conditions are removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear. The LPI2C master will continue to stall the bus until the transmit FIFO is loaded with more data.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C master will continue to stall the I2C bus until the receive FIFO is emptied.

Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. LPI2C master can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and delays the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (Master Clock Configuration 1 (MCCR1)) and other modes (Master Clock Configuration 0 (MCCR0)). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

Table 394. Timing Parameters

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) x (2 ^ PRESCALE)

Table continues on the next page...

Table 394. Timing Parameters (continued)

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
hold time (repeated) START condition	tHD:STA	(SETHOLD +1) x (2 ^ PRESCALE)
LOW period of the SCL clock	tLOW	(CLKLO + 1) x (2 ^ PRESCALE)
HIGH period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
setup time for a repeated START condition or STOP condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
data hold time	tHD:DAT	(DATAVD + 1) x (2 ^ PRESCALE)
data setup time	tSU:DAT	(SDA_LATENCY + 1) x (2 ^ PRESCALE)
bus free time between a STOP and START condition	tBUF	(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)
data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) x (2 ^ PRESCALE)

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading and the external pull-up resistor sizing. A larger rise time increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 395. Synchronization Latency

Timing Parameter	Timing Definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

Table 396. LPI2C Timing Parameter Restrictions

Timing Parameter	Minimum	Maximum	Comment
CLKLO	0x03	-	Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	0x01	-	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	0x02	-	Also: SETHOLD x (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	0x01	CLKLO - SDA_LATENCY - 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	0x00	[CLKLO x (2 ^ PRESCALE)] - 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)

Table continues on the next page...

Table 396. LPI2C Timing Parameter Restrictions (continued)

Timing Parameter	Minimum	Maximum	Comment
FILTSDA	FILTSCL	[CLKLO x (2 ^ PRESCALE)] - 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO+SETHOLD+2) x 2	-	Must also be greater than (CLKHI+1)

The timing parameters must be configured to meet the requirements of the I2C specification; this depends on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

Table 397. LPI2C Example Timing Configurations

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast	8 MHz	400 kbps	0x0	0x0/0x0	0x04	0x0B	0x05	0x02
Fast+	8 MHz	1 Mbps	0x0	0x0/0x0	0x02	0x03	0x01	0x01
Fast	48 MHz	400 kbps	0x0	0x1/0x1	0x1D	0x3E	0x35	0x0F
Fast	48 MHz	400 kbps	0x2	0x1/0x1	0x07	0x11	0x0B	0x03
Fast+	48 MHz	1 Mbps	0x2	0x1/0x1	0x03	0x06	0x04	0x04
HS-mode	48 MHz	3.2 Mbps	0x0	0x0/0x0	0x07	0x08	0x03	0x01
Fast	60 MHz	400 kbps	0x1	0x2/0x2	0x11	0x28	0x1F	0x08
Fast+	60 MHz	1 Mbps	0x1	0x2/0x2	0x07	0x0F	0x0B	0x01
HS-mode	60 MHz	3.33 Mbps	0x1	0x0/0x0	0x04	0x04	0x02	0x01

Error Conditions

The LPI2C master monitors for errors while it is active. The following conditions generate an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PLTF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[RST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when

BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the MCFGR1[IGNACK] bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This configures the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

69.3.2 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

Address Matching

The LPI2C slave can be configured:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- To match a range of addresses in either 7-bit or 10-bit addressing modes
- To match the General Call Address, and generate appropriate flags
- To match the SMBus Alert Address, and generate appropriate flags
- To detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave automatically performs slave-transmit or slave-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] is set)
- A bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- A (repeated) START or STOP condition is detected

Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.

- The Transmit Data register should only be written when the Transmit Data flag (SSR[TDF]) is set.
- The Receive Data register should only be read when the Received Data flag (SSR[RDF]) is set (or the Address Valid flag is set and SCFGR1[RXCFG] = 1).
- The Address Status register should only be read when the Address Valid flag is set.

Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.
- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching extends for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag sets when the LPI2C slave is driving SDA, but samples a different value than what is expected.
- FIFO error flag sets due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag also sets due to an address overrun when SCFGR1[RXCFG] is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

69.3.3 Low power modes

Table 398. LPI2C low power modes

Mode	LPI2C Operation
Run	Normal operations
Stop	Can continue operating in Stop mode if the Doze Enable bit is clear (MCR[DOZEN] = 0) and LPI2C uses an external or internal clock source that remains operating during Stop mode. LPI2C can generate an interrupt or DMA request to cause a wakeup from Stop mode.

69.3.4 Debug mode

Table 399. LPI2C Debug mode

Mode	LPI2C Operation
Debug	Can continue operating in Debug mode if the Debug Enable bit is set (MCR[DBGEN] = 1).

69.3.5 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- The LPI2C master and slave interrupts are combined
- The LPI2C master and slave transmit DMA requests are combined
- The LPI2C master and slave receive DMA requests are combined

Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.

Table 400. Master Interrupts and DMA Requests

Master Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER]	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER]	Y	RX	Y
EPF	End Packet Flag	Master has transmitted a Repeated START or STOP condition	Y	N	Y
SDF	STOP Detect Flag	Master has transmitted a STOP condition	Y	N	Y

Table continues on the next page...

Table 400. Master Interrupts and DMA Requests (continued)

Master Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
NDF	NACK Detect Flag	• During an address byte, the master expected an ACK but detected a NACK • During an address byte, the master expected a NACK but detected an ACK • During a master-transmitter data byte, the master detected a NACK	Y	N	Y
ALF	Arbitration Lost Flag	• The master lost arbitration due to a START/STOP condition detected at the wrong time • Or the master was transmitting data but received different data than the data that was transmitted	Y	N	Y
FEF	FIFO Error Flag	The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition	Y	N	Y
PLTF	Pin Low Timeout Flag	Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout	Y	N	Y
DMF	Data Match Flag	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry	Y	N	Y
MBF	Master Busy Flag	LPI2C master is busy transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C master is enabled and activity is detected on the I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred.	N	N	N

Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

Table 401. Slave Interrupts and DMA Requests

Slave Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to the Slave Transmit Data (STDR)	Y	TX	Y

Table continues on the next page...

Table 401. Slave Interrupts and DMA Requests (continued)

Slave Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
RDF	Receive Data Flag	Data can be read from the Slave Receive Data (SRDR)	Y	RX	Y
AVF	Address Valid Flag	Address can be read from the Slave Address Status (SASR)	Y	RX	Y
TAF	Transmit ACK Flag	ACK/NACK can be written to the Slave Transmit ACK (STAR)	Y	N	Y
RSF	Repeated Start Flag	Slave has detected an address match followed by a Repeated START condition	Y	N	Y
SDF	STOP Detect Flag	Slave has detected an address match followed by a STOP condition	Y	N	Y
BEF	Bit Error Flag	Slave was transmitting data, but received different data than what was transmitted	Y	N	Y
FEF	FIFO Error Flag	• Transmit data underrun • Receive data overrun • Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1). FEF flag can only set when clock stretching is disabled.	Y	N	Y
AM0F	Address Match 0 Flag	Slave detected an address match with SAMR[ADDR0] field	Y	N	N
AM1F	Address Match 1 Flag	Slave detected an address match with SAMR[ADDR1] field or using an address range	Y	N	N
GCF	General Call Flag	Slave detected an address match with the General Call address	Y	N	N
SARF	SMBus Alert Response Flag	Slave detected an address match with the SMBus Alert address	Y	N	N
SBF	Slave Busy Flag	LPI2C slave is busy receiving an address byte or is transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected	N	N	N

69.3.6 Clocks

Table 402. LPI2C clocks

LPI2C Functional clock	The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth.
External clock	The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled. **NOTE** The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers.

For device-specific clocking information, refer to the Clocking chapter.

69.3.7 Resets

Table 403. LPI2C Resets

Chip reset	The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset.
Software reset	• The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] bit resets all master logic and registers to their default state, except for the MCR register itself. • The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] bit resets all slave logic and registers to their default state, except for the SCR register itself.
FIFO reset	• The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. • The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

69.3.8 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

Table 404. LPI2C Triggers

Trigger	Description
Master Output Trigger	The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.

Table continues on the next page...

Table 404. LPI2C Triggers (continued)

Trigger	Description
Slave Output Trigger	The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.
Input Trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

69.4 External signals

Table 405. Signals

Signal	Name	2-Wire Scheme	4-Wire Scheme	I/O
SCL	LPI2C clock line	SCL	In 4-wire mode, this is the SCL input pin.	I/O
SDA	LPI2C data line	SDA	In 4-wire mode, this is the SDA input pin.	I/O
SCLS	Secondary I2C clock line	Not used	In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SCL pin.	I/O
SDAS	Secondary I2C data line	Not used	In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SDA pin.	I/O
HREQ	Host request	If host request is asserted and the I2C bus is idle, then it initiates an LPI2C master transfer. HREQ is an additional pin separate from the 2-wire or 4-wire scheme.		I

The I^2C 2-wire serial bus diagram shows the 2 signal connection.

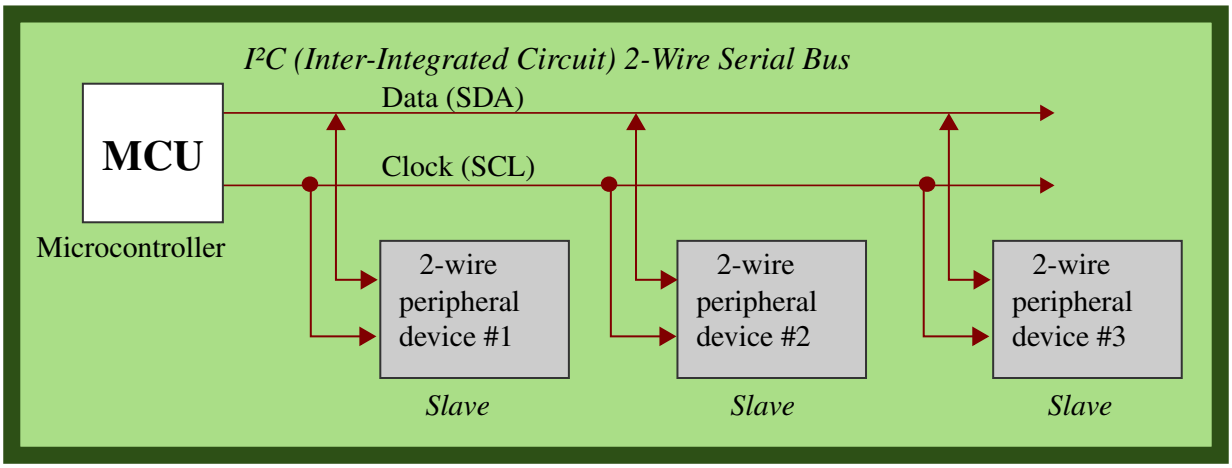

Figure 365. I²C 2-wire serial bus

The I²C 4-wire serial bus diagram shows a possible 4 signal connection.

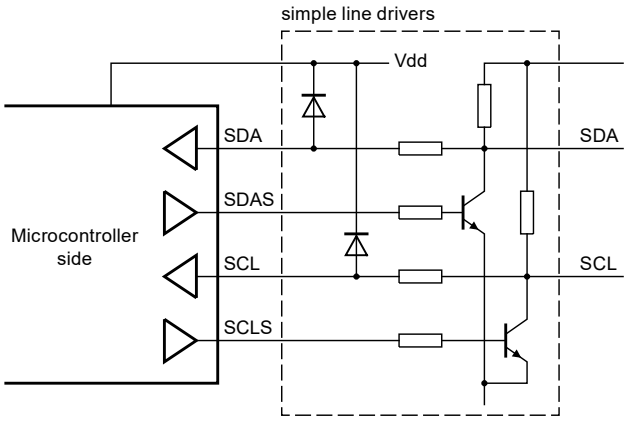

Figure 366. I²C 4-wire serial bus

69.5 Memory Map and Registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

2 DOZEN	Doze mode enable Enables or disables the master in Doze mode. 0b - Master is enabled in Doze mode 1b - Master is disabled in Doze mode
1	Software Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
RST	Resets all internal master logic and registers, except the Master Control (MCR) register. RST remains set until cleared by software. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - Master logic is not reset 1b - Master logic is reset
0 MEN	Master Enable Enables the Master logic. 0b - Master logic is disabled 1b - Master logic is enabled

69.5.1.5 Master Status (MSR)

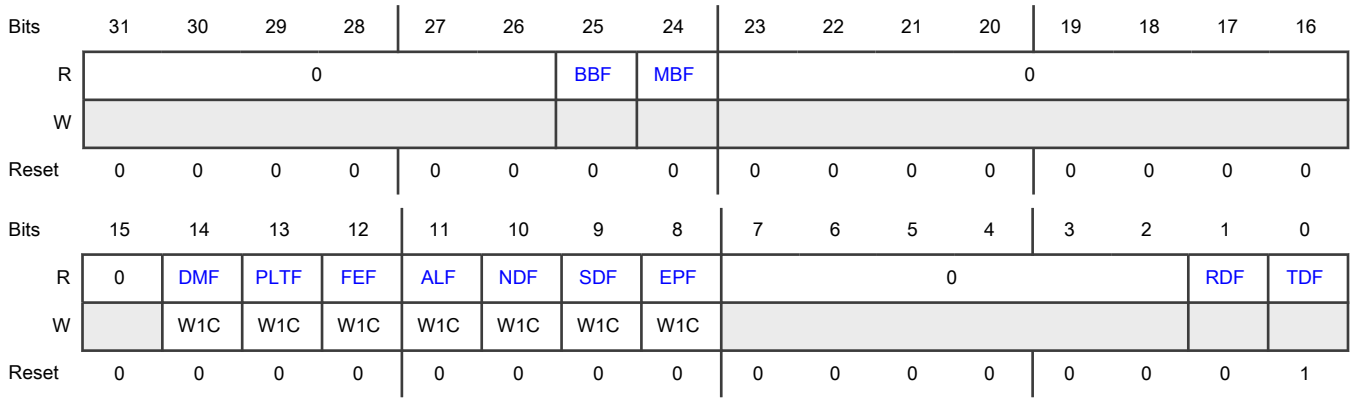
Offset

Register	Offset
MSR	14h

Function

MSR contains status flags for transmit and receive data; Start and Stop conditions; and bus and master busy or idle status.

Diagram



Fields

Field	Function
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 BBF	Bus Busy Flag Indicates that the I2C bus is busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 MBF	Master Busy Flag Indicates that the I2C Master is busy. 0b - I2C Master is idle 1b - I2C Master is busy
23-16 —	Reserved
15 —	Reserved
14 DMF	Data Match Flag Indicates that the received data has matched the MDMR[MATCH0] and/or MDMR[MATCH1] fields (as configured by MCFGR1[MATCFG]. Received data *that is discarded due to CMD field* does not cause DMF to set. 0b - Have not received matching data 1b - Have received matching data
13 PLTF	Pin Low Timeout Flag Sets when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, MCFGR3[PINLOW]), even when the LPI2C master is idle. • Software is responsible for resolving the pin low condition. • PLTF cannot be cleared as long as the pin low timeout continues. • Before the LPI2C can initiate a START condition, the PLTF must be cleared. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. 0b - Pin low timeout has not occurred or is disabled 1b - Pin low timeout has occurred
12 FEF	FIFO Error Flag Detects an attempt to send or receive data without first generating a (repeated) START condition. This can occur if the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When FEF is set, the LPI2C master sends a STOP condition (if busy), and does not initiate a new START condition until FEF has been cleared. 0b - No error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Master sending or receiving data without a START condition
11 ALF	Arbitration Lost Flag Set if either of these conditions exist: • The LPI2C master transmits a logic one and detects a logic zero on the I2C bus • The LPI2C master detects a START or STOP condition while the LPI2C master is transmitting data When ALF sets, the LPI2C master releases the I2C bus (goes idle), and the LPI2C master does not initiate a new START condition until the ALF has been cleared. 0b - Master has not lost arbitration 1b - Master has lost arbitration
10 NDF	NACK Detect Flag Set if the LPI2C master detects a NACK it was not expecting when transmitting an address or data. When set, the master does not initiate a new START condition until NDF has been cleared. If a NACK is expected for a given address (as configured by the command word), then the NDF sets if a NACK is not generated. When NDF is set, the LPI2C master automatically transmits a STOP condition if MCFGR1[AUTOSTOP] = 1, or the transmit FIFO is not empty. 0b - Unexpected NACK was not detected 1b - Unexpected NACK was detected
9 SDF	STOP Detect Flag Set when the LPI2C master generates a STOP condition. 0b - Master has not generated a STOP condition 1b - Master has generated a STOP condition
8 EPF	End Packet Flag Set when the LPI2C master generates either a repeated START condition or a STOP condition. Does not set when the master first generates a START condition. 0b - Master has not generated a STOP or Repeated START condition 1b - Master has generated a STOP or Repeated START condition
7-2 —	Reserved
1 RDF	Receive Data Flag RDF sets whenever the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive Data is not ready 1b - Receive data is ready
0	Transmit Data Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDF	TDF sets whenever the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data is not requested 1b - Transmit data is requested

69.5.1.6 Master Interrupt Enable (MIER)

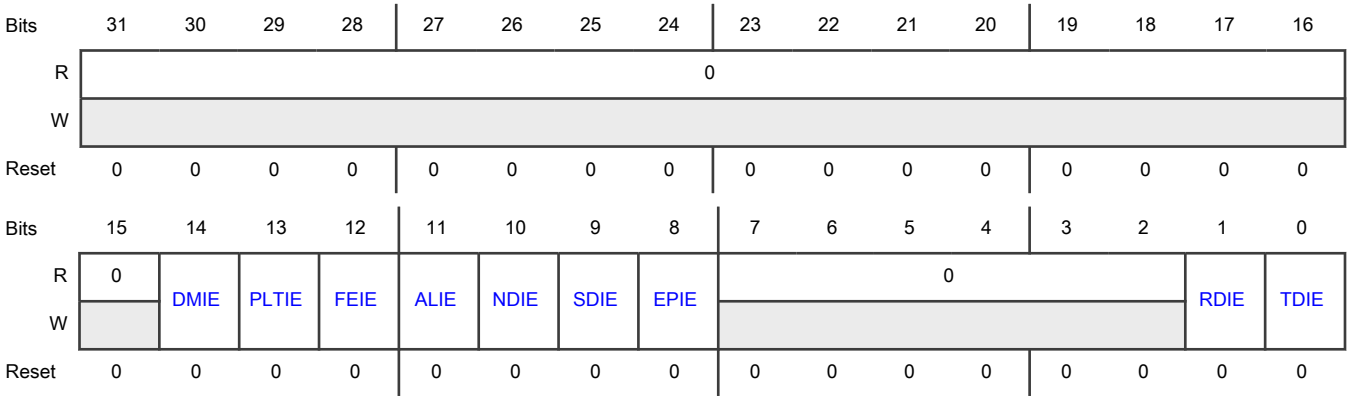
Offset

Register	Offset
MIER	18h

Function

MIER contains transmit and receive data interrupt enables; START, STOP, and NACK detect interrupt enables; and DMA interrupt enables.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 DMIE	Data Match Interrupt Enable Enables interrupt for data match.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
13 PLTIE	Pin Low Timeout Interrupt Enable Enables interrupt for pin low timeout. 0b - Disabled 1b - Enabled
12 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disabled 1b - Enabled
11 ALIE	Arbitration Lost Interrupt Enable Enables interrupt for arbitration lost. 0b - Disabled 1b - Enabled
10 NDIE	NACK Detect Interrupt Enable Enables interrupt for NACK detect. 0b - Disabled 1b - Enabled
9 SDIE	STOP Detect Interrupt Enable Enables interrupt for STOP detect. 0b - Disabled 1b - Enabled
8 EPIE	End Packet Interrupt Enable Enables interrupt for end packet. 0b - Disabled 1b - Enabled
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disabled 1b - Enabled

69.5.1.7 Master DMA Enable (MDER)

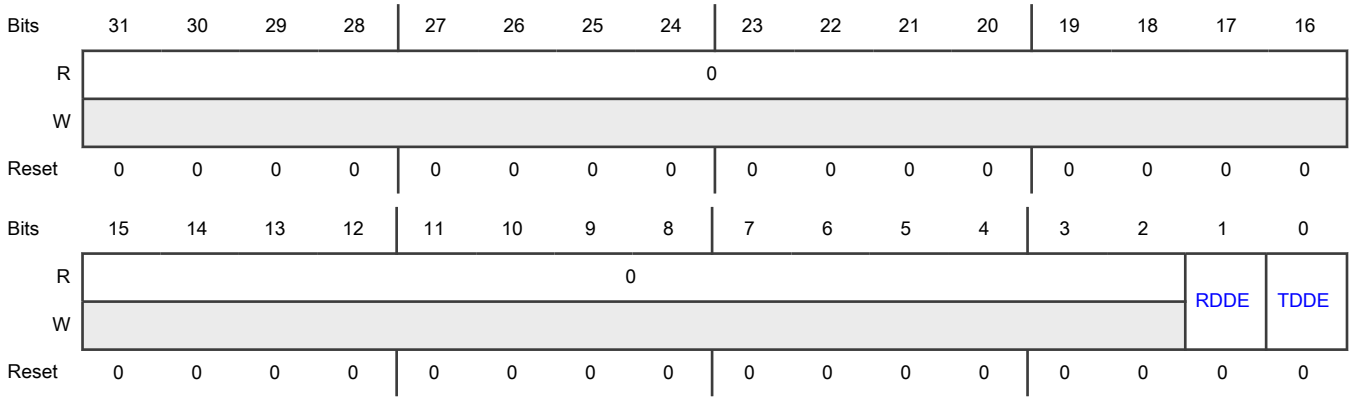
Offset

Register	Offset
MDER	1Ch

Function

MDER contains DMA transmit, request, and receive enables.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables DMA receive data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - DMA request is disabled 1b - DMA request is enabled
0 TDDE	Transmit Data DMA Enable Enables DMA transmit data. 0b - DMA request is disabled 1b - DMA request is enabled

69.5.1.8 Master Configuration 0 (MCFGR0)

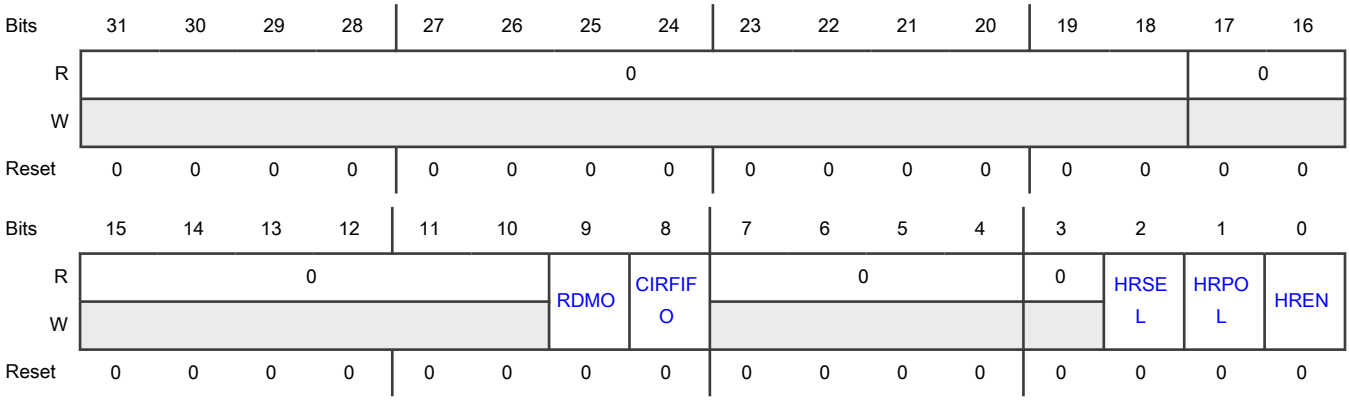
Offset

Register	Offset
MCFGR0	20h

Function

MCFGR0 contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-10 —	Reserved
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (MSR[DMF]) to set is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, clear RDMO before clearing MSR[DMF], to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless the the Data Match Flag (MSR[DMF]) is set
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO empties as normal, but after the LPI2C master is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is set, then a STOP condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Circular FIFO is disabled 1b - Circular FIFO is enabled
7-4 —	Reserved
3 —	Reserved
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, HRSEL should remain static (the Host Request Select should not change). 0b - Host request input is pin HREQ 1b - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request input. When host request is enabled, HRPOL should remain static (Host Request Polarity should not change). 0b - Active low 1b - Active high
0 HREN	Host Request Enable When enabled, the LPI2C master only initiates a START condition if the host request input is asserted and the bus is idle. A repeated START is not affected by the host request.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Host request input is disabled 1b - Host request input is enabled

69.5.1.9 Master Configuration 1 (MCFGR1)

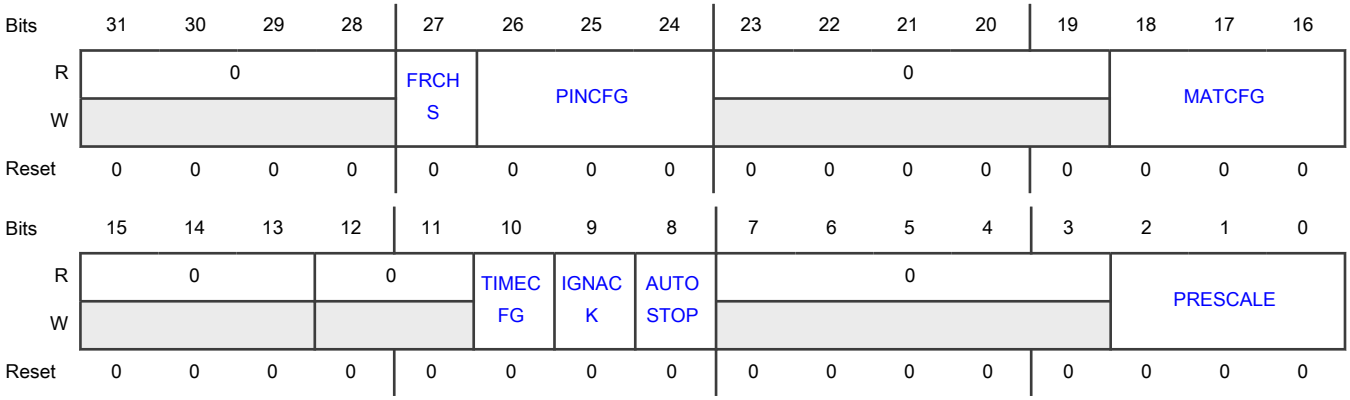
Offset

Register	Offset
MCFGR1	24h

Function

The MCFGR1 should only be written when the I2C Master is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 FRCHS	Force HS-mode When set, forces the LPI2C pin state into HS-mode. Setting this does not impact the digital filter configuration or digital timing parameters. 0b - No effect 1b - LPI2C pin state forced into HS-mode.
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C.

Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C master digital glitch filters for SDA input. • A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSDA cycles long are filtered out and ignored • The latency through the glitch filter is equal to FILTSDA cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is automatically bypassed in High Speed mode
23-20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19-16 FILTSCL	Glitch Filter SCL Configures the I2C master digital glitch filters for SCL input. • A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSCL cycles long are filtered out and ignored. The FILTSCL cycles are based on the functional clock. • The latency through the glitch filter is equal to FILTSCL cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is automatically bypassed in High Speed mode
15-12 —	Reserved
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period in clock cycles. • If both SCL and SDA are high for longer than BUSIDLE cycles, then the I2C bus is assumed to be idle and the master can generate a START condition • When Bus Idle Timeout is set to zero, the Bus Idle Timeout is disabled

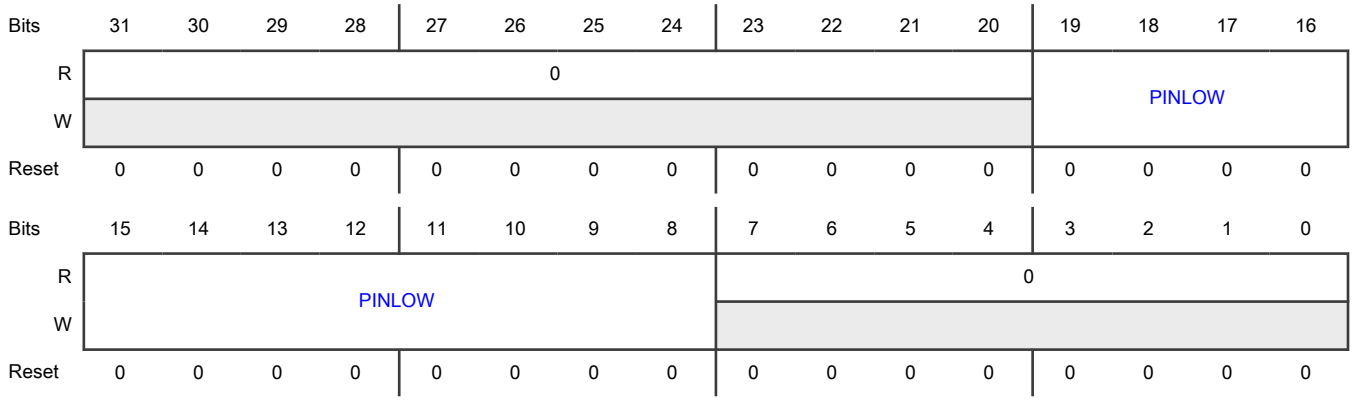
69.5.1.11 Master Configuration 3 (MCFGR3)

Offset

Register	Offset
MCFGR3	2Ch

Function
The MCFGR3 should only be written when the I2C Master is disabled.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the pin low timeout flag in clock cycles. • If SCL or, either SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW * 256) cycles, then MSR[PLTF] is set. • When Pin Low Timeout is set to zero, the Pin Low Timeout feature is disabled
7-0 —	Reserved

69.5.1.12 Master Data Match (MDMR)

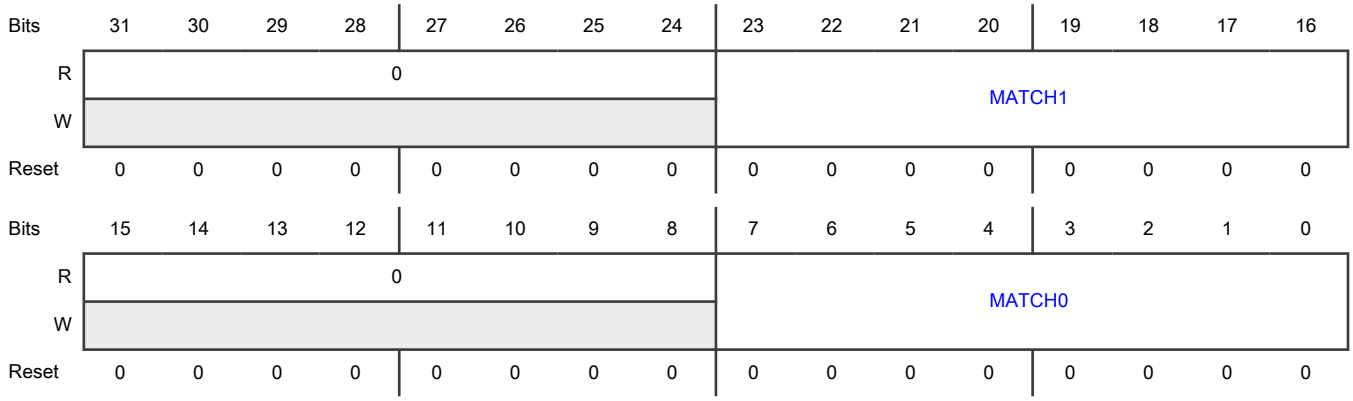
Offset

Register	Offset
MDMR	40h

Function

The MDMR should only be written when the I2C Master is disabled or idle.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 MATCH1	Match 1 Value Compared against the received data when receive data match is enabled.
15-8 —	Reserved

69.5.1.13 Master Clock Configuration 0 (MCCR0)

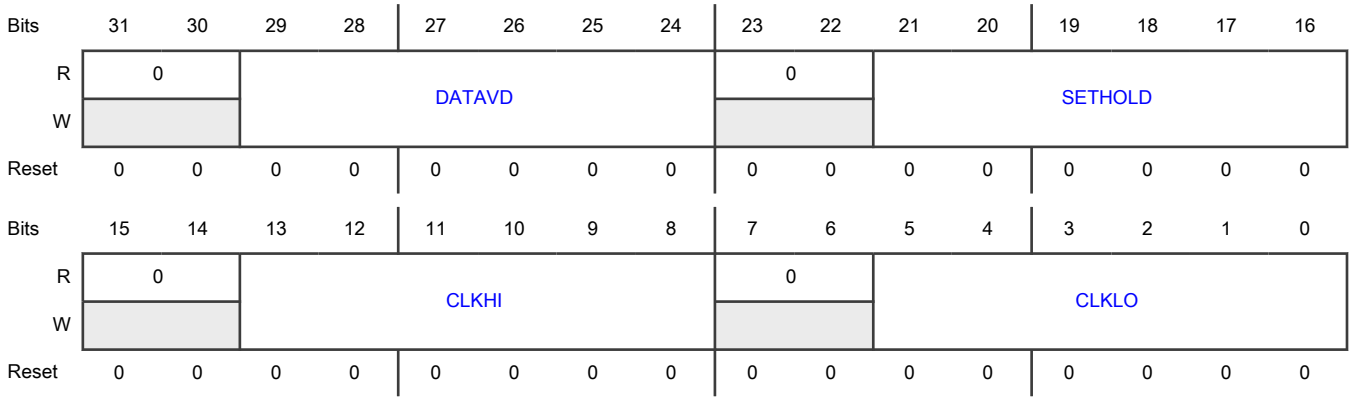
Offset

Register	Offset
MCCR0	48h

Function

The MCCR0 cannot be changed when the I2C master is enabled and is used for standard, fast, fast-mode plus and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. Must be configured less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Minimum number of cycles (minus one) that is used by the master for these conditions: • Hold time for a START • Setup and hold time for a repeated START • Setup time for a STOP The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Minimum number of cycles (minus one) that the SCL clock is driven high by the master. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
7-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5-0 CLKLO	Clock Low Period Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.

69.5.1.14 Master Clock Configuration 1 (MCCR1)

Offset

Register	Offset
MCCR1	50h

Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by Master Clock Configuration 0 (MCCR0)), before switching to high speed mode (with timing configured by MCCR1).

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates if an I2C bus is idle or busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 SBF	Slave Busy Flag Indicates if an I2C slave is idle or busy. 0b - I2C Slave is idle 1b - I2C Slave is busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag • SARF is cleared by reading the Slave Address Status (SASR) register • SARF cannot generate an asynchronous wakeup 0b - SMBus Alert Response is disabled or not detected 1b - SMBus Alert Response is enabled and detected
14 GCF	General Call Flag Indicates whether a slave has detected the General Call Address. • General Call Flag is cleared by reading the Slave Address Status (SASR) register • General Call Flag cannot generate an asynchronous wakeup 0b - Slave has not detected the General Call Address or the General Call Address is disabled 1b - Slave has detected the General Call Address
13 AM1F	Address Match 1 Flag Indicates that the received address has matched the ADDR1 field or ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. • Address Match 1 Flag is cleared by reading the Slave Address Status (SASR) register • Address Match 1 Flag cannot generate an asynchronous wakeup 0b - Have not received an ADDR1 or ADDR0/ADDR1 range matching address 1b - Have received an ADDR1 or ADDR0/ADDR1 range matching address
12	Address Match 0 Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
AM0F	Indicates that the received address has matched the ADDR0 field as configured by SCFGR1[ADDRCFG]. • AM0F is cleared by reading the Slave Address Status (SASR) register • AM0F cannot generate an asynchronous wakeup 0b - Have not received an ADDR0 matching address 1b - Have received an ADDR0 matching address
11 FEF	FIFO Error Flag FEF can only be set when clock stretching is disabled. 0b - FIFO underflow or overflow was not detected 1b - FIFO underflow or overflow was detected
10 BEF	Bit Error Flag BEF sets if the LPI2C slave transmits a logic one and detects a logic zero on the I2C bus. The slave ignores the rest of the transfer until the next (repeated) START condition. 0b - Slave has not detected a bit error 1b - Slave has detected a bit error
9 SDF	STOP Detect Flag SDF sets when the LPI2C slave detects a STOP condition and if the LPI2C slave matched the last address byte. 0b - Slave has not detected a STOP condition 1b - Slave has detected a STOP condition
8 RSF	Repeated Start Flag RSF sets when the LPI2C slave detects a repeated START condition and if the LPI2C slave matched the last address byte. The RSF does not set when the slave first detects a START condition. 0b - Slave has not detected a Repeated START condition 1b - Slave has detected a Repeated START condition
7-4 —	Reserved
3 TAF	Transmit ACK Flag TAF is cleared by writing to the Slave Transmit ACK (STAR) register. 0b - Transmit ACK/NACK is not required 1b - Transmit ACK/NACK is required
2 AVF	Address Valid Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	AVF is cleared by reading the Slave Address Status (SASR) register. When SCFGR1[RXCFG] = 1, SSR[AVF] is also cleared by reading the Slave Receive Data (SRDR) register. 0b - Address Status Register is not valid 1b - Address Status Register is valid
1 RDF	Receive Data Flag RDF is cleared by reading the Slave Receive Data (SRDR) register. When SCFGR1[RXCFG] = 1, RDF is not cleared when reading the Slave Receive Data (SRDR) register and if SSR[AVF] is set. 0b - Receive data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag TDF is cleared by writing the to the Slave Transmit Data (STDR) register. When SCFGR1[TXCFG] = 0 and if a NACK or a Repeated START or STOP condition is detected, then TDF is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

69.5.1.21 Slave Interrupt Enable (SIER)

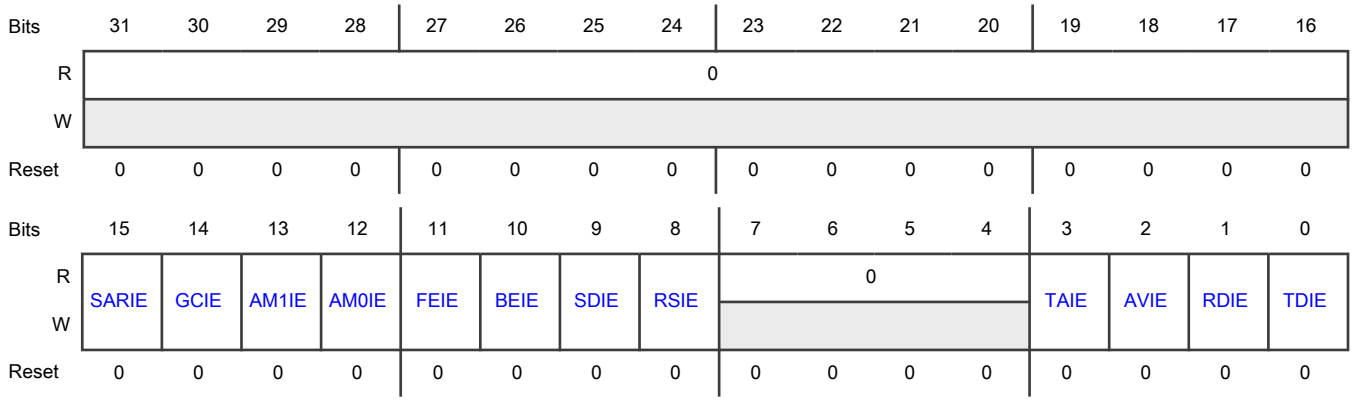
Offset

Register	Offset
SIER	118h

Function

SIER contains transmit and receive data interrupt enables; Start and Stop detect interrupt enables; and other slave interrupt enables.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 SARIE	SMBus Alert Response Interrupt Enable Enables interrupt for SMBus alert response. 0b - Disabled 1b - Enabled
14 GCIE	General Call Interrupt Enable Enables interrupt for general call. 0b - Disabled 1b - Enabled
13 AM1IE	Address Match 1 Interrupt Enable Enables interrupt for address match 1. 0b - Disabled 1b - Enabled
12 AM0IE	Address Match 0 Interrupt Enable Enables interrupt for address match 0. 0b - Disabled 1b - Enabled
11 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disabled 1b - Enabled
10 BEIE	Bit Error Interrupt Enable Enables interrupt for bit error. 0b - Disabled 1b - Enabled

Field	Function
31-27 —	Reserved
26-24 —	Reserved
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or Address match 1 (7-bit) 011b - Address match 0 (10-bit) or Address match 1 (10-bit) 100b - Address match 0 (7-bit) or Address match 1 (10-bit) 101b - Address match 0 (10-bit) or Address match 1 (7-bit) 110b - From Address match 0 (7-bit) to Address match 1 (7-bit) 111b - From Address match 0 (10-bit) to Address match 1 (10-bit)
15-14 —	Reserved
13	High Speed Mode Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
HSMEN	Enables detection of the High-Speed Mode master code of slave address 0000_1XX, but does not cause an address match on this code. When set and any HS-mode master code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] bits are ignored until the next STOP condition is detected. 0b - Disables detection of HS-mode master code 1b - Enables detection of HS-mode master code
12 IGNACK	Ignore NACK When Ignore NACK is set, the LPI2C slave continues transfers after a NACK is detected. Ignore NACK bit is required to be set in Ultra-Fast mode. 0b - Slave ends transfer when NACK is detected 1b - Slave does not end transfer when NACK detected
11 RXCFG	Receive Data Configuration 0b - Reading the Receive Data register returns received data and clears the Receive Data flag. See MSR[RDF]. 1b - Reading the Receive Data register when the Address Valid flag (SSR[AVF]) is set, returns the Address Status register and clear the Address Valid flag. Reading the Receive Data register when the Address Valid flag is clear, returns received data and clears the Receive Data flag (MSR[RDF]). See SSR[AVF] and MSR[RDF].
10 TXCFG	Transmit Flag Configuration The transmit data flag always asserts before a NACK is detected at the end of a slave-transmit transfer. This can cause an extra word to be written to the transmit data FIFO. • When TXCFG = 0, the Transmit Data register is automatically emptied when a slave-transmit transfer is detected. This causes the transmit data flag to assert whenever a slave-transmit transfer is detected, and causes the transmit data flag to negate at the end of the slave-transmit transfer. • When TXCFG = 1, the Transmit Data flag asserts whenever the Transmit Data register is empty, and the Transmit Data flag negates when the Transmit Data register is full. This allows the Transmit Data register to be filled before a slave-transmit transfer is detected, but can cause the Transmit Data register to be written before a NACK is detected on the last byte of a slave transmit transfer. 0b - Transmit Data Flag only asserts during a slave-transmit transfer when the Transmit Data register is empty 1b - Transmit Data Flag asserts whenever the Transmit Data register is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disables match on SMBus Alert 1b - Enables match on SMBus Alert
8 GCEN	General Call Enable Enables a general call address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - General Call address is disabled 1b - General Call address is enabled
7-5 —	Reserved
4 —	Reserved
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during slave-transmit address byte(s) and slave-receiver address and data byte(s), to allow software to write the Slave Transmit ACK (STAR) register before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the 9th bit, and is therefore not compatible with High Speed mode. When ACKSTALL is enabled, there is no need to set either RX SCL Stall (SCFGR1[RXSTALL]) or Address SCL Stall (SCFGR1[ADRSTALL]). When ACKSTALL is enabled and there is an address match on the first byte of a 10-bit address, SSR[AVF] sets allowing software to read the Received Address before writing to the Slave Transmit ACK (STAR) register. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
2 TXDSTALL	TX Data SCL Stall Enables SCL clock stretching when the SSR[TDF] = 1 during a slave-transmit transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with High Speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a slave-receive transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with High Speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the 9th bit, and is therefore compatible with High Speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled

69.5.1.24 Slave Configuration 2 (SCFGR2)

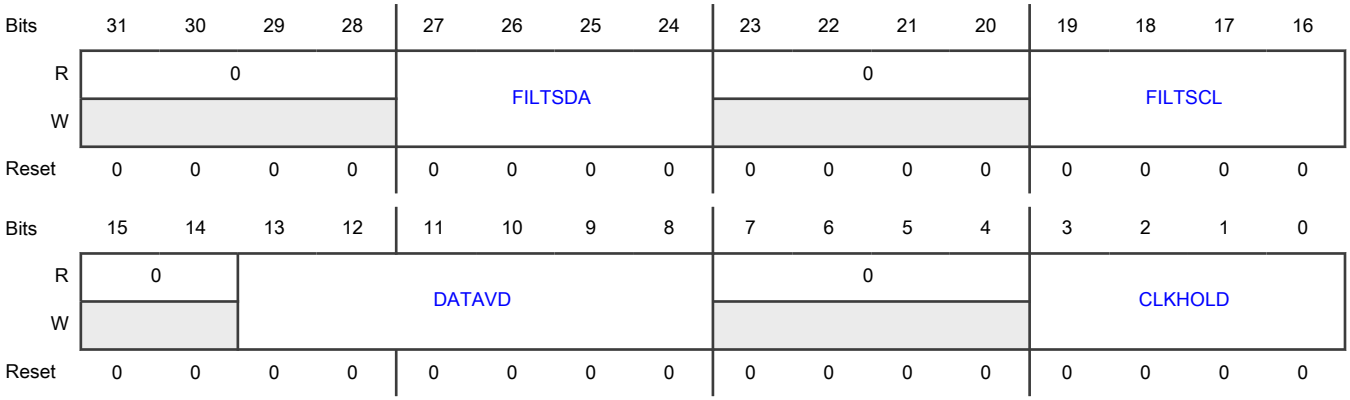
Offset

Register	Offset
SCFGR2	128h

Function

The Slave Configuration Register 2 should only be written when the I2C Slave is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C slave digital glitch filters for SDA input. • A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSDA cycles long are filtered out and ignored • The latency through the glitch filter is equal to FILTSDA+3 cycles, and must be configured to be less than the minimum SCL low or high period. • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is disabled in High Speed mode
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C slave digital glitch filters for SCL input.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSCL cycles long are filtered out and ignored • The latency through the glitch filter is equal to FILTSCL+3 cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is disabled in High Speed mode
15-14 —	Reserved
13-8 DATAVD	Data Valid Delay Configures the SDA data valid delay time for the I2C slave, which is equal to FILTSCL+DATAVD+3 cycles. • The data valid delay must be configured to be less than the minimum SCL low period • The I2C slave data valid delay time is not affected by the PRESCALE configuration, and the I2C slave data valid delay time is disabled in High Speed mode
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C slave, when clock stretching is enabled. • The minimum hold time is equal to CLKHOLD+3 cycles • The I2C slave clock hold time is not affected by the PRESCALE configuration, and the I2C slave clock hold time is disabled in high speed mode

69.5.1.25 Slave Address Match (SAMR)

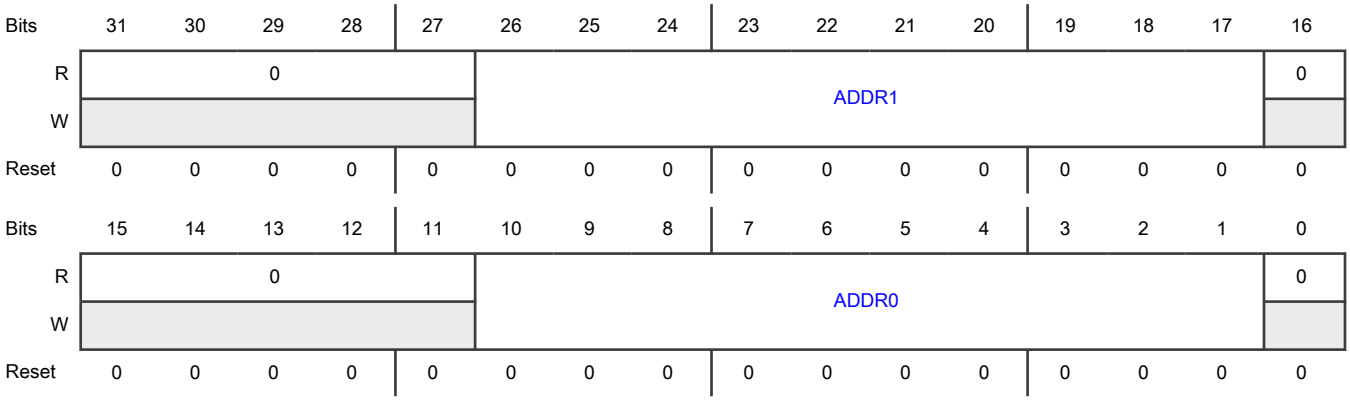
Offset

Register	Offset
SAMR	140h

Function

The SAMR should only be written when the I2C Slave is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Compared against the received address to detect the Slave Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR1[26:25] } and the second address byte is compared to ADDR1[24:17] • In 7-bit mode, the address is compared to ADDR1[23:17]
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Compared against the received address to detect the Slave Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR0[10:9] } and the second address byte is compared to ADDR0[8:1] • In 7-bit mode, the address is compared to ADDR0[7:1] •
0 —	Reserved

69.5.1.26 Slave Address Status (SASR)

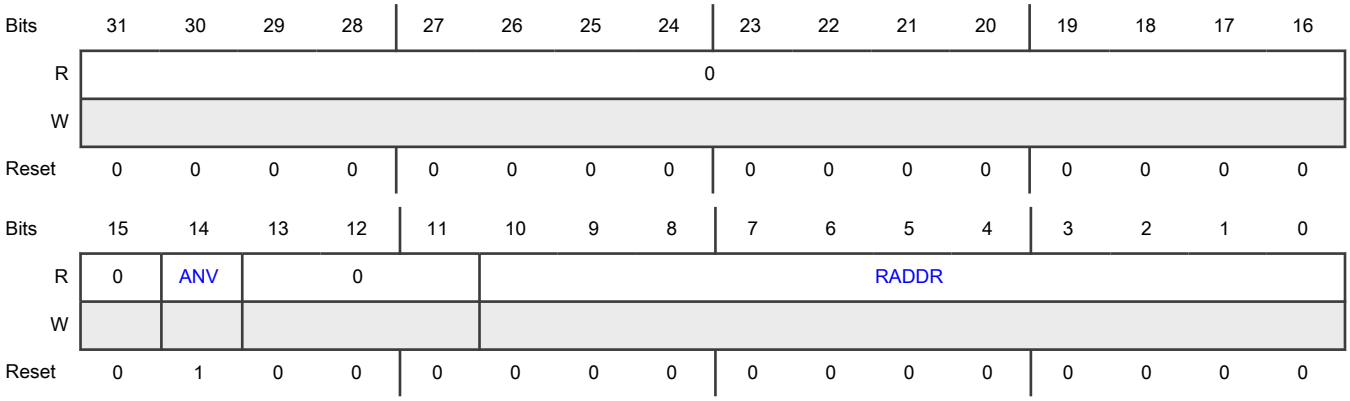
Offset

Register	Offset
SASR	150h

Function

SASR contains the read-only RADDR and ANV fields.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid 0b - Received Address (RADDR) is valid 1b - Received Address (RADDR) is not valid
13-11 —	Reserved
10-0 RADDR	Received Address The Received Address updates whenever SSR[AM0F] or SSR[AM1F] are set. SSR[AM0F] or SSR[AM1F] are cleared by reading the Slave Address Status register. • In 7-bit mode, the address byte is stored in RADDR[7:0] • In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0] • When SCFGR1[ACKSTALL] is set, if the first address byte matches in 10-bit mode, then the first address byte is stored in RADDR[7:0] so software can read the Received Address before writing the Transmit ACK. The Received Address then updates with the full 10-bit address if the second address byte matches.

69.5.1.27 Slave Transmit ACK (STAR)

Offset

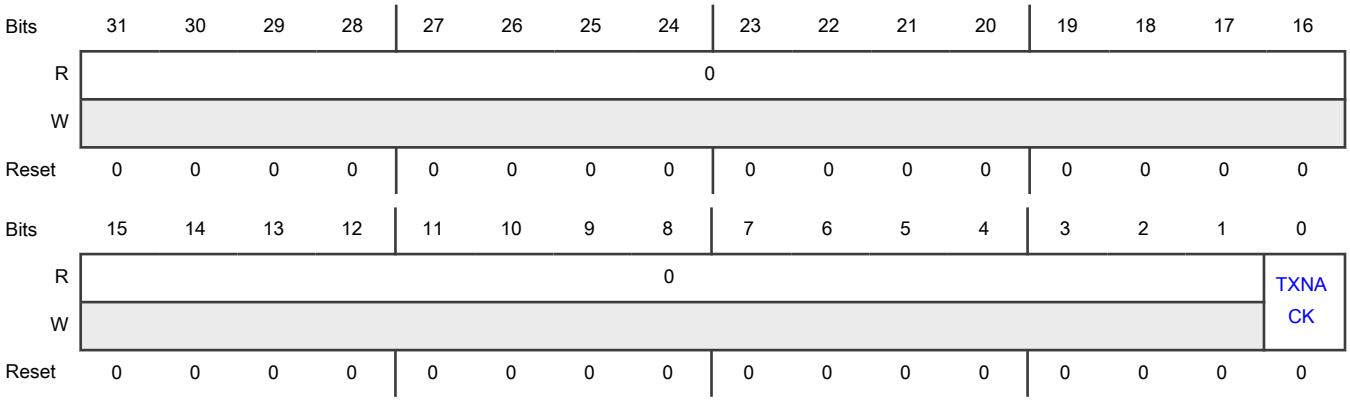
Register	Offset
STAR	154h

Function

STAR can only be written when the ACK SCL Stall bit is set (SCFGR1[ACKSTALL]).

- The SCFGR1[ACKSTALL] bit enables clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD]).

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK. • When SCFGR1[ACKSTALL] is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that stalls the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK). • To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle. 0b - Write a Transmit ACK for each received word 1b - Write a Transmit NACK for each received word

69.5.1.28 Slave Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The SCFGR1[TXDSTALL] bit enables clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (SCFGR1[TXDSTALL] = 1)**, then the transmit data transfer is stalled until the STDR is updated. Clock stretching is extended by at least 1 bus clock cycle after STDR is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD].
- **If clock stretching is disabled (SCFGR1[TXDSTALL] = 0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (that is, if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) sets.

Chapter 70
Improved Inter-Integrated Circuit (I3C)

70.1 Chip-specific I3C information

70.1.1 I3C instances and configuration

Table 407. I3C instances

Instance	K311/K312/K342/K358	K3x4
I3C	Yes	No

NOTE

- I3C muxing on S32K312 pins PTD5 and PTC16 work upto maximum SCL clock frequency of 10MHz.
- For configuring SDA and SCL pad type, see column 'Pad Type' in 'S32K3xx_IO Signal Table' worksheet of the IOMUX files attached to this document.

I3C includes following features:

- Supports Tx FIFO and Rx FIFO of size 16 bytes.
- Allows half-word read and write.
- Supports mipi specification of v1.0.
- Supports static address.
- Allows DDR mode.

NOTE

I3C offers an internal delayed CLK which can be used instead of pad loopback clock, in case any issue is seen on chip.

NOTE

In I3C there are Sync and Async timing controls 0/1/2/3 but the controller supports asynchronous mode 0.

70.2 Overview

[DIP_I3C_00001]The MIPI Alliance Improved Inter-Integrated Circuit (MIPI I3C) brings major improvements in use and power over I2C, and provides an alternative to SPI for mid-speed applications.[end]

The I3C bus protocol supports:

- In-band interrupts: interrupts can go from Slave to Master without extra wires, such that the Master knows which Slave sent the interrupt.
- Common Command Codes (CCC)
- Dynamic addressing
- Multi-master/multi-drop
- Hot-Join (HJ)
- I2C compatibility

The I3C peripheral supports all required and most optional features of the MIPI Alliance Specification for I3C, v1.0 and v1.1, except for the ternary data rates (HDR-TSP and HDR-TSL).

70.2.1 Block diagram

The following figure shows the I3C block diagram.

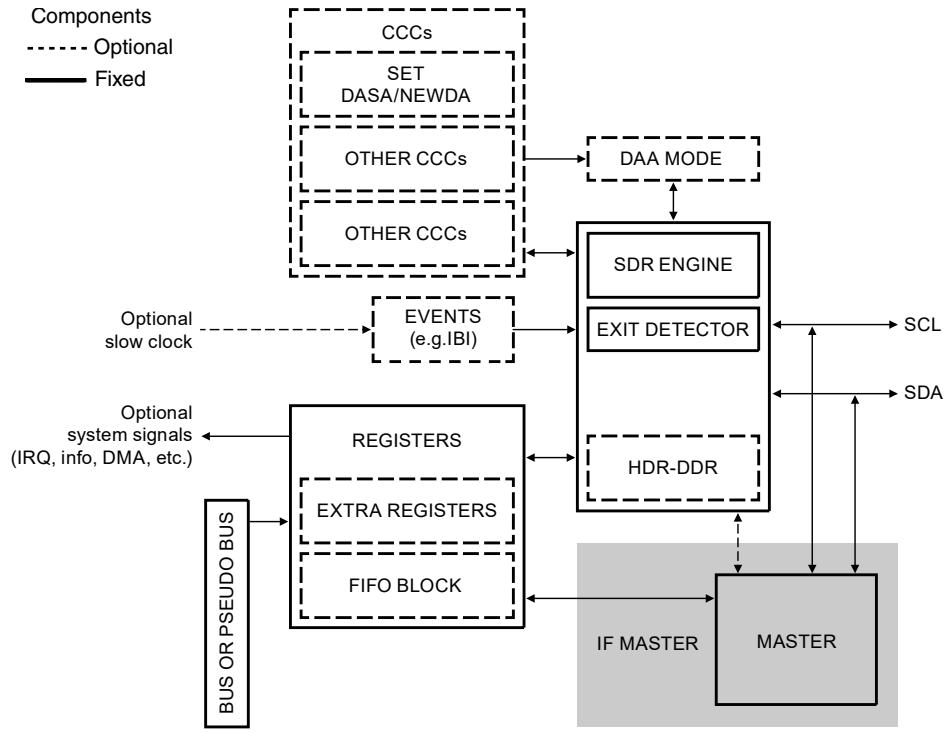

Figure 367. **[DIP_I3C_00057]**I3C block diagram**[end]**

70.2.2 Features

I3C module:

- [DIP_I3C_00003]2-wire multi-drop bus capable of 12.5 MHz clock speeds, with up to 11 devices.[end]
  - Uses standard pads (I2C uses special pads) with 4 mA drive
  - Slave addresses are dynamically assigned, and slaves do not require a static address.[DIP_I3C_00025] However, slaves may have an I2C static address assigned at start-up, so that the slave can operate on an I2C bus. By default, I3C supports 7-bit I2C style address.[end]
  - [DIP_I3C_00026]It can also support extended I2C 10-bit addressing through SMAPCTRL1 register.[end]
  - Slaves may use the inbound SCL clock as the peripheral clock, which means that devices can have slow or inaccurate clocks internally.
  - Simple slaves can have no internal clock; for example, like a temperature sensor.
  - [DIP_I3C_00016]I3C master supports handoff from Open Drain to Push-Pull mode for ACK to data transfer.[end]
  - For reads from a slave, the slave normally ends the read, but the I3C master can also terminate the read. For I2C and SPI, the master must know the length of the data that is being read, but for I3C the master does not require the length of the data being read.
- [DIP_I3C_00029]In-Band Interrupts (IBI) are allowed, which allow slaves to notify a master.[end]
  - Can be both equivalent to a separate GPIO, but can also be directly data-bearing.

  - IBIs are prioritized, so that if multiple Slaves want to interrupt a master at the same time, then the order is resolved. Dynamic addresses are used to establish the priority of the slaves, which means the master controls the priority of the slaves.
  - Slaves with lower value dynamic addresses are of higher Priority Levels IBIs.
  - Interrupts can be started even when the master is not active on the bus, and yet no free-running clock is needed (for that situation).
  - A time-stamping option allows the resolution of an initial event, not just when an interrupt gets through
- Built-in commands are in separate space, so that these commands do not collide with normal Master->Slave messages.
  - Controls bus behavior, modes and states, low power state, inquiries and more
  - Has additional room for new built-in commands to be used by other groups
- Organized forms of multi-master modes:
  - Secondary masters that can use clean handoffs between different Masters
- [DIP_I3C_00032]Hot-join onto I3C bus allows devices to connect to the bus later than when the bus starts.[end]
  - This enables a device or module to get onto the I3C bus, because it woke up after power-up, or was physically inserted onto the I3C bus.
  - Also, provides a clean method for notification when new devices or modules get onto the I3C bus.
- Capable of using both I2C and I3C buses:
  - I3C supports specific legacy I2C devices on the bus
  - I3C Slave devices can operate on I2C buses
  - Supports bridging to I2C, SPI, UART, and other buses
- [DIP_I3C_00006]Higher data rate modes are optionally available
  - Only the master and the specific slave has to support the higher data rate; the other slaves are able to ignore the higher data rate.
  - Has a High Data Rate - Double Data Rate (HDR-DDR) mode, which is 2x the data rate of SDR (so about 20 Mbps)[end]

The I3C peripheral supports the full I3C feature set, except for the ternary data rates (HDR-TSP and HDR-TSL).

70.3 Functional description

The following sections describe functional details of the I3C module.

70.3.1 Operating modes

This section describes all functional operation modes of the I3C module.

70.3.1.1 Master vs. slave roles for I3C

The I3C protocol defines 5 roles for devices on the I3C bus:

- **[DIP_I3C_00007]Main Master**: Controls the I3C bus
- **Secondary Master**: Controls the I3C with permission from the Main Master, and returns control of the bus back to the Main Master when it (Secondary Master) has finished with its tasks.[end]
- **[DIP_I3C_00008]Slave**: Responds to commands from any I3C master [end]
- **I2C Slave**: Responds to commands from any I2C slave

The I3C peripheral contains both a master and slave component and can be parameterized to be either master or slave, or both master and slave. However, if the I3C is chosen to be a master, then the I3C peripheral supports slave mode to make handoffs to multiple masters easier to do.

In general, any I3C master should be able to be a master or a slave, because a master becomes a slave when giving over control to another master. The only exception to this rule would be when using a point-to-point master or when using a master that will never share mastership.

Master requirements

Master mode uses software that supports the various requirements of the master (including as a Secondary Master):

- [DIP_I3C_00011]Special handling of Enter Dynamic Address Assignments (ENTDAA) assigning dynamic addresses to each slave. This process is supported by the I3C peripheral but requires the software to make choices.[end]
- [DIP_I3C_00015]Master can drive SDA in both Open Drain and Push-Pull mode. SDA after Start is in Open Drain and after Repeated Start it is in Push-Pull.[end]
- [DIP_I3C_00014]SDA is subject to arbitration as both Master and Slave can drive the SDA line. Arbitration is also useful for Handoff from Master to Slave. [end]
- [DIP_I3C_00018]9th bit of SDA Master write data is an odd parity bit.[end]
- Building up a table of slaves and their capabilities, which are used to control what kinds of actions and commands may be sent to the slaves.
- Handling requests such as IBI and master request (handoff).
- Adjusting clock speed or write-to-read timing to match the slave's limitations. This can be done in hardware using dividers and uneven duty cycles, but the software must make the decisions.
- Adjusting the maximum data length.
- Being a slave after a master handoff to another master

Additionally, a master needs 3 pins, unless a very precise, high-strength pullup is included in the SDA pad. The 3-pin model allows 1 pad/pin to enable a system-provided pullup, which is sized to system requirements.

The master needs an accurate clock, capable of a frequency that is a multiple of a frequency between 11 MHz and 12.5 MHz. For example:

- 24 MHz (multiple of 12 MHz)
- 48 MHz (multiple of 12 MHz)
- 25 MHz (multiple of 12.5 MHz)
- 50 MHz (multiple of 12.5 MHz)
- 33 MHz (multiple of 11 MHz)
- 66 MHz (multiple of 11 MHz)

Higher ratios can also be used.

Slave requirements

The I3C slave mode is intended to allow the use of simple module, allowing the device implementation to use fewer logic circuits on limited space. For example, when the slave minimum requirements are just I3C SDR mode and a few Common Command Code (CCC) commands. Conversely, slave functionality in the module logic can be increased, increasing the module's area on the device but saving software development costs.

NOTE

The Slave can be scaled for system requirements by doing more in software or in hardware. This decision is made when the module is integrated into the device.

[DIP_I3C_00023]I3C slave acts like I2C slave on I3C buses

The I3C slave, if assigned an I2C static address, acts like an I2C device when the I3C slave first comes up. If the I3C slave is placed on an I2C bus with an I2C master, then the I3C slave stays in I2C mode and operates normally.[end] The software knows that the I3C slave is in I2C mode, because:

- There has not been a DACHG indicating that a dynamic address was assigned

[DIP_I3C_00028]If full I2C support for Fast Mode (FM) and Fast Mode Plus (FM+) is required, then the pads must support a 50 ns spike filter, which must be turned off when the I3C 0x7E broadcast address is seen (indicating an I3C master). You can turn off the spike filters by hardware using the raw net indicating that the address was seen or by software. [end][DIP_I3C_00024] A 50 ns spike filter is not needed for the I3C to operate on an I2C bus. Therefore, the spike filter is not a requirement for the I3C peripheral.[end]

Depending on the configuration, the block supports most I2C features, except for clock stretching. These features include Extended 10-bit address, DeviceID, SW reset, and HS mode (affects pads).

How a slave re-joins the I3C bus

When a slave powers up or after a hard reset, when the slave tries to rejoin the I3C bus, the slave needs a new Dynamic Address (DA). The slave provides 3 ways to rejoin the I3C bus:

- If the dynamic address is lost, then Hot-Join is used.
- If the dynamic address is retained in the peripheral (for example, with SRFFs), then the SCONFIG[OFFLINE] bit is used (see below).

When SCONFIG[SLVENA] = 1, the SCONFIG[OFFLINE] may be set. [DIP_I3C_00033]This causes the peripheral to safely rejoin the bus, by ensuring that the I3C bus is not in High Data Rate (HDR) mode, using the same approach as S0/S1 exit does. Waiting for the first of the HDR Exit Pattern, or waiting for 60 µs of SCL and SDA lines not changing.[end]

After using SCONFIG[OFFLINE], the I3C peripheral cannot safely use IBI until it sees a STOP (SSTATUS register), which ensures that the next START is safe to use for IBI).

If the application needs to do an IBI, then the application should wait for the first STOP (SSTATUS register), or should wait for 200 µs of SCL and SDA lines being High. This can be done using the SSTATUS and SINTSET controls.

- If the SSTATUS indicates that the bus is not busy and the peripheral interrupts on START or STOP, then use a timer to measure 200 µs. If the timer goes off with no START or STOP, then it is safe to use IBI.
- If a START causes an interrupt, then the timer should be turned off and the application should wait for a STOP.
- If a STOP causes an interrupt, then it is safe to use IBI.

70.3.1.2 Using the I3C Master for I2C and I3C

The I3C Master operates with a set of built-in capabilities mixed with the application flow.

- Built-in Enter Dynamic Address Assignment (ENTDAA) mechanism to simplify the assignment of DAs to slaves (when Set Dynamic Address from Static Address (SETDASA) is not available).
- Request for START+Address with IBI support, including both I2C and I3C modes
- SDR Write flow via FIFO, with automatic parity in I3C and ACK/NACK detect in I2C
- SDR Read flow via the FIFO, with an automatic NACK generator for I2C, and optional use of a terminate generator for I3C
- Request for repeated START+Address or STOP when finished with previous, including both I2C and I3C
- Auto-IBI mode which responds immediately to a Slave-initiated IBI can be used when in sleep or deep sleep
- Special message mode for SDR and DDR to simplify for DMA use
- All SCL, SDA, Pull-up, and High-Keeper controls are automated
- I2C and I3C Frequency and duty cycle configurations from functional clock

NOTE

The MCONFIG register and the MIBIRULES register must be configured before using the Master.

70.3.1.3 Protocol modes and states

The following modes are activated in I3C:

- I2C mode is the default mode on startup.
  - If no I2C static address is used, this has no effect other than to track frames looking for I3C transitional frames.
  - If an I2C static address is used, the device can interact with the I2C bus master using the address.
- While in I2C mode, an I3C Transitory Frame mode occurs whenever the I3C Broadcast address is seen (0x07). In particular:
  - 0x07 is broadcast and then an ENTDASA from the Master. If there is a static address match or 0x01, the Slave is assigned a Dynamic Address and enters I3C SDR mode.
  - 0x7E is broadcast and then an ENTDAA from the Master. [DIP_I3C_00009]If the Slave can send a 48b ID out, a Dynamic Address is assigned and the Slave enters I3C SDR mode. [end]
  - If a Hot-Join arbitrated event generates (sending 0x02 when the Master generates some other address such as 0x7E), there is a conceptual Hot-Join mode. ENTDAA or ENTDASA sets a Dynamic Address to resolve the event and the Slave enters I3C SDR mode.

    NOTE

    An I3C Slave can operate as a normal I2C slave only when it has a static address. Otherwise, it matches nothing in I2C and waits for the above events.
- [DIP_I3C_00005]I3C SDR mode is the standard mode once I3C activates, which is defined by a Dynamic Address being assigned. This is the resting mode of I3C and all devices are normally in SDR mode.[end]
  - RSTDAA CCC causes an exit from SDR mode and a return to I2C mode. This is not normally used.
  - SETNEWDA does not affect the SDR mode, only the Dynamic Address.
  - When in SDR mode, the device ignores messages to or from its original I2C static address.
- [DIP_I3C_00020]I3C CCC command submode of type Direct or Broadcast.
  - Exit the Broadcast CCC submode by a repeated START or by a STOP.
  - Exit the Direct CCC submode by a 0x7E broadcast address after a repeated START or by a STOP.
  - I3C DAA CCC command enters the DAA mode. This is a special mode for DDA. Use STOP to exit. If a Slave has a DA, the command is ignored.
- I3C SETDASA CCC command enters the Static Address match submode. This allows matching the device's Static Address (if any).
  - The command is ignored when a Slave has a Dynamic Address, or the Slave in I2C mode has no Static Address.

    NOTE

    The special point-to-point address is also matched.
- I3C HDR modes are activated by ENTHDRn CCC commands with the n value being the type of HDR (0 to 7). This is valid until HDR Exit Pattern, whether supported or not.[end]
  - DDR included
  - Exit Pattern detection must be set on at all times to prevent errors. Alternatively, it could be set to only activate on ENTHDR.
- [DIP_I3C_00065]I3C HDR-BT modes are also activated by ENTHDRn CCC commands and exited by HDR Exit Pattern. [end]

- [DIP_I3C_00066]ML data transfer is available for data transfers between ML-capable I3C Devices that have ML functionality enabled.[end]
- [DIP_I3C_00060]A special HDR-DDR syntax is used for transmitting Common Command Codes in the HDR-DDR protocol.[end]
- [DIP_I3C_00062]As an optional feature, multiple I3C Slave Devices can share a single Group Address, allowing a Master Device to send a given I3C Message to all Slave Devices in the Group at once rather than one at a time.[end]
- The internal states also exist, such as IBI/no-IBI, low-power mode, and so on. These are flagged internally. They are exported to the application and also affect the engine so it does not perform a prohibited operation.

70.3.1.4 Address match

The Slave matches 2 of 3 possible addresses, depending on the internal state:

- 0b111_1110 (written as 0x7E in spec), which is the I3C broadcast address.
- I2C style Static Address, but only if:
  - The device has a Static Address.
  - Is not in I3C mode. Only matches until the ENTDAA or the SETDASA command has assigned a DA.

NOTE

SETDASA matches the Static Address or special point-to-point magic address.

- I3C DA once assigned by ENTDAA or SETDASA or modified by SETNEWDA.

The address match is inactive (just listening) for all repeated START commands and also for START, unless an IBI/MR/HotJoin has been activated. If inactive, it simply tries to match. If not matched, it waits for a repeated START or a STOP. [DIP_I3C_00010]If an IBI/MR/HotJoin, the arbitration mechanism is used for START (but never repeated START).[end]

If matching the 0x7E broadcast address, it listens for a CCC until the next repeated START or a STOP. The CCC_possible bit is set and cleared.

70.3.1.5 Data handling with or without FIFO

[DIP_I3C_00034]The low-level slave engine is fed a buffer for to-bus, and provides its buffer for from-bus (so bit insertions do not build a deep mux into a FIFO).[end]

[DIP_I3C_00048]The full wrapper and so APB interface allows for 3 methods:[end]

- Ping-pong buffers (two entry FIFOs) for each of from-bus and to-bus only.
  - This interfaces to the APB register model, if used, using the byte read and byte write regs, along with interrupts.
  - If not used, these form the buffering and Clock Domain Crossing (CDC) interface for direct nets and external FIFOs.
  - The from-bus one ends up with a three entry buffer (but two entry FIFO) since it has a holding buffer. The holding buffer in the CLK domain is to keep the path short for an external FIFO (no mux) and to give a bit more time for a processor ISR.
- [DIP_I3C_00035]Deeper than two entry internal FIFO
  - These replace the ping-pong buffers with deeper FIFOs which form the CDC interface as well as deeper buffering. [end]
  - This allows for lower speed system clocks without having to slow the I3C bus rate.
  - It is possible to engage in only one direction (for example, from-bus).
  - [DIP_I3C_00036]The TXFIFO depth size can be in the power of 2.[end]
  - [DIP_I3C_00037]The RXFIFO depth size can be in the power of 2.[end]

- External FIFO that works with the ping-pong buffers. The external FIFO is operating in the system clock domain and moves data to/from the ping-pong buffers a byte at a time. So, the CDC is still in the ping-pong buffers.

70.3.2 Operations

This section describes the I3C module's operations.

70.3.2.1 Reading and writing I2C messages using the normal method

The normal method:

1. Set up interrupts. Normally:
    a. MCTRLDONE: Optional
    b. COMPLETE: To fire when the end of data
    c. RXPEND if read: This can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to read out bytes.
    d. TXNOTFULL if write: tThis can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to supply bytes.
    e. IBIWON: The software knows if an IBI has occurred
    f. MERRWARN: In case of an error
2. Write the MCTRL register with:
    a. REQUEST set to 1 (EmitStartAddr)
    b. TYPE set to 1 (I2C)
    c. IBIRESP set depending on how you want IBIs handled
    d. DIR set to 1 if Read, or set to 0 if Write
    e. ADDR set to the static address of the I2C slave
    f. If read, then RDTERM may be set for the length, or may be set as the data is read out (for example, set to 1 (with REQUEST=0) when you want it to stop next).
3. If Write: Write the MWDATAB register for each byte before the last byte, then write the MWDATABE register for the last byte.
    a. This can be done or started before set up interrupts.
    b. If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level to allow the application to provide more or use DMA.
4. If Read: wait for RXPEND, and then read out data via the MRDATAB register. DMA may also be used
5. On COMPLETE, the message may be ended with a STOP, or a new message started with a repeated START.
    a. Write MCTRL with REQUEST of 2 (EmitStop to STOP). Then wait for MCTRLDONE status to be asserted for its completion. (While sending STOP in I2C mode MCONFIG[ODSTOP] should be 1.)
    b. Write MCTRL with REQUEST of 1 (EmitStartAddr to start another message).

NOTE

IBI is not possible in this case.

70.3.2.2 Reading/writing I3C messages using the normal methods (SDR and HDR-DDR)

The normal method for I3C is the same as for I2C with a few differences. Option 2 is preferred from stopped (bus free condition) when in Single Data Rate (SDR) mode and not in High Data Rate - Double Data Rate (HDR-DDR) mode, because it allows any slave to issue an IBI, and avoids collisions with IBI address. Moreover, it is faster (when MSB of dynamic address is always 0).

NOTE

HDR-DDR requires writing a command value (7-bit value) for Read or Write. This must be written into the TX FIFO via MWDATAB (or can be combined with the first data byte via MWDATAH). The END bit is not used for this byte.

1. Set up interrupts. Normally:
   - MCTRLDONE: Optional
   - COMPLETE: To fire when end of data
   - RXPEND if read: This can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to read out bytes.
   - TXNOTFULL if Write: This can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to supply bytes.
   - IBIWON: So the software knows if an IBI has occurred
   - [DIP_I3C_00021]MERRWARN: In case of an error[end]
2. Write the MCTRL register:
   - **Option 1:** Write the MCTRL register with:
     a. REQUEST set to 1 (EmitStartAddr)
     b. TYPE set to 0 (if I3C) or set to 2 (if DDR)
     c. IBIRESP set depending on how you want IBIs handled
     d. DIR set to 1 (if Read) or set to 0 (if Write)
     e. ADDR set to the dynamic address of the I3C slave
     f. If read, then optionally RDTERM is set for the maximum length to auto-terminate.
     g. If write, then pre-writing the data (MWDATAB or MWDATAW) is preferred to ensure that no time delays waiting on the data. If HDR-DDR, the first byte must be written through MWDATATB only for Read or Write, which is the “Command’ byte (8-bit value).
   - **Option 2:** From stopped and not in HDR-DDR mode, write MCTRL register with;
     a. REQUEST set to 1 (EmitStartAddr). note: Cannot have pre-written TX data in the FIFO.
     b. TYPE set to 0 (I3C)
     c. IBIRESP set depending on how you want IBIs to be handled
     d. DIR set to 0
     e. ADDR set to 0x7E
     f. Wait for MCTRLDONE (for example, by interrupt), then proceed with previously mentioned Option 1. This Option 2 method has advantages for IBIs when 7E is emitted on START (but not on repeated STARTs).

NOTE

The Option 2 method does not allow an immediate switch to read. The normal I3C process is to write index, then read data. So, if doing a blind read (no index is written), do not use the Option 2 method.

3. If Write: then write the MWDATAB register for each byte before the last byte, then write the MWDATABE register for the last byte. For HDR-DDR, the byte with END must be even (2nd, 4th, 6th, and so on) because DDR uses byte-pairs.
   - This can be done or started before step 1 [REQUEST set to 1 (EmitStartAddr)]) of the Option 1 and not before the Option 2 method.
   - If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level to allow the application to provide more or use DMA.
4. If Read, wait for RXPEND, and then read out data using the MRDATAB register. DMA may also be used.

5. On COMPLETE, the message may be ended with STOP (or EXIT if HDR), or a new message started with a repeated START (or HDR-Restart if HDR).
   - For SDR: Write MCTRL with REQUEST of 2 (EmitStop to STOP). Then wait for MCTRLDONE status to be asserted for its completion.
   - For HDR: Write MCTRL with REQUEST of 6 – ForceExit to end HDR mode. Then wait for MCTRLDONE status to be asserted for its completion.

     NOTE

     ODSTOP needs to be zero when sending HDR exit pattern.

   - Write MCTRL with REQUEST of 1 (EmitStartAddr to start another message).

     NOTE

     IBI is not possible in this case.

70.3.2.3 Sending a CCC to one or all I3C slaves

The normal Common Command Code (CCC) method is to use an I3C Write with an address of 0x7E. The first byte is the CCC.

- If Broadcast, then any remaining bytes go with the Common Command Code (CCC). This ends with a STOP or a repeated START and 0x7E.
- If Direct, after a write with an address of 0x7E, either only a CCC follows or a CCC and a Defining byte follows, if required by the CCC.

  This is followed by a repeated START and the address of the I3C Slave (for SETDASA, this is its I2C Static address). This may be repeated with more repeated START and addresses until done. Then, it may end in STOP or a repeated START and 0x7E. After the repeated start and target address, the values are read or write depending on the CCC.
- [DIP_I3C_00052] I3C provided interrupts for Unhandled, Handled CCC when received by the slave and its state is reflected in the SSTATUS register.[end]

The I3C spec requires I3C Controllers to emit a single START, 7E/W with both SCL High and SCL Low half periods being full Open-drain timing (for example, 200 ns). This allows I3C Targets which are acting as I2C legacy devices to turn off their I2C 50 ns spike filters, if they have one.

After that, addresses following START may be sent with Open-Drain Low (for example, 200 ns) but High of Push-Pull timing (for example, 40 ns). This is just a note to the Application SW developer to have the I3C Controller emit this START,7E/W with MCONFIG[ODHPP] = 0. ODHPP is “Open Drain High period at Push-Pull speeds”; ODHPP=1 is used normally.

NOTE

Note that MCONFIG[ODHPP] is ignored when sending a message to an i2c legacy device on an I3C bus.

NOTE

Each repeated START is just a new EmitStart request. This can be chained by interrupt or pushed by message model using DMA.

70.3.2.4 [DIP_I3C_00029]In-Band Interrupt (IBI) handling [end]

An IBI occurs when a slave sends its address after a START, and the slave's address is numerically lower than the address that the master sent (and any other slaves trying to send their addresses). When the master sends a 0x7E, the master will always lose, which is the intention.

The IBI can happen unexpectedly when any new START (vs. repeated START) is emitted, but the IBI can also be in response to a slave pulling SDA low, which can happen in one of two ways:

- The slave has set the request to AutoIBI mode, and so it happens automatically (the engine emits 0x7E to allow the slave to win).

- The application gets the SLVSTART (slave START request) interrupt and so emits 0x7E.

In either of these cases, the application can decide:

- To always accept (ACK) the IBI
- To always reject (NACK) the IBI
- Allow the decision to be made by the application on a case-by-case.

The IBI is configured by the MCTRL[IBIRESP] field, which can be set to ACK, NACK, or manual.

- If the manual is selected, then the application rewrites it when stopped, pending on an IBI. The application can ACK or NACK based on the IBI address (which is in the MSTATUS register). Note that manual mode chooses if there is an IBI byte or not when doing ACK.
- If always ACK was selected in the MCTRL[IBIRESP] field, then the MIBIRULES register must be configured so that the engine knows if bytes will follow.
- If IBI bytes will follow (also known as IBI Mandatory byte), then the COMPLETE bit is not set when IBIWON is set, and RXPEND will be set for 1 or more bytes in RX FIFO. When the last byte is received, then the COMPLETE status is set. The Master automatically stops IBI data after 9 total bytes (including MDB) MCTRL[RDTERM] can be used with MCTRL[REQ] = 0 to end sooner. [DIP_I3C_00017] I3C will support Address ACK to Mandatory Byte transition during IBI from Open_Drain (Master ACKs the Slave Address) to Push Pull (Slave sends SDR data). [end]
- [DIP_I3C_00030]I3C slave supports up to 7 bytes of Extended IBI Data following Mandatory Data byte. Extended Data to send would be present in register IBIEXT1 and IBIEXT2.[end]

[DIP_I3C_00044]Accurate timestamping of I3C Slave data is supported in I3C though Async Mode 0. In I3C Asynchronous Timing Control, a Slave Device timestamp event occurring within that Slave, and then notifies the Master about it by generating an In-Band Interrupt (IBI).[end]

70.3.2.5 Assigning dynamic addresses to I3C devices

If Dynamic Addresses (DAs) are all assigned below 0x40 (7-bit values from 0x3F down to 0x03, except where this is not allowed), then the MSB0 bit can be set in the Master In-Band Interrupt Registry and Rules register (MIBIRULES). This optimizes the START timing. When dynamic addresses are assigned, the MIBIRULES register must be programmed based on which I3C slave uses IBI bytes [DIP_I3C_00013](known from Bus Capabilities Register (BCR))[end].

Any Set Dynamic Address from Static Address (SETDASA) assignments can be done using the normal Common Command Code (CCC) model (except when using the static address for the directed part).

There is a built-in mechanism to process the Dynamic Address Assignment (DAA) mode:

1. Set up interrupts. Normally:
   - [DIP_I3C_00050]MCTRLDONE: Need to know when a slave has sent its ID and BCR/DCR and a new DA is needed.[end]
   - COMPLETE: To fire when DAA done (NACKed by all slaves).
   - RXPEND to read the IDs of the slaves. The alternative is for DMA to read out bytes.
   - [DIP_I3C_00050]IBIWON: The software knows if an IBI happened, which should not be possible normally.[end]
   - MERRWARN: In case of an error
2. Write the MCTRL register with:
   - REQUEST set to 4 - ProcessDAA
   - IBIRESP set to IBI response if that is possible (if not the 1st Slave assignment)
3. Wait for the MCTRLDONE interrupt, while reading in ID using the RXPEND interrupt. If MSTATUS indicates in DAA mode (STATE=5) and BETWEEN (bit 4=1), then it is waiting for a dynamic address for the slave whose ID was read in.
   - Write the dynamic address into MWDATAB using bits 6:0, such as 0x14 for dynamic address=7'h14.

- Write MCTRL REQUEST to 4 (ProcessDAA again). This writes the dynamic address, and then moves to the next dynamic address.
- If MSTATUS indicates all is done via the COMPLETE bit being set and STATE=0, then all slaves have been assigned.
- If MSTATUS indicates NACK after having written a new dynamic address, then the dynamic address was not accepted by the slave. The 76next step is REQUEST set to EmitStop and start over. However, it is also OK to just set REQUEST to 4 (ProcessDAA again).

70.3.2.6 Using master message mode

Master message mode is intended for use with DMA, although message mode can also be used by the processor. The message mode concept is that all writes are to the same location, including the control and then the data. The read back is from an associated location.

NOTE

The data writes for message mode work in the same way as the half-word access registers MWDATAH and MRDATAH.

To send a message via Single Data Rate (SDR), do the following steps (from DMA or processor):

1. Write to the MWMSG_SDR register with the control request, which includes the address, I2C vs. I3C, read or write, the count of bytes to process, and how to end (on STOP or ready for repeated START).
2. Process the Data:
   - [DIP_I3C_00051]If Write: Then write the rest of the data to MWMSG, using the DMA trigger (or interrupt) to keep the TX FIFO full, and stop asking when the count is down to 0.
   - If Read: Then a DMA trigger (or interrupt) indicates when the RX FIFO is to be read out via the MRMSG_SDR.[end]
3. In-band Interrupt (IBI) behavior is selected in the MCTRL register.
4. Use END type STOP to exit MSG mode with the original message, with a 0 length message or by using the MCTRL register.

To send a message via Double Data Rate (DDR), do the following steps (from DMA or processor):

1. Write to the MWMSG_DDR register with the control request, which includes the count of byte-pairs and how to end (on High Data Rate (HDR) Exit or ready for HDR Restart).
2. Write the second control data to MWMSG_DDR, which includes the address, read or write, and the 7-bit command value.
3. Process the Data:
   - If Write: Then write the rest of the data to the same register, using the DMA trigger (or interrupt) to keep the TX FIFO full, and stop asking when the count is down to 0.
   - If Read: Then a DMA trigger (or interrupt) indicates when the RX FIFO is to be read out.
4. In-band Interrupt (IBI) behavior is selected in the MCTRL register.
5. Use END type Exit to exit DDR MSG mode with the original message, with a 0 length message or by using the MCTRL register.

70.3.2.7 [DIP_I3C_00031]Handing off mastership to another slave and getting it back [end]

To hand off mastership, the master either:

- Waits for a Master Request (MR) ([DIP_I3C_00050]an IBIWON interrupt with MSTATUS indicating that an MR is using the IBITYPE field[end])
- Pushes the request manually

In either case, the master sends a GETACCMST request, which is a directed GET that tells the slave that the slave is being assigned mastership (if the slave wants it). If the slave accepts this request (and sends back its dynamic address in bits 7:1 and

the negative parity of the dynamic address in bit 0), then a STOP must be issued and the MCONFIG[MSTENA] field must be set to 2 (switching to the slave mode).

To gain mastership, the slave sends an MR using the SCTRL register.

- If the MSTENA field is 2, then the GETMSTACC CCC accepts.
- If the MSTENA field is not 2, then the GETMSTACC CCC refuses.

[DIP_I3C_00050]After mastership has granted, the MSTATUS[NOWMASTER] bit is set. The application must enable the MINTSET[NOWMASTER] bit, so the application is interrupted when a mastership transfer happens.[end]

70.3.2.8 Master engine flow diagram

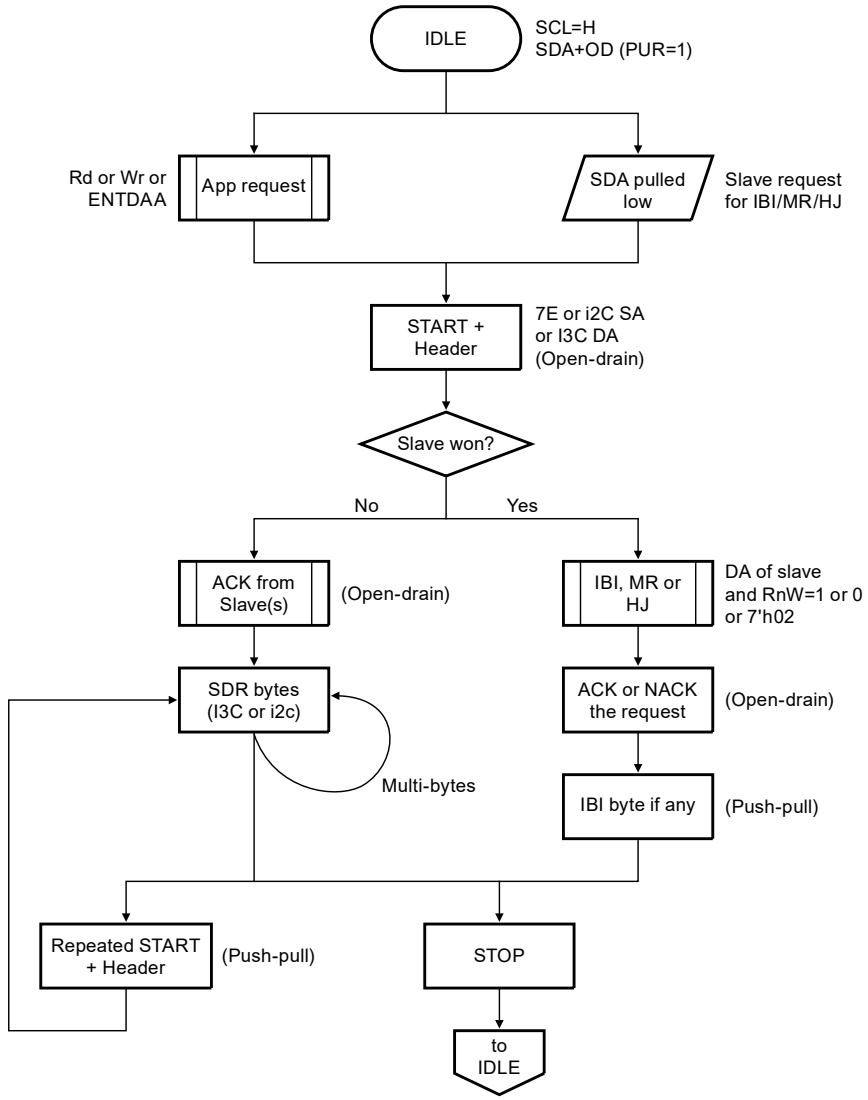

Figure 368. Master engine flow diagram for SDR (HDR would just progress off SDR bytes)

70.3.2.9 Slave data write from Master

When the address match was valid for the Slave Dynamic address and the type was W (write from master), the slave will ACK the address, unless some condition prevents it, such as a full buffer. On ACK, the WRITE state is entered. Once ACKed, it waits for each complete data byte. This is handled in two steps:

- 8 bits clocked in and stored in the next buffer location while in the WRITE state
- [DIP_I3C_00018]I3C: On the 9th bit, the W9TH state is used and the parity is checked. The buffer is marked as complete with or without a parity error.[end]
- I2C: On the 9th bit, the W9TH state is used and the data is ACKed and stored.

When the address match was valid for 0x7E broadcast address, the Slave acknowledges it and sets the in_ccc Possible flag. On 1st data complete, it sets the in_ccc Broadcast or Direct flag (based on bit 7 of cmd). It then parses the command if recognized, setting that bit as well. The recognized ones are for Dynamic Address work and modes. The CCC and DAA blocks handle the work load after that. If not supported, then they are passed up to the system.

70.3.2.10 Slave data write to Master

When the address match is valid for the Slave Dynamic address, and the type was R (read by master), the slave will ACK the address, unless no data waiting for the read. On ACK, the READ state is entered.

Once ACKed, it emits the data byte at a time, with the 9th bit using R9TH state.[DIP_I3C_00019]

- If I3C, the T bit is emitted to allow the device to indicate the last byte (from input signal from upper layers) or not the last byte. If not last byte, the Master may terminate the read via the T bit.
- If I2C, the 9th bit allows the master to terminate via NACK, or else allows to continue via ACK. On completion of each byte read, the done signal is pulsed to get the next byte. [end]

[DIP_I3C_00043]The application is notified if the read was terminated by the Master unexpectedly (abort in I3C, NACK before END marked).[end]

70.3.3 DMA (for internal FIFO use only)

The DMA model supports a few types of DMA uses:

- [DIP_I3C_00053]Normal Request/ACK: The peripheral holds Request = 1 while RXFIFO has data or TXFIFO has space.
  - DMA_TYPE = 0 is used if ACK is before the access to the WDATA/RDATA MMR. This ensures that the Request is dropped if last byte/half-word.[end]
- Other DMA types are not supported such as Trigger-burst, 4-phase before the MMR access, and so on.

NOTE

Do not enable DMA after a transaction starts. It must be enabled only while enabling the slave and interrupts, to avoid any kind of RX FIFO overrun.

70.3.4 Clocks

The Master block has 2 basic clocks feeding:

- The System clock, which controls the access into the memory mapped registers.
- [DIP_I3C_00002]A Functional clock (FCLK), which is used to generate the SCL clock rate on the I2C/I3C bus.[end]
- [DIP_I3C_00046]I3C provides support for adjusting clock frequency and accuracy. They can be set through register STCCLOCK, The default values are configured through parameters.[end]

[DIP_I3C_00039]CLK_SLOW is used to check conditions like Bus Availability, Bus free for IBI, or Hot Join. Slow clock helps to save power.[end]

- [DIP_I3C_00041]To determine Bus Available Condition for IBI, the Slave needs a clock to generate the ~1µ s timing. To support this, a Slow clock (CLK_SLOW) can be provided to save on power.[end]
- [DIP_I3C_00038]Additionally, the block provide a slow clock gate (slow_gate) which is 1 if the CLK_SLOW can be turned off.[end]
- [DIP_I3C_00040]I3C supports a counter register BAMATCH to calculate the Bus Available condition. BAMATCH provides the count of the slow clock to count out 1 us or more to allow an IBI to drive SDA low when the master is not doing so. The maximum width and maximum values are controlled by the I3C module.[end]

The system has 3 basic choices:

- Use the same clock as CLK, which may be variant. If variant, the slow match register can be used to change the match rule.
- Provide a truly slow clock, which makes it inexpensive in power to count 1 µs or more.
- Provide some other clock, but use the slow_gate signal to gate the clock near its source.
- [DIP_I3C_00042]The I3C module supports a timeout if stalled too long in a frame. This happens when - The TX FIFO or RX FIFO is not handled and the bus is stuck in the middle of a message or No STOP was issued and between messages or IBI manual is used and no decision was made.[end]

This model is used in conjunction with the parameters for width of counter and match rule.

70.3.5 Resets

These are the I3C resets:

- Global reset fed into block. Everything is reset by this global reset. Release is assumed synchronized to the system clock (if provided). It is not synchronized to SCL/SDA since those should not be active when the block is released (or it would be in Hot-Join and so not active).
- [DIP_I3C_00027] A Software Reset is provided by the I3C block.[end]
- STOP is reset by START as well.
- The DAA block is reset when not in DAA mode.
- The CCC state detector is reset by STOP. This is because no clock accompanies STOP.
- HDR modes are held in reset and clock gated by not_HDR which is set by Exit Pattern and cleared by EnterHDR.

70.3.5.1 Slave Reset and RSTACT CCC

[DIP_I3C_00061] The Slave Reset mechanism is designed to allow an always-on tiny block to monitor SDA and SCL for a specific pattern based on HDR Exit – extended with repeated START and STOP at the end. This detector can be used to wake or reset the device or just a peripheral, as well as do nothing for any specific reset. The normal use is that the Master emits a RSTACT CCC message saying not to reset when this pattern is emitted just after; devices which are broken reset (since they miss the CCC) and devices in deepest sleep (for example, an unpowered core domain) wake (since they also miss the CCC).[end]

The 1st default action is only to reset the peripheral. If that does not work, the next time will reset the chip/system.

The Master may also request a specific action, which the slave can dial in if it supports that (for example, reset the peripheral only).

The Slave Reset is connected into the system as shown in Figure 369. Note that it is outside of the I3C Peripheral, and may be in an always-on domain. Sleep/wake signals are not shown. The common connections are as follows:

Table 408. Slave resets

Reset detector	Connect to IP	Connect to System	Notes
I3c_slave_active	raw_slvr_isslave if master+slave	If I3C can be unused	Connect to enable if can be unused — should probably not clear for safety reasons.
iRstAction[3:0]	raw_slvr_reset	—	Result of RSTACT CCC
oRstRstAction	iraw_rst_slavr_reset	—	Clear RSACT state
oResetBlock	iraw_slvr_irq	—	Triggers IRQ in IP
oRstAll	—	System reset	Should perform similar to pin RSTn
oRstCustom	—	Custom Reset if enabled	Must be setup via RSTACT_CONFIG[2]
iDeepestSleep	—	Feed from system or 0	Only used if deepest sleep supported
oWake	—	Wake controller	—

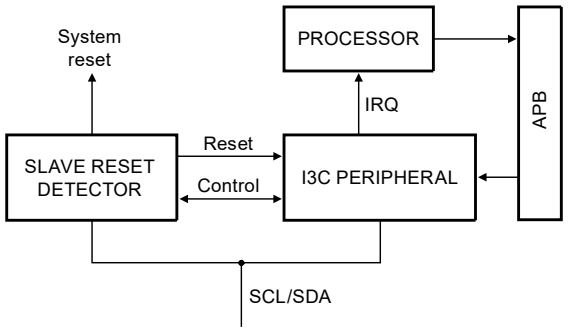

Figure 369. Slave reset detector connected in the system (Slave Reset may be in Always-on domain)

Figure 370 shows the connections of the Slave Reset detector, including support for deepest sleep and wake. If those are not used, they are just not connected. If the I3C peripheral may be powered off when the reset detector is powered, the isolation cells are used to protect it, although the nets are logically gated off when iDeepestSleep is 1.

Note that the block wants the SCL and SDA signals to be fed as clocks. This is done outside the block, using any method needed. 3 domains are needed to support the reset.

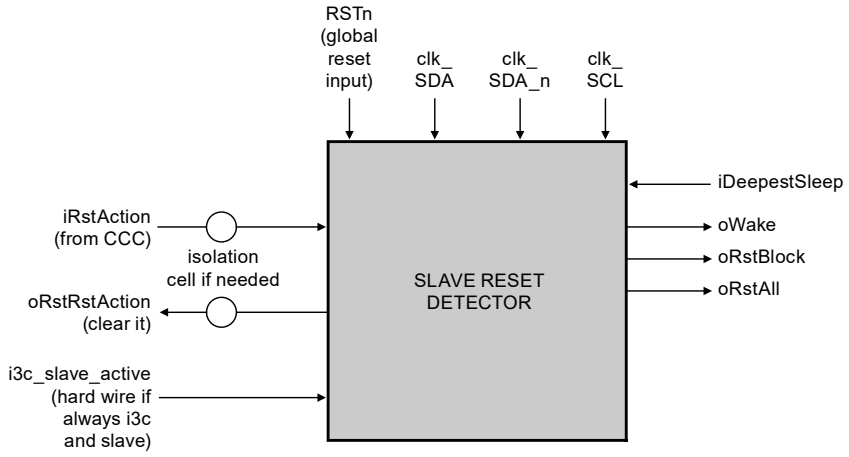

Figure 370. Showing reset detector connections — not all used in many systems

The i3c_slave_active signal must be used with caution, as it disables the reset detector when 0; it should be strapped 1 if always i3c and slave, else should be safely controlled (or may defeat the purpose of the Slave Reset block). If the i3c peripheral is optional, then it must be selected by some system control feature – that should be what controls i3c_slave_active.

The block is connected to the I3C peripheral through the iRstAction and oRstRsttAction ports. These are clamped off if iDeepestSleep signal is 1; if that kind of sleep is not possible, the iDeepestSleep port should be strapped 0. The 2 nets can be treated as asynchronous even though from the same SCL. This is to avoid having to do setup/hold timing between the modules when the reset detector is in a separate domain. That is, the clk_SCL and clk_SDA_n are not intended to be treated the same clocks as used in the peripheral – this allows freedom in placement of the detector.

Finally, the reset and wake signals are connected to the system; they are 0 when inactive, 1 when actively driven. There are clearing events used to clear: RstAll waits for the Reset input to assert (or i3c_active to go to 0); the RstBlock waits for the I3C peripheral to clear its cause register or to see a RSTACT or GETSTATUS. Wake clears on release of iDeepestSleep.

70.3.6 Interrupts

This section describes all the interrupts (IRQs) that the I3C module generates. All status interrupts are updated in the Master Status (MSTATUS) and Slave Status (SSTATUS) registers.

Supported interrupts:

- For pending IBI, MR, or Hot-Join that have been sent.
- When a CCC is received and is handled by the block. (CHANDLED).
- When an error or warning occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition.
- [DIP_I3C_00044]When a CCC is received which is unhandled by the I3C block. The register SCCCMASK allows the user to suppress any CCC which is intended to be unhandled.[end]

70.4 External signals

This table describes the I3C module signals.

Signal	I/O	Description
SCL	I/O	Serial clock

Table continues on the next page...

Table continued from the previous page...

Signal	I/O	Description
SDA	I/O	Serial data
PUR	O	Pull up resistance. There is internal pull up resistance on SDA, which is contolled by the I3C master. PUR can be used to actively control an external pull up resistance on SDA, if the internal pull up is not enough.

70.5 Initialization

70.5.1 Configuration initialization

[DIP_I3C_00004]The configuration is handled when initializing the I3C module. Configuration is done using the MCONFIG register, which controls the frequencies, duty cycle, optimizations for performance, and other parameters.[end]

[DIP_I3C_00055]Parameters govern several features that are supported in the design. [end]

[DIP_I3C_00058]High keeper controls are also included in the below configuration list. [end]

Table 409. Configuration parameters used to initialize the I3C module

Configuration prameter		Description
MSTENA	Master Enable	Determines whether the I3C peripheral starts in Master mode (that is, the “Main Master” in I3C terms) or starts in slave mode (and switches to Master later).
HKEEP	High Keeper	Determines how the high-keeper (weak pullup) is implemented, depending on the device capabilities.
PPBAUD	Push-Pull BAUD	Sets the push-pull frequency as a divider from the FCLK (alternative clock fed to the peripheral). This sets the SCL half-clock period baseline (used at least for the high time of SCL). Formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL (Freq in MHz) = FCLK/((2 + 2*PPBAUD) + PPLOW). If PPLOW is 0, then SCL high = SCL low (in ns) = (1 + PPBAUD)*1000/FCLK(MHz) Examples: • If FCLK = 24 MHz, then PPBAUD = 0 yields 12 MHz (42.67 ns per half period) • If FCLK = 50 MHz, then PPBAUD = 1 yields 12.5 MHz (20 + 20 = 40 ns per half period)
PPLOW	Push-Pull Low	Changes the duty cycle for Push-Pull. It indicates how many more FCLKs to use for low. Formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL(Freq in MHz) = FCLK/((2 + 2 * PPBAUD) + PPLOW) If PPLOW is non-zero, then SCL High (in ns) = (1 + PPBAUD)*1000/FCLK(MHz) SCL low (in ns) = (1 + PPBAUD + PPLOW)*1000/FCLK(MHz)

Table continues on the next page...

Table 409. Configuration parameters used to initialize the I3C module (continued)

Configuration prameter		Description
		For example, a 50 MHz FCLK, a PPBAUD of 1, and a PPLOW of 1, yields (1 + 1) * 1000/50 = 20 + 20 = 40 ns high and (1 + 1 + 1) * 1000/50 = 20 + 20 + 20 = 60 ns low. This would be equivalent of 10 MHz SCL timing, but maintaining the 40 ns high needed, so that I2C devices do not see the high periods. **NOTE** The PPLOW value does not have any impact on open-drain and I2C mode SCL rate calculations.
ODBAUD	Open Drain BAUD	The number of PPBAUD periods to make up one I3C Open-Drain half-clock baseline. ODBAUD half-clock time period = (ODBAUD + 1)* PPBAUD high period. (if ODHPP is 0) Formula for SCL in Open-Drain mode is (if ODHPP=0) SCL(in MHz) = FCLK/(2 + 2 * PPBAUD)*(ODBAUD + 1) Target to get open-drain half clock period is 200ns. For example: • If PPBAUD yields 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 can be used to get 200ns. See also ODHPP for details on short High and long Low. • If PPBAUD = 1, FCLK = 50MHz, ODBAUD = 4 then open-drain SCL = 50/(2 + 2*1)*5 = 2.5 MHz.
ODHPP	Open-Drain High Push-Pull	Optional field that allows for the I3C open-drain to be long Low and short High. The High period of SCL is the PPBAUD period. This leaves enough time for the pull-up resistor to pull the SDA high when SCL is low, but is quick when SCL is high and there are no changes happening. ODBAUD low half-clock time period = (ODBAUD + 1) * PPBAUD high period. ODBAUD high half-clock time period = PPBAUD high period Formula for SCL in Open-Drain mode is (if ODHPP = 1): SCL(in MHz) = FCLK/(1 + PPBAUD)*(ODBAUD + 1) + (1 + PBAUD) For example: • If PPBAUD yields 12.5 MHz (40ns per PPBAUD period), then ODBAUD = 4 and ODHPP = 1 will give high and low period as 40ns and 200ns respectively. • If PPBAUD = 1, FCLK = 50MHz, ODBAUD = 4 then open-drain SCL = 50/(1 + 1)*5 + (1 + 1) = 4.16 MHz.
I2CBAUD	I2C Baud	Indicates how many ODBAUD periods are needed to communicate with I2C devices (MCTRL[TYPE] = 2 or MWMSG_SDR_CONTROL[I2C] = 1). For example, if ODBAUD gives 200 ns, and the goal is Fm+ (Fast Mode, 1 MHz), then the sum needs to be 1 µs. If odd vs. even, then I2CBAUD acts differently. For example, if I2CBAUD = 3, it gives 3 ODBAUD periods low and 2 ODBAUD periods high. • If I2CBAUD = 4, then it gives 3 ODBAUD periods for low and 3 ODBAUD periods for high.

Table continues on the next page...

Table 409. Configuration parameters used to initialize the I3C module (continued)

Configuration prameter		Description
		• Also, if I2CBAUD = 3, this yields 200 * 3 = 600 ns and 200 * 2 = 400 ns, with the sum 600 + 400 = 1000 ns = 1µs.
SKEW	Skew	The normal SDA skew from SCL is handled by using the time for the SCL to reach its pad and come back to the design. This is normally 2 ns to 5 ns (or sometimes more). If the SKEW is too fast, then add more delay, the SKEW allows specifying the number of FCLKs to insert.

Additional optimizations:

- Use MIBIRULES[MSB0] to get much faster START header times. If the master application assigns all I3C Dynamic Addresses to be less than 0x40 (it does not have MSB set), then MIBIRULES[MSB0] can be set. This means that when the master emits 0x7E (broadcast) and the 1st bit is not driven low by a slave, the rest of the header can be at push-pull speeds. This is 2x faster (or more, depending on optimizations above).
- Auto-emit 0x7E speeds up the frame when used in conjunction with MIBIRULES[MSB0], because it allows the processor to be sleeping when the frame starts automatically (in response to a slave).

70.5.2 Interrupt service flow

Set up interupts, normally:

1. MCTRLDONE: optional
2. COMPLETE: to fire when end of data
3. RXPEND if read; this can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to read out bytes.
4. TXNOTFULL if write; this can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to supply bytes.
5. IBIWON: so the software knows if an IBI has occurred
6. MERRWARN: in case of an error

70.6 I3C register descriptions

This section describes the registers in the I3C module.

Table 410. Register Types

Type		
RO	Read-Only	
RW	Read/Write	
W1C	Write 1 to Clear	W1S and W1C registers are readable (they can be read).
W1S	Write 1 to Set	
WO	Write-Only	

NOTE

[DIP_I3C_00047]Writing to a Read-Only (RO) register, except the MINTMASKED register, causes bus errors. This module does not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.[end]

[DIP_I3C_00049]However, the I3C peripheral ignores writes to RO registers, and the I3C peripheral returns 0 for reads from WO or non-existent registers. It requires all 32-bit regs to be read and written as 32-bit and aligned to 32 bits. The peripheral uses the Advanced Peripheral Bus (APB), so the peripheral would not know if partial read or write operations (less than 32 bits) are used. [end]

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 I2CBAUD	I2C Baud Rate The I2C low and high times in ODBAUD counts. • I2CBAUD > 1 is the main count load, and it is *count-1*. Therefore, for I2CBAUD > 1: I2CBAUD==0 is 1 ODBAUD beat, and I2CBAUD==1 is 2 ODBAUD beats. • If I2CBAUD[28] is 1, then low will be 1 extra ODBAUD beat. This means that the I2CBAUD field is normally 3, where ODBAUD gives 200 ns. Therefore, this means that for I2CBAUD > 1 I2CBAUD==1, which means 2 ODBAUD. Therefore, (2 + 1) * 200 = 600 ns low, with 2 * 200 = 400 ns high for 1 µs period, to match Fast Mode Plus (FM+). For Fast Mode (FM), I2CBAUD is normally 11 (giving 2.6 µs) or is 6 (giving 2.4 µs).
27-25 SKEW	Skew Number of FCLK counts for an SDA change after SCL for I3C push-pull. This is in addition to the roundtrip of the SCL line from the pad back to the module (3 ns to 4 ns or more). • SKEW is normally not needed, so assign SKEW=0. • SKEW is only used if SDA is not naturally skewing from an SCL change. • I2C automatically skews SDA (but not PUR) to match I2C rules.
24 ODHPP	Open Drain High Push-Pull If ODHPP = 1, then the Open-Drain High SCL half-lock period should be 1 PPBAUD count for I3C messages. If ODHPP = 0, the Open-Drain SCL High half-clock period will be the same as the Open-Drain Low SCL half-period. The use of ODHPP = 1 is both because it is faster (and works for I3C devices) and because any legacy I2C devices on the bus will not see the SCL High at all (less than the spike filter period). See Sending a CCC to one or all I3C slaves for open-drain timing check on first broadcast 0x7E, allowing I3C peripherals acting as I2C legacy devices to turn off their I2C 50 ns Spike filters.
23-16 ODBAUD	Open Drain Baud Rate ODBAUD= (number of PPBAUD counts) - 1. ODBAUD should not be 0 (not the same as push-pull). This would normally go for 200 ns (see I2CBAUD for I2C counts). When used with ODHPP, this gives 250 ns per clock in I3C. Therefore, if PPBAUD gives 12 MHz, then 1 PPBAUD is ½ of 12 MHz or 41.67 ns, and then to get around 200 ns, use 5-1=4 for ODBAUD.
15-12 PPLOW	Push-Pull Low Adder for push-pull low, to create a duty-cycle with a longer low period, with up to 15 more FCLKs low than high. PPLOW=0 means a 50:50 duty cycle.
11-8 PPBAUD	Push-Pull Baud Rate The FCLK Counter for each push-pull low and normally high period. So, PPBAUD=0 if run at ½ input FCLK speed (for example, a 24 MHz FCLK yields a 12 MHz SCL, because each FCLK is SCL Low or SCL High). Note the use of duty-cycle via Push-Pull Low (PPLOW). For example, 24 MHz with 50:50 duty cycle is 12 MHz, but with PPLOW adding 3 more low beats, the push-pull baud rate becomes 4.8 MHz (from 24 MHz/5 beats).
7	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6 ODSTOP	Open Drain Stop If ODSTOP=1, then STOP will be emitted at open-drain speeds even for I3C messages. This can be useful for legacy devices, to ensure that the legacy devices see the STOP. ODSTOP needs to be zero when sending HDR exit pattern.
5-4 HKEEP	High-Keeper Indicates how High-Keeper is to be supported. **NOTE** Your specific device may not support any or all of these High-Keeper methods. See the chip-specific section for this module, at the beginning of this chapter. 00b - NONE. Use PUR (Pull-Up Resistor). Hold SCL High. 01b - WIRED_IN. High Keeper controls, use pin_HK (High Keeper) controls. SCL may use a HK or that signal (pin_HK_SCL) may only OR into SCL_oena. 10b - PASSIVE_SDA. Passive on SDA, can Hi-Z (high impedance) for Bus Free (IDLE) and hold. 11b - PASSIVE_ON_SDA_SCL. Passive on SDA and SCL, can Hi-Z (high impedance) both for Bus Free (IDLE), and can Hi-Z SDA for hold.
3 DISTO	Disable Timeout This timeout detects application errors. • If DISTO=1, then it disables the timeout (if the timeout is configured). • If the master has been left in a state other than Stopped for more than 100 us (because 10 kHz is the slowest allowed I3C speed), then the timeout will send an MERRWARN (interrupt). • To prevent the MERRWARN interrupt when doing development or testing, write 1 to DISTO to disable the timeout. • In systems that support timeouts, timeout will be disabled automatically during debug.
2 —	Reserved
1-0 MSTENA	Master Enable Indicates if the master is enabled and what states are allowed for it (the master). 00b - MASTER_OFF. Master is off (disabled). If MASTER_OFF is enabled, then the I3C module can only use slave mode. 01b - MASTER_ON. Master is on (is enabled). When used from start-up, this I3C module is master by default (the main master). The module controls the bus unless the master is handed off. If the master is handed off, then MSTENA must move to 2 after that happens. The handoff means emitting GETACCMST and if accepted, the module emits a STOP and set the MSTENA bit to 2 (or 0).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - MASTER_CAPABLE. The I3C module is master-capable, however the module is operating as a slave now. When used from the start, the I3C module starts as a slave, but will be prepared to switch to master mode. To switch to master mode, the slave emits a Master Request (MR), or gets a GETACCMST CCC command and accepts it (to switch on the STOP). 11b - Reserved

70.6.3 Slave Configuration (SCONFIG)

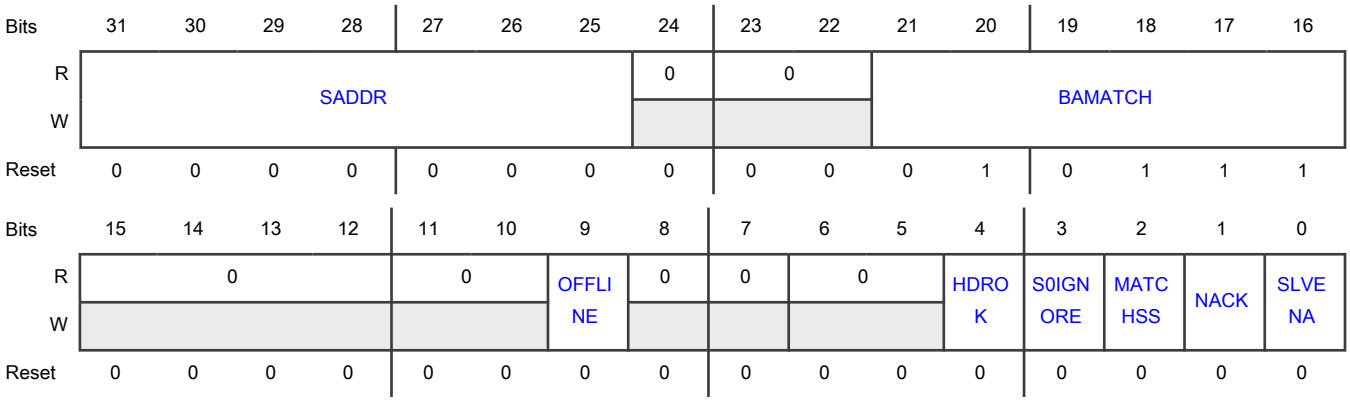
Offset

Register	Offset
SCONFIG	4h

Function

Contains fields that must be configured before the module is activated.

Diagram



Fields

Field	Function
31-25 SADDR	Static Address SADDR sets the I2C 7-bit static address, else must be 0.
24 —	Reserved
23-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 BAMATCH	Bus Available Match This is the Bus Available condition match value for the current slow clock. BAMATCH provides the count of the slow clock to count out 1 µs (or more) to allow an In-Band Interrupt (IBI) to drive SDA low when the master is not doing so. The maximum width and maximum values are controlled by the I3C module.
15-12 —	Reserved
11-10 —	Reserved
9 OFFLINE	Offline If OFFLINE = 1 when the slave enable (SCONFIG[SLVENA]) is set to 1, then the I3C module waits for either 60 µs of bus quiet or a High Data Rate (HDR) Exit Pattern. This ensures that the bus is not in HDR mode, and so can safely track Single Data Rate (SDR) mode.
8 —	Reserved
7 —	Reserved
6-5 —	Reserved
4 HDROK	HDR OK Deprecated: If HDROK = 1, allow HDR-DDR and/or HDR-BT messaging if available by setting the corresponding SIDEXT[BCR] bit to say HDR is available, and the corresponding GETCAPS bit for DDR and/or BT bit permitting use. **NOTE** Use the SIDEXT[BCR] field instead.
3 S0IGNORE	S0/S1 Errors Ignore If S0IGNORE = 1, the Slave will not detect S0 or S1 errors and so does not lock up waiting on an Exit Pattern. This should only be used when the bus will not use HDR mode.
2 MATCHSS	Match START or STOP If MATCHSS = 1, then the START and STOP sticky SSTATUS bits will only be set if SSTATUS[MATCHED] is set. This allows START and STOP to be used to detect the end of a message to/from this slave.
1 NACK	Not Acknowledge

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If NACK = 1, then the slave will NACK all requests to it, except a Common Command Code (CCC) broadcast. NACK = 1 should be used with caution, because the master may decide that the slave is missing, if NACK is overused.
0 SLVENA	Slave Enable • If SLVENA = 1, then a slave can operate on the I2C or I3C bus. • If SLVENA = 0, then a slave will ignore the I2C or I3C bus. SLVENA must not be set before registers like SCONFIG (SIDPARTNO, SIDEXT, and others) are set, because these registers affect the data to/from the master. Slave enable is configured just one time before the I3C bus comes up. If slave enable is used at other times, see Hot-Join. In the case of Hot-Join, the Hot-Join bit (SCAPABILITIES[IBI_MR_HJ]) must be set before setting the slave enable bit (SLVENA), so that the device does not see a START or STOP incorrectly. Default: 0 unless configured to be 1 by default.

70.6.4 Slave Status (SSTATUS)

Offset

Register	Offset
SSTATUS	8h

Function

Not all bits are used if the module only acts as a slave. The Slave Status register is used to indicate both sticky status for interrupts, as well as “states” and “modes” related to the I3C bus. The fields are divided into current activity, interrupt maskable actions, then states and modes on the bus.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-30 TIMECTRL	Time Control Indicates if time control is currently enabled. 00b - NO_TIME_CONTROL. No time control is enabled 01b - Reserved 10b - ASYNC_MODE. Asynchronous standard mode (0 or 1) is enabled 11b - Reserved
29-28 ACTSTATE	Activity State from Common Command Codes (CCC) 00b - NO_LATENCY. Normal bus operations 01b - LATENCY_1MS. 1 ms of latency 10b - LATENCY_100MS. 100 ms of latency 11b - LATENCY_10S. 10 seconds of latency
27 HJDIS	Hot-Join Is Disabled HJDIS = 1 if Hot-Join is disabled at this time. While Hot-Join is disabled, CTRL requests will be held off (not responded to).
26 —	Reserved
25 MRDIS	Master Requests Are Disabled MRDIS = 1 if Master Requests are disabled at this time. While Master Requests are disabled, CTRL requests will be held off (not responded to).
24 IBIDIS	In-Band Interrupts Are Disabled IBIDIS = 1 if In-Band Interrupts are disabled at this time. While In-Band Interrupts are disabled, CTRL requests will be held off (not responded to).
23-22 —	Reserved
21-20 EVDET	Event Details Current details of the last (EVENT = 1) or pending event. 00b - NONE. no event or no pending event 01b - NO_REQUEST. Request is not sent yet. Either there was no START yet, or is waiting for Bus-Available or Bus-Idle (HJ). 10b - NACKED. Not acknowledged (Request sent and NACKED), the module will try again. 11b - ACKED. Acknowledged (Request sent and ACKED), so Done (unless the time control data is still being sent).
19	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
18 EVENT	Event For a Slave, a pending In-Band Interrupt (IBI), Master Request (MR), or Hot-Join (HJ) has been sent as requested. See the upper status register fields for details. **NOTE** For a Slave, a pending In-Band Interrupt (IBI), Master Request (MR), or Hot-Join (HJ) has been sent as requested. See the upper status register fields for details.
17 CHANDLED	Common Command Code Handled A CCC is being handled by the module. This is a notification only, but the result may be an updated SSTATUS register.
16 HDRMATCH	High Data Rate Command Match An HDR command matched this device's I3C Dynamic Address. The HDR command will be available as the 1st byte and RXPEND will be set (whether the command is read or write, the MSb of that command byte indicates if it is a read or a write command). If the HDR command is a read, and there are to-bus bytes waiting, then the command will be ACKED and the data sent back; otherwise the HDR command will be NACKED. Note that when HDRMATCHED is set, the ERRWARN bit should be checked, because the HPAR error may have be encountered after signaling this HDR command (the parity is after the destination address and command).
15 ERRWARN	Error Warning An error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition. See the Slave Errors and Warnings (SERRWARN).
14 CCC	Common Command Code A CCC has been received, and is not handled by the I3C module. There are 2 types of Common Command Codes: • Broadcasted CCC, which will then also correspond with RXPEND and the 1st byte is the CCC (command). • Direct CCC, which may never be directed to this device. If Direct CCC are directed to this device, then the TXSEND or RXPEND are triggered, and the RXPEND contains the command.
13 DACHG	Dynamic Address Change The Slave Dynamic Address (DA) has been assigned, re-assigned, or reset (lost) and is now in that state of being valid or none. Actual DA can be seen in the DYNADDR register. Note that DACHG will also be used when MAP Auto feature is configured. This will be changing one or more MAP items. See DYNADDR and/or MAPCTRLn. DYNAADDR for the main DA (0) indicates if last change was due to Auto-MAP.
12 TXNOTFULL	Transmit Buffer Is Not Full

Table continues on the next page...

Table continued from the previous page...

Field	Function
	TXNOTFULL = 1 when the To-bus buffer/FIFO can accept more data to go out. For all but External FIFO, this uses SDATACTRL[TXTRIG], which defaults to not-full. If DMA is enabled for transmitting, then it will also be signaled to provide more data.
11 RX_PEND	Received Message Pending Receiving a message from master, which is not being handled by the I3C module (not a Common Command Code (CCC), so is internally processed by the module). For all but External FIFO, this uses SDATACTRL[RXTRIG], which defaults to not-empty. If DMA is enabled for receiving, then DMA is signaled as well. RX_PEND self-clears if data is read (from FIFO and non-FIFO sources).
10 STOP	Stop The STOP bit is from a stopped state being detected, meaning that a STOP state was present on the bus since the bus was last cleared. The STNOTSTOP state will also indicate if the I3C module is in stop mode. A fast STOP/START combination may not trigger the STOP status. In that case, START is always set.
9 MATCHED	Matched An incoming header matched this device's I3C Dynamic or I2C Static address (if any) since the bus was last cleared.
8 START	Start START = 1 if a START or repeated START was seen after the START bit was last cleared. This is not usually needed, but can be used for wake events.
7 —	Reserved
6 STHDR	Status High Data Rate STHDR = 1 if the I3C bus is in HDR-DDR mode, regardless of whether HDR mode is supported by this module or not, and regardless of whether the message is to this module or to some other module.
5 STDAA	Status Dynamic Address Assignment STDAA = 1 if the I3C bus is in Enter Dynamic Address Assignment (ENTDAA) mode, regardless of whether this bus slave has or does not have a Dynamic Address.
4 STREQWR	Status Request Write STREQWR = 1 if the request (REQ) in process is SDR write data from the master to this bus slave (or all I3C slaves), but not in ENTDAA mode. See Status High Data Rate (STHDR) for Double Data Rate (DDR) handling.
3 STREQRD	Status Request Read STREQRD = 1 • If the REQ in process is an SDR read from this slave • If an In-Band Interrupt (IBI) is being pushed out Also see Status High Data Rate (STHDR) for Double Data Rate (DDR) handling.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 STCCCH	Status Common Command Code Handler STCCCH = 1 if a Common Command Code (CCC) message is being handled automatically.
1 STMSG	Status message STMSG = 1 if this bus slave is listening to the bus traffic or responding. If STNOSTOP = 1, then STMSG is 0 when a non-matching address is seen, until the next repeated START or STOP occurs.
0 STNOTSTOP	Status Not Stop • When the bus is busy (has activity), STNOTSTOP = 1. • When the I3C module is in a STOP condition, STNOTSTOP = 0. Other SSTATUS bits may also be set when busy. Note that STNOTSTOP can also be true (= 1) after an S0 or S1 error, where the I3C module is waiting for an Exit Pattern.

70.6.5 Slave Control (SCTRL)

Offset

Register	Offset
SCTRL	Ch

Function

Contains controls for the active use of the I3C bus, like event generation (for example, interrupts to the master). The Slave Control register is used to activate various special operations for the Slave, but only if the module is configured to support those operations. This includes events such as IBI and GETSTATUS fields (except the Protocol error, which is automatically set).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	VENDINFO								0		ACTSTATE		PENDINT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IBIDATA								0			MAPIDX	EXTDATA	0	EVENT	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 VENDINFO	Vendor Information Should be set to the Vendor Reserved field that the GETSTATUS CCC returns. The vendor information should be maintained by the application, because the master reads this field. If VENDINFO is not configured, then the GETSTATUS field always returns 0.
23-22 —	Reserved
21-20 ACTSTATE	Activity State (of slave) Should be set to the slave's activity state that the GETSTATUS CCC returns as activity mode. The activity state should be maintained by the application, because the master will read this field. If the activity state is not configured, then the GETSTATUS command will always return 0.
19-16 PENDINT	Pending Interrupt Should be set to the pending interrupt that the GETSTATUS CCC returns. The pending interrupt should be maintained by the application, because the master reads this field. If PENDINT=0 and • If an IBI interrupt is pending, then the GETSTATUS command returns 1. • If an IBI interrupt is not pending, then the GETSTATUS field returns 0.
15-8 IBIDATA	In-Band Interrupt Data Data byte to go with an In-Band Interrupt (IBI), if the module is enabled for IBI. If SCTRL[IBIDATA] is enabled, then IBI is required.
7-5 —	Reserved
4 MAPIDX	Map Index Index of Dynamic Address that IBI is for. This is 0 for the main or base Dynamic Address, or can be any valid index. See DYNADDR register for more details. Used only if Mapping is enabled.
3 EXTDATA	Extended Data If 1, then after IBIDATA is emitted, extended data will be taken from IBIEXT1 and IBIEXT2 if configured，see the IBIEXT1[MAX] field. This may be used with time control, in which case the data follows the time information.
2 —	Reserved
1-0 EVENT	Event • If EVENT is set to non 0, it will request an event. • After being requested, SSTATUS[EVENT] and SSTATUS[EVDET] show the status as it progresses.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• After completion, the EVENT field automatically returns to 0. • After EVENT is non 0, only 0 can be written to EVENT (to cancel), until the event processing is done (finished). 00b - NORMAL_MODE. If EVENT is set to 0 after was a non 0 value, event processing will cancel if the event processing has not yet started. If event processing has already been started, then event processing will not be canceled. 01b - IBI. Start an In-Band Interrupt. This will try to push an IBI interrupt onto the I3C bus. If data is associated with the IBI, then the data will be read from the SCTRL[IBIDATA] field. If time control is enabled, then this data also includes any time control-related bytes. Additionally, the IBIDATA byte will have bit 7 set to 1 automatically (as is required for time control). The IBI interrupt will occur after the 1st (mandatory) IBIDATA, if any. 10b - MASTER_REQUEST. Start a Master-Request. 11b - HOT_JOIN_REQUEST. Start a Hot-Join request. A Hot-Join Request is used when the device is powered on after the I3C bus is already powered up or when the device is connected using hot insertion methods (the device is powered up when it is physically inserted in the powered-up I3C bus). The HJ waits for Bus Idle, and SCTRL[EVENT] = HOT_JOIN_REQUEST must be set before the slave enable (SCONFIG[SLVENA]).

70.6.6 Slave Interrupt Set (SINTSET)

Offset

Register	Offset
SINTSET	10h

Function

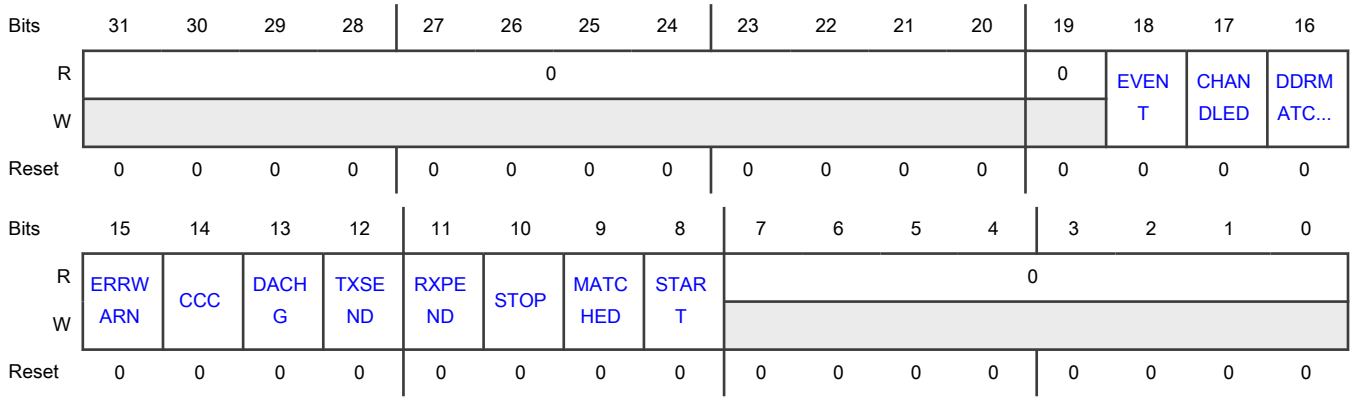
Sets interrupt enables for select Slave Status (SSTATUS) bits. Reading this register (SINTSET) returns the status of the interrupt enables.

- To activate an interrupt enable, write 1 to its field in this register (SINTSET).
- To disable an interrupt enable, write 1 to the appropriate bit in the Interrupt Clear Register (SINTCLR). Writing 0 to the interrupt enable in this register (SINTSET) does not disable the interrupt.

The Interrupt registers allow masking interrupt sources, as well as checking which interrupts have activated. The normal method is to enable an interrupt, and then once the interrupt fires, the interrupt is either cleared by writing the SSTATUS register or cleared by action on the corresponding data register. The Interrupt is level held, meaning the interrupt stays set until the cause is cleared by some method. The module prevents races, so that if a new event comes in, that new event will not be lost.

- SINTSET sets interrupt enables for Slave Status (SSTATUS) bits. Reading the SINTSET register returns the status of the interrupt enables.
- SINTCLR clears interrupt enables for SSTATUS bits.
- SINTMASKED returns the value of the SSTATUS bits ANDed with their interrupt enables.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 —	Reserved
18 EVENT	Event Interrupt Enable Slave: Interrupt when Pending IBI, MR, or Hot-Join has been sent as requested. See SSTATUS[EVDET]. Used only if configured to support events.
17 CHANDLED	Common Command Code (CCC) (that was handled by I3C module) Interrupt Enable Interrupt when a CCC was received and handled by the block (is done). SSTATUS shows new results. CHANDLED can be used to track when Activity states and masks on events (for example, IBIs) occur. Used for CCCs that are enabled.
16 DDRMATCHED	Double Data Rate Interrupt Enable Interrupt when DDR matched for Read or Write command. Used only if HDR enabled.
15 ERRWARN	Error/Warning Interrupt Enable Interrupt when an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition. See the ERRWARN register for details of the cause. Only available for errors that are configured features.
14 CCC	Common Command Code (CCC) (that was not handled by I3C module) Interrupt Enable For CCCs not handled by the block, RXPEND will also interrupt and the SSTATUS REQ field will indicate it is a CCC.
13 DACHG	Dynamic Address Change Interrupt Enable Interrupt on Dynamic address defined (SETDASA or ENTDAA) or lost (RSTDAA). See also DADDR register.
12	Transmit Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXSEND	Interrupt when Request data by Master (Read). This interrupts on 1st request (header) as well as when ready for more; the Application indicates if more or END. If FIFO, triggers on Tx emptiness trigger. If DMA, then message end (DMA end or terminate).
11 RXPEND	Receive Interrupt Enable Interrupt when Receiving a message from Master, which is not being handled by block (excludes CCCs being handled automatically). If FIFO, then Rx fullness trigger. If DMA, then message end. See also REQ in SSTATUS for context.
10 STOP	Stop Interrupt Enable Interrupt on STOP state on the bus. See START as the preferred interrupt when needed. This interrupt may not trigger for quick STOP/START combination, as it relates to the state of being stopped.
9 MATCHED	Match interrupt enable Interrupt on Matching header for I3C Dynamic Address. Also for matching header for I2C Static Address, if configured and if no Dynamic Address set (see DYNADDR register).
8 START	Start Interrupt Enable Interrupt on START and repeated START when needed (such as wakeup). See also STOP.
7-0 —	Reserved

70.6.7 Slave Interrupt Clear (SINTCLR)

Offset

Register	Offset
SINTCLR	14h

Function

Clear interrupt enables for select Slave Status (SSTATUS) bits. To clear an interrupt enable, write 1 to the corresponding bit in this register (SINTCLR). However, writing 0 has no effect.

Diagram

7-0 —	Reserved

70.6.9 Slave Errors and Warnings (SERRWARN)

Offset

Register	Offset
SERRWARN	1Ch

Function

Contains errors and warnings from I3C/I2C protocol, which includes internal issues such as overrun and underrun, detected errors and conditions like parity errors, CRC errors, and read terminations by the Master. Related to SSTATUS[ERRWARN] bit and SINTSET[ERRWARN] interrupt.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0										0		0		OWRITE	OREAD

Fields

Field	Function
31-22 —	Reserved
21 —	Reserved
20-18 —	Reserved
17 OWRITE	Over-write Error The SWDATAB/BE register was written when FULL.
16 OREAD	Over-read Error The SRDATAB register was read for more bytes than were available by the application. Likewise the SRDATAH if enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-14 —	Reserved
13 —	Reserved
12 —	Reserved
11 S0S1	S0 or S1 Error A S0 or S1 error has occurred and the slave is locked and waiting for an HDR Exit Pattern. Writing 1 to S0S1 causes the module to release the lock, but that should be used with great care. S0S1 clears automatically when an Exit Pattern is detected. Therefore, writing 1 to S0S1 must be used under controlled circumstances to avoid problems. Before starting to operate normally, the module then waits for a START (or repeated START) or STOP.
10 HCRC	HDR-DDR CRC Error HDR-DDR Cyclic Redundancy Check (CRC) error on a message from the master. This calls into question the data from the whole DDR command frame. This includes an HDR Restart or Exit being issued before an HDR-DDR message from master has finished.
9 HPAR	HDR Parity Error HDR Parity error or framing error on a message from the master. Note that the corresponding command or data that had the error will normally be in the Rx buffer (which can be read using the Slave Read Data Byte Register (SRDATAB)).
8 SPAR	SDR Parity Error SDR Parity error on a message from the master. This also sets the GETSTATUS Protocol Error sticky bit (which is cleared after a GETSTATUS read). For Read, this will be set if a Read Abort (timeout) occurs due to Master not driving clock for >100 µs during an I3C SDR Read.
7-5 —	Reserved
4 INVSTART	Invalid Start Error Invalid start with SCL falling while SDA = 1 is in a STOP condition.
3 TERM	Terminated Error The master terminated a read from a slave when an END was not set (on the same or previous read).
2 URUNNACK	Underrun and Not Acknowledged (NACKED) Error The internal to-bus buffer/FIFO was underrun in the read header and so the module NACKED the header.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 URUN	Underrun Error The internal to-bus buffer/FIFO was underrun during data read (the application did not provide the data fast enough). The END bit or register should be used if that was the last one.
0 ORUN	Overrun Error The internal from-bus buffer/FIFO was overrun (too many characters are coming in and cannot be processed by the the user application fast enough). Cutoff the RX_FIFO too close to the boundary when DUT is slave for SDR write/HDR-DDR write can cause an ORUN error to get set when FIFO is full.

70.6.10 Slave DMA Control (SDMACTRL)

Offset

Register	Offset
SDMACTRL	20h

Function

[DIP_I3C_00056]The DMA Control register allows for DMA to be used for inbound messages and outbound messages. The DMA Control register is limited in value for Slave use because the Slave has to be reactive. [end]Two common use models:

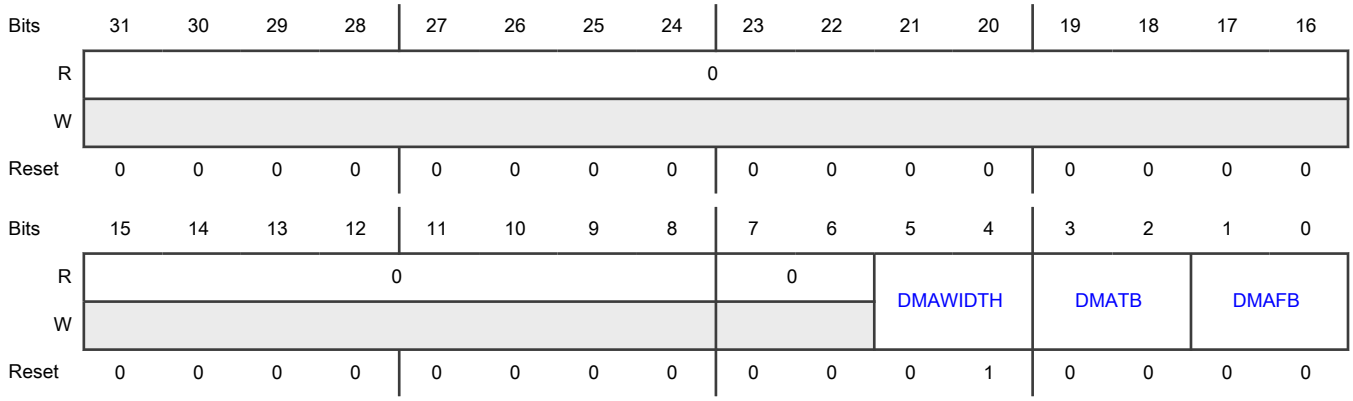
- From-bus collection to avoid being overrun: The SCONFIG[MATCHSS] bit is set, and then the processor enables the interrupts for START, and STOP, as well as enabling the DMA to collect the data. The START or STOP interrupt only occurs after a message is directed to the Slave (MATCHED bit set), and the DMA copied data can then be examined.

  NOTE

  Do not enable DMA after a transaction starts. DMA must be enabled only while enabling the slave and interrupts, to avoid any kind of RX FIFO overrun.

- To-bus for larger reads: Because I3C and I2C reads are preceded by a write that indicates what will be read (or in response to an IBI from the Slave), the DMA can be used to push through the data.
  - For I3C, the last value needs to be handled by the processor, unless the DMA moves wider words and is able to set the END bit (that is, 16-bit values when in byte mode or 32-bit values when in half-word mode).
  - For I2C, the last value is determined by the Master, so the DMA may end early or may run out when the Master still wants more.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	Width of DMA Operations The width of DMA operations, if configured to allow half-word data access. 00b,01b - BYTE, Default = 1 10b - HALF_WORD. Half word (16 bits). This will make sure that 2 bytes are free/available in the FIFO. 11b - Reserved
3-2 DMATB	DMA Write (To-bus) Trigger If enabled with 1 or 2, DMATB starts a request DMA on a Tx trigger. See the Slave Data Control Register (SDATACTRL). DMATB requests until full unless the DMA is set up as a trigger. DMATB cancels on MSTATUS[ERRWARN]. 00b - NOT_USED. DMA is not used 01b - ENABLE_ONE_FRAME. DMA is enabled for 1 Frame (ended by DMA or terminated). DMATB auto-clears on a STOP or START (see the Match START or STOP bit (SCONFIG[MATCHSS]). 10b - ENABLE. DMA is enabled until turned off. ENABLE must only be used with Master Message mode. 11b - Reserved
1-0 DMAFB	DMA Read (From-bus) Trigger If enabled with 1 or 2, DMAFB requests DMA on Rx trigger (see Slave Data Control Register (SDATACTRL)). It requests until empty unless the DMA is set up as a trigger.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DMAFB will cancel on SSTATUS[ERRWARN]. 00b - DMA not used 01b - DMA is enabled for 1 frame. Auto-clears on STOP or repeated START. See the Match START or STOP bit (SCONFIG[MATCHSS]). 10b - DMA Enable. DMA is enabled until it is turned off. 11b - Reserved

70.6.11 Slave Data Control (SDATACTRL)

Offset

Register	Offset
SDATACTRL	2Ch

Function

Assists in data control when no FIFO and FIFO when the FIFO is available (regardless of size). This allows some control over the FIFO behavior. In particular, it allows control of when to interrupt on fullness/emptiness and also controls behavior related to width, when not 1 byte wide.

2 —	Reserved
1 FLUSHFB	Flushes The From-bus Buffer/FIFO Not normally used.
0 FLUSHTB	Flush The To-bus Buffer/FIFO Used when the master terminates a to-bus (read) message prematurely.

70.6.12 Slave Write Data Byte (SWDATAB)

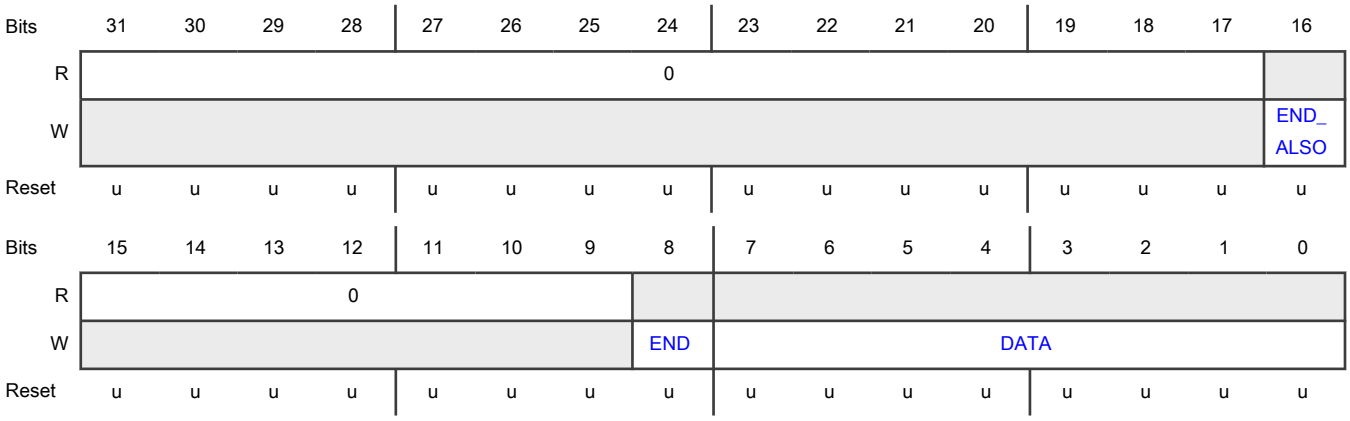
Offset

Register	Offset
SWDATAB	30h

Function

Write a byte of data, using the 9th bit to mark as the end (the last byte of the message). This register allows writing a byte to the bus (to Master) unless an external FIFO is used. This takes a byte and an end-of-data (last) marker bit. A byte should not be written unless there is room, as indicated by the TXNOTFULL bit being set in the SSTATUS register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End Also • If END_ALSO = 1, then this bit marks the last byte of the message • If END_ALSO = 0, then there are more bytes in the message END_ALSO is required to be used in I3C, but is optional in I2C. For HDR-DDR, the byte with the END_ALSO must be an even byte (2nd, 4th, 6th, and so on.) because DDR uses byte-pairs.
15-9 —	Reserved
8 END	End • If END = 1, then this bit marks the last byte of the message. • If END = 0, then there are more bytes in the message. END is required to be used in I3C, but is optional in I2C. For HDR-DDR, the byte with the END must be an even byte (2nd, 4th, 6th, and so on.) because DDR uses byte-pairs.
7-0 DATA	Data The data byte to send to the master.

70.6.13 Slave Write Data Byte End (SWDATABE)

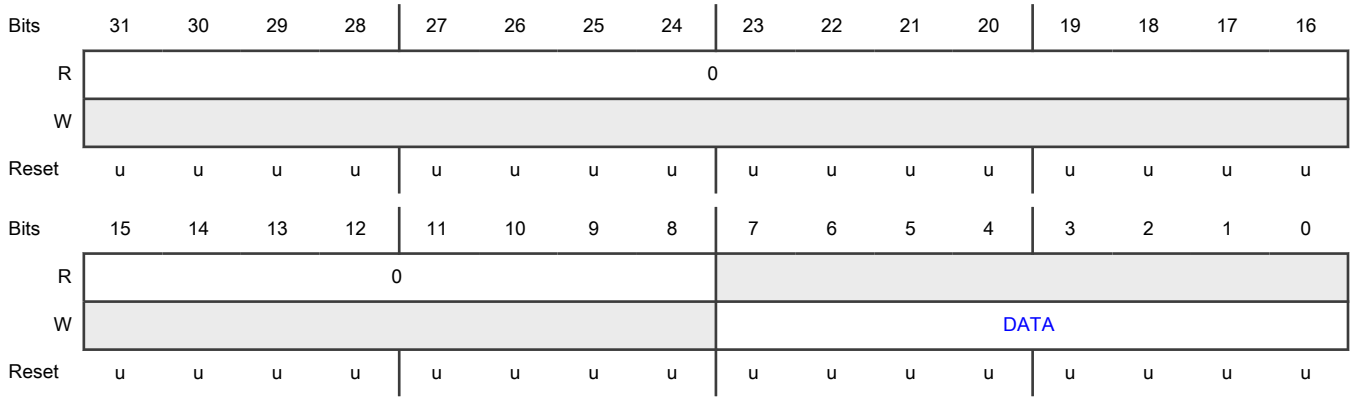
Offset

Register	Offset
SWDATABE	34h

Function

Write a byte of data, which is the end (the last byte of the message). Write a byte just like SWDATAB, but mark as end-of-data (last byte). For HDR-DDR, the byte with the END must be an even (2nd, 4th, 6th，and so on) because DDR uses byte-pairs. A byte should not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data The data byte to send to the master.

70.6.14 Slave Write Data Half-word (SWDATAH)

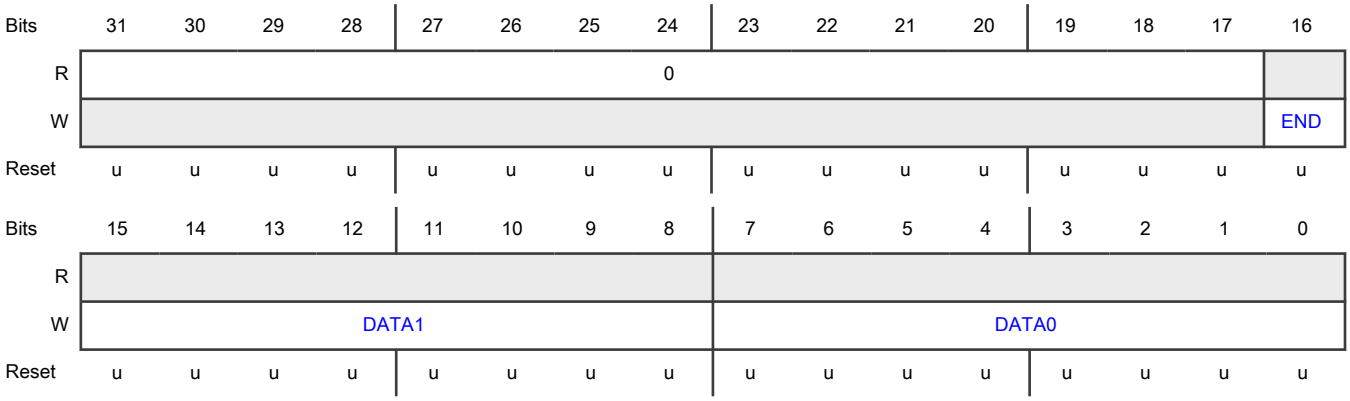
Offset

Register	Offset
SWDATAH	38h

Function

Write a half-word of data, using the 16th bit to mark as the end (the last byte of the half-word is the end). This register allows writing a half-word (pair of bytes) to the bus unless an external FIFO is used. This takes a half-word, which will send out the Low byte and then the High byte. An end-of-data (last) marker bit is allowed (or must be 0). A half-word should not be written unless there is room for both, as indicated by the use of Tx FIFO level trigger or TXCOUNT available space in the SDATACTRL register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of message • If END = 1, then END bit marks the last byte of the message • If END = 0, then there are more bytes in the message For this register, this always marks DATA1 as the end. END is required to be used in I3C, but is optional in I2C. For HDR-DDR (Double Data Rate), the byte with the END must be an even byte (2nd, 4th, 6th，and so on.) because DDR uses byte-pairs.
15-8 DATA1	Data 1 The 2nd byte to send to the master.
7-0 DATA0	Data 0 The 1st byte to send to the master.

70.6.15 Slave Write Data Half-word End (SWDATAHE)

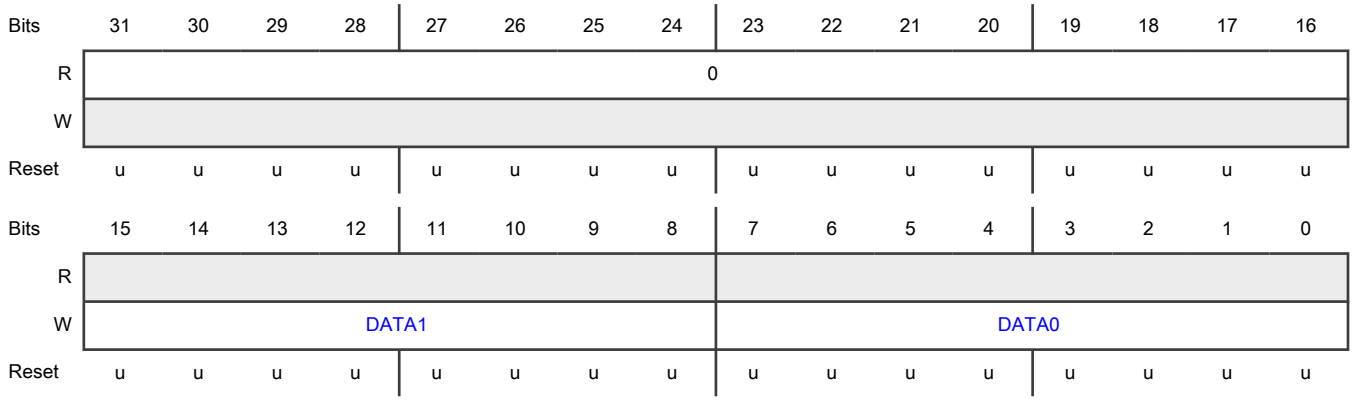
Offset

Register	Offset
SWDATAHE	3Ch

Function

Write a half word of data, which is the end (the last byte of the half word is the end). Write a half word (byte pair) just like MWDATAH, but mark the 2nd bytes as end-of-data (last byte). For HDR-DDR, the byte with the END must be an even (2nd, 4th, 6th，and so on) because DDR uses byte-pairs. A half word should not be written unless there is room for both, as indicated by the use of Tx FIFO level trigger or TXCOUNT available space in the SDATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data 1 The 2nd byte to send to the master.
7-0 DATA0	Data 0 The 1st byte to send to the master.

70.6.16 Slave Read Data Byte (SRDATAB)

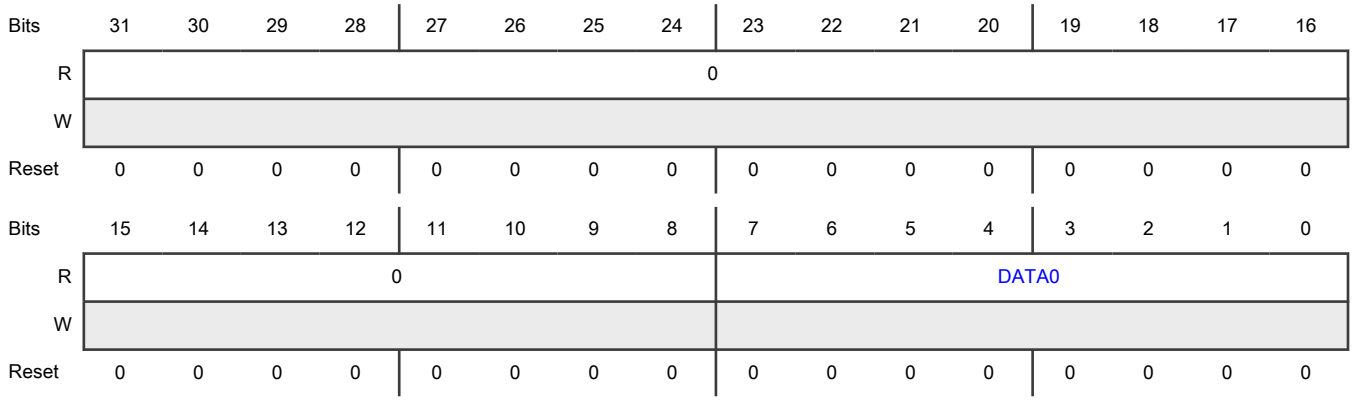
Offset

Register	Offset
SRDATAB	40h

Function

Read a byte of data. This register allows reading a byte from the bus (Master). A byte should not be read unless there is data waiting, as indicated by SSTATUS[RXPEND] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA0	Data 0 Byte read from the master.

70.6.17 Slave Read Data Half-word (SRDATAH)

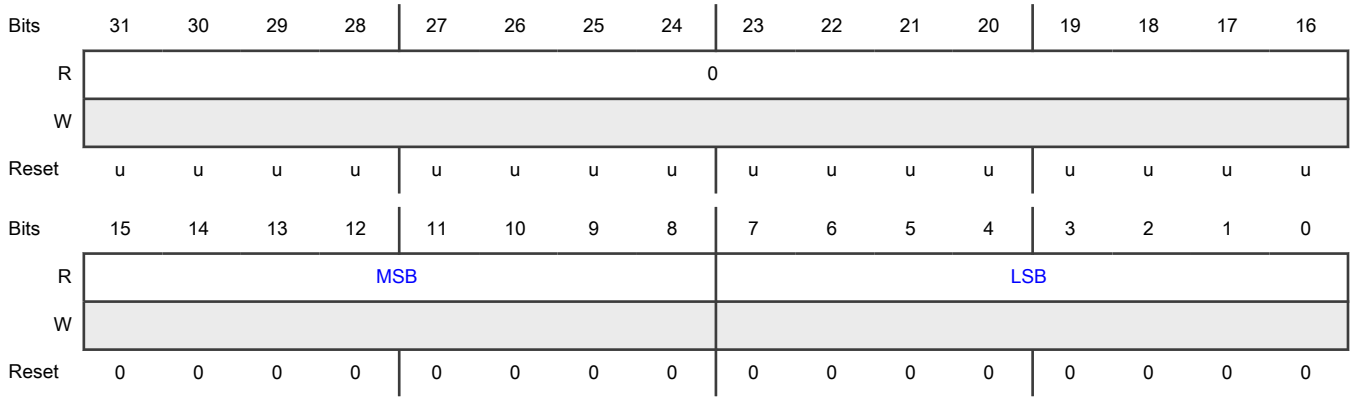
Offset

Register	Offset
SRDATAH	48h

Function

Read a half word of data. This register allows reading a half word (byte pair) written by the Slave on an SDR Read or DAA or DDR. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. A half word should not be read unless there is at least 2 bytes of data waiting, as indicated the Rx FIFO level trigger or RXCOUNT available space in the SDATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	The 2nd byte read from the slave.
7-0 LSB	The 1st byte read from the slave.

70.6.18 Slave Capabilities 2 (SCAPABILITIES2)

Offset

Register	Offset
SCAPABILITIES2	5Ch

Function

Indicates which features are available and supported in this I3C module, including master and/or slave capabilities, HDR modes, and others.

Diagram

4 I2C10B	I2C 10-bit Address Is 1 if I2C 10-bit address is allowed in MAP 1 (so MAPCNT must be 1 or greater). 0b - Does not support I2C10B 1b - Supports I2C10B
3-0 MAPCNT	Map Count Is 0 if no mapping ([DIP_I3C_00064]DYNADDR used to add more Static and/or Dynamic addresses to act as virtual slaves[end]). Else, indicates how many are allowed.

70.6.19 Slave Capabilities (SCAPABILITIES)

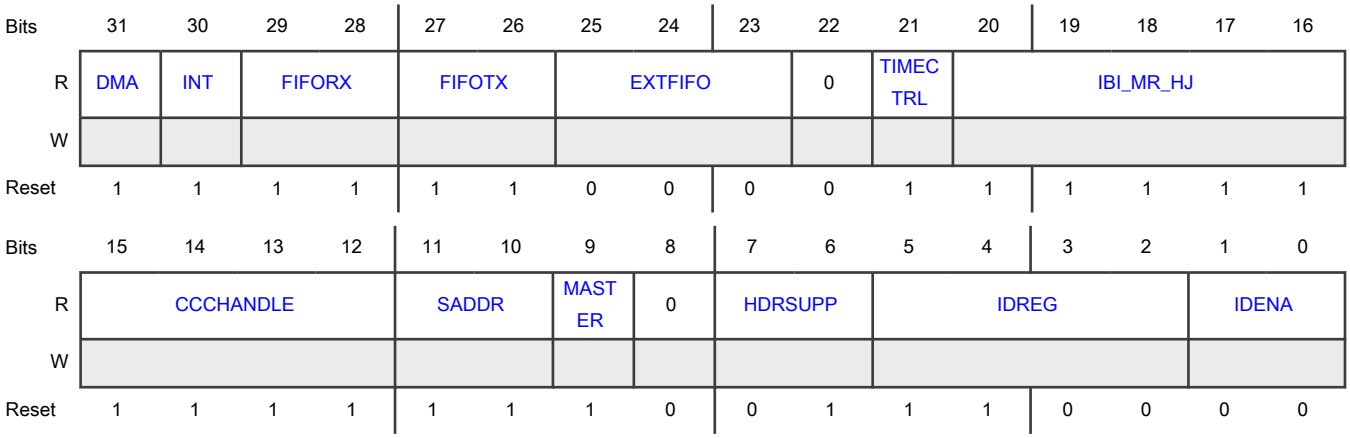
Offset

Register	Offset
SCAPABILITIES	60h

Function

Indicates which features are available and supported in this I3C module, including master and/or slave capabilities, HDR modes, and others.

Diagram



Fields

Field	Function
31 DMA	Direct Memory Access 0b - DMA is not supported 1b - DMA is supported
30 INT	Interrupts 0b - Interrupts are not supported 1b - Interrupts are supported
29-28 FIFORX	FIFO Receive Indicates if Rx (from-bus) is enabled and what size it is. 00b - FIFO_2BYTE. 2 (or 3)-byte Rx FIFO, the default FIFO receive value (FIFORX) 01b - FIFO_4BYTE. 4-byte Rx FIFO 10b - FIFO_8BYTE. 8-byte Rx FIFO 11b - FIFO_16BYTE. 16-byte Rx FIFO or larger

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-26 FIFOTX	FIFO Transmit Indicates if Tx (to-bus) is enabled and what size it is. 00b - FIFO_2BYTE. 2-byte Tx FIFO, the default FIFO transmit value (FIFOTX) 01b - FIFO_4BYTE: 4-byte Tx FIFO 10b - FIFO_8BYTE: 8-byte Tx FIFO 11b - FIFO_16BYTE: 16-byte Tx FIFO or larger
25-23 EXTFIFO	External FIFO Indicates whether External FIFOs are enabled. If External FIFOs are not enabled, then check FIFOTX and FIFORX for the internal FIFO. 000b - NO_EXT_FIFO. No external FIFO is available 001b - STD_EXT_FIFO. Standard available/free external FIFO 010b - REQUEST_EXT_FIFO. Request track external FIFO 011b - Reserved
22 —	Reserved
21 TIMECTRL	Time Control Specifies if any time-control type is supported or not. 0b - NO_TIME_CONTROL_TYPE. No time control is enabled 1b - ATLEAST1_TIME_CONTROL. At least one time-control type is supported
20-16 IBI_MR_HJ	In-Band Interrupts, Master Requests, Hot-Join Events Indicates which events (IBI, MR, and HJ) are allowed. For example, if this field is set to 00011b, it means that IBI (bit 0) and IBI_HAS_DATA (bit 1) functionality are both enabled. • Bit 0: IBI: Supports the application generating an IBI • Bit 1: IBI_HAS_DATA: When bit 0 = 1, the IBI has data from the SCTRL register • Bit 2: MASTER_REQUEST: Supports the application generating a Master Request for a secondary master • Bit 3: HOT_JOIN: Supports the application generating Hot-Join • Bit 4: BAMATCH_FOR_BUS: Use the BAMATCH register for bus-available timing
15-12 CCCHANDLE	Common Command Codes Handling Indicates who handles CCC between I3C module and the user application. • Bit 0: BLOCK_HANDLE: The block (I3C module) handles events, activities, status, HDR, and if enabled for it, ID and static address related things

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Bit 1: MAX_READ_WRITE: The block handles maximum read and write lengths, and max data speed • Bit 2: PENDINT_ACTSTATE: GETSTATUS CCC (command code) returns the SCTRL register's Pending interrupt (PENDINT) and activity state (ACTSTATE) fields • Bit 3: VENDINFO: GETSTATUS CCC returns the SCTRL register's VENDINFO (vendor info) bits
11-10 SADDR	Static Address Indicates how the static address is handled. 00b - NO_STATIC. No static address 01b - STATIC. Static address is fixed in hardware 10b - HW_CONTROL. Hardware controls the static address dynamically (for example, from the pin strap) 11b - CONFIG. SCONFIG register supplies the static address
9 MASTER	Master Specifies if a master capability is supported or not. 0b - MASTERNOTSUPPORTED. Master capability is not supported. 1b - MASTERSUPPORTED. Master capability is supported.
8 —	Reserved
7-6 HDRSUPP	High Data Rate Support Indicates which HDR modes are supported. • Bit 0 = 1: Double Data Rate • Bit 1: Reserved
5-2 IDREG	ID Register Bits indicate what is in the registers vs. what is in the hardware. • Bit 0: ID_INSTANCE: ID Instance is a register, and is used if there is no PARTNO register. • Bit 1: IDRAND: an ID Random field is available • Bit 2: DCR: a Device Characteristic Register (DCR) is available • Bit 3: BCR: a Bus Characteristics Register (BCR) is available
1-0 IDENA	ID 48b Handler Indicates who handles the ID 48b value. 00b - APPLICATION. Application handles ID 48b 01b - HW. Hardware handles ID 48b

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - HW_BUT. In hardware but the I3C module instance handles ID 48b. 11b - PARTNO. A part number register (PARTNO) handles ID 48b

70.6.20 Slave Maximum Limits (SMAXLIMITS)

Offset

Register	Offset
SMAXLIMITS	68h

Function

Indicates the limits set by the master (or the original requested limits). The maximum limits are not enabled in the hardware design, including maximum read and write lengths. If the maximum read/write lengths are enabled, then the current setting (including default request) shows up in this register (SMAXLIMITS).

Diagram

Fields

Field	Function
31-28 —	Reserved
27-16 MAXWR	Maximum Write Length The maximum write length must be between 8 to 4095 (saturation). The application must not set the maximum write length longer than what the master sets the maximum write length to. The application should set the maximum write length to be less than what the master sets the maximum write length to.
15-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-0 MAXRD	Maximum Read Length The maximum read length must be between 16 to 4095 (saturation). The application should not set the maximum read length longer than what the master sets the maximum read length to. The application should set the maximum read length to be less than what the master sets the maximum read length to.

70.6.21 Slave ID Part Number (SIDPARTNO)

Offset

Register	Offset
SIDPARTNO	6Ch

Function

Allows an application to write the ID part-number. The application must write a non-zero value into the PARTNO field, because 0 is not valid.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-0 PARTNO	Part number

70.6.22 Slave ID Extension (SIDEXT)

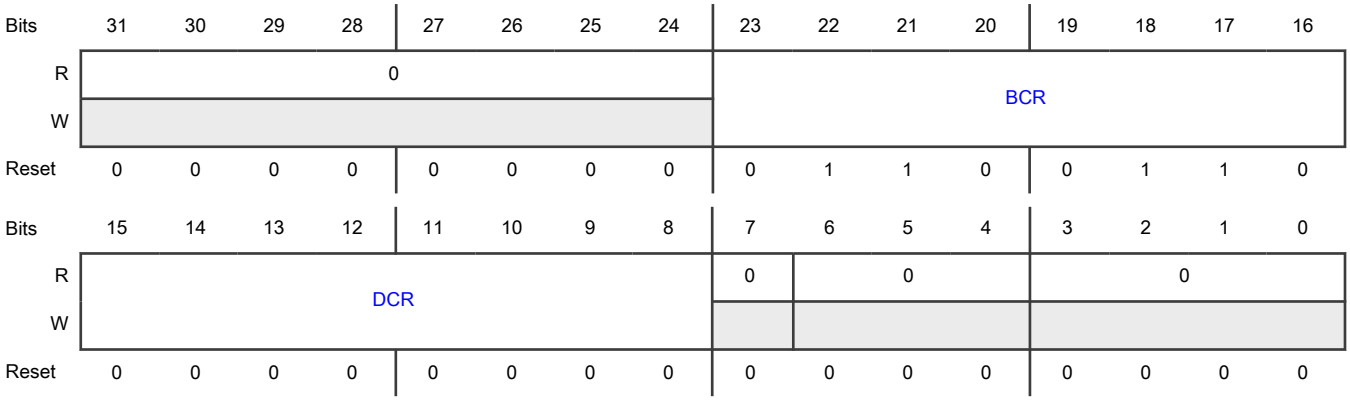
Offset

Register	Offset
SIDEXT	70h

Function

Allows an application to write the ID extension of the Device Characteristic Register (DCR) and/or the Bus Characteristics Register (BCR).

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BCR	Bus Characteristics Register Set the Bus Characteristics Register (BCR) if configured for it. This controls features like Secondary Master, slow speed requirements, and others.
15-8 DCR	Device Characteristic Register Set the Device Characteristic Register (DCR) if configured for it.
7 —	Reserved
6-4 —	Reserved
3-0 —	Reserved

70.6.23 Slave Vendor ID (SVENDORID)

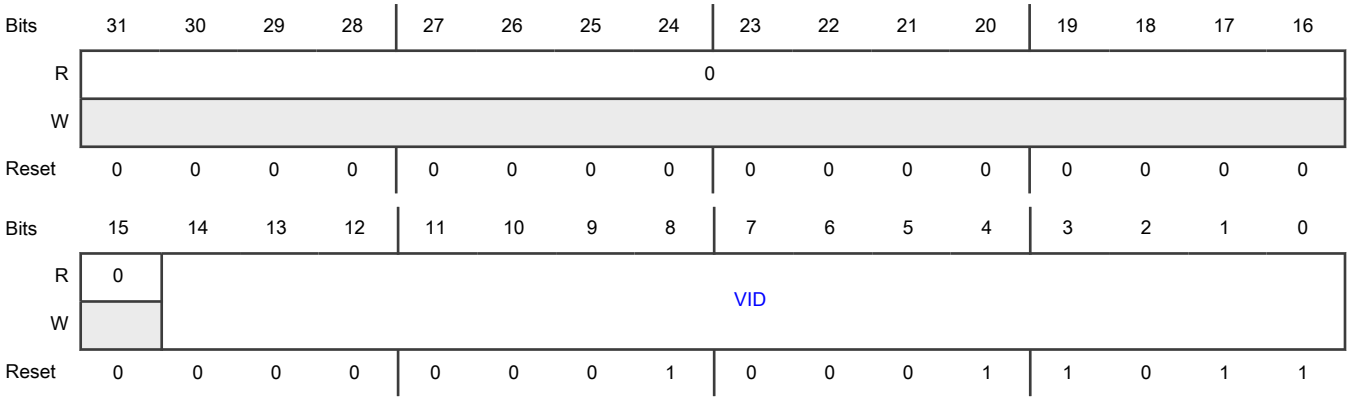
Offset

Register	Offset
SVENDORID	74h

Function

Allows an application to write the Vendor ID. The default is set from the constant field and is the chip vendor ID. If using the chip vendor ID, the PARTNO does not collide with other uses. The MIPI Vendor ID is available to all companies (MIPI membership is not required) to get a vendor ID make a request at the mipi.org website.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 VID	Vendor ID May be set to the 15-bit MIPI Vendor ID, if used.

70.6.24 Slave Time Control Clock (STCCLOCK)

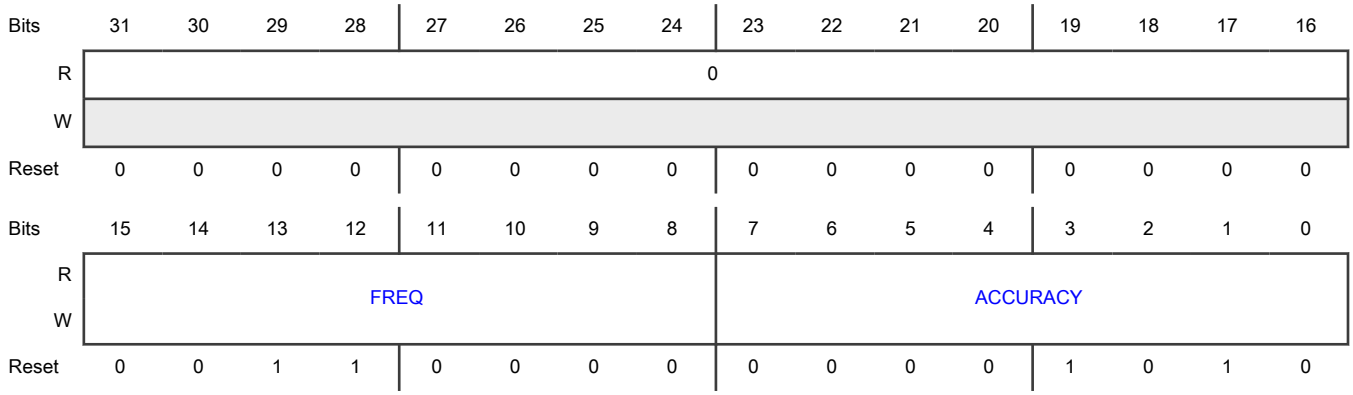
Offset

Register	Offset
STCCLOCK	78h

Function

Allows an application to dynamically set the time control clock and accuracy information. The clock frequency and accuracy are constant set by the hardware. But, if the clock can be adjusted (that is, divided) or if the accuracy could vary with knowable information, then the clock may be set via this register. This register must be updated whenever the clock source is changed.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 FREQ	Clock Frequency Clock frequency in 0.5-MHz steps. For example, 10 MHz is FREQ = 20. Default set by parameters if configured.
7-0 ACCURACY	Clock Accuracy Clock accuracy in 1/10ths of %. For example, 1.5% is 15. Default set by parameters if configured.

70.6.25 Slave Message Map Address (SMSGMAPADDR)

Offset

Register	Offset
SMSGMAPADDR	7Ch

Function

When the DYNADDR register is used to build a list of extra DAs or SAs to match, this register allows the software to determine which address was matched when STATUS[MATCHED]= 1. It holds the last 3 matches.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3-0 —	Reserved

70.6.27 Master Control (MCTRL)

Offset

Register	Offset
MCTRL	84h

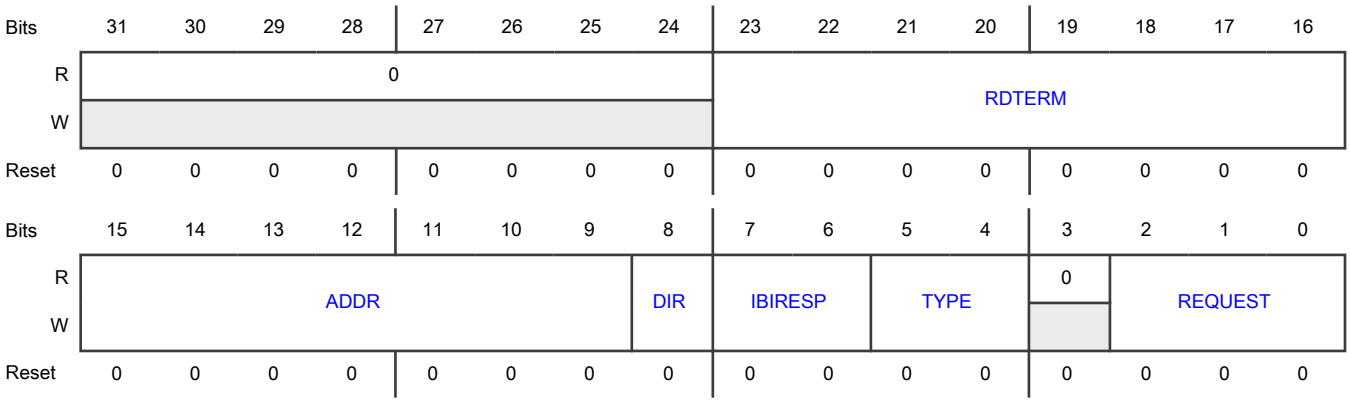
Function

Starts activities on the I3C or I2C bus. Also see the MWMSG register. A request cannot be changed when a message is in flight, the REQUEST field will go to 0 automatically.

NOTE

If MCONFIG[MSTENA] is set for I2C Master mode (legacy I2C), then no REQUEST other than 1 or 2 are accepted. Likewise, fields are constrained to I2C supported fields.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RDTERM	Read Terminate The termination counter for reads. • For I2C, RDTERM controls when to NACK the read. • For I3C, RDTERM can be use to terminate (end) a read that is too long. — RDTERM = 0 has no effect — RDTERM = 1 terminates after the next character — RDTERM = 2 terminates after the next 2 characters Supports up to 255 characters. If in Double Data Rate (DDR) mode, then RDTERM terminates the read, based on word counts (for DDR) vs. byte counts (for SDR). **NOTE** The value 1 may be written any time, but a number larger than 1 should normally be written when starting the EmitStartAddress. Self clears on complete.
15-9 ADDR	Address I3C Dynamic Address or I2C Static Address. Some values are not allowed depending on whether using I3C or I2C bus.
8 DIR	Direction 0b - DIRWRITE: Write 1b - DIRREAD: Read
7-6 IBIRESP	In-Band Interrupt Response The response to use when you get an IBI from START, and to force using a IBI ACK NACK request when completing a manual IBI. Completion of a manual IBI means that the slave Dynamic Address (DA) is known, and so the mandatory byte (or not) is specified by the application when ACKing. **NOTE** Master Request and Hot-Join will always go to Manual and so the application will have to decide. MIBIRESP register is also used when a message is emitted in Message Mode using the MWMSG_SDR or MWMSG_DDR registers. If an IBI with MDB (mandatory byte) is ACKED, the Master will limit to a max of 8 more bytes after the MDB. RDTERM = 1 can be used with Request = None to terminate data from Slave sooner.

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Meaning when REQUEST = 1 (EmitStartAddr) or REQUEST = 7 (AutoIBI)</th><th>Meaning when REQUEST = 3 (IBIAckNack)</th></tr>
<tr><td>0</td><td>ACK. Mandatory byte (or not) is decided by Master In-band Interrupt Registry and Rules (MIBIRULES).</td><td>ACK. No mandatory byte.</td></tr>
<tr><td>1</td><td>NACK</td><td>NACK</td></tr>
<tr><td>2</td><td>ACK with mandatory byte ignores MIBIRULES. Do not use unless only Slaves with a mandatory byte can cause an IBI.</td><td>ACK with mandatory byte.</td></tr>
<tr><td>3</td><td>Manual. Stop and wait for a decision using the IBIAckNack request.</td><td>Reserved</td></tr>
</table>
00b - ACK. Acknowledge. A mandatory byte (or not) is decided by the Master In-band Interrupt Registry and Rules Register (MIBIRULES). The meaning for Manual (IBI ACK NACK) mode is that this setting is ACK with no mandatory byte.
01b - NACK. Not acknowledge
10b - ACK_WITH_MANDATORY. Acknowledge with mandatory byte (ignores the MIBIRULES register). Acknowledge with mandatory byte should not be used, unless only slaves with a mandatory byte can cause an IBI.
11b - MANUAL. Stop and wait for a decision using the IBI ACK NACK request. The meaning for Manual (IBI ACK NACK) mode is that this setting is reserved.
</td></tr>
<tr><td>5-4

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Meaning - DAA processing TYPE (rules) when REQUEST = 4 (ProcessDAA)</th></tr>
<tr><td>1</td><td>Reserved</td></tr>
<tr><td>2</td><td>DA comes from MWDATAB[VALUE], if not 1st time, STOPs after assignment.</td></tr>
<tr><td>3</td><td>Reserved</td></tr>
</table>
00b - I3C. When REQUEST = 1 (EmitStartAddr), the SDR mode of I3C. When REQUEST = 6 (ForceExit), the Exit pattern.
01b - I2C. When REQUEST = 1 (EmitStartAddr), the Standard I2C protocol.
10b - DDR. When REQUEST = 1 (EmitStartAddr), the HDR-DDR mode of I3C. Enter DDR mode (7E and then ENTHDR0), if the module is not in DDR mode. The 1st byte written to the Tx FIFO must be a command and already in the FIFO. To end DDR mode, use ForceExit. When REQUEST = 6 (ForceExit), Slave Reset.
11b - Reserved
</td></tr>
<tr><td>3
—</td><td>Reserved</td></tr>
<tr><td>2-0
REQUEST</td><td>Request
Emits the requested operation when doing in pieces vs. doing by message. The Master Status (MSTATUS) should be checked because the state of the Master must be such that the request makes sense. For example, the system cannot do SDR from DDR (but can do DDR from SDR since it enters), cannot use an incorrect request if in DAA mode, and other similar situations.
000b - NONE. Returns to NONE when finished with any request. The MSTATUS register indicates the master's state. See also AutoIBI mode. NONE is only written as 0: when setting RDTERM to 1 (to stop a read in progress) or when setting IBI response field (IBIRESP) for MSG use.
001b - EMITSTARTADDR. Emit START with address and direction from a stopped state or in the middle of a Single Data Rate (SDR) message. If from a stopped state (IDLE), then emit start may be prevented by an event (like IBI, MR, HJ), in which case the appropriate interrupt is signaled. Emit START can be resubmitted.
010b - EMITSTOP. Emit a STOP on bus. Must be in Single Data Rate (SDR) mode. If in Dynamic Address Assignment (DAA) mode, Emit stop will exit DAA mode.
011b - IBIACKNACK. Manual IBI ACK or NACK. When IBIRESP has indicated a hold on an IBI to allow a manual decision, this request completes it. Uses IBIRESP to provide the information.
100b - PROCESSDAA. If not in Dynamic Address Assignment (DAA) mode now, will issue START, 7E, ENTDAA, and then emits 7E/R to process first Slave. Stops just before the new Dynamic Address (DA) is to be emitted. The DA is written using MWDATAB and then Process DAA is requested again to write the new address, and then starts the next unless marked to STOP. An MSTATUS indicating NACK means DA was not accepted (for example, parity error). If PROCESSDAA is NACKED on the 7E/R, which means no more Slaves need a DA, then a
</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	COMPLETE will be signaled (along with DONE) and a STOP issued. If TYPE = 2 or TYPE = 3, the DA will be assigned and then it will emit a STOP vs. starting a new 7E/R request. If TYPE = 1 or TYPE = 3, then the DA is taken from the ADDR field (bits 6:0). 101b - Reserved 110b - Force Exit and Slave Reset. Emit an Exit Pattern from any state, but end Double Data Rate (DDR) (including MSGDDR). If in DDR mode，include a STOP afterward. If TYPE == 2, then it performs a Slave Reset action (RSTACT can prevent the reset in the slave). Slave Reset may follow right after RSTACT CCC or after STOP. 111b - AUTOIBI. Hold in a stopped state, but auto-emit START, 7E when the slave is holding down SDA to get an IBI. Actual IBI handling is defined by IBIRESP.

70.6.28 Master Status (MSTATUS)

Offset

Register	Offset
MSTATUS	88h

Function

Status for the master, including which events caused the interrupts. The peripherals share the IRQ (called Parallel-to-Slave status).

Because a peripheral can only be in a Master or Slave mode, but not be in both modes at the same time, then only one (Slave or Master peripheral) can be the cause of the IRQ. So, if there is an IRQ and the peripheral is a Master, then this register (MSTATUS) has the status.

If there is an IRQ and the peripheral is a Slave, then the SSTATUS register has the status.

Self clears on COMPLETE.

If MCONFIG is set for I2C only, some states and bits will never be active (for example, DAA or IBI).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W			W1C			W1C	W1C	W1C								
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30-24 IBIADDR	IBI Address The address of the IBI (while IBITYPE = 1) or the Master Request (MR)(while IBITYPE = 2) or is 7'h2 if Hot-Join (while IBITYPE = 3).
23-20 —	Reserved
19 NOWMASTER	Now Master (now this module is a master) NOWMASTER = 1 if the module is now a master (it was previously a slave, acceptance was requested from the previous master and it was accepted). Note that the reverse operation (master becomes a slave) does not need an interrupt, because the application is granting it through the Common-Command-Code status bit MSTATUS[CCC].
18-16 —	Reserved
15 ERRWARN	Error Or Warning ERRWARN = 1, if an error occurred (like improper register use, overrun or underrun of FIFO/buffer, invalid parity or CRC in DDR read, and others). See the Master Errors and Warnings Register (MERRWARN).
14 —	Reserved
13 IBIWON	In-Band Interrupt (IBI) Won IBIWON is set to 1 if IBI or MR or HJ won the arbitration on a header address, regardless of whether it was NACKED or ACKED. Note that this requires manual intervention for MR and HJ, and optionally requires it for IBI if the MCTRL[IBIRESP] indicates Manual (is 3).
12 TXNOTFULL	TX buffer/FIFO not yet full TXNOTFULL = 1 if TX buffer/FIFO or message register can accept another byte or half-word; FIFO will use trigger level. If DMA enabled for TX, it will transfer data as long as not full. Default: 1.
11 RXPEND	RXPEND The receiving message from a slave and byte(s) are in the input buffer/FIFO. • If using a FIFO, this is one FIFO trigger's worth. • If DMA is enabled for Rx, then DMA will be signaled. RXPEND will self-clear when the data is read.
10	Complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
COMPLETE	A message has completed: • With MWMSG_SDR or MWMSG_DDR, this is count to 0. • With MCTRL using EmitStartAddr, this is the end of write or read by terminate or end. • With IBI (AutoIBI or EmitStartAddr), this is the end of IBI data (if any).
9 MCTRLDONE	Master Control Done After the module completes an MCTRL request, MCTRLDONE is set to 1 . MCTRLDONE self-clears when writing a new control, otherwise write to MCTRLDONE to clear it (MCTRLDONE). • When MCTRL[REQUEST] = EmitStartAddr, MCTRLDONE fires (sets to 1) when the address went out (and was ACKED or NACKED or ended in an IBI). However if ACKED, it then fires COMPLETE when the write or read data has completed. • When MCTRL[REQUEST] = ProcessDAA, this fires when the module is ready to emit the Dynamic Address (DA) for the slave, or when no more slaves are ACKing. This can be determined using the MSTATUS[BETWEEN] and MSTATUS[STATE] fields.
8 SLVSTART	Slave Start If a slave is/was requesting a START by holding SDA low, SLVSTART is set to 1. Handling starts automatically if MCTRL[REQUEST] = AutoIBI.
7-6 IBITYPE	In-Band Interrupt (IBI) Type Indicates the type of In-Band Interrupt (IBI) of the last event that won the arbitration (whether the interrupt is ACKED or NACKED or pending) 00b - NONE. Cleared when IBI Won bit (MSTATUS[IBIWON]) is cleared 01b - IBI. In-Band Interrupt 10b - MR. Master Request 11b - HJ. Hot-Join
5 NACKED	Not Acknowledged If NACKED = 1, then the last Start and Address was NACKED (was not ACKED by the addressed slave).
4 BETWEEN	Between Between messages or Dynamic Address Assignments (DAA) Active if: • STATE is MSGSDR, DDR, or DAA, the state is between messages/DAAs and so is expecting a new messages/DAAs to start (or STOP or Exit). • STATE is NORMACT, then the module is stuck waiting on the Tx FIFO to be not-empty or the Rx FIFO to be not full. 0b - Inactive. For other cases. 1b - Active. If STATE is MSGSDR, DDR, DAA, or if STATE is NORMACT.
3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2-0 STATE	State Of The Master Indicates the current master state 000b - IDLE: the bus has Stopped. 001b - SLVREQ. (Slave Request state) the bus has Stopped but a slave is holding SDA low. If using auto-emit IBI (MCTRL[AutoIBI]), then the master will not stay in the Slave Request state. 010b - MSGSDR. In Single Data Rate (SDR) Message state (from using MWMSG_SDR) 011b - NORMACT. Normal active Single Data Rate (SDR) state (from using MCTRL and MWDATAn and MRDATAn registers). The master stays in the NORMACT state until a STOP is issued. 100b - MSGDDR. In Double Data Rate (DDR) Message mode (from using MWMSG_DDR or using the normal method with DDR). The master stays in the DDR state, until the master exits using EXIT (emits the Exit pattern). 101b - DAA. In Enter Dynamic Address Assignment (ENTDAA) mode 110b - IBIACK. Waiting for an In-Band Interrupt (IBI) ACK/NACK decision 111b - IBIRCV. Receiving an In-Band Interrupt (IBI), this IBIRCV state is used after IBI/MR/HJ has won the arbitration, and IBIRCV state is also used for IBI mandatory byte (if any) and any bytes that follow.

70.6.29 Master In-band Interrupt Registry and Rules (MIBIRULES)

Offset

Register	Offset
MIBIRULES	8Ch

Function

Contains the rules for using IBI, and keeps a registry of the slaves that use the IBI byte.

Allows defining the IBI mandatory byte rules for the Slaves. It allows defining the Slaves which do not have a mandatory byte or the ones which do (whichever is easier and fits).

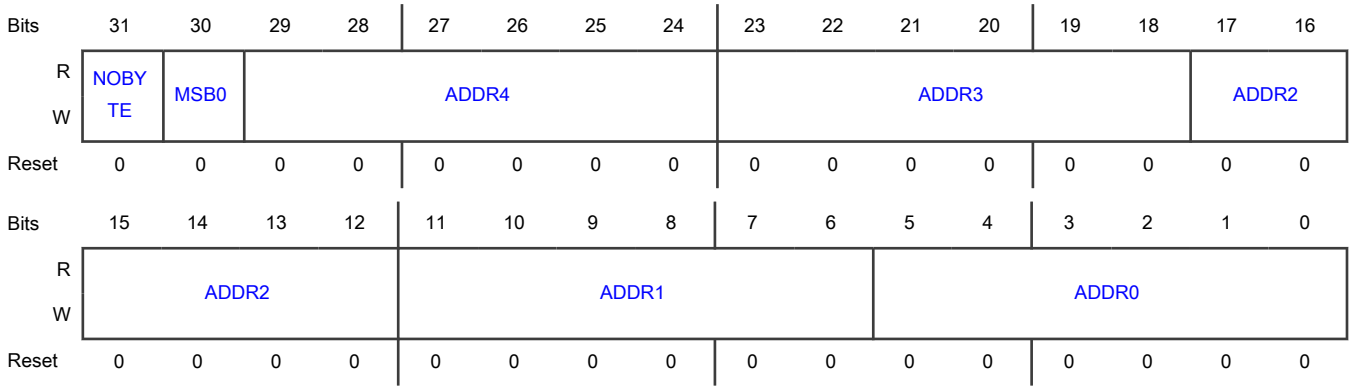
Concerning ADDRn fields: The address is 6 bits. Assuming that MIBIRULES[MSB0] = 1, then each address has its most significant bit = 0. This means that each address is 7 bits (usually written as A7 to A1) and the A7 must be 0. If the application does not use that optimal convention, then the Manual method of IBI ACK handling must be used (see MCTRL).

- The default is that the ADDRn values indicate the slaves with a mandatory byte.
- If MIBIRULES[NOBYTE] is set, then the ADDRn values indicate slaves that do not have a mandatory IBI byte.

NOTE

A7 = 0 is only needed for Slaves that use IBI. For legacy I2C devices, A7 can use any valid value, because I2C devices cannot cause an IBI.

Diagram



Fields

Field	Function
31 NOBYTE	No IBI byte • If NOBYTE = 1, then the ADDRx fields refer to slaves without a mandatory IBI byte. • If NOBYTE = 0, then the ADDRx fields refer to slaves with a mandatory IBI byte.
30 MSB0	Set Most Significant address Bit to 0 If MSB0 = 1, then all I3C dynamic addresses are assigned with the MSb==0 (most significant bit). This allows the START header to be optimized.
29-24 ADDR4	ADDR4 Address of slave with or without Mandatory IBI byte. If 0, then the address does not apply.
23-18 ADDR3	ADDR3 Address of slave with or without Mandatory IBI byte. If 0, then the address does not apply.
17-12 ADDR2	ADDR2 Address of slave with or without Mandatory IBI byte. If 0, then the address does not apply.
11-6 ADDR1	ADDR1 Address of slave with or without Mandatory IBI byte. If 0, then the address does not apply.
5-0 ADDR0	ADDR0 Address of slave with or without Mandatory IBI byte. If 0, then the address does not apply.

70.6.30 Master Interrupt Set (MINTSET)

Offset

Register	Offset
MINTSET	90h

Function

Set interrupt enables for select bits in MSTATUS. Reading the MINTSET register returns the status of the interrupt enables.

- To activate an interrupt enable, write 1.
- To disable an interrupt enable, write 1 to the appropriate bit in the Interrupt Clear Register (MINTCLR). Writing 0 to the interrupt enable in this register (MINTSET) does not disable the interrupt.

The Interrupt registers allow masking interrupt sources, as well as checking which interrupts have activated in the MSTATUS register. The normal method is to enable an interrupt and then once that interrupt fires, the interrupt is either cleared by writing the MSTATUS register or cleared by action on the corresponding data register. The interrupt is level held, meaning that the interrupt stays set until the cause is cleared, by some method. The module prevents races so that if a new event comes in, that new event will not be lost.

These interrupts are parallel to the Slave Interrupt Set (SINTSET)/Slave Interrupt Clear (SINTCLR) set, and only one interrupt set is active depending on state (Master or Slave operation).

- MINTSET: Sets interrupt enables for MSTATUS bits. Reading MINTSET register returns the status of the interrupt enables.
- MINTCLR: Clears interrupt enables for MSTATUS bits.
- MINTMASKED: Returns the value of the MSTATUS bits ANDed with their interrupt enables.

70.6.33 Master Errors and Warnings (MERRWARN)

Offset

Register	Offset
MERRWARN	9Ch

Function

Contains errors and warnings from I3C/I2C protocol. When any errors or warnings are not 0, then the MSTATUS[ERRWARN] bit will be set.

Parallel-to-slave ERRWARN:

- In Master mode, use this register (MERRWARN).
- In Slave mode, use the slave register Slave Errors and Warnings (SERRWARN).

The error bits in both registers (MERRWARN and SERRWARN) are similar in meaning.

10 HCRC	High Data Rate CRC Error A Cyclic Redundancy Check (CRC) error occurred from a DDR read.
9 HPAR	High Data Rate Parity • Parity error from a DDR read, this includes a bad preamble on a read. • Does not stop the read, because it is not safe to terminate (because the read data may get mis-framed). • Will end on a run of 1 second.
8-5 —	Reserved
4 —	Reserved
3 WRABT	Write Abort Error • The I2C slave NACKED the write data, terminating the message. • WRABT self-clears if the MCTRL register is written. For example, the Master is writing in I2C and the Slave NACKED the write.
2 NACK	Not Acknowledge Error • The slave or slaves NACKED (not acknowledged) the last address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If 7E was the address, then all slaves NACKED the last address. • NACK self-clears if the MCTRL register is written. **NOTE** If HDR, it would be "not accept" (vs. NACK).
1 —	Reserved
0 —	Reserved

70.6.34 Master DMA Control (MDMACTRL)

Offset

Register	Offset
MDMACTRL	A0h

Function

[DIP_I3C_00063]The DMA Control register allows for DMA to be used for inbound and outbound messages. DMA is much more useful for a Master than for a Slave, because the Master is directing the bus traffic and actions, so setting up DMA is more natural for a Master.[end] DMA can be used with a Master in following ways:

- Push or Pull data to go with an MCTRL[REQUEST] = EMITSTARTADDR request written by the processor.
- Implementing a message mode, to be completely DMA-controlled.

7-6 —	Reserved
5-4 DMAWIDTH	DMA Width Specifies the data width of DMA operations. 00b,01b - BYTE 10b - HALF_WORD. Half-word (16 bits). This makes sure that 2 bytes are free/available in FIFO. 11b - Reserved
3-2 DMATB	DMA To Bus DMA Write (to-bus) trigger. If enabled with DMATB = 1 or DMATB = 2, then the I3C module starts request DMA on TX trigger. See the Master Data Control Register (MDATACTRL). The I3C module requests until full, unless DMA is set up as a trigger. DMAFB cancels on MSTATUS[ERRWARN]. 00b - NOT_USED. DMA is not used 01b - ENABLE_ONE_FRAME. DMA is enabled for 1 frame (ended by DMA or Terminated). DMATB auto-clears on STOP or START. See MCONFIG[MATCHSS]. 10b - ENABLE. DMA is enabled until DMA is turned off. Normally DMA ENABLE should only be used in Master Message mode. 11b - Reserved
1-0 DMAFB	DMA From Bus DMA Read (from-bus) trigger. If enabled with DMAFB = 1 or DMAFB = 2, then the I3C module requests DMA on an Rx trigger (see MDATACTL register). The I3C module requests until empty, unless the DMA is set up as a trigger. DMAFB cancels on MSTATUS[ERRWARN]. 00b - NOT_USED. DMA is not used 01b - ENABLE_ONE_FRAME. DMA is enabled for 1 frame. DMAFB auto-clears on STOP or repeated START. See MCONFIG[MATCHSS]. 10b - ENABLE. DMA is enabled until the DMA is turned off. 11b - Reserved

70.6.35 Master Data Control (MDATACTRL)

Offset

Register	Offset
MDATACTRL	ACh

Function

The Data Control register (alias of the Slave one) assists in data control when there is no FIFO, and assists FIFO when FIFO is available (regardless of size). This allows some control over the FIFO behavior. In particular, it allows control of when to interrupt on fullness/emptiness and also controls behavior related to width, when not 1 byte wide.

NOTE

If flushing a FIFO when DMA is in use, disable the DMA channel first.

NOTE

FIFO flush should not be used when a message (in that direction) is in flight.

Diagram

1 FLUSHFB	Flush From-bus Buffer/FIFO Flushes the from-bus buffer/FIFO. FLUSHFB is not normally used.
0 FLUSHTB	Flush To-bus Buffer/FIFO Flush the to-bus buffer/FIFO. Used when the master terminates a to-bus message (read) prematurely.

70.6.36 Master Write Data Byte (MWDATAB)

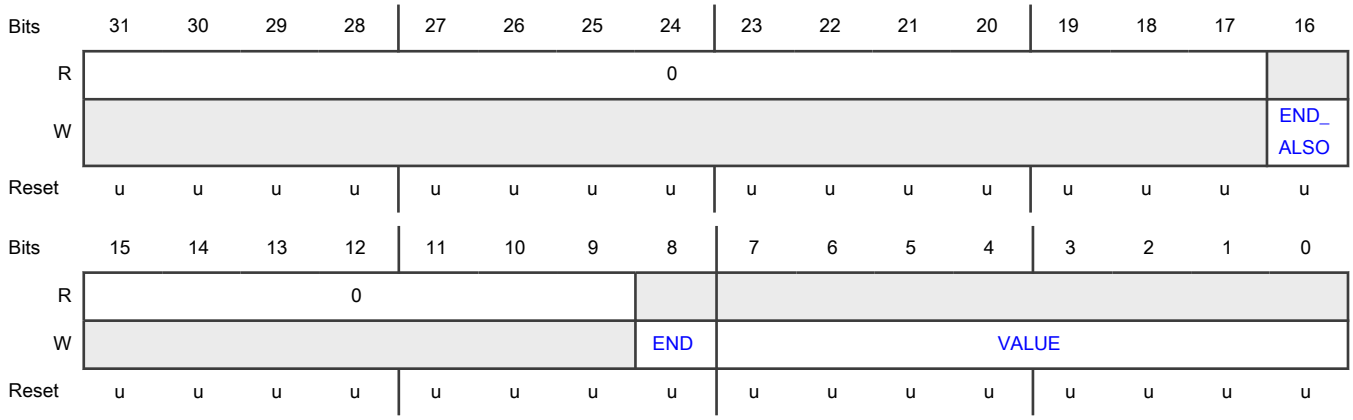
Offset

Register	Offset
MWDATAB	B0h

Function

Write a byte of data, possibly the last byte. The MWDATAB register is the alias of the Slave Write Data Byte (SWDATAB). The MWDATAB register allows writing bytes to send onto the bus. This is only used when using Master Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 END_ALSO	End of Message Also End outbound message normally. Any message has to end indicates that it is the last message to go out. This method can be used and also the MDATABE register. • If END_ALSO = 1, this marks the last byte of the message. • If END_ALSO = 0, it is assumed there are more bytes. This is required to be used in I3C and is optional in I2C. For HDR-DDR, the byte with the END_ALSO must be an even byte (2nd, 4th, 6th，and so on) because DDR uses byte-pairs.
15-9 —	Reserved
8 END	End of Message • If END = 1, then the END bit marks the last byte of the message. • If END = 0, then it is assumed there are more bytes. This is required to be used in I3C and is optional in I2C. For HDR-DDR, the byte with the END must be an even byte (2nd, 4th, 6th, and so on) because DDR uses byte-pairs.
7-0 VALUE	Data Byte The byte that is sent to (written to) the slave (stored in TX FIFO). • If I3C, the block will compute the parity. • If I2C, the block will handle the ACK/NACK.

70.6.37 Master Write Data Byte End (MWDATABE)

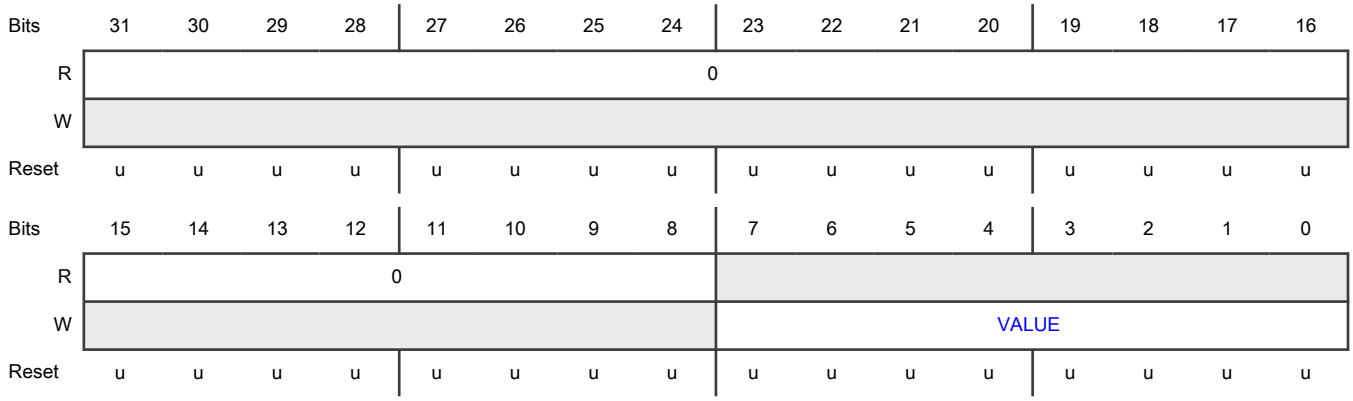
Offset

Register	Offset
MWDATABE	B4h

Function

The MWDATABE register is the alias of the Slave Write Data Byte End (SWDATABE). The MWDATABE register allows writing the last byte to send onto the bus. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. Note that MWDATAB can also indicate END using bit 8.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Data The last byte that is sent to (written to) the slave (stored in TX FIFO). • If I3C, the block computes the parity. • If I2C, the block handles the ACK/NACK.

70.6.38 Master Write Data Half-word (MWDATAH)

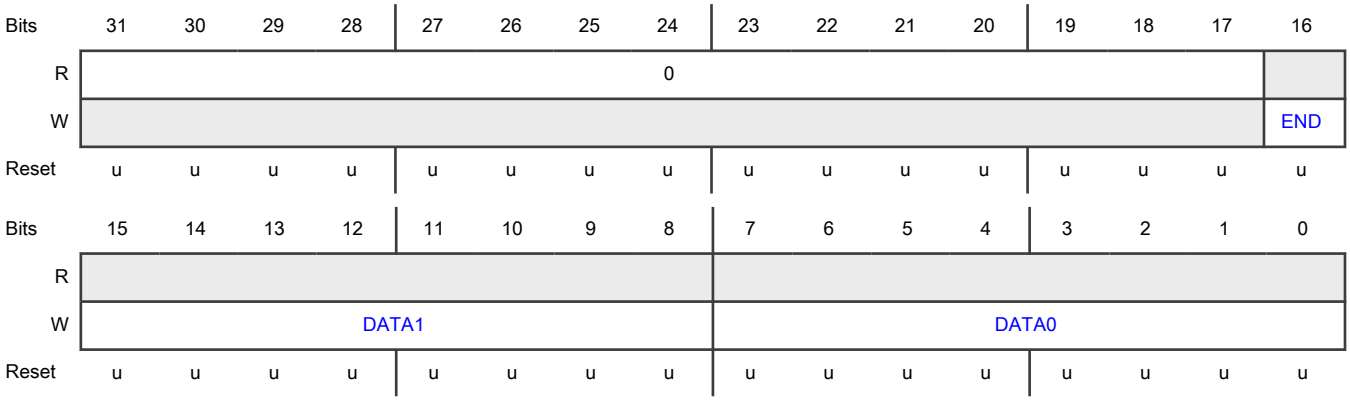
Offset

Register	Offset
MWDATAH	B8h

Function

Write a halfword of data, possibly the last half word. The MWDATAH register is the alias of the Slave Write Data Half-word (SWDATAH). This Master Write Data Half-word register allows writing a half word (pair of bytes) to the bus, unless an external FIFO is used. This takes a halfword, which will send out the Low byte and then the High byte. An end-of-data (last) marker bit is allowed (or must be 0). A halfword should not be written unless there is room for both, as indicated by use of Tx FIFO level trigger or TXCOUNT available space in the MDATACTRL register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of message • If END = 1, then END bit marks the last byte of the message. • If END = 0, then there are more bytes in the message. For this register, this always marks DATA1 as the end. END is required to be used in I3C, but is optional in I2C. For HDR-DDR, the byte with the END must be an even byte (2nd, 4th, 6th，and so on.) because DDR uses byte-pairs.
15-8 DATA1	Data Byte 1 The 2nd byte that is sent to the slave (written to TX FIFO).
7-0 DATA0	Data Byte 0 The 1st byte that is sent to the slave (written to TX FIFO).

70.6.39 Master Write Data Byte End (MWDATAHE)

Offset

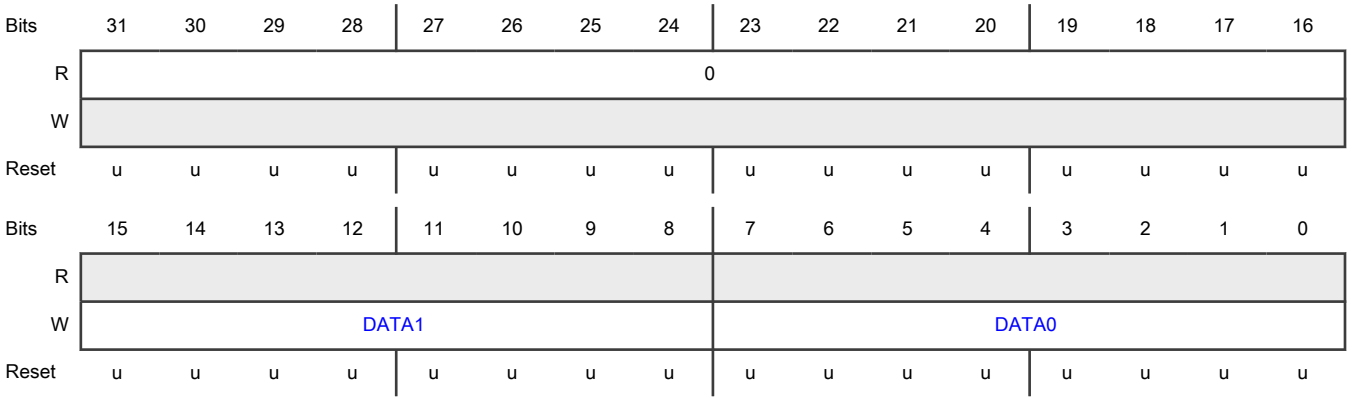
Register	Offset
MWDATAHE	BCh

Function

Write the last halfword of data. The MWDATAHE register is the alias of the Slave Write Data Half-word End (SWDATAHE). Write a halfword (byte pair) just like the MWDATAH register, but mark the 2nd byte as end-of-data (last byte). Note that for HDR-DDR, the byte with the END must be an even (2nd, 4th, 6th，and so on) because DDR uses byte-pairs. A halfword

should not be written unless there is room for both half-words, as indicated by use of Tx FIFO level trigger or TXCOUNT available space in the MDATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data Byte 1 The 2nd byte that is sent to the slave (written to TX FIFO).
7-0 DATA0	ata Byte 0 The 1st byte that is sent to the slave (written to TX FIFO).

70.6.40 Master Read Data Byte (MRDATAB)

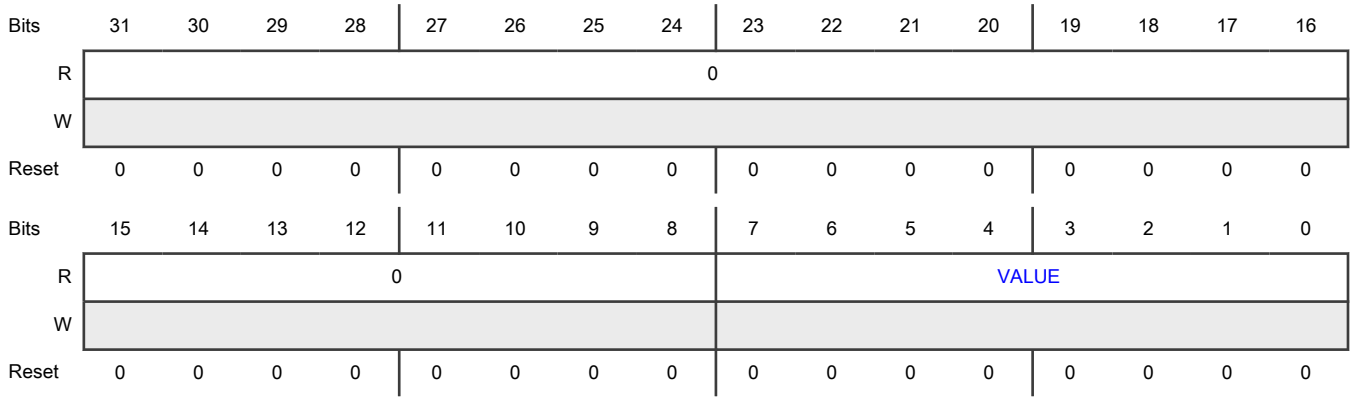
Offset

Register	Offset
MRDATAB	C0h

Function

Read a byte of data. The MRDATAB register is the alias of the Slave RDATAB register (SRDATAB). The MRDATAB register is used to read bytes written by the Slave on an SDR Read or DAA or DDR. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value The byte read from the master (and written by the Slave).

70.6.41 Master Read Data Half-word (MRDATAH)

Offset

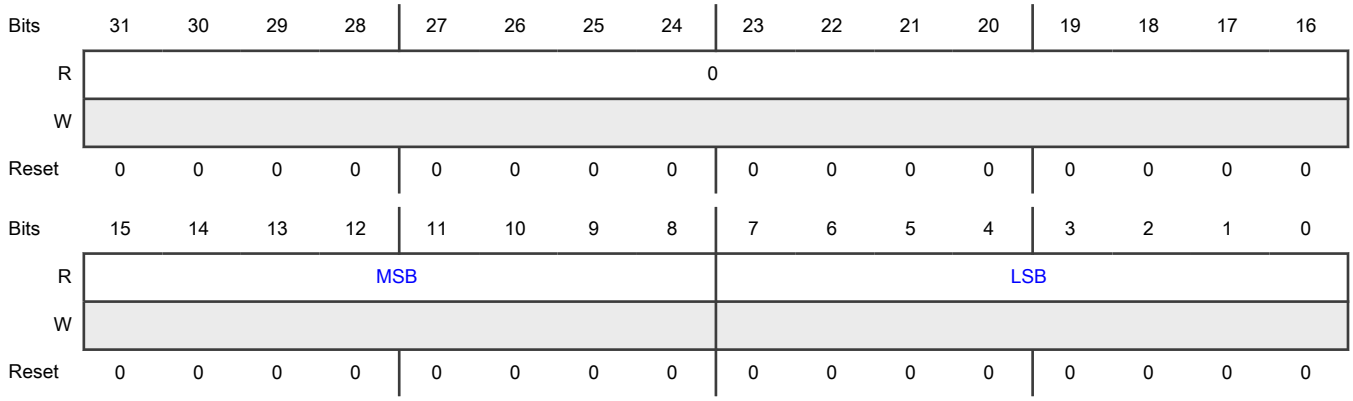
Register	Offset
MRDATAH	C8h

Function

MRDATAH allows reading a Half-word (byte pair) written by the Slave on an SDR Read or DAA or DDR. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

A Half-word should not be read unless there is at least 2 bytes of data waiting, as indicated the Rx FIFO level trigger or RXCOUNT available space in the DATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	MSB The 2nd byte read from the master (and written by the Slave).
7-0 LSB	LSB The 1st byte read from the master (and written by the Slave).

70.6.42 Byte-only Write Byte Data (to bus) (MWDATAB1)

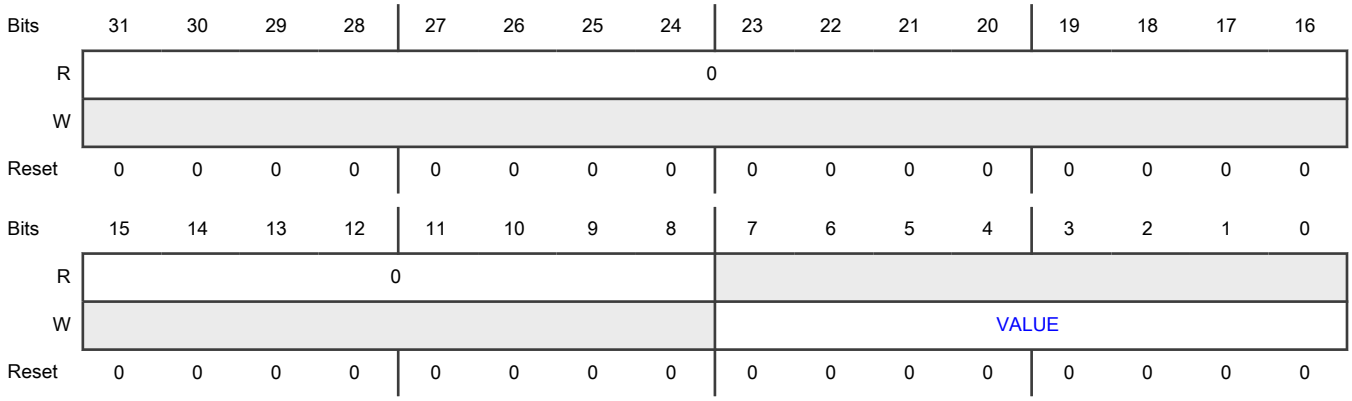
Offset

Register	Offset
MWDATAB1	CCh

Function

The MWDATAB1 register allows writing bytes to send onto the bus, and is intended for DMAs which do not clear the upper bits of the word – it does not have the END bits. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Is byte to write out. The block will compute the parity if I3C, or handle the ACK/NACK if I2C.

70.6.43 Master Write Message in SDR mode (MWMSG_SDR_CONTROL)

Offset

Register	Offset
MWMSG_SDR_CONTROL	D0h

Function

Set up and write 16-bit words in Single Data Rate (SDR) mode. The MWMSG_SDR_ register is modal and has 2 modes: control and data.

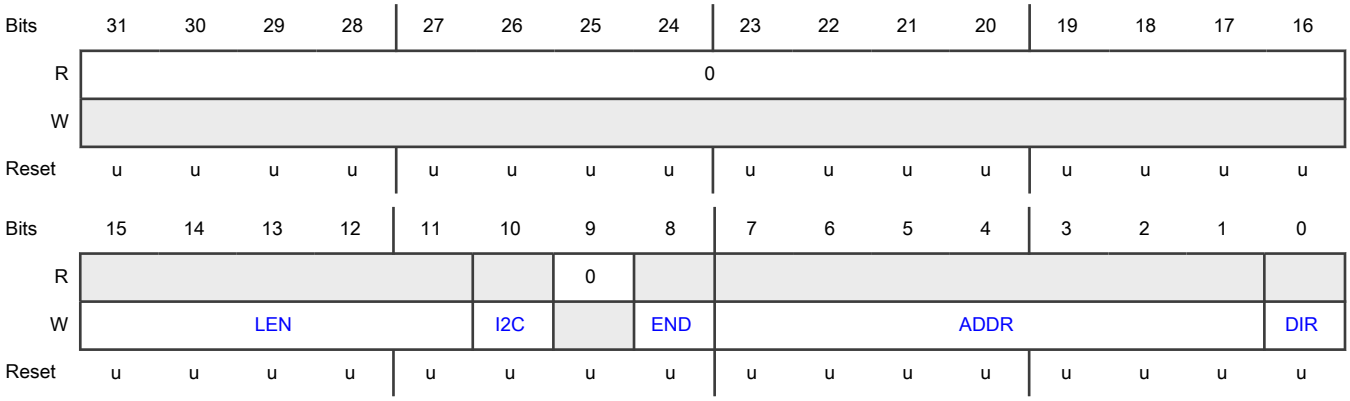
- On the first write to set up a new message, this register functions as the MWSMSG_SDR_CONTROL register.
- On subsequent writes, this register functions as the MWMSG_SDR_DATA register.

When not in the middle of a message, the MWMSG_SDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_SDR_DATA register is used until the Length (see LEN field) counts down, or until data with END = 1 is used.

The MWMSG_SDR_CONTROL register is written with the 16-bit Control word if currently stopped or past the end of the previous message. If MSTATUS[STATE] is MSGSDR and MSTAT[BETWEEN] = 0, then the register (at this offset address) is functioning as the MWMSG_SDR_DATA register. Otherwise, this register (at this offset address) is functioning as the MWMSG_SDR_CONTRL register, as long as MSTATUS[STATE] is not in another mode. The control word contains the byte length (6-bit), the address, the direction, and how it ends (stop, ready for next, continuation with more length). Note that if START and if an event (IBI, MR, HJ) occurs, the MCTRL register's IBIRESP field will be used to determine action, and the corresponding interrupt will occur. The message will be restarted in that case.

The MWMSG_SDR_CONTROL and MWMSG_SDR_DATA registers are oriented to DMA operations, but the MWMSG_SDR_CONTROL register can also be written by the processor (instead of using MCTRL and MxDATAB).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-11 LEN	Length The byte length of the message. If LEN = 0, then only END is used (and it will not use the address if Stopped). LEN = 1 must not be used. The minimal LEN size is 2 bytes (LEN = 2).
10 I2C	I2C Specifies if the message is I2C or I3C. 0b - I3C message 1b - I2C message
9 —	Reserved
8 END	End of SDR Message • If END = 1, then the single data rate message ends on STOP. • If END = 0, then the single data rate message ends waiting for a new SDR message (will issue a repeated START for a new message). Sets MSTATUS[COMPLETE] when done. This can happen before LEN bytes are read in I3C if a slave ends sooner or before LEN bytes are written in I2C if a slave NACKs.
7-1 ADDR	Address Address to be written.
0	Direction

70.6.45 Master Read Message in SDR mode (MRMSG_SDR)

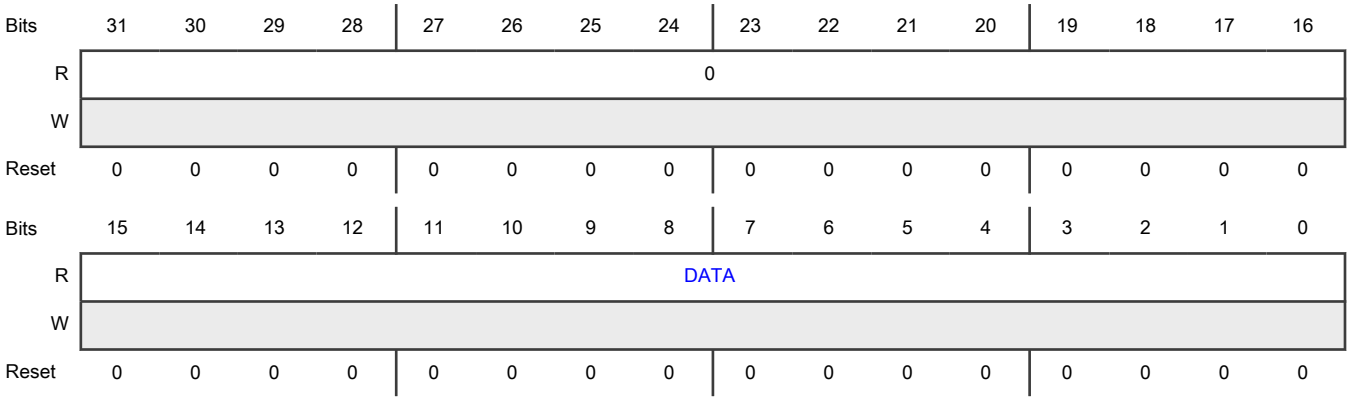
Offset

Register	Offset
MRMSG_SDR	D4h

Function

Read 16-bit words from a slave in Single Data Rate (SDR) message mode. The MRMSG_SDR register is used to read 16-bit words from an active message started with MWMSG_SDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data DATA is the 16-bit word read from the slave. • If the length (LEN) was an uneven number, then the upper byte is 0. • If the slave ends before LEN is finished, then it treats the read as completed. • If the slave is not done before LEN is finished and END is not a continuation, then the read is terminated.

70.6.46 Master Write Message in DDR mode (MWMSG_DDR_CONTROL)

Offset

Register	Offset
MWMSG_DDR_CONTROL	D8h

Function

Set up and write 16-bit words in Double Data Rate (DDR) mode. The MWMSG_DDR_ register is modal and has 2 modes: control and data.

- On the first write to set up a new message, this register functions as the MWSMSG_DDR_CONTROL register.
- On subsequent writes, this register functions as the MWMSG_DDR_DATA register.

When not in the middle of a message, the MWMSG_DDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_DDR_DATA register is used until the Length (see LEN field) counts down or until data with END=1 is used.

The MWMSG_DDR_CONTROL register is written with the 16-bit Control word if currently stopped or past the end of the previous message. If MSTATUS.STATE is MSGDDR and MSTAT[BETWEEN] = 0, then the register (at this offset address) is functioning as the MWMSG_DDR_DATA register. Otherwise, this register (at this offset address) is functioning as the MWMSG_DDR_CONTRL register, as long as MSTATUS[STATE] is not in another mode. The main control word contains the 16-bit word length and how it ends (stop, ready for next, continuation with more length). Then the 1st data word has the command and address for read or write. Note that if START and if an event (IBI, MR, HJ) occurs, then the MCTRL register's IBIRESP field will be used to determine action, and the corresponding interrupt will occur. The message will be restarted in that case. Note that the module handles preamble, parity, and CRC.

The MWMSG_DDR_CONTROL and MWMSG_DDR_DATA registers are oriented to DMA operations, but the MWMSG_DDR_CONTROL register can also be written by the processor (instead of using MCTRL and MxDATAB).

70.6.48 Master Read Message in DDR mode (MRMSG_DDR)

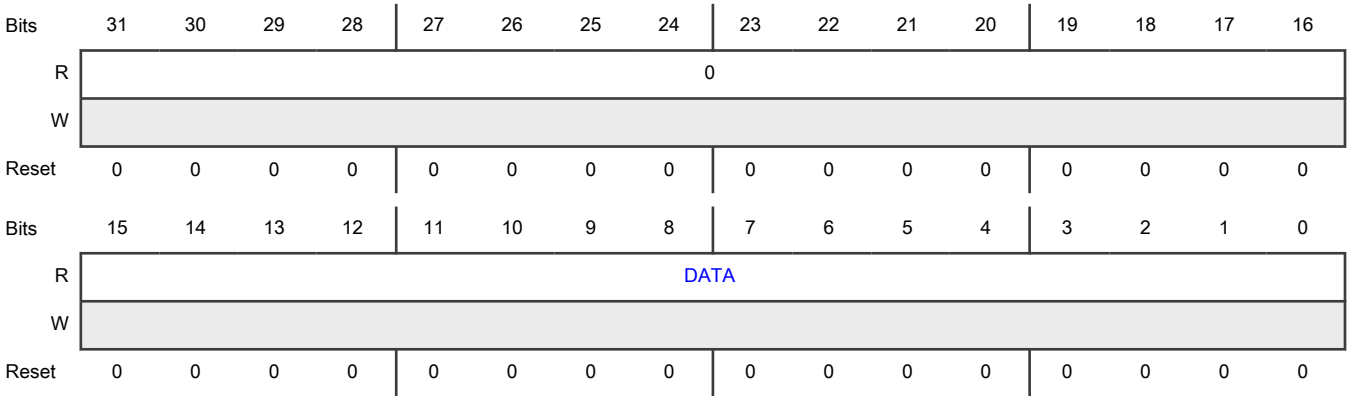
Offset

Register	Offset
MRMSG_DDR	DCh

Function

Read 16-bit words from a slave in Double Data Rate (DDR) message mode. The MRMSG_DDR register is used to read 16-bit words from an active message started with MWMSG_DDR. This is intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DATA is the 16-bit word read from a slave. The 1st byte is the LSB and the 2nd byte is the MSB. The 1st byte is in DATA[7:0] and the 2nd byte is in DATA[15:8]. • If the slave ends before the entire length of the message (MWMSG_DDR[LEN]) is read, then the module will consider the DATA read as completed. In I3C, the slave can indicate the end of message (the last byte). Otherwise, the master would terminate the message if the message is more than the master will accept. • If the slave has not yet finished sending DATA before the entire length of the message (MWMSG_DDR[LEN]) is read and END is not a continuation, then the DATA read will be terminated.

70.6.49 Master Dynamic Address (MDYNADDR)

Offset

Register	Offset
MDYNADDR	E4h

Function

Allows an I3C module to write its own Dynamic Address when the I3C module changes from master mode to slave mode.

If this device is the Main Master (the Master at bus initialization), then this device may use this mechanism to assign itself its Dynamic Address. When the device hands off control to a secondary Master, it becomes a Slave itself. This must be written before switching to Slave mode and must not be changed once in Slave mode (it is not clock safe for that). It must be written with a valid address value in DADDR if DAVALID = 1. Note that the Main master also uses DEFSLVS to define the slave addresses, including itself; this is how secondary Masters know this address. If the Master is not the Main Master, then this should not be used.

70.6.52 Map Feature Control 0 (SMAPCTRL0)

Offset

Register	Offset
SMAPCTRL0	11Ch

Function

The MAPCTRLn registers are named MAPCTRL0, MAPCTRL1，and so on based on number of mapped addresses. MAPCTRL0 represents the Primary DA/SA with MAPCTRL1 onwards being the Mapped addresses.

The features of the SMAPCTRLn registers depend on configurations. The MAPCTRL0 acts differently, as shown below.

In general, this mechanism is intended to replace the DYNADDR register for all MAP related uses.

Note that when using the Auto-MAP and DASA or AASA, the slot is changed from SA to DA. If the Master then issues RSTDAA, the application would need to rewrite the static addresses and enable them, as they will be marked disabled.

Diagram

Chapter 71
Flexible I/O (FlexIO)

71.1 Chip-specific FlexIO information

71.1.1 FlexIO instances and configuration

The device contains one instance of FlexIO.

FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial communication protocols like UART, I2C, SPI, SAI. It can work either as master or slave.
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions.

Table 411. FlexIO instances

Chip	Instance	No. of pins	No. of timers	No. of shift registers	No. of bits in counter
S32K312, S32K322, S32K342, S32K314, S32K324, S32K344, S32K358	FlexIO	32	8	8	16
S32K311	FlexIO	16	8	8	16

Table 412. Data rate limitation

FlexIO operation	Data rate limitation
Master Tx	FlexIO_clk/4
Slave Tx	FlexIO_clk/10
Master Rx	FlexIO_clk/8
Slave Rx	FlexIO_clk/6

NOTE

FlexIO supports 32 bit accesses only.

NOTE

When I2S is emulated on FlexIO, you could observe a skew between bit-clock (BCLK) and frame sync pulse amounting to 1/2 of BCLK.

Table 413. FlexIO configuration

No. of pins	No. of timers	No. of shift registers	No. of bits in counter
32	8	8	16

71.2 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

71.2.1 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

The FlexIO uses shifters, timers and external triggers to shift data into or out of the FlexIO. The timing of the data shift is controlled by the timers, as shown in the block diagram. The timers can be configured to use generic timer functions, external triggers, or various other conditions to determine this control.

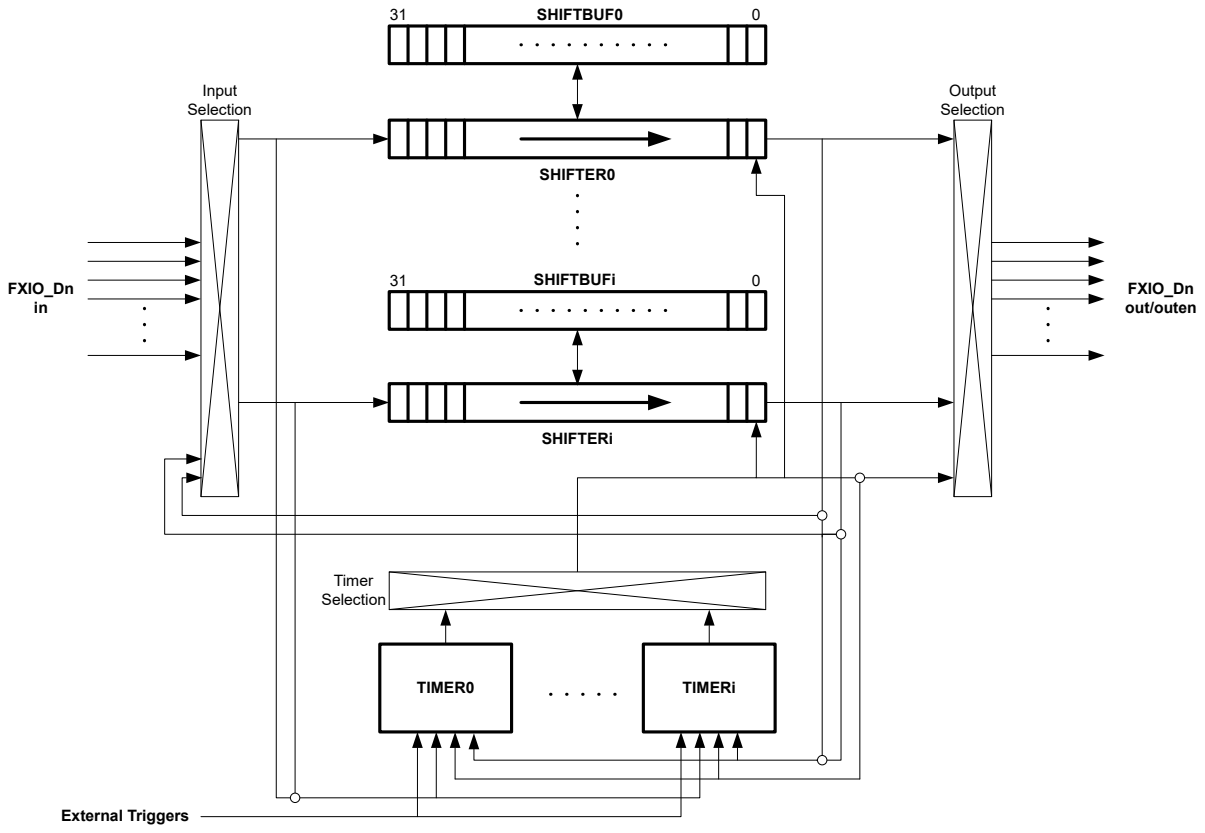

Figure 371. FlexIO block diagram

71.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus

- PWM/Waveform generation
- Input-capture (pulse edge interval measurement) - Example: SENT

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive, data match, logic mode, and state modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state
- Integrated general purpose input/output registers and pin rising/falling edge interrupts to simplify software support

71.3 Functional description

71.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

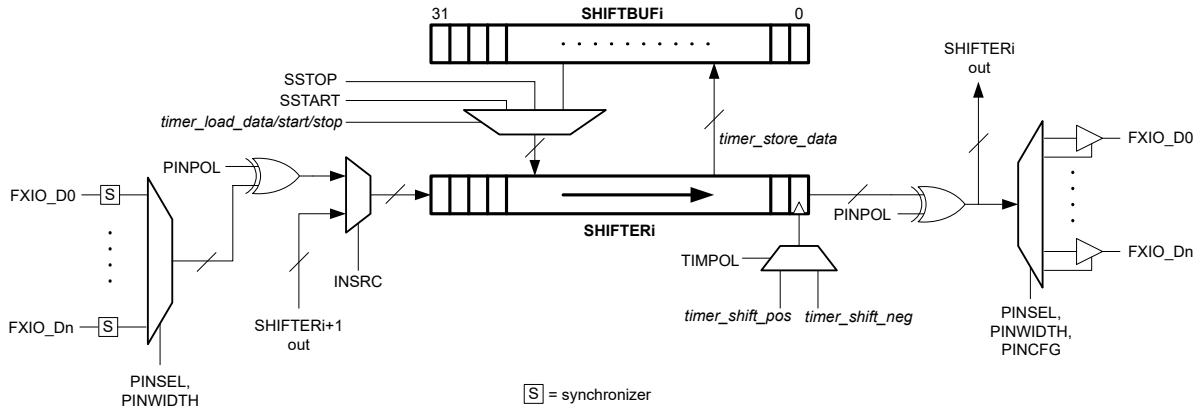

Figure 372. Shifter Microarchitecture

Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter loads data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/ afterSHIFTBUFdata by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

NOTE

The shifter immediately loads a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag clears when new data has been written into the SHIFTBUF register or a logic 1 is written to this flag. In transmit mode, any write of the SHIFTBUF register clears the corresponding Shifter Status Flag. It does not matter what is writing or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/cleared for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter shifts data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the data has been read from theSHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Receive mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store data into a fullSHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter shifts data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the matched data has been read from the SHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Match Store mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter shifts data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register. **The flag cannot be cleared by reading the SHIFTBUF register.**

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. The flag clears when there is a read from the SHIFTBUF register or it written with logic 1.

State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

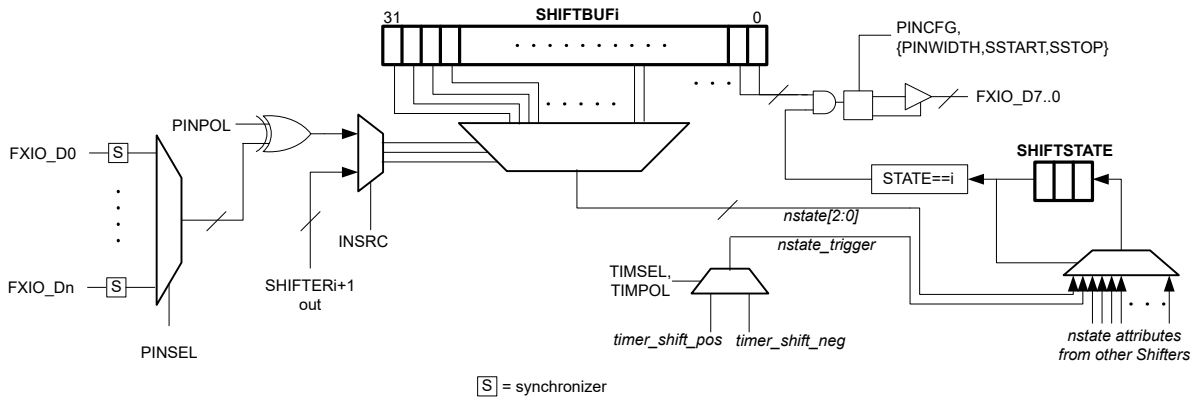

Figure 373. State Microarchitecture

When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] are driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTLi[PINCFG]. When set, SHIFTCFGi{PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTLi[PINSEL] together with SHIFTBUFi[23:0].

NOTE

Each state could potentially use a different set of 3 input pins.

The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

Table 414. Next State computation for SHIFTSTATE[STATE]=i

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State Value
0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTLi[TIMSEL] with polarity controlled by SHIFTCTLi[TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs are not driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the Shifter has been selected by the current state pointer. The flag clears when the current state pointer is updated to a different Shifter.

Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (SHIFTCTL[SMOD]=Logic), theSHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

The SHIFTBUFi configures the lookup table for the 4 pin inputs and the SHIFTERi can optionally be used to configure a feedback or delayed pin source as the 5th input to the look up table.

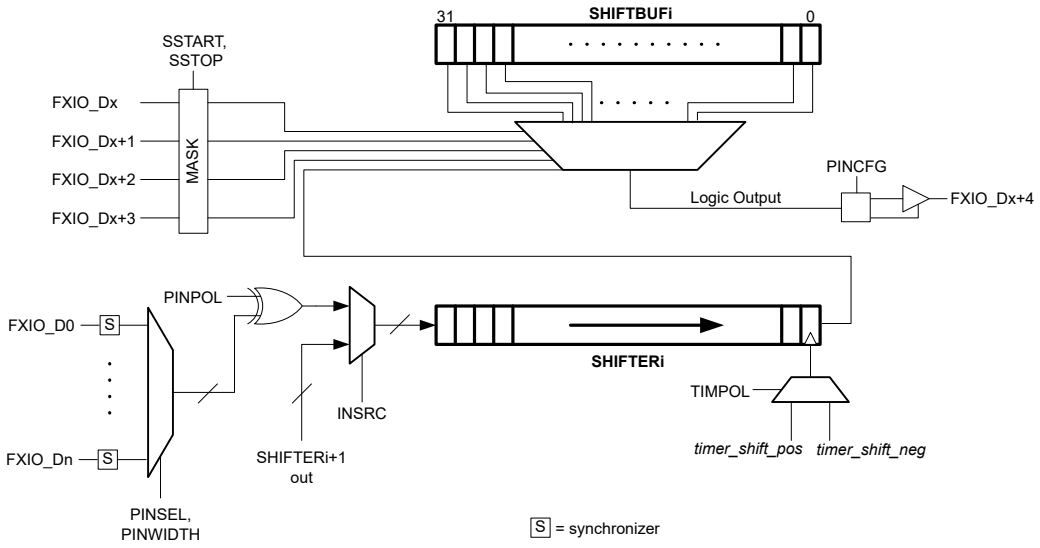

Figure 374. Logic Microarchitecture

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

Table 415. Logic Look-up table for Shifter 'i'

SHIFTERi[0]	FXIO_D[x+3][1]	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUFi[0]
0	0	0	0	1	SHIFTBUFi[1]
0	0	0	1	0	SHIFTBUFi[2]
0	0	0	1	1	SHIFTBUFi[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUFi[31]

1. for Shifter i=0...3, x=i

for Shifter i=4...7, x=i+4

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} mask FXIO_D[x+3]...FXIO_D[x] inputs respectively, so that any transitions on these pins does not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter introduces a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter introduces a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag clears when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic look-up table has asserted. The flag can be cleared by writing it with logic 1.

The logic mode input pins (including pins driven by other shifters/timers) are first synchronized to the FlexIO functional clock before they are input to the programmable logic look-up table.

71.3.2 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode only resets the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Counter Disable Mode

In 16-bit Counter Disable Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

Timer 8-bit Word Counter Mode

In 8-bit Word Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the number of shift clock edges in each word and the upper 8-bits are used to configure the number number of words in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits only decrement when the lower 8-bits equal zero and decrement.

A timer compare event occurs when the lower 8-bits equal zero and decrements. The timer status flag is set when the upper 8-bits equal zero and decrements.

Timer 8-bit Low PWM Mode

In 8-bit Low PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output low period and the upper 8-bits are used to configure the timer output high period. The lower 8-bits decrement when the output is low. When the lower 8-bits equal zero and decrement, the timer output is set and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is high. When the upper 8-bits equal zero and decrement, the timer output is cleared and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Input Capture Mode

In 16-bit Input Capture Mode, the 16-bit counter uses a fixed initial value of 0xFFFF to load the counter. Whenever a timer counter disable condition is detected (as configured by TIMDIS), the timer status flag is set and the inverted timer counter value is stored in the timer compare register, then the timer counter is immediately restarted from 0xFFFF. The timer output is always output on the FlexIO trigger outputs (which can also be used by other timers as an input trigger) and can also be output to a pin (PINCFG/PINPOL/PINSEL) or a shifter.

If the timer status flag is already set, then the input capture event is missed. When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads with 0xFFFF. The timer output can be used to count the number of counter overflows between two input capture events. Input capture mode is not intended to be used to control shift registers, it is to enable software to count the number of bits in a variable length transfer or to monitor the period or frequency of an input.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event. Whenever the status flag asserts, the inverted timer counter value is stored in the timer compare register.

Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur. When ONETIM is set, then the timer status flag must also be clear to generate a timer enable event, otherwise the timer enable event is blocked. This can be used to enforce software intervention after each timer iteration.

- Timer counter loads the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift does not load correctly.

Timer Decrement and Reset

The Timer then generates the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a Timer is configured to decrement on the FlexIO functional clock divided by 16 or 256 (when TIMDEC = 100 or 101), then a common prescaler that is shared by all Timers is used to generate the two divide ratios. This prescaler is reset when all Timers are either idle or configured to not use the prescaler (TIMDEC != 100 or 101).

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter loads the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event causes the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events occur.

- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter reloads the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter reloads the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When ONETIM is set, the timer status flag must be clear before the next timer enable condition is detected. Receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

71.3.3 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

Parallel Interface

Shifters can be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter is sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits are masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins are not driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each Shift clock.

Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

Pin Override

The state of any FlexIO pin can be overriden at any time by software. The Pin Output Enable register configures any pin as an output and drives that pin with the value in the Pin Output Data Register.

Alias registers for the Pin Output Enable/Data Registers also exist, writing a logic one to an alias register updates the corresponding register bits in both the Pin Output Enable Register and the Pin Output Data Register as follows.

- Pin Output Disable Register clears Output Enable Register and clear Output Data Register.
- Pin Output Clear Register sets Output Enable Register and clear Output Data Register.
- Pin Output Set Register sets Output Enable Register and set Output Data Register.
- Pin Output Toggle Register sets Output Enable Register and toggle Output Data Register.

Pin Interrupt

The state of any FlexIO pin can be read by software at any time. Software can also configure any pin to set a status flag when either a rising and/or falling edge is detected on that pin. The pin status flag can also be configured to generate an interrupt.

71.3.4 Low Power Modes

The FlexIO remains functional during low power modes, provided the FlexIO functional clock remains enabled.

71.3.5 Debug Mode

The FlexIO remains functional in debug mode provided the Debug Enable bit (CTRL[DBGE]) is set.

71.3.6 Clocks

Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least equal to the bus clock, the CTRL[FASTACC] bit can be set to support fast register accesses.

Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

71.3.7 Reset

Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[SWRST] resets all logic and registers to their default state, except for the CTRL itself.

71.3.8 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

Table 416. FlexIO Interrupts and DMA Requests

Flag	Description	Interrupt	DMA Request	Low Power Wakeup
SSF	Shifter Status Flag.	Y	Y	Y
SEF	Shifter Error Flag.	Y	N	Y
TSF	Timer Status Flag.	Y	Y	Y
PSF	Pin Status Flag.	Y	N	Y
ETSF	External Trigger Status Flag.	Y	N	Y

71.3.9 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. If a rising edge is detected on an external trigger when the FlexIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

71.4 Application Information

This section provides examples for a variety of FlexIO module applications.

See the register descriptions for bitfield details.

71.4.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUFn (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

Table 417. UART Transmit Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.

Table continues on the next page...

Table 417. UART Transmit Configuration (continued)

Register	Value	Comments
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_2222	Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=0x3.
TIMCTLn	0x01C0_0001	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

An alternative configuration is possible that supports slower baud rates but requires two Timers.

Table 418. UART Transmit Configuration for Slow Baud Rate

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1.
TIMCMPn	0x0000_000F	Configure for 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFGn	0x0030_2622	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.

Table continues on the next page...

Table 418. UART Transmit Configuration for Slow Baud Rate (continued)

Register	Value	Comments
TIMCTLn	0x0740_0003	Configure 16-bit counter using Timer 1 output as internal trigger source.
TIMCMP(n+1)	0x0000_0001	Configure baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (baud rate divider / 2) - 1.
TIMCFG(n+1)	0x0000_1200	Configure enable on trigger asserted and disable on Timer 0 disable. Can support CTS by configuring TIMEN=0x3.
TIMCTL(n+1)	0x01C0_0003	Configure 16-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

71.4.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters cause the error flag to set and the shifter buffer register returns 0x00.

FlexIO does not support automatic verification of parity bits.

Table 419. UART Receiver Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.

Table continues on the next page...

Table 419. UART Receiver Configuration (continued)

Register	Value	Comments
TIMCFGn	0x0204_2422	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x0000_0081	Configure dual 8-bit counter using inverted Pin 0 input.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS asserts when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit is detected while the RTS is asserted, the received data is simply ignored.

Table 420. UART Receiver with RTS Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2522	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x02C0_0081	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(n+1)	0x0000_FFFF	Never compare.
TIMCFG(n+1)	0x0030_6100	Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.

Table 420. UART Receiver with RTS Configuration (continued)

Register	Value	Comments
TIMCTL(n+1)	0x0143_0003	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

71.4.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

NOTE

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 421. SPI Master (CPHA=0) Configuration

Register	Value	Comments

SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUF, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS register instead.

71.4.4 SPI Slave

SPI slave mode can be supported using one Timer, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external slave select asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

71.4.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter loads 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

NOTE

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

Table 425. I2C Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTLn	0x0101_0082	Configure transmit using Timer 1 on rising edge of clock with inverted output enable (open drain output) on Pin 0.
SHIFTCFG(n+1)	0x0000_0020	Start bit disabled and stop bit enabled (logic 0) for ACK/NACK detection.
SHIFTCTL(n+1)	0x0180_0001	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMPn	0x0000_2501	Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0102_2222	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTLn	0x01C1_0101	Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(n+1)	0x0000_000F	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_1112	Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.
TIMCTL(n+1)	0x01C0_0183	Configure 16-bit counter using inverted Pin 1 input (SCL).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0], use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

71.4.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer

before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

NOTE

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 426. I2S Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0001	Load transmit data on first shift and stop bit disabled.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on rising edge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0080_0101	Configure receive using Timer 0 on falling edge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_0202	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTLn	0x01C3_0281	Configure dual 8-bit counter using inverted Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Clear PINPOL to invert the polarity of the output shift clock.
TIMCMP(n+1)	0x0000_007F	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(n+1)	0x0000_0100	Enable when Timer 0 is enabled and never disable.
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter using inverted Pin 3 output (as frame sync). Clear PINPOL to invert the polarity of the output frame sync

		Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

71.4.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until rising edge of bit clock (when frame sync is normally sampled). Timer 0 detects rising edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects falling edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 427. I2S Slave Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.

TIMCFG(n+1)	0x0020_2500	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(n+1)	0x0340_0283	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(n+2)	0x0000_0000	Compare on zero (first edge).
TIMCFG(n+2)	0x0020_6400	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock), initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(n+2)	0x04C0_0383	Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 inverted input (bit clock) as the trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

71.4.8 SENT Receiver

SENT receiver can be supported by using one Timer and one Pin. The Timer is configured as Input-Capture mode, and captures the conter value at falling edge of the Pin input. Once the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value is always indicating the period between previous falling edge and current falling edge. CPU interrupt or DMA trigger can be configured at each capture of the counter, and the entire SENT frame decoding with the latest tick width adustment is performed by CPU software.

Table 428. SENT Receiver Configuration

Register	Value	Comments
TIMCMPn	-	Counter value at the falling edge of the Pin is stored in this register.
TIMCFGn	0x0000_6000	Timer always enabled, Timer disabled on Trigger falling edge, Decrement counter on FlexIO clock.
TIMCTLn	0xnn40_0007	Single 16-bit input capture mode, Timer pin input and output are selected by PINSEL, Timer pin output disabled, Internal trigger selected, Select Pin nn as Trigger.

71.4.9 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

Table 429. Camera Interface Configuration for 8-bit CMOS sensor

Register	Value	Comments
SHIFTCFGn...n+2[1]	0x0007_0100	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFGn+3	0x0007_0000	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTLn...n+3	0x0080_0001	Configure receive using Timer 0 on negedge of clock.
TIMCMPn	0x0000_001F	Configure 16-pixel (8 bits/pixel x 16 pixels = 128-bits) transfer. Set TIMCMP[15:0] = (number of pixels x 2) - 1.
TIMCFGn	0x0120_6600	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge, initial Shift clock state is logic 0 and decrement on PCLK input.
TIMCTLn	0x12C0_0803	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUFn...n+3	Data to receive	Received data can be read from SHIFTBUFn...n+3, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

1. n=0 or 4

71.4.10 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 430. Motorola 68K/Intel 8080 Write Configuration

Register	Value	Comments
SHIFTCFG0...7	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0x0000_0002	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2200	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x01C3_1001 (Motorola 68K, 1-beat) 0x1DC3_1001 (Motorola 68K, 16-beats) 0x01C3_1081 (Intel 8080, 1-beat) 0x1DC3_1081 (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table 431. Motorola 68K/Intel 8080 Read Configuration

Register	Value	Comments
SHIFTCFG0...6	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCFG7	0x000F_0000	Configure 16-bit parallel shift in from pin.

Table continues on the next page...

Table 431. Motorola 68K/Intel 8080 Read Configuration (continued)

Register	Value	Comments
SHIFTCTL0...7	0x0080_0001	Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0].
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2220	Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x1DC3_1001 (Motorola 68K, 1 beat) 0x01C3_1001 (Motorola 68K, 16 beats) 0x1DC3_1181 (Intel 8080, 1 beat) 0x01C3_1181 (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K/8080 bus slave begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

71.4.11 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted (This assumes comparator is connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings). The state diagram below shows the states and transitions implemented by this example.

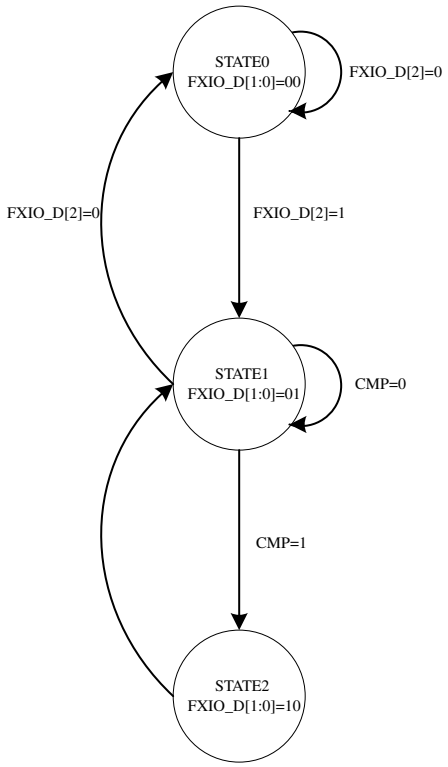

Figure 375. State Diagram

Table 432. State Machine Configuration

Register	Value	Comments
SHIFTCFG0...2	0x0000_0003	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF0	0x0020_8208	State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.
SHIFTCTL1	0x0000_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state.
SHIFTBUF1	0x0140_8408	State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)

Table continues on the next page...

Table 432. State Machine Configuration (continued)

Register	Value	Comments
SHIFTCTL2	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF2	0x0224_9249	State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low
TIMCMP0	0x0000_FFFF	Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_0000	Configure timer always enabled.
TIMCTL0	0x0000_0003	Configure single 16-bit counter.
TIMCFG1	0x0010_7600	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0x0F03_0303	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

71.4.12 Keypad Interface

The Keypad Interface can support a 3x4 keypad matrix using 3 timers and 3 shifters, although a larger matrix could be supported using additional shifters. The configuration is designed for 4 columns which are configured as active low open drain pins, and 3 rows which are configured as input pins with pullup resistors enabled.

One shifter is configured in logic mode and is configured to assert its output when any of the row inputs are low, indicating a key is pressed. A timer is used to filter the shifter output to ensure the key is pressed for a minimum amount of time before performing the column scan.

Another shifter is configured for parallel transmit, this shifter is used to scan each column when a key press is detected. Whenever not scanning, the shifter output is configured to assert all active low open drain column outputs to detect any keypress. A dedicated timer is used to control the transmit shifter.

The last shifter is configured for parallel receive, this shifter is used to capture the result of the column scanning for software to decode which key or keys was pressed. This configuration captures the state of both row and colum pins for each scan, although the row state could also be deduced by the shift order. A dedicated timer is used to control the receive shifter, it shifts at half the frequency of the transmit shifter.

Once the result of the key scan is available in the receive shifter register, FlexIO continues to monitor the row inputs and can trigger multiple scans from the one key press. To support debouncing, software can decide how many consecutive scans should be considered a single key press.

Since the pins used in logic mode are fixed per shifter, and the shifters that support parallel shifts are limited, this configuration is restricted in what pins and shifters it can use. Increasing the matrix beyond 4 row inputs requires multiple shifters in logic mode and increasing beyond 4 column outputs requires concatenating transmit shifters to create a larger shift register.

Table 433. Keypad Interface Configuration

Register	Value	Comments
SHIFTCFG0	0x0003_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1), configired for 4-bit shift.
SHIFTCTL0	0x0101_0402	Configure transmit using Timer 1 on rising edge of clock generating open drain output on Pins [7:4] (column outputs).
SHIFTBUF0	0x0804_0201	Static data containing the column scan pattern, each column is scanned one-hot with deadtime inbetween.
SHIFTCFG1	0x0000_0020	In logic mode, mask input 3.
SHIFTCTL1	0x0000_0007	Configure logic mode.
SHIFTBUF1	0x07ff_07ff	Static data configuring logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0x0007_0000	Configured for 8-bit shift.
SHIFTCTL3	0x0280_0001	Configure receive using Timer 2 on falling edge of clock with input data on Pins [7:0] (both rows and columns, pin 0 is don't care).
TIMCMP0	0x0000_00ff	Configures pre-scanning glitch filter to 256 FlexIO clock cycles. For different filter cycles, set TIMCMP[15:0] = (filter cycles) - 1.
TIMCFG0	0x0103_6600	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0x0540_0003	Configure 16-bit counter using Shifter 1 flag (logic state) as trigger.
TIMCMP1	0x0000_0f3f	Configure 8 shifts (twice for each column) at column scan rate of divide by 128. For different scan frequency, set TIMCMP[7:0] = (scan divider / 2) - 1.
TIMCFG1	0x0020_2622	Enable on trigger rising edge, disable on compare, start and stop bits are enabled.
TIMCTL1	0x0340_0001	Configure dual 8-bit counter using Timer 0 output as the trigger.
TIMCMP2	0x0000_0801	Configure 4 shifts at half the frequency of Timer 1 trigger.
TIMCFG2	0x0110_2100	Enable on Timer 1 enable, disable on compare, decrement on trigger input

Table continues on the next page...

Table 433. Keypad Interface Configuration (continued)

Register	Value	Comments
		with output initially negated and not affected by reset
TIMCTL2	0x0740_0001	Configure dual 8-bit counter using Timer 1 output as the trigger.
SHIFTBUF3	Keypad Scan Result	Keypad scan result can be read from SHIFTBUF3, each byte is the result of one scan with both row and column pin state from the scan (note that pin 0 is not used). Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: For SMOD=Receive, the status flag is set when SHIFTBUF has been loaded with data from Shifter (SHIFTBUF is full), and the status flag is cleared when SHIFTBUF register is read. For SMOD=Transmit, the status flag is set when SHIFTBUF data has been transferred to the Shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit, and the status flag is cleared when the SHIFTBUF register is written. For SMOD=Match Store, the status flag is set when a match has occured between SHIFTBUF and Shifter, and the status flag is cleared when the SHIFTBUF register is read. For SMOD=Match Continuous, returns the current match result between the SHIFTBUF and Shifter. The status flag cannot be cleared by reading SHIFTBUF. For SMOD=State, the status flag for a shifter sets when it is selected by the current state pointer. For SMOD=Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/ State /Logic. 0b - Status flag is clear. 1b - Status flag is set.

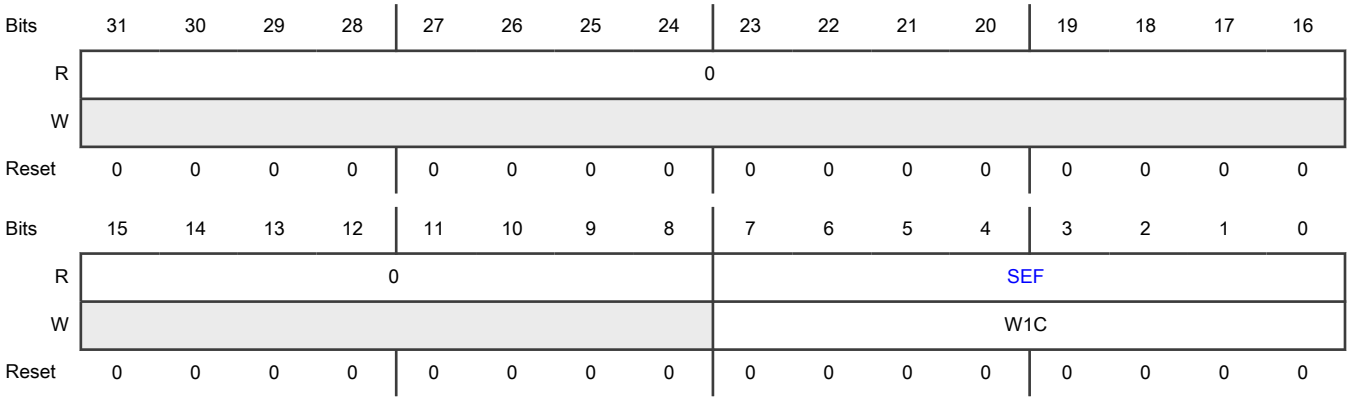
71.6.1.7 Shifter Error Register (SHIFTERR)

Offset

Register	Offset
SHIFTERR	14h

Function
This register reports shifter error flags. Write one to clear.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: For SMOD=Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value. For SMOD=Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun). For SMOD=Match Store, indicates a match event occured before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun). For SMOD=Match Continuous, the error flag is set when a match has occured between SHIFTBUF and Shifter. For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted. Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read. 0b - Shifter Error Flag is clear. 1b - Shifter Error Flag is set.

71.6.1.8 Timer Status Register (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function

This register reports timer status flags. Write one to clear.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flags The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. In 8-bit baud counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit high PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements. In 16-bit counter disable mode, the timer status flag is set when a timer disable event is detected. In 8-bit word counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit low PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit input capture mode, the timer status flag is set when a timer disable event is detected and the timer status flag is clear. In this mode, the timer compare register should only be read when the timer status flag is set. 0b - Timer Status Flag is clear. 1b - Timer Status Flag is set.

71.6.1.9 Shifter Status Interrupt Enable (SHIFTSIEN)

Offset

Register	Offset
SHIFTSIEN	20h

Function
Enables for Shifter Status Interrupts.

Fields

Field	Function
31-8 —	Reserved
7-0 SSIE	Shifter Status Interrupt Enable Enables interrupt generation when corresponding SSF is set. 0b - Shifter Status Flag interrupt disabled. 1b - Shifter Status Flag interrupt enabled.

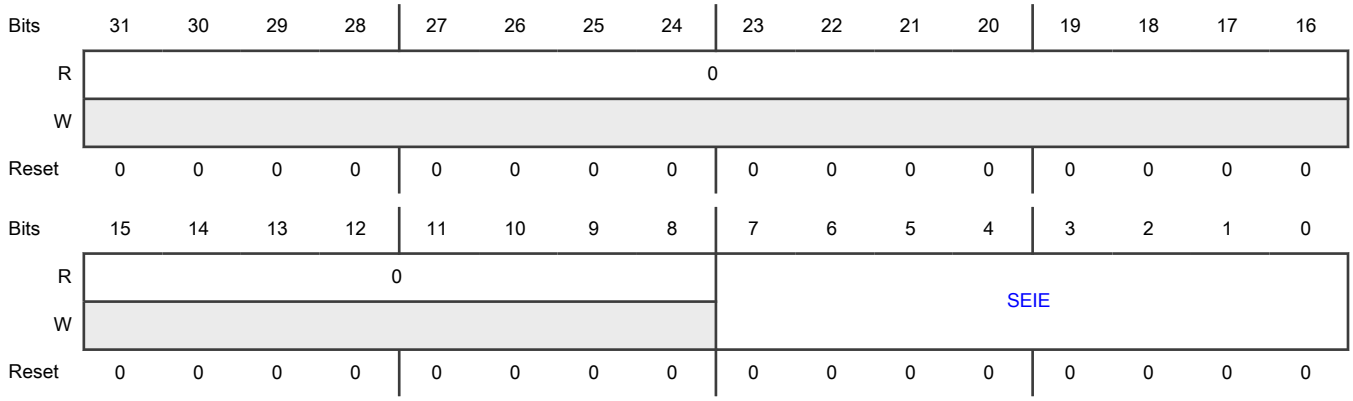
71.6.1.10 Shifter Error Interrupt Enable (SHIFTEIEN)

Offset

Register	Offset
SHIFTEIEN	24h

Function
Enables for Shifter Error Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEIE	Shifter Error Interrupt Enable Enables interrupt generation when corresponding SEF is set. 0b - Shifter Error Flag interrupt disabled. 1b - Shifter Error Flag interrupt enabled.

71.6.1.11 Timer Interrupt Enable Register (TIMIEN)

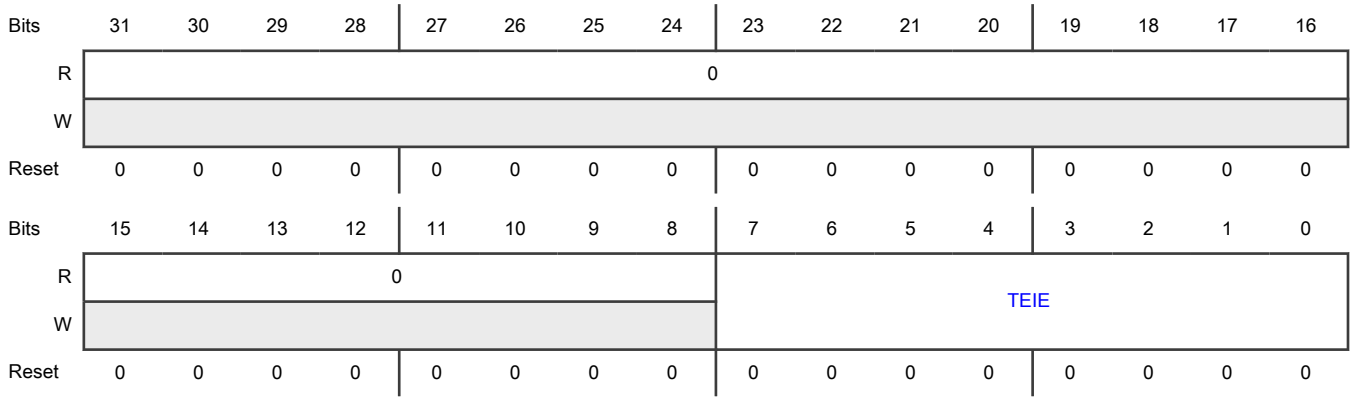
Offset

Register	Offset
TIMIEN	28h

Function

Enables for Timer Status Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIE	Timer Status Interrupt Enable Enables interrupt generation when corresponding TSF is set. 0b - Timer Status Flag interrupt is disabled. 1b - Timer Status Flag interrupt is enabled.

71.6.1.12 Shifter Status DMA Enable (SHIFTSDEN)

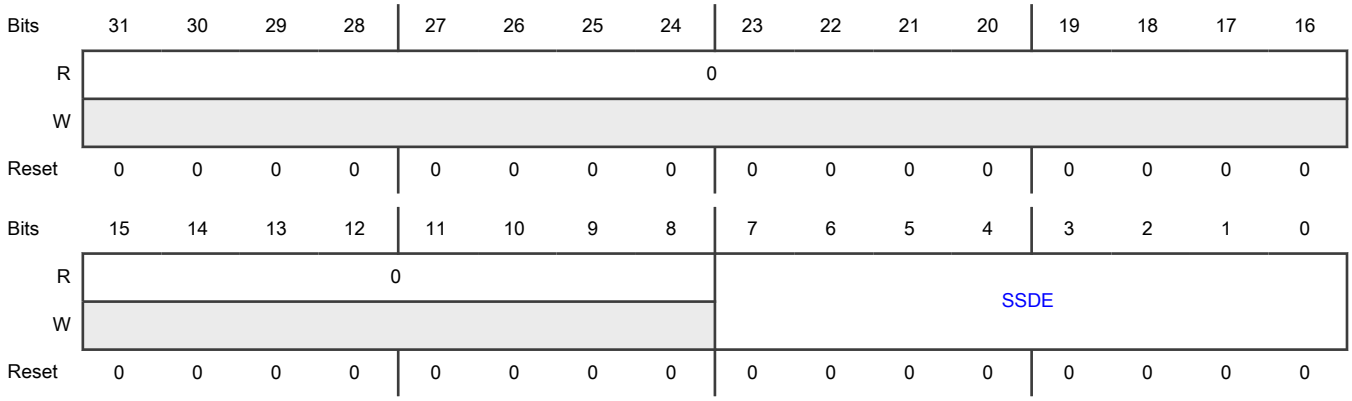
Offset

Register	Offset
SHIFTSDEN	30h

Function

Enables for Shifter DMA requests.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSDE	Shifter Status DMA Enable Enables DMA request generation when corresponding SSF is set. 0b - Shifter Status Flag DMA request is disabled. 1b - Shifter Status Flag DMA request is enabled.

71.6.1.13 Timer Status DMA Enable (TIMERSDEN)

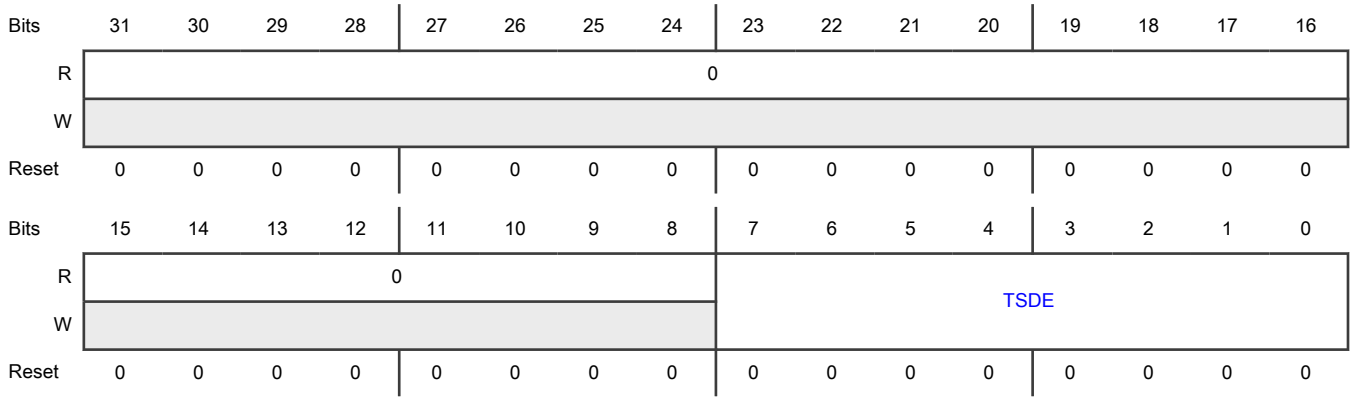
Offset

Register	Offset
TIMERSDEN	38h

Function

Enables for DMA requests when Timer Status Flag is set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSDE	Timer Status DMA Enable Enables DMA request generation when corresponding TSF is set. When the Timer Status DMA request is enabled, reading or writing a Timer Compare Register clears the corresponding Timer Status Register. The DMA must therefore read or write the Timer Compare Register as part of the DMA transfer, otherwise the DMA request remains asserted. 0b - Timer Status Flag DMA request is disabled. 1b - Timer Status Flag DMA request is enabled.

71.6.1.14 Shifter State Register (SHIFTSTATE)

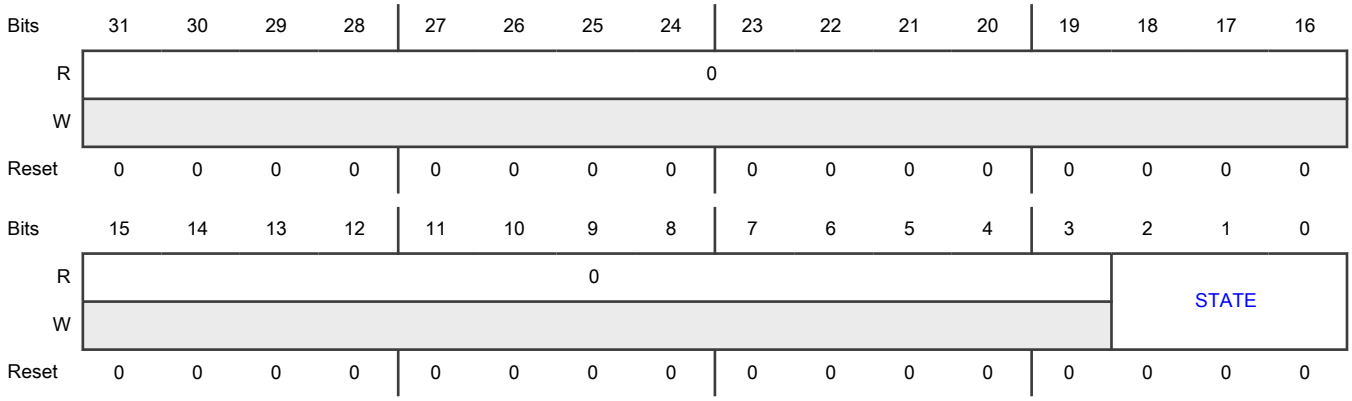
Offset

Register	Offset
SHIFTSTATE	40h

Function

Contains the pointer to keep track of the current shifter.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 STATE	Current State Pointer The current state field maintains a pointer to keep track of the current Shifter (configured for State mode) enabled to drive outputs and compute the next state. Reading this register when the state pointer is updating can result in the incorrect state returned. This bitfield is writable and the value written overrides the current state.

71.6.1.15 Trigger Status Register (TRGSTAT)

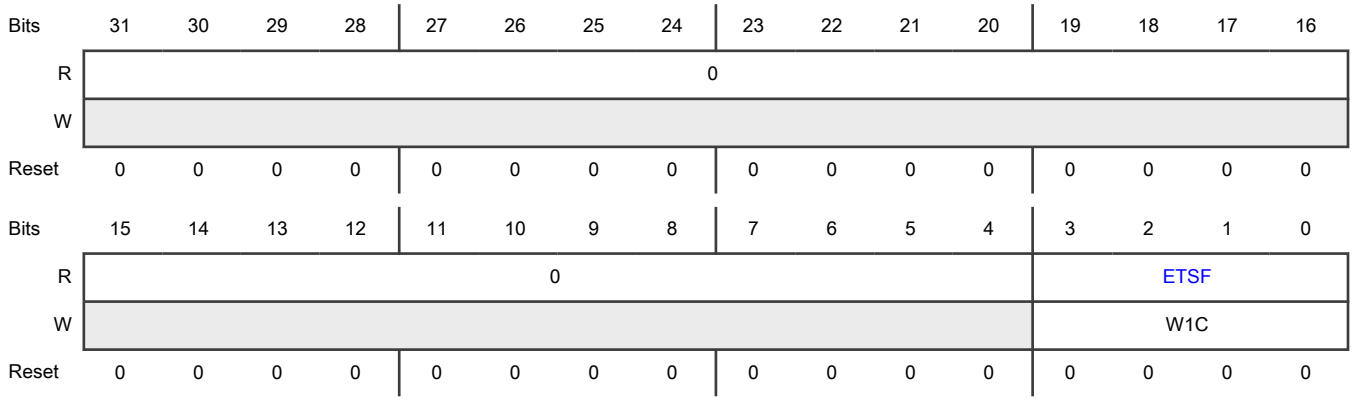
Offset

Register	Offset
TRGSTAT	48h

Function

External Trigger Status Flags. Write one to clear.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 ETSF	External Trigger Status Flags The external trigger status flag is set when a rising edge is detected on the corresponding external trigger input. 0b - External Trigger Status Flag is clear 1b - External Trigger Status Flag is set

71.6.1.16 External Trigger Interrupt Enable Register (TRIGIEN)

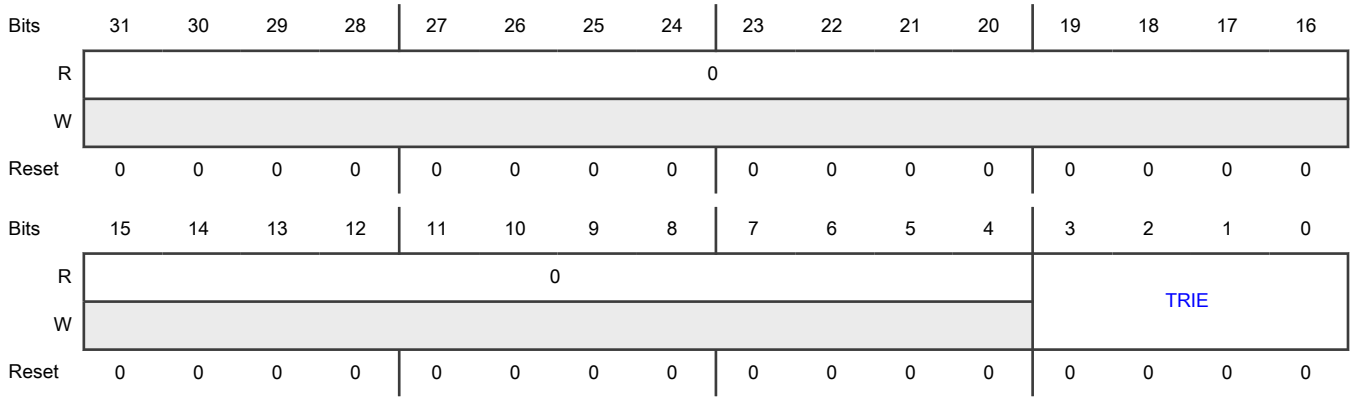
Offset

Register	Offset
TRIGIEN	4Ch

Function

Enables for external trigger interrupts.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TRIE	External Trigger Interrupt Enable Enables interrupt generation when corresponding ETSF is set. 0b - External Trigger Status Flag interrupt is disabled. 1b - External Trigger Status Flag interrupt is enabled.

71.6.1.17 Pin Status Register (PINSTAT)

Offset

Register	Offset
PINSTAT	50h

Function

Pin Status Flags. Write one to clear.

Diagram

71.6.1.27 Shifter Control N Register (SHIFTCTL0 - SHIFTCTL7)

Offset

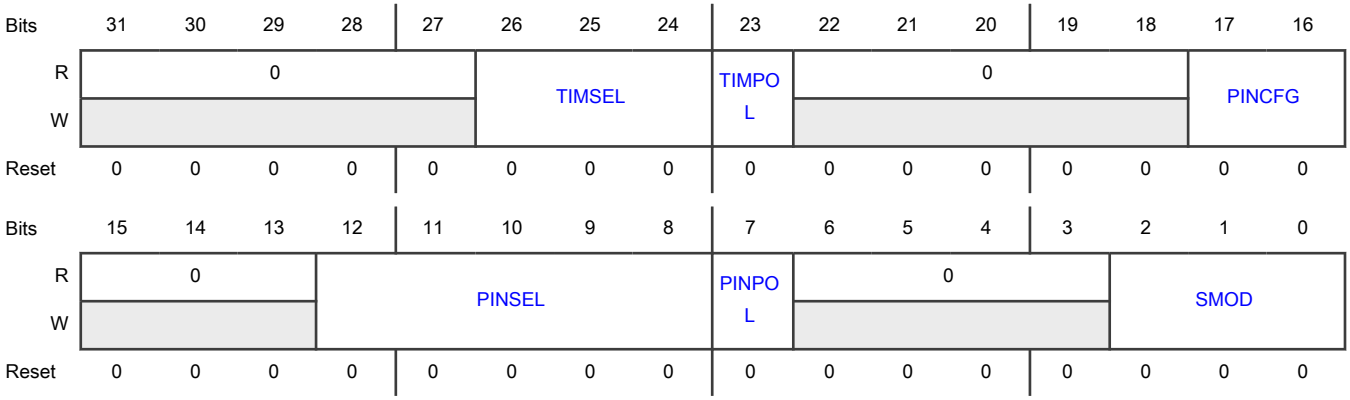
For a = 0 to 7:

Register	Offset
SHIFTCTLa	80h + (a × 4h)

Function

Control for Shift Register N

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which Timer is used for controlling the logic/shift register and generating the Shift clock. TIMSEL=i selects TIMERi.
23	Timer Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMPOL	Determines the shift occurs on the positive edge or negative edge of the shift clock. 0b - Shift on posedge of Shift clock 1b - Shift on negedge of Shift clock
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration For pins configured as an output (PINCFG=11), this field takes effect when the register is written. **NOTE** When initially configuring PINCFG=0x11, FlexIO may briefly drive the pin low. To avoid this, software can configure PINCFG=0x10 along with the rest of the control register and then perform a subsequent write to set PINCFG=0x11. 00b - Shifter pin output disabled 01b - Shifter pin open drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects which pin is used by the Shifter input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.
7 PINPOL	Shifter Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the Shifter. 000b - Disabled. 001b - Receive mode. Captures the current Shifter content into the SHIFTBUF on expiration of the Timer. 010b - Transmit mode. Load SHIFTBUF contents into the Shifter on expiration of the Timer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	011b - Reserved. 100b - Match Store mode. Shifter data is compared to SHIFTBUF content on expiration of the Timer. 101b - Match Continuous mode. Shifter data is continuously compared to SHIFTBUF contents. 110b - State mode. SHIFTBUF contents are used for storing programmable state attributes. 111b - Logic mode. SHIFTBUF contents are used for implementing programmable logic look up table.

71.6.1.28 Shifter Configuration N Register (SHIFTCFG0 - SHIFTCFG7)

Offset

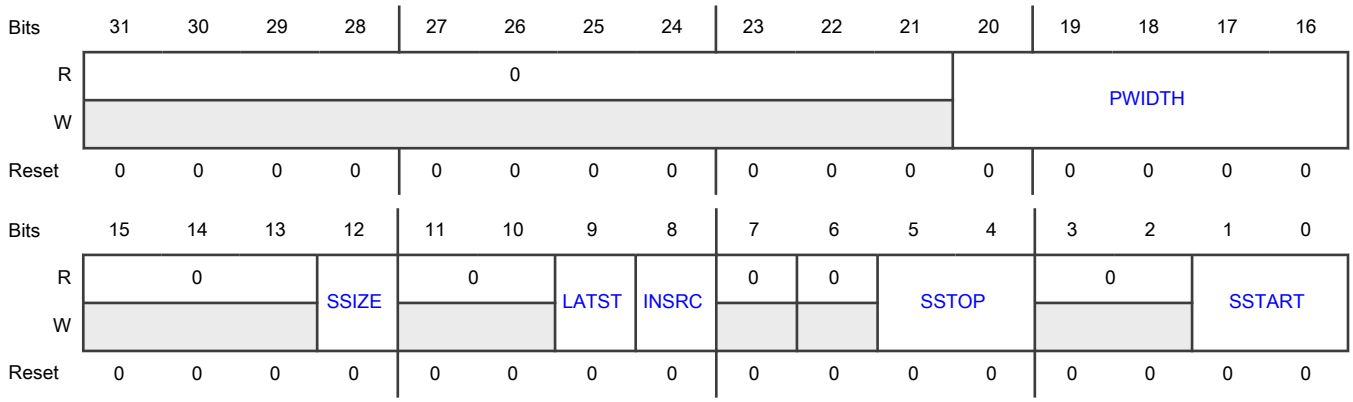
For a = 0 to 7:

Register	Offset
SHIFTCFGa	100h + (a × 4h)

Function

Contains configuration bit fields for Shifter Register N.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16	Parallel Width

Table continues on the next page...

Table continued from the previous page...

Field	Function
PWIDTH	For all Shifters, this register field configures the number of bits to be shifted on each Shift clock as follows: 1-bit shift for PWIDTH=0 2-bit shift for PWIDTH=1 4-bit shift for PWIDTH=2...3 8-bit shift for PWIDTH=4...7 16-bit shift for PWIDTH=8...15 32-bit shift for PWIDTH=16...31 For Shifters which support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this register field, together with SHIFTCTL[PINSEL], also selects the pins to be driven or sampled on each Shift clock as follows: • FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL] Shifters which do not support parallel transmit or parallel receive only support parallel shift when INSRC=1. For SMOD=State, this field is used to disable state outputs. See State Mode section for more detail.
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift Registers. A 24-bit shift register shifts data into bits [23:0] only and does not update bits [31:24] during shift operations. When shift register is configured for 24-bit, configuring PWIDTH=8..15 performs a 12-bit shift and PWIDTH=16..31 performs a 24-bit shift. 0b - Shift register is 32-bit. 1b - Shift register is 24-bit.
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match shift register is configured to both shift and store on the same cycle. 0b - Shift register stores the pre-shift register state. 1b - Shift register stores the post-shift register state.
8 INSRC	Input Source Selects the input source for the shifter. Configuring INSRC=1 is not supported for the last shifter. 0b - Pin 1b - Shifter N+1 Output

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop bit For SMOD=Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit. For SMOD=Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Stop bit disabled for transmitter/receiver/match store 01b - Stop bit disabled for transmitter/receiver/match store, receiver/match store will store receive data on the configured shift edge when timer in stop condition 10b - Transmitter outputs stop bit value 0 on store, receiver/match store sets error flag if stop bit is not 0, receiver/match store will also store receive data on the configured shift edge when timer in stop condition 11b - Transmitter outputs stop bit value 1 on store, receiver/match store sets error flag if stop bit is not 1, receiver/match store will also store receive data on the configured shift edge when timer in stop condition
3-2 —	Reserved
1-0 SSTART	Shifter Start bit For SMOD=Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit. For SMOD=Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Start bit disabled for transmitter/receiver/match store, transmitter loads data on enable 01b - Start bit disabled for transmitter/receiver/match store, transmitter loads data on first shift 10b - Transmitter outputs start bit value 0 before loading data on first shift, receiver/match store sets error flag if start bit is not 0 11b - Transmitter outputs start bit value 1 before loading data on first shift, receiver/match store sets error flag if start bit is not 1

71.6.1.29 Shifter Buffer N Register (SHIFTBUF0 - SHIFTBUF7)

Offset

For a = 0 to 7:

Register	Offset
SHIFTBUFa	200h + (a × 4h)

Function

Contains Shift buffer data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Shift buffer data is used for a variety of functions depending on the SMOD setting: For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins. For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See Logic Mode section for more detail. For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See State Mode section for more detail.

71.6.1.30 Shifter Buffer N Bit Swapped Register (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For a = 0 to 7:

Register	Offset
SHIFTBUFBISa	280h + (a × 4h)

Function

SHIFTBUF register contents, but contents of this register are bit swapped.

Diagram

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Alias to SHIFTBUF register, except reads/writes to this register are bit swapped within each byte. Reads return { SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7] }.

71.6.1.33 Timer Control N Register (TIMCTL0 - TIMCTL7)

Offset

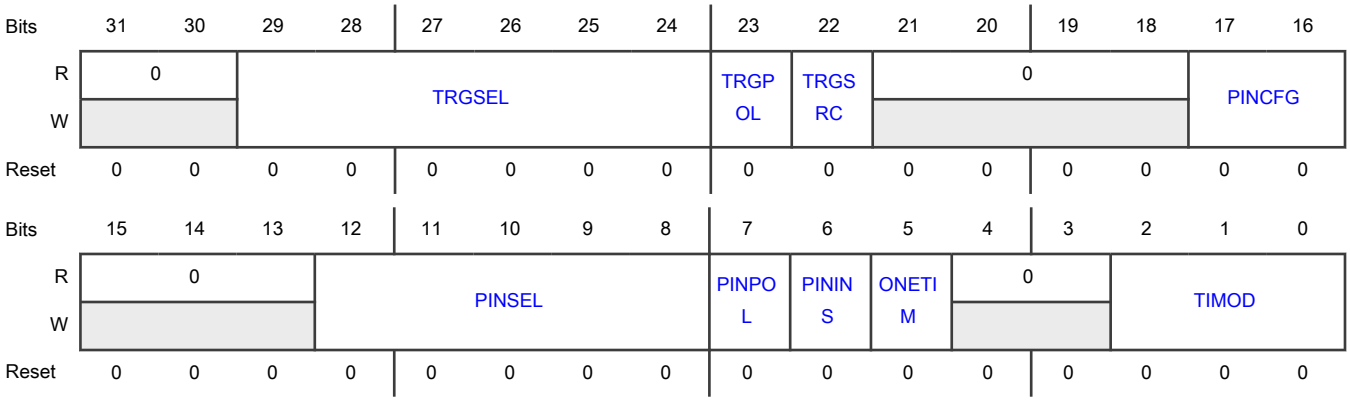
For a = 0 to 7:

Register	Offset
TIMCTLa	400h + (a × 4h)

Function

Timer Control for Timer N.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select The valid values for TRGSEL depends on the FLEXIO_PARAM register. • When TRGSRC = 1, the valid values for N depends on PIN, TIMER, SHIFTER fields in the FLEXIO_PARAM register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When TRGSRC = 0, the valid values for N depends on TRIGGER field in FLEXIO_PARAM register. Refer to the chip-specific FlexIO information for external trigger selection. **NOTE** For a pin, N=0 to 31. For a Shifter, N=0 to 7. For a Timer, N=0 to 7. When TRGSRC = 0 the trigger selection is configured as follows: • N - External trigger N input When TRGSRC = 1 the internal trigger can be configured to select an input pin as follows: • 2*N - Pin N input When TRGSRC = 1 the internal trigger can be configured to select a shifter/timer signal as follows: • 4*N+1 - Shifter N status flag • 4*N+3 - Timer N trigger output In other words, the expanded internal trigger selection (TRGSRC = 1) is as follows: • 0000 = Pin 0 • 0001 = Shifter 0 Flag • 0010 = Pin 1 • 0011 = Timer 0 Trigger • 0100 = Pin 2 • 0101 = Shifter 1 Flag • 0110 = Pin 3 • 0111 = Timer 1 Trigger • ... • This continues up to the Pin 31, Shifter 7 and Timer 7.
23 TRGPOL	Trigger Polarity Determines if the trigger is active high or active low. 0b - Trigger active high 1b - Trigger active low
22 TRGSRC	Trigger Source Determines if the trigger source is external or internal. 0b - External trigger selected 1b - Internal trigger selected
21-18 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
17-16 PINCFG	Timer Pin Configuration Configures the direction of the Timer pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written. **NOTE** When initially configuring PINCFG=0x11, FlexIO may briefly drive the pin low. To avoid this, software can configure PINCFG=0x10 along with the rest of the control register and then perform a subsequent write to set PINCFG=0x11. 00b - Timer pin output disabled 01b - Timer pin open drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects which pin is used by the Timer input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6 PININS	Timer Pin Input Select When set, the timer input pin is a different pin from the timer output pin. PINSEL must select an even numbered pin when this bit is set, so the output pin is even numbered and input pin is odd numbered. 0b - Timer pin input and output are selected by PINSEL. 1b - Timer pin input is selected by PINSEL+1, timer pin output remains selected by PINSEL.
5 ONETIM	Timer One Time Operation When set, configures the timer to perform a single enable/disable iteration, after which software must clear the timer status flag for the timer to be enabled again. 0b - The timer enable event is generated as normal. 1b - The timer enable event is blocked unless timer status flag is clear.
4-3 —	Reserved
2-0	Timer Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMOD	In 8-bit baud counter mode, the lower 8-bits of the counter and compare register are used to configure the baud rate of the timer shift clock, and the upper 8-bits are used to configure the shifter bit count. In 8-bit PWM high mode, the lower 8-bits of the counter and compare register are used to configure the high period of the timer shift clock, and the upper 8-bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit counter mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 16-bit counter disable mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 8-bit word counter mode, the lower 8-bits of the counter and compare register are used to configure the shifter bit count, and the upper 8-bits are used to configure the shifter word count. In 8-bit PWM low mode, the lower 8-bits of the counter and compare register are used to configure the low period of the timer shift clock and the upper 8-bits are used to configure the high period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit input capture mode, the inverted value of 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMDIS). This also sets the timer status flag. The timer counter is immediately restarted from 0xFFFF 000b - Timer Disabled. 001b - Dual 8-bit counters baud mode. 010b - Dual 8-bit counters PWM high mode. 011b - Single 16-bit counter mode. 100b - Single 16-bit counter disable mode. 101b - Dual 8-bit counters word mode. 110b - Dual 8-bit counters PWM low mode. 111b - Single 16-bit input capture mode.

71.6.1.34 Timer Configuration N Register (TIMCFG0 - TIMCFG7)

Offset

For a = 0 to 7:

Register	Offset
TIMCFGa	480h + (a × 4h)

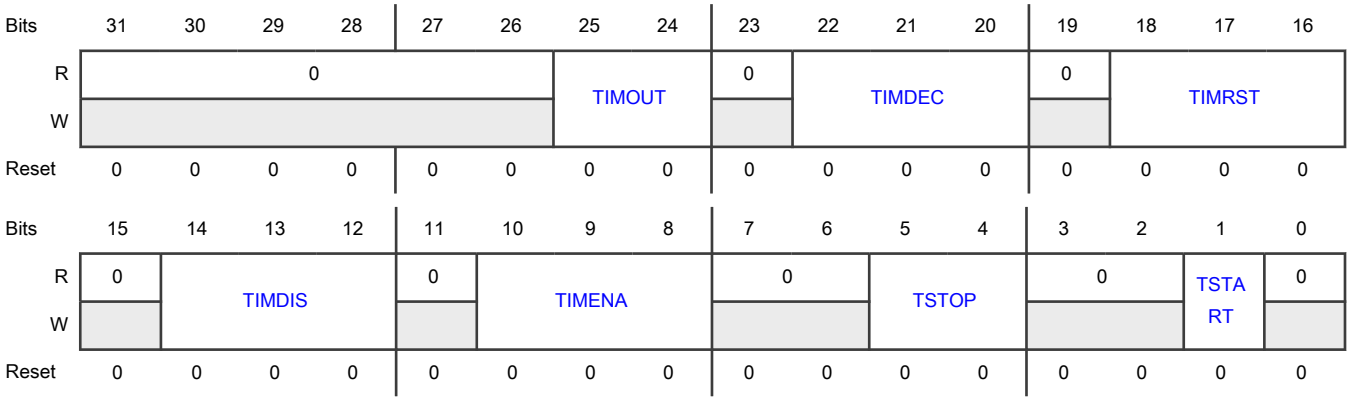
Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the Timer Output and whether it is affected by the Timer reset. 00b - Timer output is logic one when enabled and is not affected by timer reset 01b - Timer output is logic zero when enabled and is not affected by timer reset 10b - Timer output is logic one when enabled and on timer reset 11b - Timer output is logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the Timer decrement and the source of the Shift clock. 000b - Decrement counter on FlexIO clock, Shift clock equals Timer output. 001b - Decrement counter on Trigger input (both edges), Shift clock equals Timer output. 010b - Decrement counter on Pin input (both edges), Shift clock equals Pin input. 011b - Decrement counter on Trigger input (both edges), Shift clock equals Trigger input. 100b - Decrement counter on FlexIO clock divided by 16, Shift clock equals Timer output. 101b - Decrement counter on FlexIO clock divided by 256, Shift clock equals Timer output.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - Decrement counter on Pin input (rising edge), Shift clock equals Pin input. 111b - Decrement counter on Trigger input (rising edge), Shift clock equals Trigger input.
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8-bits that configure the baud rate. In all other modes, the timer reset resets the full 16-bits of the counter. 000b - Timer never reset 001b - Timer reset on Timer Output high. 010b - Timer reset on Timer Pin equal to Timer Output 011b - Timer reset on Timer Trigger equal to Timer Output 100b - Timer reset on Timer Pin rising edge 101b - Reserved 110b - Timer reset on Trigger rising edge 111b - Timer reset on Trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the Timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on Timer N-1 disable 010b - Timer disabled on Timer compare (upper 8-bits match and decrement) 011b - Timer disabled on Timer compare (upper 8-bits match and decrement) and Trigger Low 100b - Timer disabled on Pin rising or falling edge 101b - Timer disabled on Pin rising or falling edge provided Trigger is high 110b - Timer disabled on Trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the Timer to be enabled and start decrementing.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Timer always enabled 001b - Timer enabled on Timer N-1 enable 010b - Timer enabled on Trigger high 011b - Timer enabled on Trigger high and Pin high 100b - Timer enabled on Pin rising edge 101b - Timer enabled on Pin rising edge and Trigger high 110b - Timer enabled on Trigger rising edge 111b - Timer enabled on Trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Bit The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Stop bit disabled 01b - Stop bit is enabled on timer compare 10b - Stop bit is enabled on timer disable 11b - Stop bit is enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Bit When start bit is enabled, configured shifters outputs the contents of the start bit when the timer is enabled and the timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Start bit disabled 1b - Start bit enabled
0 —	Reserved

71.6.1.35 Timer Compare N Register (TIMCMP0 - TIMCMP7)

Offset

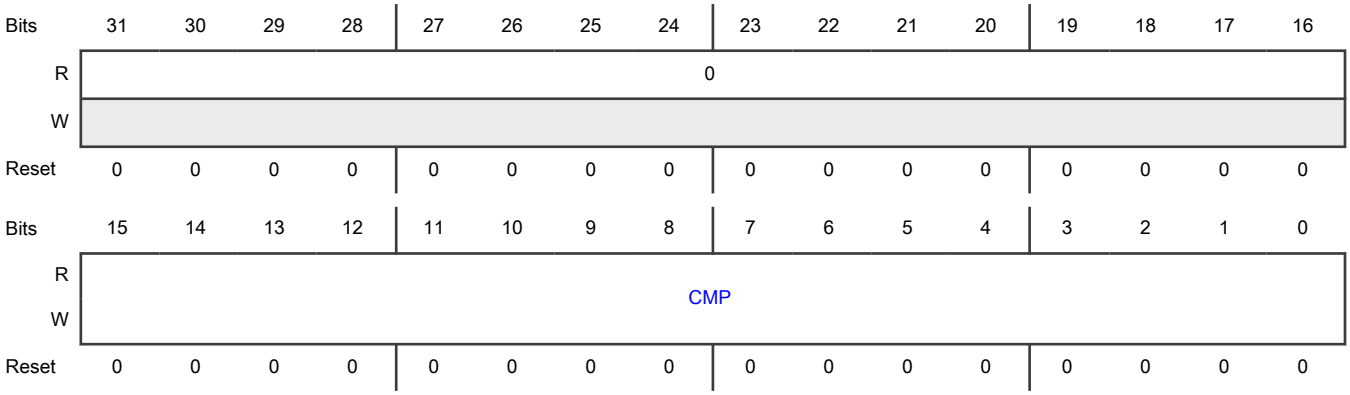
For a = 0 to 7:

Register	Offset
TIMCMPa	500h + (a × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8-bits configure the baud rate divider equal to (CMP[7:0] + 1) * 2. The upper 8-bits configure the number of bits in each word equal to (CMP[15:8] + 1) / 2. In 8-bit PWM high mode, the lower 8-bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 8-bit word counter mode, the lower 8-bits configure the number of bits in each word equal to (CMP[7:0] + 1) / 2. The upper 8-bits configure the number of words to transfer equal to (CMP[15:8] + 1) / 2. In 8-bit PWM low mode, the lower 8-bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the high period of the output to (CMP[15:8] + 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. The timer compare register should only be read when the timer status flag is set.

71.6.1.36 Shifter Buffer N Nibble Byte Swapped Register (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

For a = 0 to 7:

Register	Offset
SHIFTBUFNBSa	680h + (a × 4h)

Function

SHIFTBUF register contents, but contents of this register are nibble swapped within each byte.

71.7 Glossary

Baud rate Number of bits transmitted or received per second by the LPUART

Break character Break character is generated when the transmitter is holding the data line at the space level for at least 1 character time

Idle character	Idle character is generated when the transmitter is holding the data line at logic 1 for at least 1 character time
PWM	Pulse Width Modulation

Chapter 72
CAN (FlexCAN)

72.1 Chip-specific FlexCAN information

72.1.1 FlexCAN instances and configuration

This chip contains up to 8 instances of FlexCAN:

- FlexCAN_0
- FlexCAN_1
- FlexCAN_2
- FlexCAN_3
- FlexCAN_4
- FlexCAN_5
- FlexCAN_6
- FlexCAN_7

NOTE

The availability of 'Interrupt Masks 3 Register (IMASK3)' and 'Interrupt Flags 3 Register (IFLAG3)' registers for an instance depends upon the number of message buffers supported. See Table 435 for details.

Table 435. FlexCAN configuration and instances

Chip	Instances	Flexible Data Rate (CAN FD) protocol specification and CAN protocol.	Number of message buffers (assuming 8B payload)	Rx FIFO ID Filtering	ECC	External tick time	DMA	Enhanced RX FIFO feature (size)
S32K358	FlexCAN_0	Yes	96	Yes	Yes	Yes (PIT_RTI_2)	Yes	Yes (20)
	FlexCAN_1	Yes	96	Yes	Yes	Yes (PIT_RTI_2)	Yes	Yes (20)
	FlexCAN_2	Yes	96	Yes	Yes	Yes (PIT_RTI_2)	Yes	Yes (20)
	FlexCAN_3	Yes	64	Yes	Yes	Yes (PIT_RTI_2)	Yes	No
	FlexCAN_4	Yes	64	Yes	Yes	Yes (PIT_RTI_2)	Yes	No
	FlexCAN_5	Yes	64	Yes	Yes	Yes (PIT_RTI_2)	Yes	No
	FlexCAN_6	Yes	64	Yes	Yes	Yes (PIT_RTI_2)	Yes	No

Table continues on the next page...

Table 435. FlexCAN configuration and instances (continued)

Chip	Instances	Flexible Data Rate (CAN FD) protocol specification and CAN protocol.	Number of message buffers (assuming 8B payload)	Rx FIFO ID Filtering	ECC	External tick time	DMA	Enhanced RX FIFO feature (size)

FlexCAN memory initialization

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization.

These locations are as listed in this table from 080h–ADFh and from C20h–31FFh.:

Chip	Instance	Offset address ranges to be initialized
S32K344, S32K324, S32K314	FlexCAN0	080h–ADFh; C20h–31FFh
	FlexCAN1–FlexCAN5	080h–ADFh; C20h–FFFh
S32K342, S32K322	FlexCAN0	080h–ADFh; C20h–31FFh
	FlexCAN1–FlexCAN3	080h–ADFh; C20h–FFFh
S32K312	FlexCAN0	080h–DFh; C20h–31FFh
	FlexCAN1–FlexCAN5	080h–ADFh; C20h–FFFh
S32K311	FlexCAN0	080h–ADFh; C20h–31FFh
	FlexCAN1–FlexCAN2	080h–ADFh; C20h–FFFh

NOTE

The reset value of CAN0_CTRL2 register for S32K312 and S32K342 is 0080_0000h.

72.1.3 Reset value of MDIS bit

The CAN_MCR[MDIS] bit is set to 1 when the module is reset. Therefore, FlexCAN module is disabled following a reset. For details of CAN_MCR[MDIS] register refer to "CAN register description" section.

72.1.4 CAN Timestamp Implementation

FlexCAN uses Ethernet Media Access Controller (EMAC) and System Timer Module (STM_0) counters as time source. For details see 'FlexCAN timestamp implementation' section in Clocking chapter.

72.1.4.1 Considerations while using FlexCAN timestamp in S32K344

While using FlexCAN timestamp feature, the message buffers should be unlocked within each 20 CAN bits. A failure to do so while using FlexCAN timestamp feature alongwith FlexCAN RX FIFO or enhanced RX FIFO might result in timestamp information being missed.

72.1.5 CAN clock setup

For clock setup, see Clocking chapter.

72.2 Overview

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the EMI environment of a vehicle. The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol, and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads.

NOTE

Legacy Rx FIFO cannot be used in FD mode.

NOTE

In CAN FD mode, the Enhanced Rx FIFO feature should be used instead of Legacy Rx FIFO.

72.2.1 Block diagram

A general block diagram is shown in Figure 376, which describes the main subblocks implemented in the FlexCAN module.

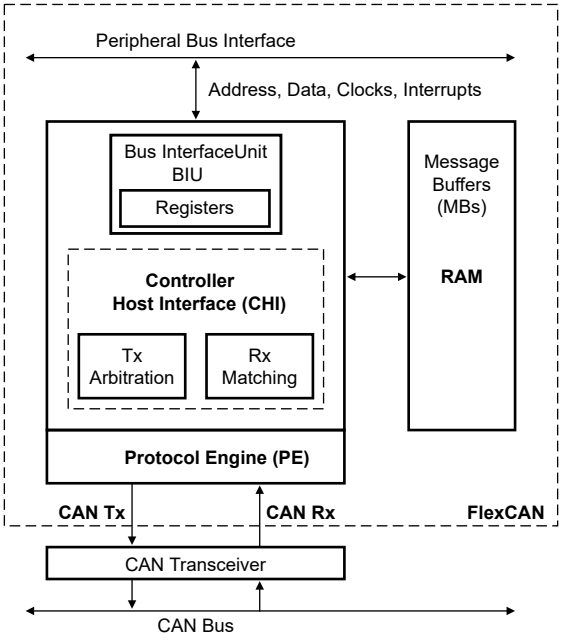

Figure 376. FlexCAN block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) submodule manages message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

72.2.2 Features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing
- Compliant with the ISO 11898-1:2015 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32, or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages

- Individual Rx Mask registers per mailbox
- Full-featured legacy Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Full-featured enhanced Rx FIFO with storage capacity for up to 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 96 message buffers of 8 bytes data length each, configurable as Rx or Tx
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 32-bit free running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power mode
- Transceiver delay compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be managed automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to indicate that the module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful legacy Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- Powerful Enhanced Rx FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask + filter, range, and two filters without mask.
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses

  Each byte of FlexCAN memory is associated to 5 parity bits, and the error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors).

72.3 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed of a set of message buffers (MB) that store configuration and control data, time stamp, message ID, and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a Legacy

FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID filter table elements.

For Classical CAN frames, simultaneous reception through Legacy FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes and Enhanced Rx FIFO. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A message buffer is said to be active at a given time if it can participate in both the matching and arbitration processes. An Rx MB with a 0b code is inactive (see Table 469). Similarly, a Tx MB with a 1000b or 1001b code is also inactive (see Table 470).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The message buffers are sized to adequately store the quantity of data bytes selected by the FDCTRL[MBDSRn] fields. The quantity of FD MBs available for a given quantity of data bytes is described in the FDCTRL register. See also FlexCAN memory partition for CAN FD.

72.3.1 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are managed normally, and all CAN Protocol functions are enabled. User and Supervisor modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when MCR[FRZ] is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when CTRL1[LPB] is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

  The module enters this mode when CTRL1[LOM] is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

  It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

Table 436. Differences between CAN classical and CAN FD

Feature	CAN classical	CAN FD
Legacy Rx FIFO DMA	Yes	No

Table continues on the next page...

Table 436. Differences between CAN classical and CAN FD (continued)

Feature	CAN classical	CAN FD
Legacy Rx FIFO	Yes	No
Enhanced Rx FIFO DMA	Yes	Yes
Enhanced Rx FIFO	Yes	Yes

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when MCR[MDIS] is asserted by the CPU and MCR[LPM_ACK] is asserted by FlexCAN. When disabled, the module issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating MCR[MDIS]. See Module Disable mode for more information.

72.3.1.1 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

72.3.1.1.1 Freeze mode

This mode is requested either by the CPU through the assertion of MCR[HALT] or when the chip is put into Debug mode. In both cases it is also necessary that MCR[FRZ] be asserted and the module not be in a low-power mode. This mode is also requested by FlexCAN through the automatic assertion of both MCR[HALT] and MCR[FRZ] when MECR[NCEFAFRZ] is set and a non-correctable error is detected in a memory read access performed by FlexCAN internal processes (see Response to errors).

The acknowledgement is obtained through the assertion by the FlexCAN of MECR[FRZ_ACK]. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off, or Idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the Error Counters register, which is read-only in other modes.
- Sets MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, the user must wait for MCR[FRZ_ACK] to be asserted before executing any other action; otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory-mapped registers are accessible.

Exiting Freeze mode is done in one of the following ways:

- CPU negates MCR[FRZ].
- The chip is removed from Debug mode and/or the HALT bit is negated.

MCR[FRZ_ACK] is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

72.3.1.1.2 Module Disable mode

This low-power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of MCR[MDIS], and the acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register, the Legacy Rx FIFO Global Mask register. The Legacy Rx FIFO Information register, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Disable mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

72.3.2 Transmit process

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001b) to the CODE field of the Control and Status word to request an abort of the transmission.
3. Wait for the corresponding IFLAG bit to be asserted by polling the IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.
4. Read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO_EN]).
7. Write payload data bytes.
8. Configure the Control and Status word with the desired configuration.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] is enabled, also configure the MB_CS[EDL] and MB_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB_CS[ESI] field, see Table 447.[7]
    d. Set Data Length Code in bytes via MB_CS[DLC]. See Table 472 for detailed information.
    e. Activate the message buffer to transmit the CAN frame by setting MB_CS[CODE] to Ch.

[7] The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB_CS[ESI] bit according to the error status of the node which sent the message.

NOTE

It is strongly recommended that all the fields in MB_CS word be configured in only one 32-bit write operation to maximize software performance. If the fields are configured in separate writes, the MB_CS[CODE] must be the last write in the C/S word.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant CCh pattern to complete the expected DLC.

At the end of the successful transmission:

- The value of the free running timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CRC and FDCRC registers are updated.
- A status flag is set in the Interrupt Flag register.
- An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The new CODE field after transmission depends on the code that was used to activate the MB (see Table 469 and Table 470 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

NOTE

If backwards compatibility is desired (MCR[AEN] is negated), write the INACTIVE code (1000b) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see Mailbox inactivation).

72.3.3 Arbitration process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the value of CTRL2[TASD].
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is a CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the Intermission field, the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the settings of both CTRL1[LBUF] and MCR[LPRIOEN].

72.3.3.1 Lowest-number mailbox first

If CTRL1[LBUF] is asserted, the first (lowest number) active Tx mailbox found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is asserted.

72.3.3.2 Highest-priority mailbox first

If CTRL1[LBUF] is negated, then the arbitration process searches the active Tx mailbox with the highest priority, which means that this mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the MCR[LPRIOEN] setting.

72.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the local priority is disabled.

Table 437. Composition of the arbitration value when local priority is disabled

Format	Mailbox arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

72.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be asserted. In this case the mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 438. Composition of the arbitration value when local priority is enabled

Format	Mailbox arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values regardless of the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

72.3.3.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if MCR[AEN] is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU.

- FlexCAN enters Freeze mode or Bus Off.
- FlexCAN loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process, and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case the first and second C/S write in Bus Idle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in Wait For Bus Idle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during Bus Idle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If there is a re-synchronization during Wait For Bus Idle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found if lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or overload flag in the bus.
- Low Power or Freeze mode request in Idle state.

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated a Rx code to Tx code.
- Entering Bus Off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

72.3.4 Receive process

To be able to receive CAN frames into a mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx) inactivate the mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word into the mailbox.

3. Write the EMPTY code (0100b) to the CODE field of the Control and Status word to activate the mailbox. No setup is required for EDL, BRS, and ESI bits—they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (see Move-in) as follows:

1. The received data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 469 and Table 470 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU to service (read) the frame received in a mailbox is by the following procedure:

1. Read the Control and Status word of that mailbox.
2. Check if the BUSY bit is deasserted, indicating that the mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the mailbox. After the mailbox is locked, its contents won't be modified by FlexCAN move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the free running timer to unlock the mailbox.

The CPU should poll for frame reception by the status flag bit for the specific mailbox in one of the IFLAG registers and not by the CODE field of that mailbox. Polling the CODE field does not work because after a frame is received and the CPU services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 469. If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

CAUTION

In summary: never do polling by reading directly the C/S word of the mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching mailbox, thus the contents of the ID field in a mailbox may change if the match was due to masking. When MCR[SRXDIS] is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when MCR[SRXDIS] is deasserted, FlexCAN can receive frames transmitted by itself if a matching Rx mailbox exists.

To be able to receive CAN frames through the Legacy Rx FIFO, the CPU must enable and configure the Legacy Rx FIFO during Freeze mode (see Legacy Rx FIFO). Upon receiving the Frames Available in Legacy Rx FIFO interrupt (see the description of IFLAG1[BUF5I] "Frames available in Legacy Rx FIFO"), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the data field.
4. Read the RXFIR register. (This step is optional, and is executed only if the IDHIT (Identifier Acceptance Filter Hit Indicator) is required in the application.)
5. Clear the Frames Available in Legacy Rx FIFO interrupt by writing one to IFLAG1[BUF5I] (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry).

When MCR[DMA] is asserted, upon receiving a frame in Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy Rx FIFO under DMA operation). The IMASK1 bits in Legacy Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).
4. Read the last data bytes (read 8Ch address is mandatory).

72.3.5 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the Legacy Rx or Enhanced Rx FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number message buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

For enhanced Rx FIFO see Enhanced Rx FIFO.

For legacy Rx FIFO see Legacy Rx FIFO.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 439. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	—	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN

Table continues on the next page...

Table 439. Matching architecture (continued)

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Legacy Rx FIFO[5]	—	—	—	cmp_msk	cmp_msk	cmp_msk	—

1. For mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For Legacy Rx FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

NOTE

For Enhanced Rx FIFO, see Enhanced Rx FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed.
- The Legacy Rx FIFO or Enhanced Rx FIFO is not full.

The scan order for mailboxes and Legacy Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by MCR[IRMQ]. If it is negated, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched mailbox;
2. the last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and Legacy Rx FIFO or Enhanced Rx FIFO with CTRL2[MRP].

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched in the scan for the Rx FIFO.
- If both conditions above are not satisfied and a non–free-to-receive matched mailbox is found, then the matching winner determination is conditioned by MCR[IRMQ]:
  - If MCR[IRMQ] is negated, the matching winner is the first matched mailbox.
  - If MCR[IRMQ] is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non–free-to-receive matched mailbox.

See the following table for a summary of matching possibilities.

Table 440. Matching possibilities and resulting reception structures

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	—[3]	None	Frame lost by no match
0	0	X	Free[4]	—	First MB	
0	1	X	None	—	None	Frame lost by no match
0	1	X	Free	—	First MB	
0	1	X	Not free	—	Last MB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	First MB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	First MB	
1	1	X	Not free	None	Last MB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	Not full[6]	FIFO	
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO overflow)
1	0	0	Free	Full	First MB	
1	0	0	Not free	Full	First MB	
1	0	1	None	Not full	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	1	Free	X	First MB	
1	0	1	Not free	X	First MB	Overrun
FIFO enabled, queue enabled						
1	1	0	X	Not full	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	1	0	Free	Full	First MB	

Table continues on the next page...

Table 440. Matching possibilities and resulting reception structures (continued)

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	1	0	Not free	Full	Last MB	Overrun
1	1	1	None	Not full	FIFO	
1	1	1	Free	X	First MB	
1	1	1	Not free	Not full	FIFO	
1	1	1	Not free	Full	Last MB	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non–free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0 and ERFCR[ERFEN]=0).
6. Matched in FIFO "Not full" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe mailbox inactivation (see Mailbox inactivation) occurs during matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted—it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled, there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per MB (see the description of Rx Individual Mask Registers (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXFGMASK, RXMGMASK, RX14MASK, and RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR register is negated.

72.3.6 Move process

There are two types of move process: move-in and move-out.

72.3.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Legacy Rx FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each Rx SMB has its own

move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has either reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB.
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB.
- There is no ongoing matching process.
- The destination mailbox is not locked by the CPU.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in process is to be started at the same time, both are performed and the newest substitutes for the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and self-reception is disabled (MCR[SRXDIS] is asserted).
- Any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It stays on hold, only waiting for Freeze and Low-Power mode to be exited and the module to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined for the Legacy Rx FIFO.
2. Read all data words from the Rx SMB in accordance with the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox in accordance with the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination mailbox (see Mailbox inactivation). In this case the mailbox may remain partially updated, thus incoherent. The exception is if the move-in destination is a Legacy or Enhanced Rx FIFO message buffer; then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the CPU that the message buffer content is temporarily incoherent.

72.3.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

72.3.7 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

72.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abort of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be asserted.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

- The MB is transmitted correctly.
- The interrupt flag is set in the IFLAG register.
- An interrupt to the CPU is generated (if enabled).

The abort request is automatically cleared when the interrupt flag is set. On the other hand, if only one of the above conditions is reached, the frame is not transmitted; therefore:

- The abort code is written into the CODE field.
- The interrupt flag is set in the IFLAG.
- An interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU only needs to read the abort code to make sure the active MB was safely inactivated. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

72.3.7.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission mailboxes must be performed just when MCR[AEN] is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a mailbox.

To inactivate a mailbox, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you will not be able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

In order to perform a safe inactivation and avoid the above consequences for Tx mailboxes, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the mailbox (see Mailbox lock mechanism).

NOTE

Message buffers that are part of the Legacy Rx FIFO or Enhanced Rx FIFO cannot be inactivated. There is no write protection on the Legacy FIFO region by FlexCAN. CPU must maintain data coherency in the Legacy FIFO region when RFEN is asserted.

72.3.7.3 Mailbox lock mechanism

Other than mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the free running timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of the Legacy Rx FIFO and have a code different than INACTIVE (0b) or EMPTY[1] (0100b). Also, Tx MBs cannot be locked.

Suppose, for example, that the Legacy Rx FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no free-to-receive MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

NOTE

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Free Running Timer (TIMER)), or the C/S word of another MB.

[1] In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module returns to Normal or Freeze modes.

72.3.8 Enhanced Rx FIFO

FlexCAN supports an enhanced Rx FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO which should be read by the CPU. The enhanced Rx FIFO is enabled by setting EFRCR[ERFEN]. Although FlexCAN has two FIFO options, Legacy Rx FIFO and Enhanced Rx FIFO, they cannot be enabled at the same time. Refer to Legacy Rx FIFO to find detailed information about Legacy Rx FIFO.

The enhanced Rx FIFO has a watermark which is configured by setting EFRCR[ERFWM]. If EFRCR[ERFWM] is set, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in EFRCR[ERFWM], ERFSR[ERFWMI] is set by the hardware. Optionally, an interrupt or a DMA transfer can be triggered if MCR[DMA] or ERFIER[ERFWMIIE] are set, respectively.

For the Enhanced Rx FIFO to receive, the CPU must execute the configuration procedure below. The same procedure must be done if the CPU needs to change any of the configuration of the Enhanced RX FIFO.

1. Enter Freeze mode.
2. Enable Enhanced Rx FIFO by setting ERFCR[ERFEN], if it is not already enabled.[8]
3. Write one to ERFSR[ERFCLR] to reset Enhanced Rx FIFO engine.
4. Clear EFRSR[ERFUFW], EFRSR[ERFOVF], EFRSR[ERFWMI], and EFRSR[ERFDA], if they are set.
5. Write EFRCR[NFE] to configure the total number of enhanced Rx FIFO filter elements to be used in Enhanced Rx FIFO reception.
6. Write ERFCR[NEXIF] to configure the number of extended ID and standard ID filter elements to be used in Enhanced Rx FIFO reception.[9]
7. Configure the Enhanced Rx FIFO watermark by writing ERFCR[ERFWM]. If MCR[DMA] is set, ERFCR[ERFWM] should be configures as 0x0.
8. If interrupts will be used, set the interrupt enables in the ERIER register.
9. If DMA will be used, set MCR[DMA] to enable DMA operation and write ERFCR[DMALW] to configure the number of words to transfer for each Enhanced Rx FIFO data element.
10. Configure the filter elements by writing in the ERFFEL*n* registers.[10]
11. Leave Freeze mode.

There are two types of Enhanced Rx FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter element and standard-ID filter element. Each extended-ID filter element is stored in two ERFFEL*n* registers while each standard-ID filter element is stored in one ERFFEL*n* register. The total number of Enhanced RX FIFO filter elements is defined by ERFCR[NFE].

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. The figure below shows how the Enhanced Rx filter elements are defined. Detailed information about the Enhanced Rx FIFO matching process and filter element formats can be found in Enhanced Rx FIFO matching process.

[8] MCR[RFEN] must be cleared so that Enhanced Rx FIFO is enabled.
[9] NEXIF ≤ NFE + 1.
[10] ERFFEL*n* registers are implemented in RAM; thus they must be explicitly initialized prior to any reception.

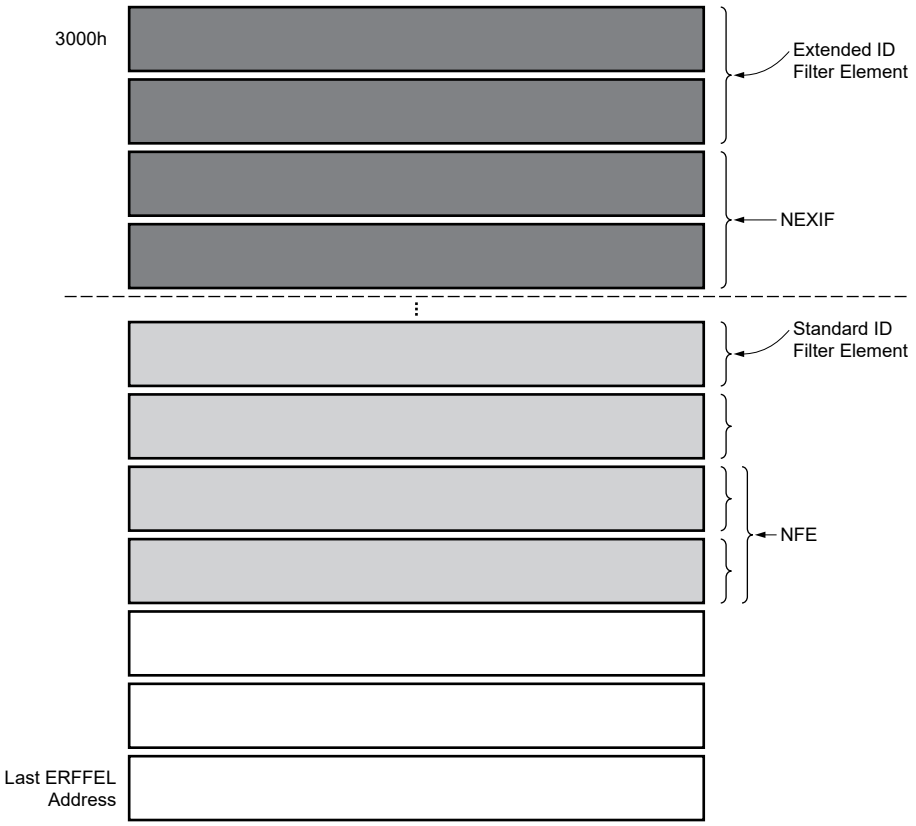

Figure 377. Number of enhanced Rx FIFO filter elements

72.3.8.1 Enhanced Rx FIFO matching process

When ERFCR[ERFEN] is enabled, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, then the CAN message content is transfered to the enhanced RX FIFO memory.

NOTE

If multiple filters match the incoming message ID, then the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. The matching criteria are defined by ERFFEL*n*[FSCH] in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] =0) for each bit *n* from 0 to 10
  3. (RTR = RTR Filter) or (RTR MASK = 0)

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in this table.

Table 441. Standard ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	27	26									16	15			12	11	10									0
FSCH=b00		Reserved		RTR filter	STD ID filter										Reserved				RTR mask	STD ID mask									

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. ID ≥ STD ID Filter1
  3. ID ≤ STD ID Filter2
  4. (RTR = RTR filter) or (RTR MASK = 0)

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in this table.

Table 442. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b01		Reserved		RTRfilter	STD ID Filter2		Reserved		RTR mask	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2)

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in this table.

Table 443. Standard ID filter element with 2-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. The matching criteria are defined by ERFFEL*n*[FSCH] in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] =0) for each bit *n* from 0 to 28
  3. (RTR = RTR Filter) or (RTR MASK = 0)

If FSCH = b00, the filters and masks are defined as shown in this table.

Table 444. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR filter	EXT ID filter	
Reserved		RTR mask	EXT ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. ID ≥ EXT ID Filter1
  3. ID ≤ EXT ID Filter2
  4. (RTR = RTR Filter) or (RTR MASK = 0)

If FSCH = b01, the filters and masks are defined as shown in this table.

Table 445. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR filter	EXT ID Filter2	
Reserved		RTR mask	EXT ID filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2)

If FSCH = b10, the filters and masks are defined as shown in this table.

Table 446. Extended ID filter element with 2-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID filter 1	

72.3.8.2 Enhanced Rx FIFO under DMA operation

The DMA feature is enabled by asserting both ERF[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the Enhanced FIFO output port at the address range defined in Enhanced Rx FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

The CPU should not access the Enhanced FIFO output port address range during DMA operation, so that the FIFO engine operates properly. Before enabling MCR[DMA], the CPU must service Enhanced Rx FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must first clear the ERFUFW, ERFOVF, ERMWMI, and ERFDA fields in the ERFSR register, and then clear the Enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

ERFSR[ERFDA] is set by the hardware when there is one frame available to be read from the Enhanced Rx FIFO. Upon receiving the request, the DMA controller can read the message in the Enhanced Rx FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

The following rules must be obeyed for Enhanced Rx FIFO DMA operation:

- Because a DMA transfer cannot be dynamically changed, ERFCR[DMALW] should be programmed so that the Enhanced Rx FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 472.

Each time one message is read from FIFO by the DMA controller, ERFSR[ERFDA] is cleared by FlexCAN and set again if there is at least one message stored in the FIFO.

For example, suppose that the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution time stamp is enabled. In that case the last Enhanced RX FIFO address offset can be found in Table 481 and Table 482. Using this address offset, ERFCR[DMALW] can be determined like this:

- Maximum number of data bytes = 8
- HR TIME STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

72.3.8.3 Enhanced Rx FIFO clear operation

When ERFCR[ERFEN] is set, the CPU can clear the Enhanced Rx FIFO by writing one into ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers although the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the ERFUFW, ERFOVF, ERFDA, and ERFWMI fields in EFRSR. Consequently the CPU must service all these fields before executing the clear FIFO task.

72.3.9 Legacy Rx FIFO

The Legacy Rx FIFO is receive-only and is enabled by asserting MCR[RFEN]. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the Legacy FIFO feature.

CAUTION

Legacy Rx FIFO must not be enabled when CAN FD feature is enabled.

The Legacy FIFO is 6-message deep. The memory region occupied by the Legacy FIFO structure (both message buffers and Legacy FIFO engine) is described in Legacy Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the Legacy FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and the RXFIR register, and then clear the interrupt. If there are more messages in the Legacy FIFO the act of clearing the interrupt updates the output of the Legacy FIFO with the next message and updates RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the Legacy FIFO is valid only while IFLAG1[BUF5I] is asserted.

IFLAG1[BUF6I] (Legacy Rx FIFO Warning) is asserted when the number of unread messages within the Legacy Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Legacy Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

IFLAG1[BUF7I] (Legacy Rx FIFO Overflow) is asserted when an incoming message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Legacy Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)

- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy Rx FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read in the IDHIT field from C/S word, as shown in the Legacy Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the RXFIR register. RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO and is valid while the IFLAG1[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the Legacy FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If MCR[IRMQ] is negated, then the Legacy Rx FIFO filter table is affected by RXFGMASK.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 436.

72.3.9.1 Legacy Rx FIFO under DMA operation

The receive-only Legacy FIFO can support DMA. This feature is enabled by asserting both MCR[RFEN] and MCR[DMA]. The reset value of MCR[DMA] is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port at the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] is asserted the CPU must not access the Legacy FIFO output port address range. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. Consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch, which clears IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

NOTE

RXFIR register contents cannot be read after DMA completes the Legacy FIFO read. The IDHIT information is also available in the C/S word at address 080h (see Legacy Rx FIFO structure.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 436.

72.3.9.2 Clear Legacy FIFO operation

When MCR[RFEN] is asserted, the clear Legacy FIFO operation is a feature used to empty Legacy FIFO contents. With MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes one in IFLAG1[BUF0I]. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently the CPU must service all FIFO IFLAGs before executing the clear FIFO task.

When Legacy Rx FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION

Clear Legacy FIFO operation does not clear IFLAGs, except when MCR[DMA] is asserted; in this case only IFLAG1[BUF5I] is cleared.

72.3.10 CAN protocol related features

This section describes the CAN protocol related features.

72.3.10.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CTRL2 register.

72.3.10.2 CAN FD frames

The ISO 11898-1:2015 standard specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When an FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

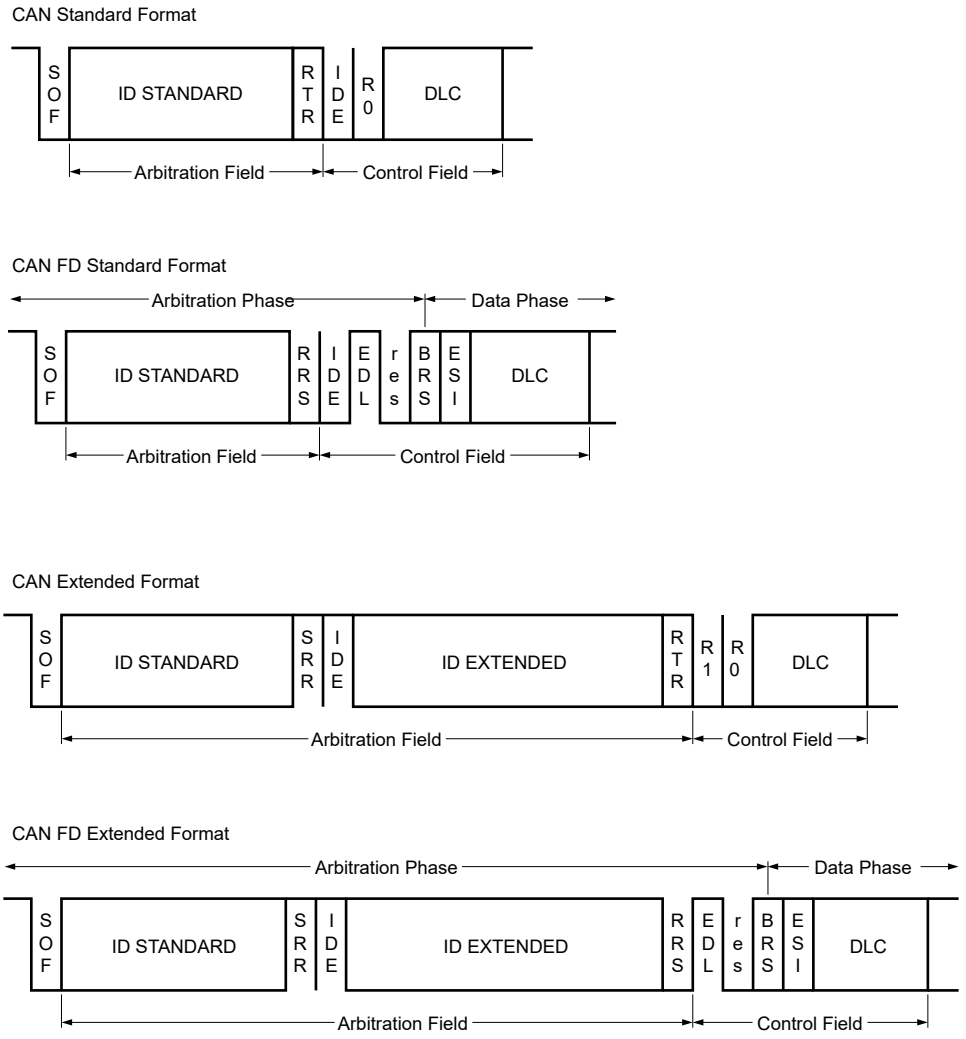

Figure 378. CAN message formats

The ability to receive and transmit CAN FD messages is enabled by MCR[FDEN]. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, and a Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance with the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission returns to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CBT register (also by CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the FDCBT register.

NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

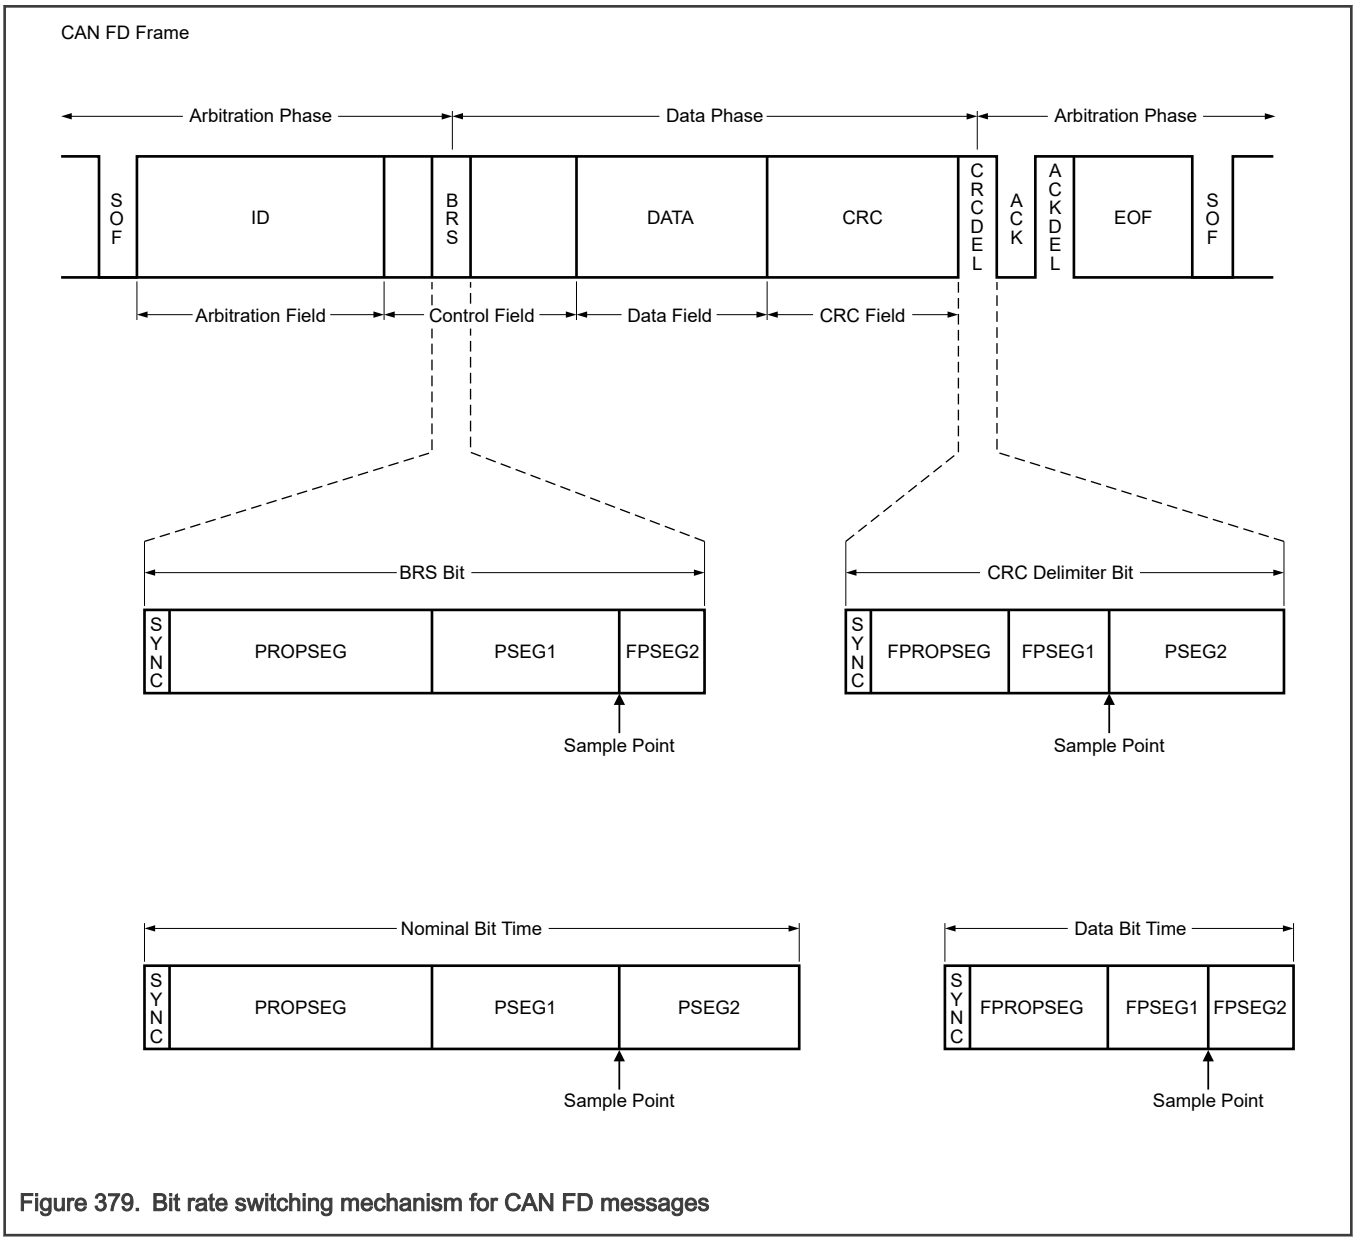

Figure 379. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE subblock. For example, with a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.[11]

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

Table 447. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit Of Tx MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indiscriminately. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR, and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CTRL1[ERRMSK] is asserted. The ESR1 register has additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST, and STFERR_FAST) to individually indicate

[11] The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.

the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag.

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a hard synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

72.3.10.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by FDCTRL[TDCEN] or ETDC[ETDCEN] and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the transceiver delay compensation mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF]. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

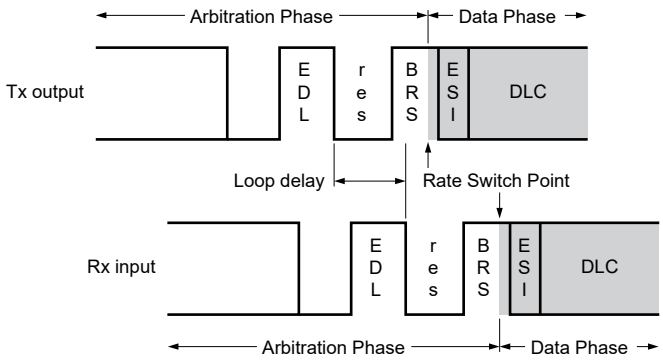

Figure 380. Transceiver loop delay measurement

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF or ETDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF or ETDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

$$\text{Offset} = (\text{FPSEG1} + \text{FPROPSEG} + 2) \times (\text{FPRESDIV} + 1)$$
or
$$\text{Offset} = (\text{DTSEG1} + 2) \times (\text{EDPRESDIV} + 1), \text{ if ETDCEN}$$

The following figure shows the SSP position when these settings are used.

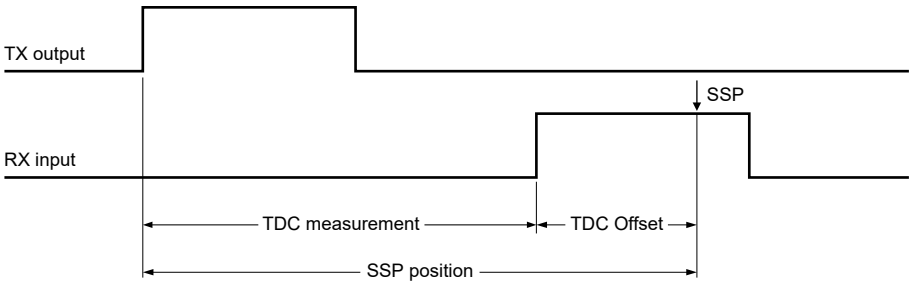

Figure 381. SSP position with optimal values

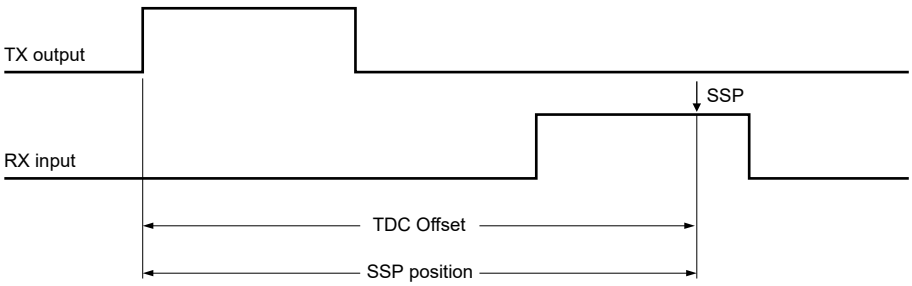

Figure 382. SSP position—TDC measurement disabled by ETDCEN and TDMDIS

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are set, the TDMDIS bit can be set to disable the transceiver delay measurement. In this case, the SSP position is defined only by the ETDCOFF field. Figure 382 shows the secondary sample point position when the transceiver delay measurement is disabled.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times – 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set to indicate when the transceiver delay compensation mechanism is out of range, unable to compensate the transceiver loop delay.

72.3.10.4 Remote frames

A remote frame is a special kind of frame. You can program a mailbox to be a remote request frame by configuring the mailbox as Transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in four ways, depending on remote request storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]):

- If RRS is negated the frame's ID is compared to the IDs of the transmit message buffers with the CODE field 1010b. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0100b, 0010b, or 0110b. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the Legacy FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered as normal frames, and generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFEN is set, FlexCAN will not generate an automatic response for remote request frames that match the Enhanced Rx FIFO filtering criteria. Remote Request Frames are considered normal frames, and generate an Enhanced Rx FIFO overflow when a successful reception occurs and Enhanced Rx FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

72.3.10.5 Overload frames

FlexCAN does transmit overload frames when the following conditions are detected on the CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

72.3.10.6 Message buffer time stamp

The value of the free running timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of move-in in the TIME STAMP field of message buffer, providing network behavior with respect to time.

When CTRL2[TIMER_SRC] is asserted, the free running timer is continuously clocked by an external time tick.

When CTRL2[TIMER_SRC] is negated, the free running timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free running timer is not incremented during Disable and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 register (CTRL1).

Alternatively, by configuring the MTSBASE field of the Control 2 register (CTRL2), the time stamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter.

72.3.10.7 High resolution time stamp

The high-resolution time stamp, HR_TIME_STAMP, uses a dedicated timer with a 32-bit counter operating in free running mode. The high-resolution time stamp is enabled by the TSTAMPCAP field of the Control 2 register (CTRL2). When this field is not zero , the dedicated 32-bit counter value is captured during a valid CAN frame and stored in the HR_TIME_STAMP register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit time stamp associated with message buffer 0, HR_TIME_STAMP1 stores the 32-bit time stamp associated with message buffer 1, and so on.

The counter value is captured according to the TSTAMPCAP field of the Control 2 register (CTRL2). For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception. For CAN FD frames, the capture points can be the start of frame, the point in time a CAN FD frame is considered valid, or the res bit of a CAN FD frame.

The 16-bit time stamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE].

72.3.10.8 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

Please see the clock distribution chapter (module clocks table) to identify the proper clock source.

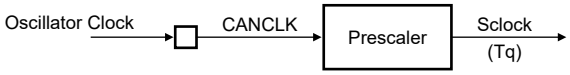

Figure 383. CAN engine clocking scheme

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The Control 1 register (CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

The CAN Bit Timing register (CBT) extends the range of the CAN bit timing variables in CTRL1. The CAN FD Bit Timing register (FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

The Enhanced Nominal CAN bit timing register (ENCBT) extends the range of CAN bit timing variables in CBT. The Enhanced Data Phase CAN bit timing register (EDCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, the bit timing nominal and data phase serial clock (Sclock) dividers must be programed in the Enhanced CAN Bit Timing Prescalers register (EPRS).

NOTE

When the CAN FD feature is enabled, always set CBT[BTF] or CTRL2[BTE] and configure the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing Register (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

The PRESDIV field (as well as its extended range EPRESDIV (or ENPRESDIV) and FDPRESDIV (or EDPRESDIV) for the data phase bits of CAN FD messages) defines the prescaler value (see the equation below) that generates the serial clock (Sclock), whose period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 12. Time quantum

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

$$\text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) * \text{Tq}$$

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

Equation 13. CAN bit time and baud rate

A bit time is subdivided into three segments[1] (see Figure 385, Figure 386 and Table 448):

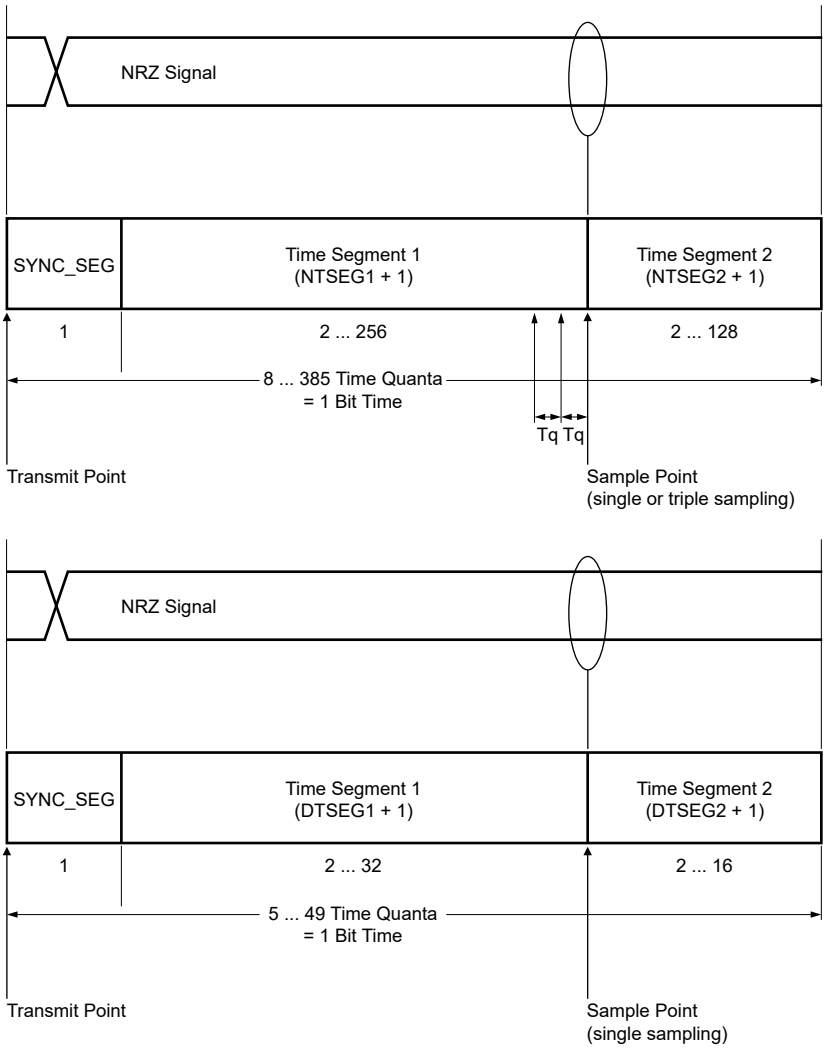

Figure 384. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting CTRL1[PROPSEG] and CTRL1[PSEG1] so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CBT[BTF] is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CBT register so that their

[1] For further explanation of the underlying concepts, see ISO 11898-1 :2015. See also the CAN 2.0A/B protocol specification for bit timing.

sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.

If CTRL2[BTE] is set, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 in the range of 2 to 256 time quanta. For the data phase in CAN FD messages with BRS set, EDCBT[DTSEG1] must be used for configuring time segment 1 in the range of 2 to 32 time quanta.

- Time Segment 2: This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting CTRL1[PSEG2] (plus 1) to be 2 to 8 time quanta long. When CBT[BTF] is asserted, FlexCAN uses EPSEG2 fields of CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

  If CTRL2[BTE] is set, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 in the range of 2 to 128 time quanta. For the data phase in CAN FD messages with BRS set, EDCBT[DTSEG2] must be used for configuring time segment 2 in the range of 2 to 16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

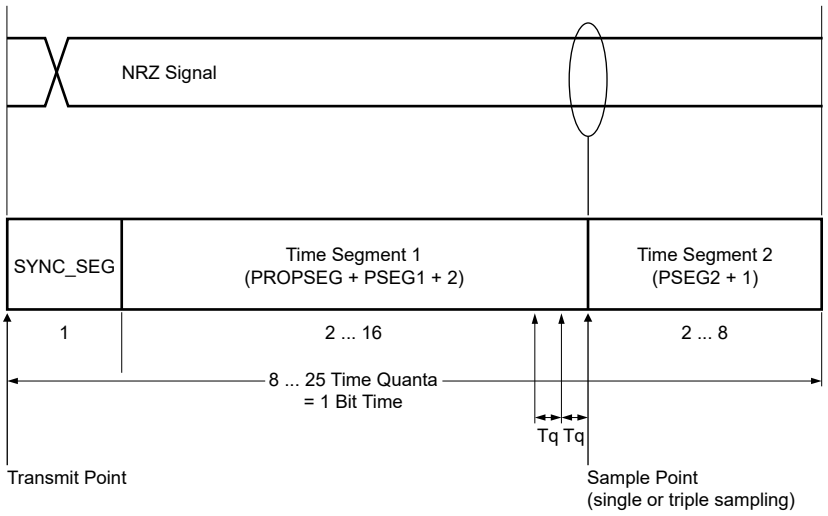

Figure 385. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

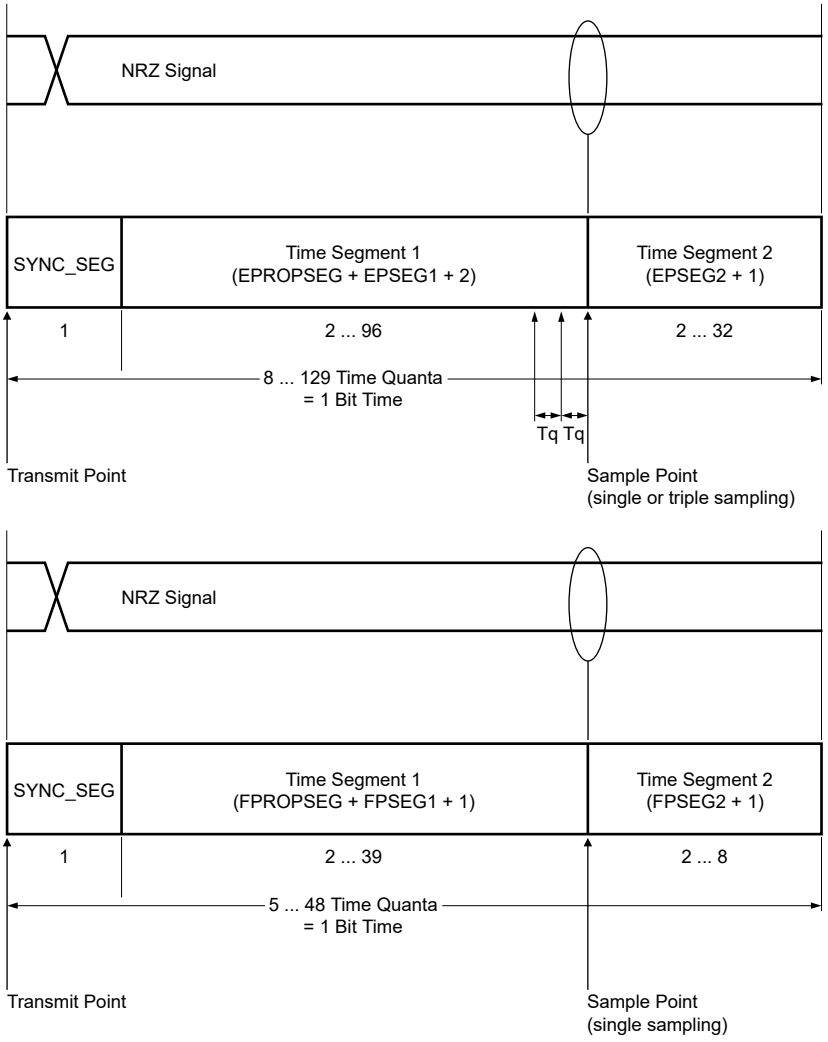

Figure 386. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 448. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 449. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 14. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 15. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 383), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value in CTRL1[PSEG1] field.
- PSEG2 is the value in CTRL1[PSEG2] field.
- PROPSEG is the value in CTRL1[PROPSEG] field.
- PRESDIV is the value in CTRL1[PRESDIV] field.
- ENPRESDIV is the value in EPRS[ENPRESDIV] field.
- NTSEG1 is the value in ENCBT[NTSEG1] field.
- NTSEG2 is the value in ENCBT[NTSEG2] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) or the Enhanced Nominal CAN bit timing (ENCBT) register and also to the CAN FD Bit Timing register (FDCBT) or the Enhanced Nominal CAN bit timing register(ENCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

72.3.10.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

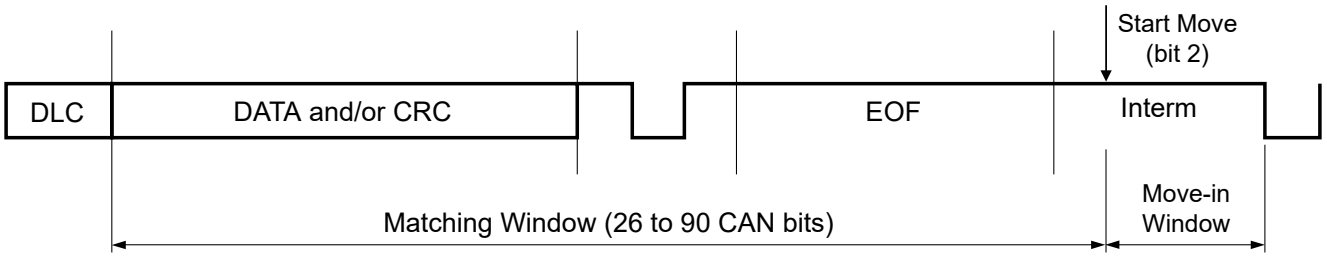

Figure 387. Matching and move-in time windows

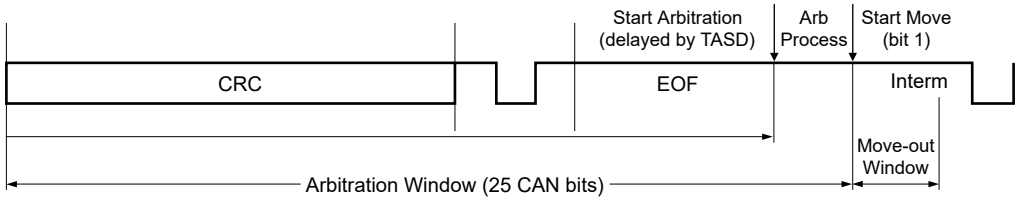

Figure 388. Arbitration and move-out time windows

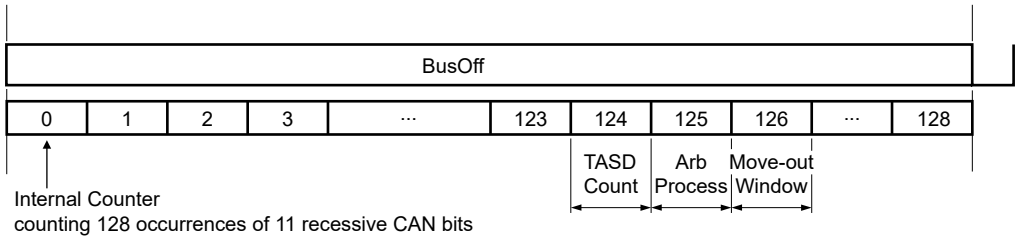

Figure 389. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

72.3.10.10 Tx arbitration start delay

CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

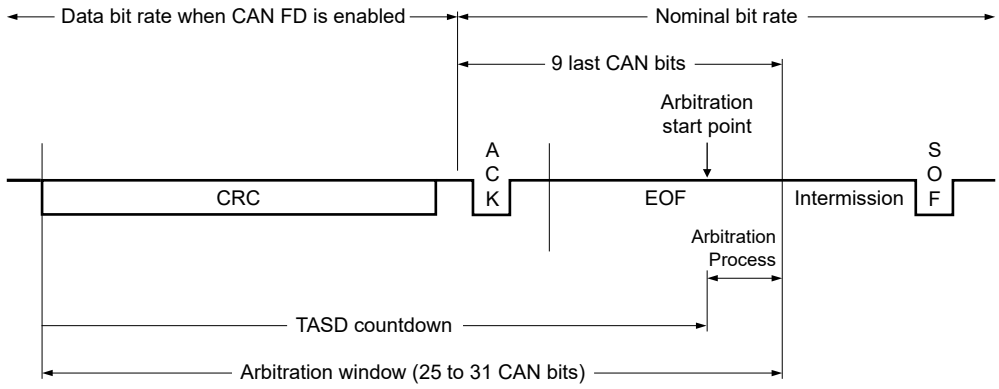

Figure 390. Optimal Tx Arbitration start point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and $(MAXMB + 1) \leq NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and $(MAXMB + 1) > NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 16. Optimal value for TASD

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 17. Variables used in TASD calculation

- MAXMB is the value in CTRL1[MAXMB].
- NMB_{END} is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].
- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] is set, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 18. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 19. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 450. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 451. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 452. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

72.3.11 Clocks

The following table describes the clock sources for FlexCAN. Please see chip clocking chapter for clock setting, configuration and gating information.

Table 453. FlexCAN clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_chi	Control Host Interface (CHI) clock
ipg_clk_pe	Protocol Engine (PE) clock
ipg_clk_pe_nogate	Protocol Engine clock (no gating)
ipg_clk_s	Peripheral access clock

72.3.11.1 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.

Table 454. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of mailboxes	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
16	1	0	16
32	1	0	17
64	1	0	30
96	1	0	42
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT) or Enhanced Nominal CAN bit timing register (ENCBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{SYS}}{f_{CANCLK}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{SYS}}{\text{NomBitRate}}$$

Equation 20. Number of peripheral clocks per nominal CAN bit

where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CBT register or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 455. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 21. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in ERFCR register.

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 22. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBit_A,\ MinNumClkFastBit_B\ )$$

Equation 23. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 24. Maximum achievable baud rate for data phase

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   Equation 25. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, and Enhanced Rx FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

   $$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

   Equation 26. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

   $$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

   Equation 27. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

   $$MinNumClkFastBit = Maximum\ (5.06,\ 6.75) = 6.75$$

   Equation 28. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667 \text{ Mbps}$$

Equation 29. Calculation example for maximum achievable baud rate

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

Table 456. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced Rx FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

72.3.12 Reset

You can reset FlexCAN in the following ways:

1. Chip level hard reset, which resets all memory-mapped registers asynchronously.
2. MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. See Table 459 to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or

reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

72.3.13 Interrupts
