- After power on, the EOUT signals have high impedance.[12] They indicate an operational state only after the software configures them.
- In case of a failure event or on software request for error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} (see DELTA_T[DELTA_T]), even if the software tries to release it before (for the case of error pin configured in Bi-Stable mode only).

The self-checking procedure checks the FCCU circuitry at the start up. The FCCU is operational with the default configuration immediately after the completion of the self-checking procedure. Internal (short functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the Configuration (CONFIG) state. FCCU is designed to function when CLKPRIM is faster than the CLKSAFE clocks.

66.4 Block diagram

The following figure represents a top-level diagram of the FCCU module.

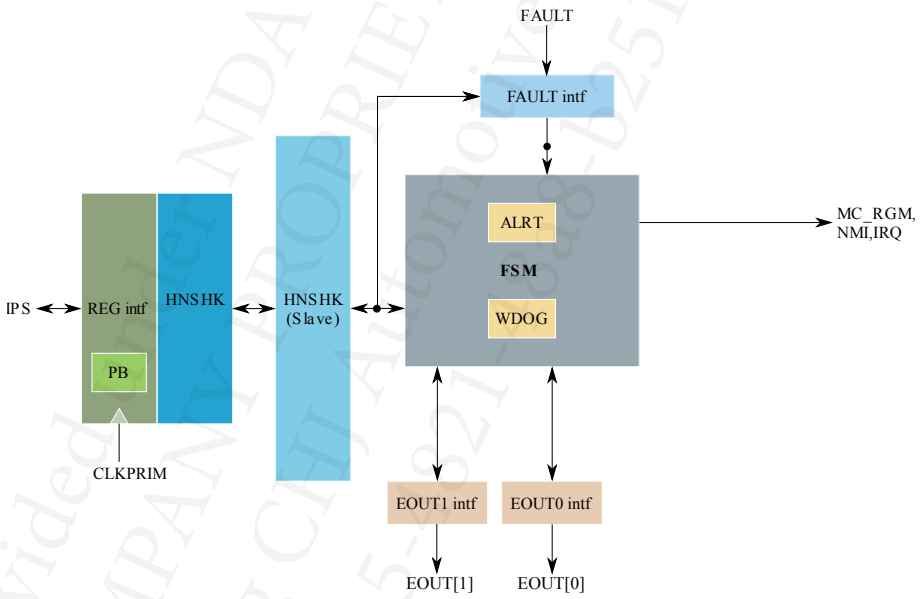

Figure 553. FCCU block diagram

This table describes the FCCU submodules.

[12] Actual value depends on device-specific setting at pad level.

Table 551. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM ability to support the handshake between the REG interface and the FSM unit because of the usage of two asynchronous clocks [CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)]
FSM unit	Implements the main functions of FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

66.5 Signal description

66.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Sensitivity	Clock
Clock and reset				
CLKPRIM	Input	Primary Clock—supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
Fault interface				
NCF[127:0]	Input	Non-critical Fault Channels—receive indications of non-critical faults from various sources. See the fault map file attached to this document.	Programmable	Asynchronous

Table continues on the next page...

Table continued from the previous page...

Signal	Direction	Function	Sensitivity	Clock
EOUT interface				
EIN[1:0]	Input	Error Inputs—provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. FCCU captures the states in the EINOUT[EIN1] and EINOUT[EIN0] fields.	—	Asynchronous
EOUT[1:0]	Output	Error Outputs—indicate FCCU's condition (faulty, nonfaulty, or configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				
FIF	Output	FCCU In Fault—indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: *Case 1* When the EOUT signals are programmed to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal until the EOUT signals are programmed not to be always low. *Case 2* When the EOUT signals are programmed not to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal when all of the following are true: • FCCU enters the FAULT state as the result of a fault. • If the fault is a non-critical fault, the associated EOUT_SIG_ENa[EOUTENn] field is set to enabled. FCCU deasserts this signal when FCCU leaves the FAULT state.	High	CLKSAFE0, CLKSAFE1
Interrupt interface				

Table continues on the next page...

Table continued from the previous page...

Signal	Direction	Function	Sensitivity	Clock
NMIOUT	Output	Non-maskable Interrupt Output—Sends a non-maskable interrupt request to the processor core or cores when FCCU enters the FAULT state as the result of a non-critical fault for which NMI is enabled as the reaction (NMI_ENa[NMIENn]).	Low	CLKPRIM

66.6 Functional description

66.6.1 Definitions

In general, the following definitions are applicable for fault management:

- HW recoverable fault: The fault indication is a level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: The fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition is corrected.

These type of chip resets reset the FCCU:

- Power-on
- Destructive

A short functional reset of the chip do not reset the FCCU.

For more information on each type of reset, see the Reset Generation Module (MC_RGM) and reset chapters.

66.6.2 FSM description

The functionality of FCCU is depicted by the FSM state diagram (see Figure 554).

FCCU has four states that are identified with the following meaning:

- CONFIG: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, non-critical fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in the NORMAL state and if the configuration is not locked. A permanent configuration lock can be disabled by a reset that also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into TRANS_LOCK[TRANSKEY] (that is, other than BCh). To lock FCCU for configuration, write FFh to PERMNT_LOCK[PERMNTKEY].

  After the release of reset, the state of the transient lock is locked, and the state of the permanent lock is unlocked.

  The locking feature only restricts the FSM movement into CONFIG state. After the user enters the CONFIG state and then tries to lock the configuration, the locking of configuration is effective only after FCCU moves to the NORMAL state; it will not be effective in the current CONFIG state.

The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request for state change to NORMAL appears at the same time, watchdog timeout has the priority and hence the configuration registers (those that are writable only in the CONFIG state) are reset to their default values. The movement to the NORMAL state is made.

The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when FCCU is moved to the NORMAL state, according to the new configuration.

All pending faults that occur during the CONFIG state result in both of the following:

— Highest-priority state transition

— Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or non-pending faults) that occurred during the CONFIG state.

- NORMAL: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:
  — Unmasked non-critical faults with the timeout disabled: FCCU moves to the FAULT state.
  — Unmasked non-critical faults with the timeout enabled: FCCU moves to the ALARM state.
  — Masked non-critical faults: FCCU stays in the NORMAL state.
- ALARM: FCCU moves into the ALARM state when an unmasked non-critical fault occurs and the timeout is enabled. Transition to the ALARM state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the FAULT state. The timeout is reinitialized if FCCU enters the NORMAL state. The timeout restarts following the recovery from the FAULT state.
- FAULT: FCCU moves into the FAULT state when one of the following condition occurs:
  — Timeout related to a non-critical fault when FCCU is in the ALARM state
  — Unmasked non-critical faults with the timeout disabled

The transition from the NORMAL or ALARM to the FAULT state goes along with the generation of:

- Internal chip reaction—NMI interrupt (optional)
- External reaction—EOUT signaling (optional)
- Internal chip reaction—SW option: Soft reaction (Short functional reset request pulse if configured)

After moving to the FAULT state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time.

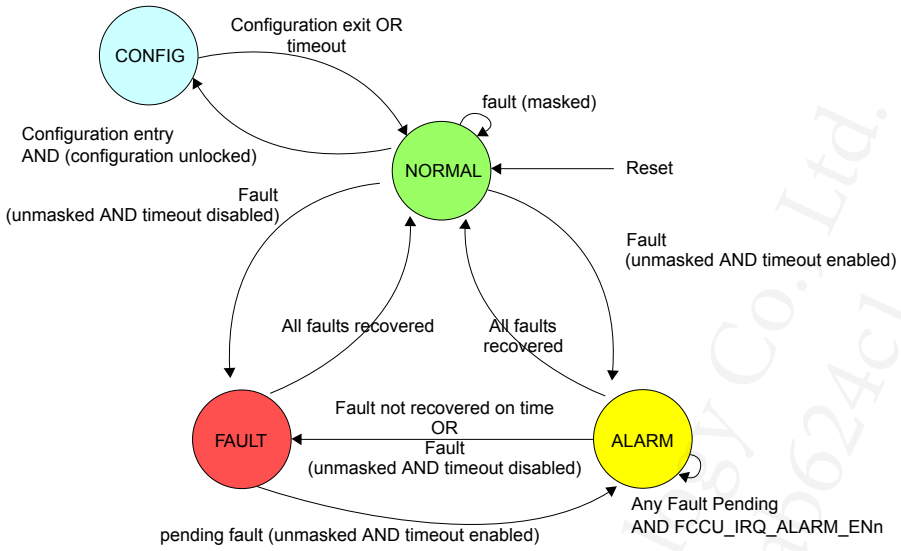

Figure 554. FCCU state diagram

66.6.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU remains in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU moves to the ALARM state (if any non-critical fault is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case, the NCF timer is stopped until the FAULT state is recovered. If FCCU is in the ALARM state and another fault occurs, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

66.6.4 Fault recovery

The following timing diagrams describe the main use cases of FCCU in terms of fault events and related recovery.

A typical sequence related to non-critical fault management (ALARM state), see Figure 555 and Figure 556, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. System state: RUN
4. Alarm interrupt management: fault recovery
   - FCCU state transition: ALARM to NORMAL

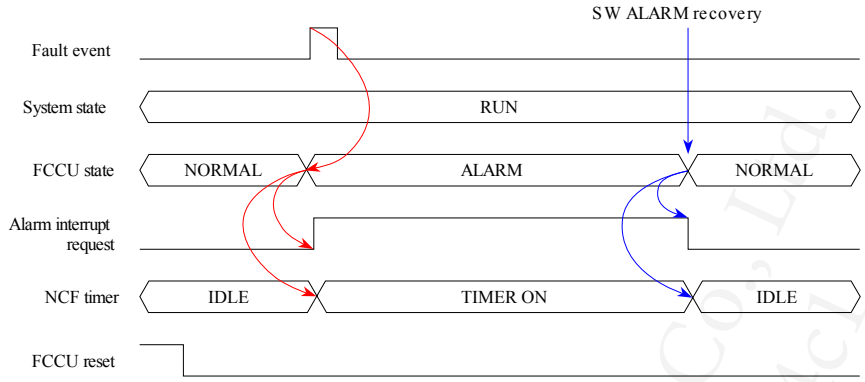

Figure 555. Non-critical fault (ALARM state) SW recovery

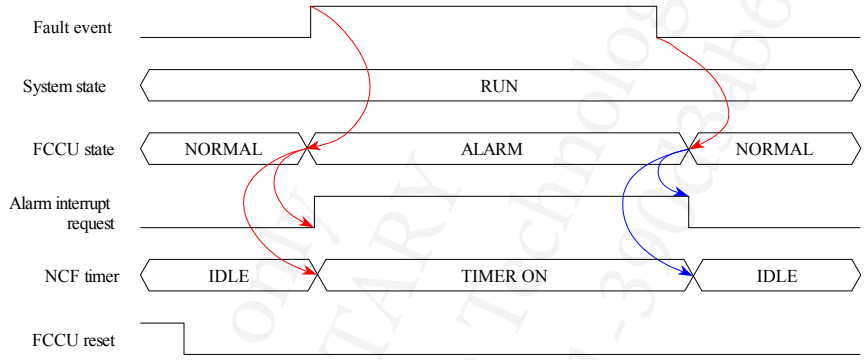

Figure 556. Non-critical fault (ALARM state) HW recovery

A typical sequence related to non-critical fault management (ALARM to FAULT state), see Figure 557, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. FCCU state transition (following the timeout trigger): ALARM to FAULT
   - NMI assertion (if enabled)
4. NMI interrupt management (if enabled)
   - Fault recovery (by software): FCCU state transition: FAULT to NORMAL

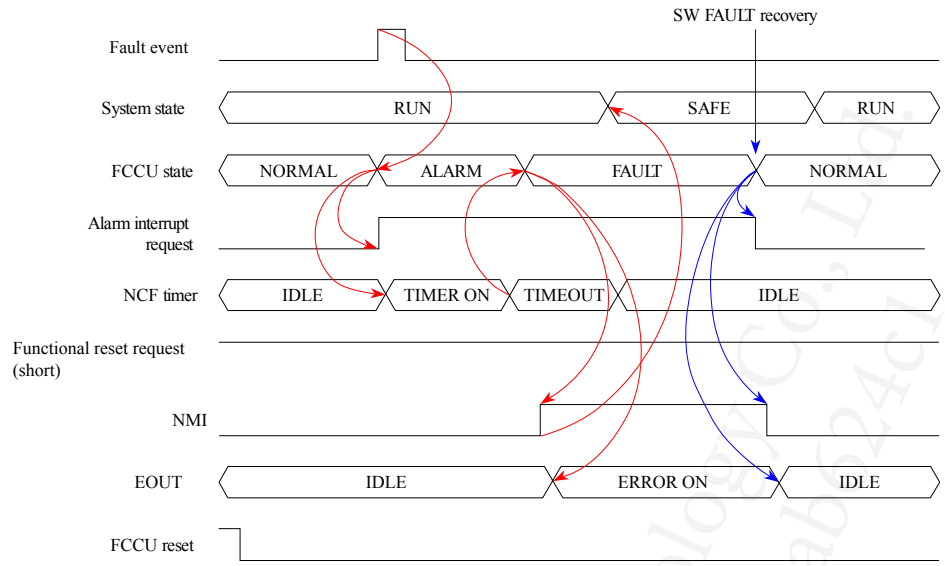

Figure 557. Non-critical fault (ALARM to FAULT state) recovery

66.6.5 EOUT interface

Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic.

NOTE

For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	All of the following are true: • The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works in Bi-Stable fault-output mode). • FCCU is in FAULT state.
Nonfaulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in ALARM or NORMAL state.
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in CONFIG state.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-482a-48a8-b251-390d3ab624c1

How the fault-output (EOUT) timer works in Bi-Stable fault-output mode

In Bi-Stable fault-output mode (FOM), FCCU starts the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable FOM, and the EOUT signals are not programmed to be always low (CFG[FCCU_SET_CLEAR]).
- The EOUT timer is not already running.
- FCCU enters the FAULT state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- If FCCU is in the CONFIG state: FCCU does not restart the EOUT timer.
- If FCCU is in the NORMAL or ALARM state:
  - And ALARM state is enabled for the fault (non-critical): FCCU enters (or remains in) the ALARM state but does not restart the EOUT timer.
  - And ALARM state is disabled for the fault (non-critical): FCCU enters the FAULT state and restarts the EOUT timer.
- If FCCU is in the FAULT state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), and T_{min} (see DELTA_T[DELTA_T]) has expired.
- All faults that caused FCCU to enter or remain in the FAULT state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to the NORMAL state.

Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), ensure that the EOUT signals are controlled by FCCU's FSM (CFG[FCCU_SET_CLEAR]).
- Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]).

NOTE

If the EOUT signals are in Bi-Stable fault-output mode, you must deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states.

More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (CFG[FOM]):

- Bi-Stable

NOTE

See the chip-specific FCCU information for the fault-output modes supported by this chip.

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Polarity selection	CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

EOUT frequency: This frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

$$EOUT_{freq} = \frac{CLKSAFE_{freq}}{2^{18}}$$

For example, with a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time (T_{min}), even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked even when software has set the error signal to high. Also, if the error signals are forced to low by software by writing to CFG[FCCU_SET_CLEAR], then the signals shall remain low (or high) for the entire duration of T_{min}. During the T_{min} by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to the CONFIG state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_{min} interval to expire, after which the FCCU automatically enters the NORMAL state and the error signal indicates OK.

In case another failure event happens within T_{min} after a first one, the T_{min} counter is restarted.

66.6.5.1 Bi-Stable protocol

The encoding scheme is provided in Table 552 and the related timing diagram is shown in Figure 558.

Table 552. Bi-Stable encoding

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Nonfaulty	Static 01	Static 10
Faulty	Static 10	Static 01
Reset	High-impedance (no toggling)[1]	High-impedance (no toggling)
Configuration	Static 01	Static 10

1. Final value depends on device specific settings at pad level.

NOTE

Figure 558 is formatted to display the behavior in all four conditions (reset, nonfaulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

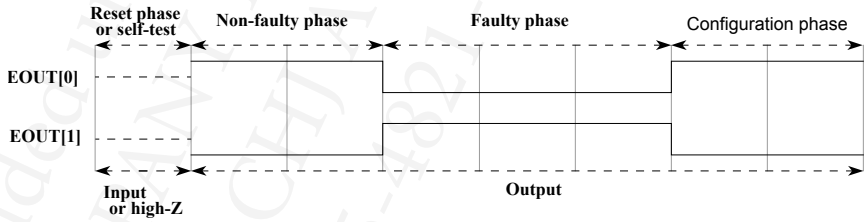

Figure 558. Bi-Stable protocol

66.7 Prepare FCCU for configuration

66.7.1 Introduction

You prepare FCCU for configuration by first configuring the CONFIG state and then putting FCCU in that state.

66.7.2 About preparing FCCU for configuration

When preparing FCCU for configuration, keep the following in mind:

- To put FCCU in CONFIG state, FCCU must be in NORMAL state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in the CONFIG state.
- When FCCU is in the CONFIG state, FCCU does not actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in the NORMAL state. If FCCU automatically leaves the CONFIG state and enters the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

66.7.3 Configure the CONFIG state

1. Set the Configuration-state timeout interval (CFG_TO[TO]).
2. Enable the Configuration-state-timeout interrupt signal (IRQ_EN[CFG_TO_IEN]), if you want FCCU to request an interrupt when a Configuration-state timeout occurs.

66.7.4 Put FCCU in the CONFIG state

1. Unlock the configuration temporarily (TRANS_LOCK[TRANSKEY]) in Supervisor mode.
2. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is CONFIG, FCCU is in the CONFIG state. Stop.
   - If the FCCU status is NORMAL, go to step 3.
   - If the FCCU status is ALARM or FAULT, go to step 5.
3. Run the OP1 operation (see Run an operation).
4. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the CONFIG state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 7.
5. Recover all faults (see Fault recovery).
6. Go to step 2.
7. Reset FCCU.

66.8 Configure FCCU

66.8.1 Introduction

You configure FCCU so it functions according to the needs of your particular application.

66.8.2 About configuring FCCU

When configuring FCCU:

- If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state when necessary but does not perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in the NORMAL state when a fault occurs on the channel, FCCU does not enter the ALARM or FAULT state and therefore does not perform any reaction.

66.8.3 Configure the non-critical fault channels

For each non-critical fault channel that you want FCCU to monitor:

1. Set the recovery type (NCF_CFGa[NCFCn]).
2. Enable at least one type of Fault-state reaction:
   - Chip functional reset (NCFS_CFGa[NCFSCn])
   - Non-maskable interrupt (NMI_ENa[NMIENn])
   - EOUT signaling (EOUT_SIG_ENa[EOUTENn])

   NOTE

   If you enable the chip functional reset as the type of Fault-state reaction for a channel, enable at least one other type of Fault-state reaction for the channel or enable the ALARM state (step 4) for the channel.
3. Set the Alarm-state timeout interval (NCF_TO[TO]), if you plan to enable the ALARM state for any non-critical fault channel.

   NOTE

   Ensure that the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timeout interval (FOSU_COUNT) is a chip-specific value. See the chip-specific FCCU information.
4. Enable the ALARM state (NCF_TOEa[NCFTOEn]) for any non-critical fault channel for which you want FCCU to enter the ALARM state before entering the FAULT state.
5. Enable the Alarm-state reaction (IRQ_ALARM_ENa[IRQENn]) for each non-critical fault channel for which you enabled the ALARM state.
6. Enable the corresponding NCF_Ea[NCFEn] field for each non-critical fault channel that you want FCCU to monitor.

66.9 Put FCCU in the NORMAL state

66.9.1 Introduction

You put FCCU in the NORMAL state to save changes to the configuration, and to allow FCCU to enter the ALARM or FAULT state when a fault occurs on an enabled fault channel.

66.9.2 About putting FCCU in NORMAL state

When putting FCCU in the NORMAL state:

- If you attempt to lock the configuration while FCCU is in CONFIG state, FCCU does not actually lock the configuration until FCCU leaves CONFIG state—that is, either you put FCCU in the NORMAL state, or FCCU puts itself in the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in the CONFIG state.

66.9.3 Put FCCU in the NORMAL state

1. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is NORMAL, go to step 6.
   - If the FCCU status is CONFIG, go to step 2.
   - If the FCCU status is ALARM or FAULT, go to step 4.
2. Run the OP2 operation (see Run an operation).
3. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the NORMAL state. Go to step 6.

- If the operation status is Aborted, go to step 2.

4. Recover all faults (see Fault recovery).
5. Go to step 1.
6. Lock the configuration if you want to prevent any changes to it:
   - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANS_LOCK[TRANSKEY]).
   - To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNT_LOCK[PERMNTKEY]).

     The configuration is permanently locked until FCCU is reset.

66.10 Manage faults

66.10.1 Introduction

After saving changes to the configuration, you are ready to use FCCU to manage faults.

66.10.2 Determine if there are any unrecovered non-critical faults

Check the unrecovered-fault indicators for the non-critical faults (NCF_Sa[NCFSn]).

66.10.3 Recover a software-recoverable non-critical fault

1. Resolve the source of the software-recoverable non-critical fault.
2. Unlock the NCF_Sa registers (NCFK[NCFK]) using a 32-bit write.
3. Initiate clearing of the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]) using a 32-bit write.

   FCCU initiates the OP12 operation.

   NOTE

   If you want to clear multiple unrecovered-fault indicators and those indicators reside in different NCF_Sa registers, you must perform steps 2 and 3 for each individual register.

4. Check the operation status (CTRL[OPS]).
   - If the operation status is In Progress, go to step 4.
   - If the operation status is Successful, go to step 5.
   - If the operation status is Aborted, go to step 2.
5. Check the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]).
   - If the indicator indicates no unrecovered fault, the fault has been recovered. Stop.
   - If the indicator still indicates an unrecovered fault, go to step 2.

66.10.4 Clear the freeze-status indicators

1. Run the OP13 operation (see Run an operation).
2. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, stop .
   - If the operation status is Aborted, go to step 1.

66.11 Run operations

66.11.1 Introduction

You run operations to perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For a complete list of operations you can run, see CTRL[OPR].

66.11.2 About running operations

When running operations:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are locked again.

66.11.3 Run an operation

1. Check the operation status (CTRL[OPS]).
2. Go to step 1 if the operation status is In Progress.
3. Unlock the operation (CTRLK[CTRLK]) using a 32-bit write, if the operation must be unlocked before you can initiate it.

NOTE

The Control Key (CTRLK) register used in this step and the Control (CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (CTRL[OPR]) using a 32-bit write.
5. Check the operation status (CTRL[OPS]).
6. Go to step 5 if the operation status is In Progress.

The operation status is now Idle (OP15 only), Aborted, or Successful.

66.12 Register descriptions

66.12.1 FCCU register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Do not read from or write to any addresses that are not shown in the following table. Doing so may or may not result in a transfer error.
- Do not write to any of the configuration registers unless FCCU is in the CONFIG state. Doing so results in a transfer error.
- Do not write to the Transient Configuration Lock (TRANS_LOCK) or Permanent Configuration Lock (PERMNT_LOCK) registers unless your code runs in the Supervisor mode. Doing so results in a transfer error.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short functional resets.

66.12.1.1 FCCU memory map

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28-10 —	Reserved
9 DEBUG	Debug Mode Enable Specifies whether the Debug mode is enabled. If so, FCCU enters the Debug mode when the Debug signal is asserted. When FCCU enters the Debug mode, it halts operation and remains in the state it was in before it entered this mode. **NOTE** FOSU does not halt when FCCU enters the Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in the Debug mode. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
8 —	Reserved
7-6 OPS	Operation Status This field can be read and cleared (via OP15 operation) by the software. 00b - Idle 01b - In progress 10b - Aborted 11b - Successful
5 —	Reserved
4-0 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (CTRL[OPS]) is "In progress". After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (CTRL[OPS]) of "Aborted": • Writing to a NCF_Sa register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK[NCFK]) • Initiating an OP1 operation when FCCU is not in the NORMAL state or the configuration is locked • Initiating an OP1, or OP2, operation without first unlocking the operation (CTRLK[CTRLK]) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in the NORMAL state, and immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the CONFIG state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the NORMAL state. 00011 Reserved 00100 Reserved 00101 Reserved 00110 Reserved 00111 Reserved 01000 Reserved 01001 Reserved 01010 Reserved

Fields

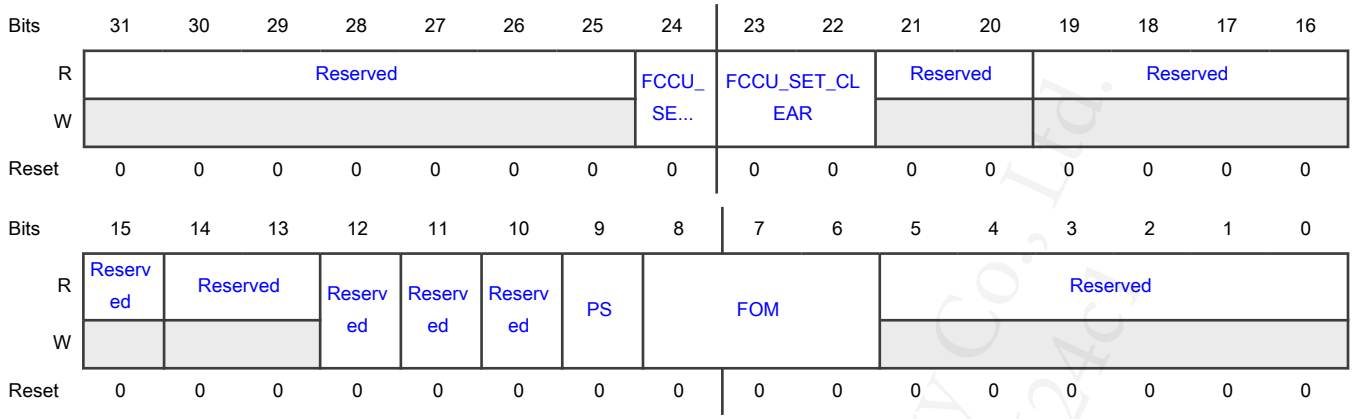
Field	Function
31-0 CTRLK	Locked-Operation Control Key Writable only with a 32-bit write. Unlocks locked operations (CTRL[OPR]) so you can initiate them. For information on how to unlock locked operations before you initiate them, see Run an operation. **NOTE** • You must initiate an operation in the FCCU register access that immediately follows the one that unlocks it; otherwise, the operation is again locked. • Reading from this register always returns the value 0000_0000h. Operations not listed here are not locked and do not need to be unlocked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. Any other value: Do nothing.

66.12.1.4 Configuration (CFG)

Offset

Register	Offset
CFG	8h

Function



Writable only when FCCU is in the CONFIG state. Changed by FCCU to another value when the chip resets FCCU, a Configuration-state timeout occurs, or you run an OP31 operation. See CFG register bit value at different events for more information. Specifies the global configuration for FCCU.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU does not use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Fields

Field	Function
31-0	Non-critical Fault Status n

Table continues on the next page...

Field	Function
NCFSn	Indicates whether there is an unrecovered fault on the associated non-critical fault channel (n). **NOTE** To recover a software-recoverable non-critical fault, which includes clearing its unrecovered-fault indicator, see Recover a software-recoverable non-critical fault. FCCU clears the unrecovered-fault indicator for a hardware-recoverable non-critical fault automatically when the source no longer indicates a fault on the fault channel's input signal; if you attempt to clear the unrecovered-fault indicator for a hardware-recoverable non-critical fault, FCCU does not clear the indicator and does not indicate an error. For the mapping of the NCF_Sa[NCFSn] fields among registers, see the earlier table in this register description. 0b - No unrecovered fault 1b - Unrecovered fault

66.12.1.8 Non-critical Fault Key (NCFK)

Offset

Register	Offset
NCFK	90h

Function

Reset	1	0	1	0	1	0	0	1	1	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TO	Non-critical-Fault Alarm-State Timeout Interval Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls the maximum amount of time that FCCU can be in the ALARM state ($T_{Max\ Alarm}$) according to this equation: $T_{Max\ Alarm} = TO \times T_{CLKSAFE}$ where $T_{CLKSAFE}$ is the safe-clock period. If FCCU enters the ALARM state (because a fault occurs on an enabled non-critical fault channel for which the ALARM state is enabled) and this timeout interval expires (called an Alarm-state timeout), then FCCU leaves the ALARM state and enters the FAULT state. **NOTE** Make sure the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, a fault that occurs while FCCU is in the ALARM state can cause FOSU to generate a chip reset. The FOSU timeout interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

2-0 TO	Configuration-State Timeout Interval Writable only when FCCU is in the NORMAL, ALARM, or FAULT state (not in the CONFIG state). Changed by FCCU to its reset value when a Configuration-state timeout occurs. Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in the CONFIG state ($T_{Max\ configuration}$) according to this equation: $T_{Max\ configuration} = T_{CLKSAFE} \times 2^{(TO + 13)}$ where $T_{CLKSAFE}$ is the safe-clock period. If you put FCCU in the CONFIG state and this timeout interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves the CONFIG state and enters the NORMAL state • Changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (CFG) register's Configuration-state-timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

66.12.1.13 IO Control (EINOUT)

Offset

Register	Offset
EINOUT	BCh

Function

The EINOUT register allows the following operations typically in the NORMAL state:

- To control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (CFG[FOM])
- To control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (CFG[FOM])
- to observe the state of signals at EIN[1:0] pins

The following table shows Bi-Stable encoding.

Table 553. Bi-Stable encoding

Mode = CFG[FOM]	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Because of the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the EINOUT register.

Register	Offset
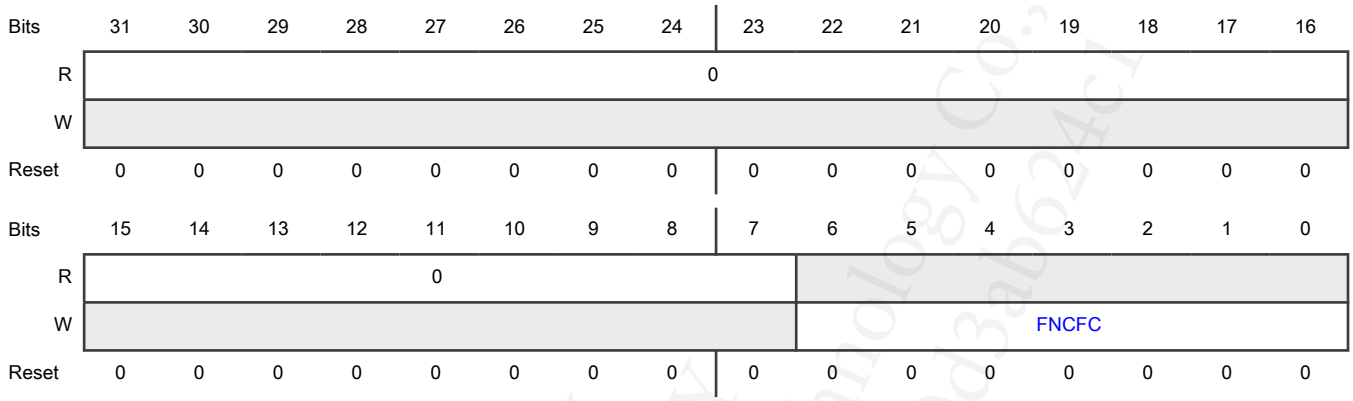
NCFF	DCh



Provided under NDA only
COMPANY PROPRIETARY
Beijing CJJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d8ab624c1

Function

This register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by injecting the fault directly in the FAULT root, to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked.

This is a write-only register with a set of codes corresponding to each non-critical fault injection.

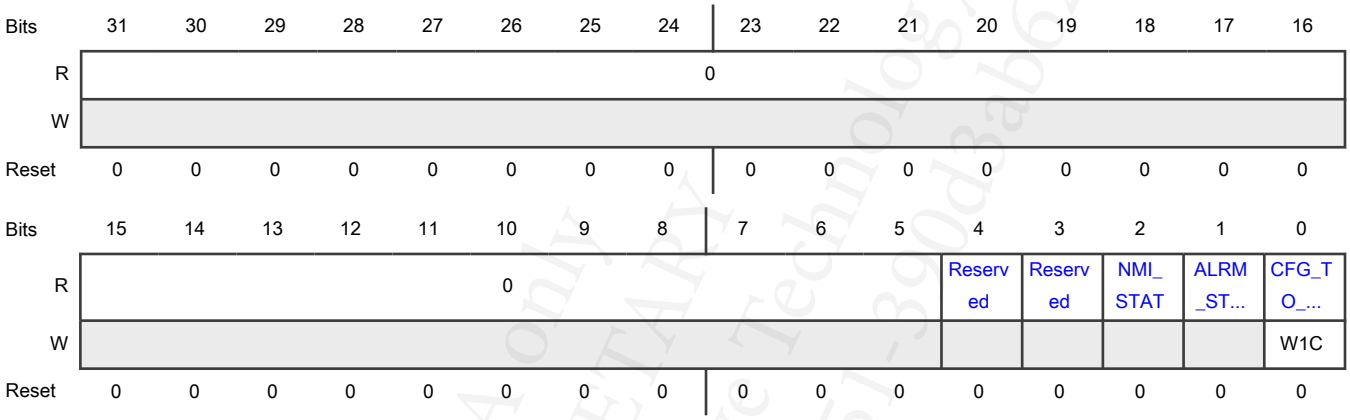
66.12.1.20 IRQ Status (IRQ_STAT)

Offset

Register	Offset
IRQ_STAT	E0h

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e54821-4c8-b251-3903ab624c1

Function



This register provides the FCCU interrupt status related to the following events:

- Configuration-state timeout error
- Alarm interrupt
- NMI interrupt

The configuration-state timeout interrupt is asserted if both IRQ_STAT[CFG_TO_STAT] and IRQ_EN[CFG_TO_IEN] bits are asserted. It is cleared when a 1 is written to the IRQ_STAT[CFG_TO_STAT] bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the IRQ_STAT trace the status of the related interrupt lines.

13-0 DELTA_T	Minimum Fault-Output (EOUT) Timer Interval Applies only to Bi-Stable mode (CFG[FOM]). Controls the minimum amount of time (T_{min}) that the fault-output (EOUT) timer runs according to this equation: T_{min} = 250 µs + DELTA_T **NOTE** The durations shown for the DELTA_T values are for CLKSAFE clock signals running at exactly 48 MHz. However, the CLKSAFE signals are sourced from an internal chip clock signal (for example, IRC)—or an integer division of it (see the chip-specific FCCU information)—that has a trimmed frequency variation. Therefore, the DELTA_T durations may vary. See your chip's data sheet for the trimmed frequency variation (for example, δF_{var}).

Fields

Field	Function
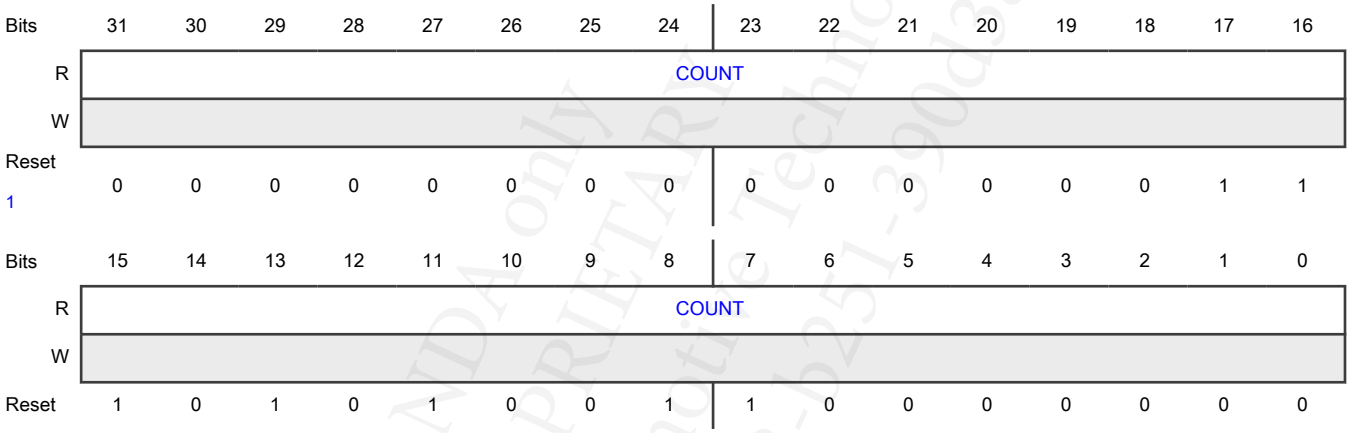
31-0 EOUTENn	Non-critical Fault-State EOUT Signaling Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Applies only when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). When FCCU is configured for Bi-Stable fault-output mode (CFG[FOM]), controls whether EOUT signaling is enabled as a Fault-state reaction for the associated non-critical fault channel (n). (For other fault-output modes, EOUT signaling is always enabled, regardless of the value of this field.) When EOUT signaling is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to indicate the faulty condition on the EOUT[1:0] signals when FCCU enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. For all fault-output modes, also controls whether FCCU asserts the FIF signal when a fault on the associated non-critical fault channel (n) causes FCCU to enter the FAULT state. **NOTE** For all fault-output modes, you must set this field to enabled to ensure that FCCU asserts the FIF signal when FCCU enters FAULT state as the result of a fault on the associated non-critical fault channel (n) so the FOSU module does not mistakenly generate a destructive chip reset. For the mapping of the EOUT_SIG_ENa[EOUTENn] fields among registers, see the earlier table in this register description. 0b - In Bi-Stable fault-output mode, both EOUT signaling and FIF assertion are disabled; in other fault-output modes, EOUT signaling is enabled and FIF assertion is disabled. 1b - Both EOUT signaling and FIF assertion are enabled in all fault-output modes.

66.12.1.28 Alarm-State Timer (TMR_ALARM)

Offset

Register	Offset
TMR_ALARM	12Ch

Function



See TMR_ALARM[COUNT].

This table shows how the Alarm-state timer's state and value vary by FCCU state:

Table 554. TMR_ALARM reset value

FCCU state	Timer state	Timer value
CONFIG	Idle	0000_0000h
NORMAL	Idle	Initial value: NCF_TO[TO]
ALARM	Running	Value when read
FAULT	Idle	End of count

66.12.2 Configuration registers

66.12.2.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in CONFIG state (see Put FCCU in the CONFIG state).
- Save the values you write to them while FCCU is in CONFIG state only after you manually put FCCU in NORMAL state. If FCCU automatically leaves CONFIG state and enters NORMAL state because the configuration-timer interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value; FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events.

66.12.2.2 Configuration registers

Following is the list of configuration registers in this module. They are listed in an offset order from lowest to highest.

- Configuration (CFG)

- Non-critical Fault Configuration (NCF_CFGa)
- Non-critical Fault-State Configuration (NCFS_CFG0 - NCFS_CFG7)
- Non-critical Fault Enable (NCF_E0 - NCF_E3)
- Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0 - NCF_TOE3)
- Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)
- Delta T (DELTA_T)
- Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0 - IRQ_ALARM_EN3)
- Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0 - NMI_EN3)
- Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0 - EOUT_SIG_EN3)

66.12.3 CFG register bit value at different events

In this chip, there are no events that affect the bits in the configuration register.

66.13 FOSU

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU's behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from FCCU which indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during the CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: short functional reset
- IRQ (triggered by ALARM state)
- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared to ensure that the timer is not restarted because of faults still 'stuck' in the capture logic. The timer is then restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at DEST0. The FOSU module is reset with the same reset as is used by the FCCU. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times out without reaction.

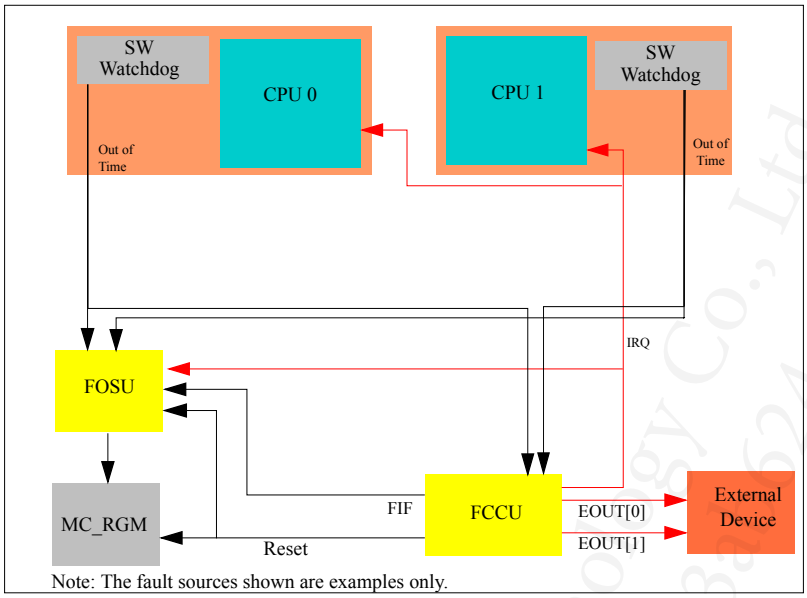

Figure 559. FOSU connections to the FCCU and MC_RGM

66.14 Use cases and limitations

Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a non-critical fault channel:
  - Enable the channel (Non-critical Fault Enable (NCF_E0 - NCF_E3)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (Non-critical Fault-State Configuration (NCFS_CFG0 - NCFS_CFG7)), fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0 - EOUT_SIG_EN3)), or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0 - NMI_EN3)).
  - If you enable chip reset as the type of Fault-state reaction for the channel (Non-critical Fault-State Configuration (NCFS_CFG0 - NCFS_CFG7)), enable either ALARM state (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0 - NCF_TOE3)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0 - EOUT_SIG_EN3)) or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0 - NMI_EN3)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0 - NCF_TOE3)), enable the Alarm-state reaction (Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0 - IRQ_ALARM_EN3)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0 - NCF_TOE3)), make sure the Alarm-state timer interval (Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

NOTE

If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state if necessary but doesn't perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in NORMAL state when a fault occurs on the channel, FCCU doesn't enter ALARM or FAULT state and therefore doesn't perform any reaction.

Recommendations to configure FCCU

1. After a power on, or 'destructive' reset (when initiated by the assertion of the chip reset pin, RESET_B), where both system and FCCU are reset, the following steps could be followed to configure FCCU:
    a. Check and clear any pending fault status
    b. Verify FCCU is in NORMAL state, else repeat step(a) above
    c. Configure FCCU
2. After any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
    a. If active, wait for the Error out T_{min} to expire
    b. Check and clear fault status
    c. Error pin moves to "non faulty" state, once fault status is cleared and T_{min} expires
    d. Verify FCCU is in NORMAL state, else repeat step(a) above
    e. Read and verify value in NCF_En
    f. Reconfigure FCCU, if necessary

Chapter 67
Clock Monitoring Unit-Frequency Check (CMU_FC)

67.1 Chip-specific CMU_FC information

67.1.1 Overview

The CMU module consists of both Frequency Check (CMU_FC) and Frequency Meter (CMU_FM) submodules. This device instantiates both of these submodules.

For details on clocks monitored by each CMU instance, see the "Clock input sources" table in the Clocking chapter.

CMU interrupts

CMU_FC and CMU_FM instances each have an Interrupt Enable Register (IER) for enabling module interrupts. However, enabled CMU_FC and CMU_FM interrupt requests do not map to system-level interrupts.

- CMU_FC interrupt requests map to system-level FCCU faults as events.
- CMU_FM interrupt requests do not map to the system level at all (not as interrupts or faults).

67.2 Introduction

CMU_FC ensures the clock integrity of selected clocks and allows continuous clock integrity verification.

CMU_FC checks if the frequency of a monitored clock (*monitored_clock*) is within a programmable frequency range specified by the user. If the frequency is outside the specified limits, it could lead to performance, protocol, and timing failures. CMU_FC requires a clock used as a base reference for the frequency check operation. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FC operation.

67.2.1 Basic operation

CMU_FC counts clock cycles of the monitored clock during a user programmable time duration of *n* clock cycles of the reference clock. There is a comparison between the final count of the monitored clock and the user programmable upper and lower threshold count limits. The control logic determines whether the cycle count is within the programmed limits. If not it sets the Frequency Higher than High frequency reference threshold event status (FHH) field or the Frequency Lower than Low frequency reference threshold event status (FLL) field in the Status Register (SR). If you enable interrupts, an interrupt asserts when the status flag sets.

c8c462e5-4821-4a1b-b251-390d8ab624c1

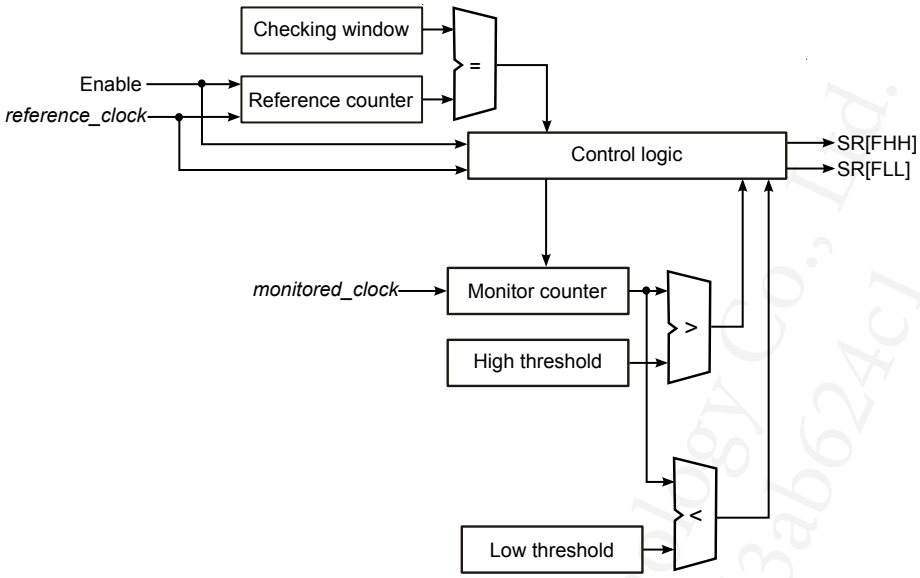

Figure 560. CMU_FC block diagram

CMU_FC cannot detect the following:

- Monitored clock duty cycle variations
- Instantaneous monitored clock frequency variations that do not cross upper or lower threshold limits

NOTE

CMU_FC has internal reset synchronizer logic for reference clock and monitored clock domains. Synchronization may take up to 10 destination clock cycles to complete.

67.2.2 Features

The CMU_FC features are:

- Programmable duration of reference clock cycles
- Initiates an event if a monitored clock frequency is higher than high frequency reference (FHH)
- Initiates an event if a monitored clock frequency is lower than low frequency reference (FLL)
- Timeout functionality generates an FLL event if a monitored clock stops functioning
- Masking of FHH event interrupt
- Masking of FLL event interrupt

Table 555. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *monitored_clock*
monitored_clock	I	Clock signal on which frequency check is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of monitored and reference clocks used on this chip.

67.3 CMU_FC register descriptions

67.3.1 CMU_FC memory map

This section describes the address order of all the CMU_FC registers. Each description includes a standard register diagram and associated field descriptions.

CMU_FC_0 base address: 4005_C000h

CMU_FC_5 base address: 4005_C0A0h

67.4 Functional description

67.4.1 Frequency checking

Frequency checking starts when software writes GCR[FCE] = 1. The Run Status field SR[RS] shows 1 after frequency check operation starts.

CMU_FC performs continuous periodic clock checking of the monitored clock. Each checking window involves the following operations:

- Stage 1 – Reference clock counter runs for RCCR[REF_CNT] reference clock cycles. Monitored clock counter runs in parallel for the same time duration as reference clock counter.
- Stage 2 – After stage 1, the module compares the final monitored clock count against the programmed thresholds.

If the monitored clock count is greater than the high threshold value in HTCR[HFREF], an FHH event occurs.

If the monitored clock count is lower than the low threshold value in LTCR[LFREF], an FLL event occurs.

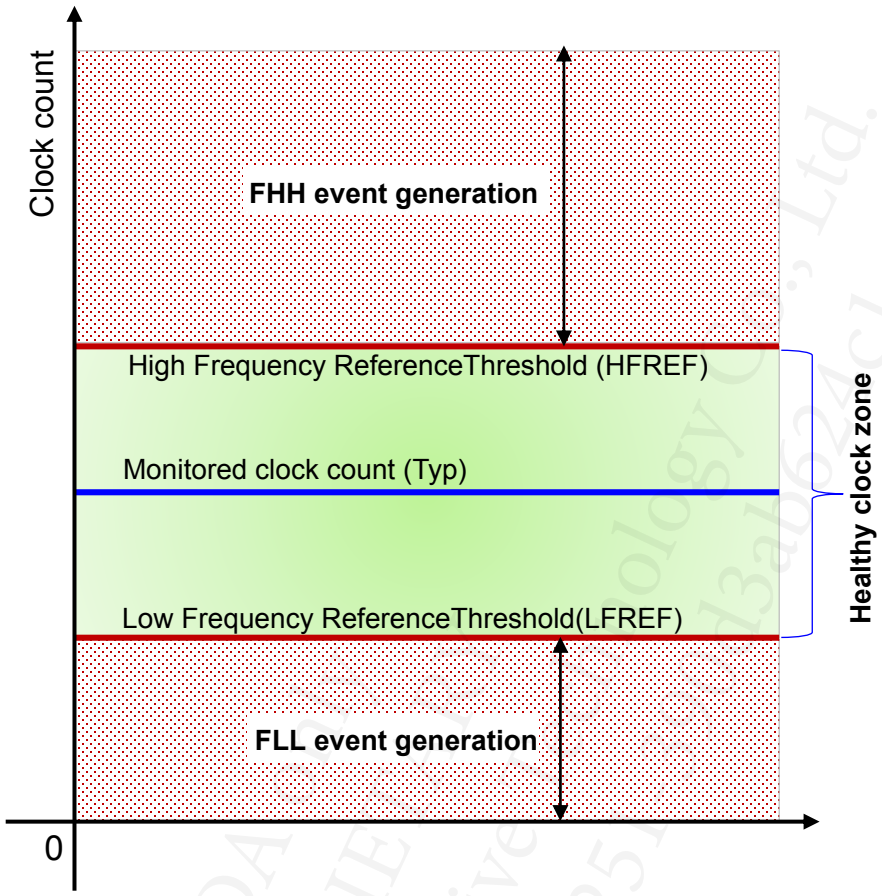

Figure 561. Frequency checking HFREF and LFREF thresholds

67.4.1.1 Monitored clock lost

If a monitored clock ceases operation before evaluation of that clock (Stage 2, see Frequency checking), CMU_FC waits for RCCR[REF_CNT] reference clock periods by extending Stage 2 before triggering an FLL event.

- If *monitored_clock* is not running when enabling CMU_FC:

  Worst case FLL response time = (2 × RCCR[REF_CNT] + 12) *reference_clock* cycles + 15 *bus_clock* cycles

- If *monitored_clock* stops when the CMU_FC is running:

  Worst case FLL response time = (2 × RCCR[REF_CNT] + 2) *reference_clock* cycles + 3 *bus_clock* cycles

67.5 Programming guidelines

67.5.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the checking operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF\_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}}\right)\right)$$

...where:

- $f_{reference\_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{monitored\_clock}$ is the frequency of the monitored clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference\_clock}$ = 8 MHz
- $f_{monitored\_clock}$ = 48 MHz

Formula #1:

$$3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}} \right)$$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2:

$$8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}} \right)$$

Inserting the values: 8 + 5 × (8 / 48) ≈ 8.83

MAX (1.5, 8.83): 8.83

CEILING value of MAX: 9

Therefore, minimum RCCR[REF_CNT]: 9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency check completion response time and overall accuracy required from CMU_FC.

- Higher values of RCCR[REF_CNT] results in longer measurement window, leading to better accuracy in monitored clock check.
- Lower values of RCCR[REF_CNT] results in shorter measurement window, leading to faster FHH and FLL event response, but higher inaccuracy in reported result.

For measurement window calculation, see step 8 in Programming HFREF and LFREF

67.5.2 Programming HFREF and LFREF

You must consider the following when programming HFREF/LFREF:

- Tolerable monitored clock frequency variation
- Maximum reference clock frequency variation
- Inherent module inaccuracy

CMU_FC has an expected maximum deviation of ± 3 *monitored_clock* cycles (CMU_FC_{VAR+} = 3, CMU_FC_{VAR-} = –3).

The following procedure shows how to calculate optimum values for HTCR[HFREF] and LTCR[LFREF] (numbers shown are from example in table):

1. Determine the ideal *monitored_clock* frequency ($f_{monitored\_clock}$ (ideal), 48 MHz).
2. Determine the specified variation of the *monitored_clock* (1.1%).

3. Calculate *monitored_clock* frequency variation: .

$$f_{monitored\_clock}\ (ideal)\ \mathrm{X}\left(1 \pm variation\ (\text{step 2})\right)$$

   - $f_{monitored\_clock}$ (max) = 48 MHz × (1 + (1.1 ÷ 100)) = 48.53 MHz
   - $f_{monitored\_clock}$ (min)= 48 MHz × (1 – (1.1 ÷ 100)) = 47.47 MHz
4. Determine the ideal *reference_clock* frequency ($f_{reference\_clock}$ (ideal), 8 MHz).
5. Determine the specified variation of the *reference_clock* (3.3%).
6. Calculate ideal *reference_clock* frequency variation:

$$f_{reference\_clock}\ (ideal)\ \mathrm{X}\left(1 \pm variation\ (\text{step 5})\right)$$

   - $f_{reference\_clock}$ (max) = 8 MHz × (1 + (3.3 ÷ 100)) = 8.26 MHz
   - $f_{reference\_clock}$ (min) = 8 MHz × (1 – (3.3 ÷ 100)) = 7.74 MHz
7. Select the value of RCCR[REF_CNT] needed (80). See Programming RCCR[REF_CNT].
8. Calculate ideal measurement window:

$$\frac{RCCR\,[REF\_CNT]}{f_{reference\_clock}\ (ideal)}$$

   - 80 ÷ 8 MHz = 10000 ns
9. Calculate ideal *monitored_clock* count:

$$\frac{RCCR[REF\_CNT]}{f_{reference\_clock}\ (ideal)} \times f_{monitored\_clock}\ (ideal)$$

   - 80 ÷ 8 MHz × 48 MHz = 480.00 (round off this value, 480 in this case)
10. Calculate high threshold value (HTCR[HFREF]):

$$\text{Ceiling value of}\ \left(\frac{f_{monitored\_clock}\ (max)}{f_{reference\_clock}\ (min)} \times RCCR[REF\_CNT]\right) + CMU\_FC_{VAR+}$$

    - HTCR[HFREF] = Ceiling(48.53 MHz ÷ 7.74 MHz × 80 + 3) = 505
11. Calculate low threshold value (LTCR[LFREF]):

$$\text{Floor value of}\ \left(\frac{f_{monitored\_clock}\ (min)}{f_{reference\_clock}\ (max)} \times RCCR[REF\_CNT]\right) + CMU\_FC_{VAR-}$$

    - LTCR[LFREF] = Floor(47.47 MHz ÷ 8.26 MHz × 80 – 3) = 456

Programmed higher threshold (HTCR[HFREF])	505	—
Programmed lower threshold (LTCR[LFREF])	456	—

67.5.3 Module programming sequence

The recommended programming sequence for CMU_FCfrequency checking is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency measuring window duration in *reference_clock* cycles.
   - Program LTCR[LFREF] and HTCR[HFREF] to set the permissible frequency range of the *monitored_clock*.
   - Program IER to enable interrupt.
2. Write GCR[FCE] = 1 to start the frequency check operation.

NOTE

When GCR[FCE] = 1, you must not write to RCCR, HTCR, LTCR, or IER. Attempting to do so generates a bus transfer error.

3. To reconfigure RCCR, LTCR, HTCR , and IER or to stop frequency check operation, wait for SR[RS] = 1, then write GCR[FCE] = 0.

67.6 Glossary

FHH The state that the monitored clock frequency is higher than the high frequency reference. FHH is also the name of the register field that indicates this state.

FHH event The event that the module triggers when it detects FHH.

FLL The state that the monitored clock frequency is lower than the lower frequency reference. FLL is also the name of the register field that indicates this state.

FLL event The event that the module triggers when it detects FLL.

Chapter 68
Clock Monitoring Unit - Frequency Meter (CMU_FM)

68.1 Chip-specific CMU_FM information

68.1.1 Overview

The CMU module consists of both Frequency Check (CMU_FC) and Frequency Meter (CMU_FM) submodules. This device instantiates both of these submodules.

For details on clocks monitored by each CMU instance, see the "Clock input sources" table in the Clocking chapter.

CMU interrupts

CMU_FC and CMU_FM instances each have an Interrupt Enable Register (IER) for enabling module interrupts. However, enabled CMU_FC and CMU_FM interrupt requests do not map to system-level interrupts.

- CMU_FC interrupt requests map to system-level FCCU faults as events.
- CMU_FM interrupt requests do not map to the system level at all (not as interrupts or faults).

68.2 Introduction

CMU_FM measures the frequency of the metered clock (*metered_clock*) using another clock as reference. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FM operation. CMU_FM operation is only guaranteed if a reference clock is within normal operating parameters.

68.2.1 Basic operation

The CMU_FM counts the clock cycles of a metered clock in the user programmable time duration *n* number of clock cycles of the reference clock. After completion of a metered clock operation, a register field sets, indicating the operation has completed. The count of the metered clock also updates in the Status Register (SR) after completion of a metered clock operation.

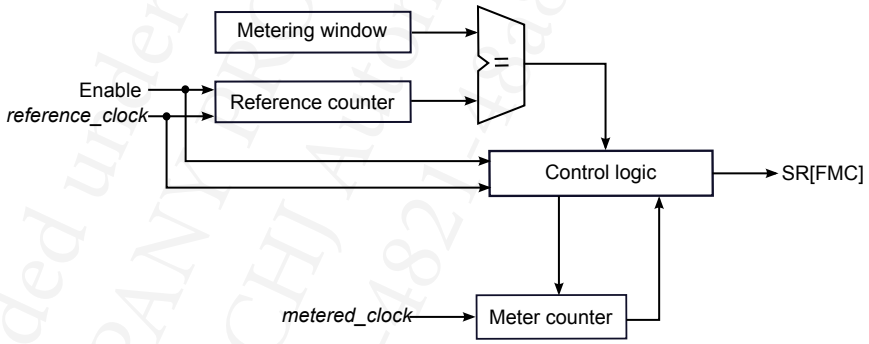

Figure 562. Block diagram

68.2.2 Features

Features of the CMU_FM are:

- Programmable duration of *reference_clock* cycles
- Timeout feature indicates loss of *metered_clock*

Table 557. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *metered_clock*
metered_clock	I	Clock signal on which frequency metering is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of metered and reference clocks used on this chip.

68.3 CMU_FM register descriptions

68.3.1 CMU_FM memory map

This section describes the address order of all the CMU_FM registers. Each description includes a standard register diagram and associated field descriptions.

Beijing CHJ Automotive Technology Co., Ltd.
c84626e5-482f-48a8-b251-390d3ab624c1

Fields

Field	Function
31-8 MET_CNT	Meter Clock Count This field stores the count value of the metered clock cycles when frequency metering operation is complete, in other words, SR[FMC] = 1. CMU_FM has a maximum deviation of ± 3 *metered_clock* cycles over the ideal *metered_clock* cycles expected by the user.
7-5 —	Reserved
4 RS	Run Status Shows the running status of module internal operation. After enabling the frequency metering operation (GCR[FME] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency metering operation, then the software should read this register and write GCR[FME] = 0 only when this field is 1. 0b - Frequency meter stopped 1b - Frequency meter running
3-2 —	Reserved
1 FMTO	Frequency Meter Time Out Sets if there is a loss of metered clock during the metering operation. After metering window, the module waits for a timeout duration of RCCR[REF_CNT] cycles before writing one to this field. GCR[FME] = 0 and SR[FMC] = 0 when FMTO = 1. Writing one clears this field.
0 FMC	Frequency Meter Operation Complete On completion of frequency metering operation, FMC = 1, SR[MET_CNT] field updates, and GCR[FME] clears. Writing one clears this field.

68.4 Functional description

The frequency meter operation initiates when software writes GCR[FME] = 1. When the operation starts, hardware writes SR[RS] = 1. Safety critical applications must poll SR[RS] to determine when metering operation starts.

Frequency metering window involves these operations:

1. Stage 1 — The reference clock counter runs for RCCR[REF_CNT] cycles of *reference_clock*. The metered clock counter runs in parallel for the same time duration as the *reference_clock* counter.
2. Stage 2 — At the end of stage 1, SR[FMC] = 1, SR[MET_CNT] updates with the *metered_clock* count, and CMU_FM writes GCR[FME] = 0.

68.5 Programming guidelines

68.5.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the metering operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF\_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right), 6 + 4 \text{ X } \left(\frac{f_{reference\_clock}}{f_{metered\_clock}}\right)\right)$$

...where:

- $f_{reference\_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{metering\_clock}$ is the frequency of the metered clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference\_clock}$ = 8 MHz
- $f_{metered\_clock}$ = 48 MHz

Formula #1:

$$3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right)$$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2:

$$6 + 4 \text{ X } \left(\frac{f_{reference\_clock}}{f_{metered\_clock}}\right)$$

Inserting the values: 6 + 4 × (8 / 48) ≈ 6.67

MAX (1.5, 6.67): 6.67

CEILING value of MAX: 7

Therefore, minimum RCCR[REF_CNT]: 7

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency metering completion response time and overall accuracy required from CMU_FM.

- Higher values of RCCR[REF_CNT] results in longer metering window, leading to better accuracy in metered clock measurement.
- Lower values of RCCR[REF_CNT] results in shorter metering window, leading to faster FMC response, but higher inaccuracy in reported result.

68.5.2 Module programming sequence

The recommended programming sequence of CMU_FM is:

1. Program RCCR[REF_CNT] to define the frequency metering window duration in *reference_clock* cycles.
2. Write GCR[FME] = 1 to start frequency metering operation. Write to RCCR is disabled after GCR[FME] = 1. Attempting a write to RCCR after GCR[FME] = 1 generates a bus transfer error.
3. To reconfigure RCCR or to stop frequency metering operation, wait for SR[RS] = 1, then write GCR[FME] = 0.

Upon completion of metering operations:

- Hardware writes SR[FMC] = 1

Chapter 69
Selftest Top General Purpose Registers (SELFTEST_GPR_TOP)

69.1 Introduction

SELFTEST_GPR_TOP contains control and status registers that are used for the global configuration of STCU2 self-tests. The configuration includes:

- Enabling self-test in different reset domains
- Providing status of self-test enablement

See the "Software resettable domains" section in the Reset chapter for more information on this chip's available reset domains.

NOTE

The register space allotted to SELFTEST_GPR_TOP is of 32 bytes. Transfer error might not be issued for the reserved or hidden register space access.

69.2 SELFTEST_GPR_TOP register descriptions

69.2.1 SELFTEST_GPR_TOP memory map

SELFTEST_GPR_TOP base address: 4001_CFE0h

Chapter 70
Selftest General Purpose Registers (SELFTEST_GPR)

70.1 Introduction

SELFTEST_GPR configures the STCU2 LBIST shift cycles. Programming self-test GPRs is a part of the self-test programming sequence. See the "Self-test programming sequence" section in the STCU2 chapter.

There are multiple self-test GPR modules in the chip, each corresponding to an LBIST partition.

70.2 Memory map for self-test GPRs

The system memory map allots a 4 KB slot for self-test GPRs, divided into 128 slots of 32 bytes each. The base address of the slot is 4001_C000h. To calculate the base address of a self-test GPR block, use the following equation:

Base address of self-test GPR(*n*) = Base address of self-test GPRs in system memory map + *n* * 20h, where *n* = self-test GPR index.

If you access a self-test GPR region that corresponds to a reserved index or reserved register space, you might not receive a transfer error.

70.3 SELFTEST_GPR register descriptions

70.3.1 SELFTEST_GPR memory map

SELFTEST_GPR base address: 4001_C000h

SELFTEST_GPR_CHIPTOP base address: 4001_C560h

SELFTEST_GPR_MEM_NOC_0 base address: 4001_C520h

SELFTEST_GPR_MEM_NOC_1 base address: 4001_C540h

SELFTEST_GPR_MISC base address: 4001_C500h

SELFTEST_GPR_NOC_PART1 base address: 4001_C480h

SELFTEST_GPR_NOC_PART2 base address: 4001_C4A0h

SELFTEST_GPR_NOC_PART3 base address: 4001_C4C0h

SELFTEST_GPR_NOC_PART4 base address: 4001_C4E0h

Chapter 71
Self-Test Control Unit (STCU2)

71.1 Chip-specific STCU2 information

71.1.1 Supported BIST sequences

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that it has validated for in-field testing usage. After the chip is validated, this section is replaced with information on the supported BIST sequences.

71.1.2 Self-test overview

The chip supports two types of BISTs. The self-test infrastructure includes scan-based testing through logic BIST (LBIST) and memory array testing through memory BIST (MBIST). STCU2 divides the logic and memories being tested into multiple groups.

Each partition of digital logic has an LBIST controller that performs the scan-based test. The LBIST controller is responsible for:

- Configuring the partition in the LBIST mode
- Running the test
- Accumulating the pass or fail signature for each partition

The MBIST controller runs algorithms to detect defects in the memory array that behave as:

- Stuck-at faults
- At-speed transition faults
- Coupling faults

The MBIST controller (MCT) connects to multiple local MBIST controllers that carry out the actual memory tests. The central master MBIST controller programs the BIST instances to run memory test algorithms and collect pass or fail status from the local MBIST controllers.

STCU2 provides central control of both the LBIST controllers and the master MBIST controller. This module configures the BIST controllers at the beginning of self-test and collects and stores the final status to be read by the core. The module also schedules the sequence of LBIST self-test between partitions and MBIST instances.

Each logical partition also includes a block called self-test GPR, a set of registers that provide miscellaneous configurations or parameters for LBIST and MBIST operation.

Figure 1 shows a self-test overview.

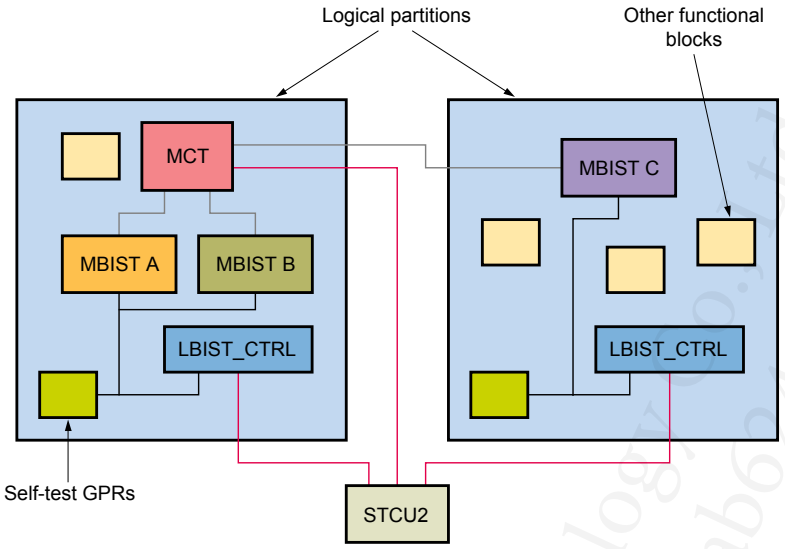

Figure 563. Self-test overview

A logical partition belongs to either the main reset domain or a software domain. The chip becomes unavailable for software application for the duration of the self-test, if software triggers a self-test on any logical partition of the main reset domain. However, a self-test running on logical partitions of a software reset domain does not affect the functionality of modules present in the main reset domain or other software reset domains. This increases the availability of the system. See the Reset chapter for a list of software reset domains available in this chip. For each LBIST and MBIST controller in the chip, STCU2 LBIST mapping and STCU2 MBIST mapping show the associated reset domain.

71.1.3 STCU2 LBIST mapping

71.1.5 Running MBIST sequences on CM7 memories

You must enable the corresponding core reset and CM7 core clock to run MBIST sequences on CM7 memories. If the corresponding CM7 core is disabled, then enable its reset and clock as follows:

1. Use the corresponding CM7 GPR to put the core in CPU_WAIT if you do not need to execute anything with the CM7 core and you need to run MBIST on its memories.
2. Ungate the clock of the corresponding CM7 core using the respective core-related registers in MC_ME.
3. Deassert the reset of the corresponding CM7 core by writing 0 to the respective field in PRST0_0.

71.1.6 Indicating fault state during the main reset domain self-test

The Software must program the MC_RGM's ERCTRL[ERASSERT] field to 1b prior to initiating the main reset domain self-test. This results in the RESET_B pin being asserted, the FCCU EOUT pins indicating the fault state, and all other pins being put into their default state as indicated by the "Pad State During Main Reset Domain Selftest" column of the "Misc With Pin Controls" tab of the IOMUX sheet.

The fault state remains asserted until the EOUT Override Clear field in SRC's FCCU_EOUT_OVERRIDE_CLEAR_REG[EOUT_OVERRIDE_CLEAR] field is programmed in the post-self-test reset sequence.

Configure the EOUT override disable during self-test field in SRC's FCCU_EOUT_OVERRIDE_CLEAR_REG[EOUT_OVERRIDE_CLEAR] field before configuring MC_RGM's ERCTRL[ERASSERT] field, if it is not required to indicate the fault state during the main reset domain self-test.

71.1.7 Error events management in main reset domain self-test

You can map error events to unrecoverable faults for the main reset domain self-test using STCU2's ERR_FM register.

71.1.8 Online self-test reset or interrupt generation

After an online self-test (LBIST or MBIST) completes or STCU2 detects an ABORT condition during self-test execution, reset is issued to all BIST partitions present inside the reset domains enabled for self-test in that run. This action resets all modules present inside those BIST partitions. Also, if the self-test includes the main reset domain, MC_RGM executes a functional reset sequence.

You must enable interrupts inside STCU2 using the RUNSW register if the self-test includes only software reset domains. STCU2 generates the interrupts and notifies the target core of those interrupts at the end of the self-test.

Enable STCU2 interrupts for those self-tests that run only on software reset domains. If the self-test includes the main reset domain, disable STCU2 interrupts.

71.1.9 AUTOLOCK_VALUE for register write access through STCU2_SKC

Register write access to STCU2 registers through the STCU2_SKC security-key mechanism times out after the number of STCU2 clock cycles as specified by the AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 1_FFFFh.

71.1.10 PLL loss of lock during self test

Detection of PLL loss of lock during LBIST or MBIST causes a destructive reset in the system.

CMU0 programming is required before the self-test programming begins.

All the registers present in LBIST domains do not retain their content after self-test reset.

71.1.11 STCU2 BIST start (BSTART) register description

Attempted accesses with the undefined reserved values in the BSTART register can result in undefined behavior. The following table defines the fields of BSTART.

Diagram

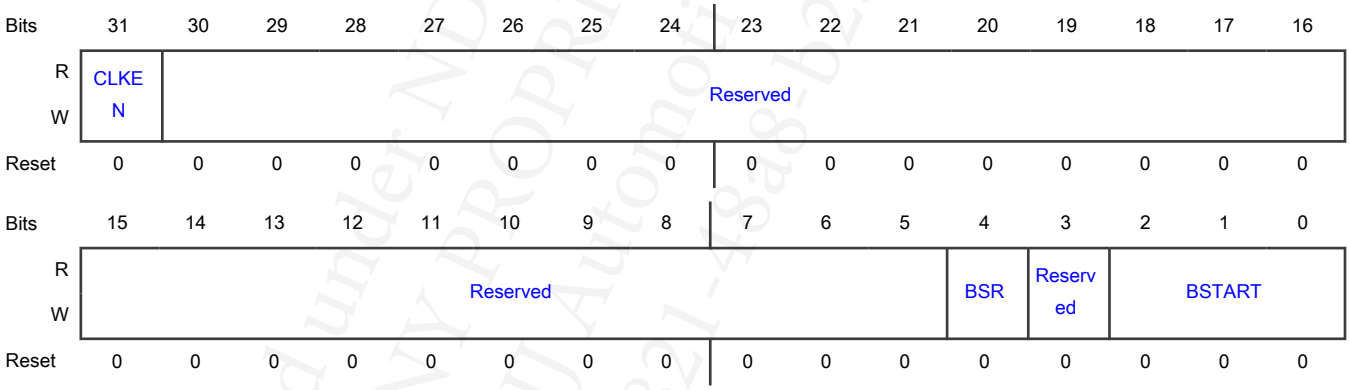

Table 559. Fields

Field	Function
31 CLKEN	Clock enable If set, it enables the clocks for the BISTs otherwise clock will remain disabled.
30-5 —	Reserved
4	BIST Status Reset

Table continues on the next page...

Table 559. Fields (continued)

Field	Function
BSR	setting this bit causes result and status information captured from MBIST run to be reset.
3 —	Reserved
2-0 BSTART	000b - NOP (reset value) 001b - Run the selected BISTs without programming them first. 010b - Reserved 011b - Reserved 100b - Program BISTs only, but do not start them. This enables different BISTs to be programmed with different algorithms before all the selected BISTs are started by setting BSTART value to 001. 101b - Program BISTs and start them. 110b - Reserved 111b - Reserved

71.1.12 STCU2 algorithm select (ALGOSEL) register description

This register selects any one of the predefined algorithms. The value used in this register is mapped to a predefined algorithm register in BIST. After MCT has programmed information on this register and starts some BIST operation, this value is transferred to the predefined algorithm register in every BIST that is selected.

If multiple predefined algorithms are selected, the order of execution is from LSB to MSB.

Any field that does not have a predefined algorithm associated with it is a reserved bit. No data is written to reserved bits and when you read these bits, they always return 0. These predefined algorithms include:

- Backgrounds
- Address modes and other register programming that may be necessary
- The number of BIST runs needed to perform the exact coverage requested.

MCT decodes this information through a series of look-up tables. The following table describes the high-level BIST algorithms that can be invoked through the MCT. The columns in that table have the following meaning:

- Index: The position in this MCT register enables this algorithm.
- Name: The symbolic name for this algorithm.
- Description: The intent and use model for this algorithm.
- BIST runs: The sequence of BIST invocations comprising this algorithm.
- Sequences: The ordered list of march elements to run. Each march element consists of a direction indicator (for increasing addresses and for decreasing addresses) and a set of march phases. A march phase consists of reading (R) or writing (W), the non-inverted (0) or inverted (1) background pattern.
- Used by default: Whether this algorithm is selected in the post-reset state of this register.

Table 560. Table 2. ALGOSEL description

Index	Name	Description	BIST runs	Sequences	Used by default
3	March C+ single	March C+ with column fast and solid background	MarchC+ column fast 1x (#4)	W0, R0W1, R1W0R0W1, R1W0, R0W1R1W0, R0	Yes
13	BasicChk	Basic self-contained checkerboard, using column fast	BasicChk (#18)	R0W1R1	_

71.1.13 Self-test programming sequence

This section contains high-level programming sequences for executing self-test in a software reset domain and the main reset domain. Detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

Software reset domain:

1. Turn off the software reset domain following the steps in the "Software reset partition turn-off flowchart" section in the Reset chapter.
2. Configure the software reset domain clocks to initial frequencies.
3. Write 1 to SELFTEST_GPR_TOP's Reset_Domain_Selftest_Enable_Register[RESET_DOMAIN_*n*_SELFTEST_ENABLE] field, where *n* corresponds to the software reset domain(s) in which self-test is to be executed.
4. Wait for SELFTEST_GPR_TOP's corresponding Reset_Domain_Selftest_Enable_Status_Register[RESET_DOMAIN_*n*_SELFTEST_ENABLE_LAST_RUN_STATUS] field to become 1.
5. Program clock sources and MC_CGMs according to the clock configuration.
6. Program self-test GPR of LBIST partitions in which self-test is to be run according to the required configuration.
7. Program STCU2 according to the required LBIST or MBIST configuration.
8. Enable LBIST or MBIST interrupt in STCU2 and trigger self-test execution by programming STCU2's RUNSW register.

At the end of the self-test run, an interrupt is generated. You can check the STCU2 status registers and take actions accordingly.

Main reset domain:

1. Turn off all software reset domains in the chip following the steps in the "Software reset partition turn-off flowchart" section in the Reset chapter.
2. Disable the modules present in the main reset domain (such as GMAC, SerDes, DDR, and TMU).
3. If any software reset domain is enabled for self-test in this run, configure the clocks of that domain to initial frequencies.
4. Write 1 to SELFTEST_GPR_TOP's Reset_Domain_Selftest_Enable_Register[RESET_DOMAIN_*n*_SELFTEST_ENABLE] field, where *n* corresponds to main reset domain. If the self-test run in any software reset domain(s) in the same configuration, write 1 to the corresponding field(s).
5. Wait for SELFTEST_GPR_TOP's Reset_Domain_Selftest_Enable_Status_Register[RESET_DOMAIN_*n*_SELFTEST_ENABLE_LAST_RUN_STATUS] field to become 1 for any main reset domains and software reset domains.
6. Program clock sources and MC_CGMs according to the clock configuration.
7. Program self-test GPR of LBIST partitions in which self-test is to be run according to the required configuration.
8. Program STCU2 according to the required LBIST or MBIST configuration.

9. Write 1 to SRC's FCCU_EOUT_OVERRIDE_CLEAR_REG[EOUT_OVERRIDE_DISABLE_DURING_SELFTEST] field if you do not want the fault state to be indicated on the EOUT pins.
10. Write 1 to MC_RGM's ERCTRL[ERASSERT] field to move the GPIO pins to a safe state and to deassert the RESET_B pin.
11. Trigger self-test execution by programming STCU2's RUNSW register.

At the end of the self-test run, a functional reset is generated. After this reset, you can check the STCU2 status registers and take actions accordingly.

SELFTEST_GPR_TOP's Reset_Domain_Selftest_Enable_Status_Register[RESET_DOMAIN_*n*_SELFTEST_ENABLE_LAST_RUN_STATUS] fields tell you whether self-test was enabled in a particular reset domain in the last self-test run.

Perform the following instructions for the configurations when the selftest is executed on the software resettable domain followed by the selftest run on the main reset domain, or software resettable domain:

- For the first MBIST run on software resettable domain, write BSTART of STCU2 at 8000_0005h, and then start selftest.
- For MBIST run on either the main reset domain or software resettable domain just after the MBIST run on the software resettable domain, write BSTART of STCU2 at 8000_0015h to clear the results and the status information from the previous MBIST run on SRD.

71.1.14 Handling unrecoverable faults

Only recoverable and non-critical faults map to FCCU. The unrecoverable faults from STCU2 do not map to FCCU. The unrecoverable and critical faults map to MC_RGM instead of FCCU. Therefore, ignore this chapter's references to mapping of these faults to FCCU.

71.2 Introduction

STCU2 is a comprehensive programmable hardware module that:

- Manages the execution of BISTs
- Indicates whether each BIST passed
- Manages the chip's LBIST and the MBIST blocks

71.3 Main features

STCU2 includes:

- System interface for reading from and writing to the STCU2 registers during runtime (online) via the CPU
- Programmable scheduler for BIST execution
- Control over LBIST concurrent or sequential execution
- Control over MBIST concurrent or sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST clocks
- Dedicated online MBIST interrupt source generation
- Dedicated online LBIST interrupt source generation
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the execution status of each BIST, see Types of BIST sequences and Types of BIST partitions

- Fields that indicate the status of each type of online STCU2 internal error condition
- Field that indicates the status of an online hardware abort
- Programmable fault mapping of each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping of each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals to report recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving after a BIST sequence is completed when watchdog timer time-out is detected
- Watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- Watchdog automatic power saving when the fixed register-write-access watchdog timer times out

71.4 Block diagram

This diagram shows the parts of STCU2:

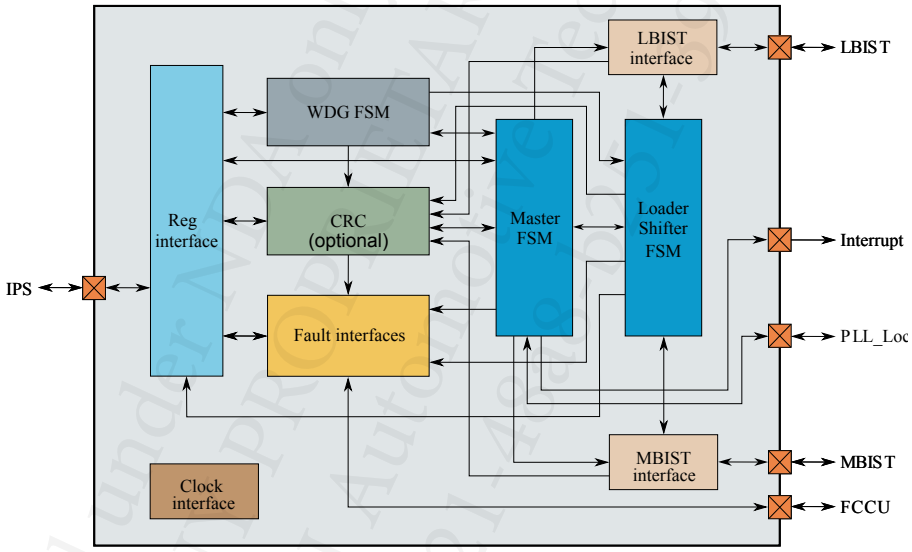

Figure 564. STCU2 block diagram

This table describes the parts of STCU2:

Table 561. STCU2 parts

Part	Function
Reg interface	Provides access to: • Registers • The security key logic • The IPS interface

Table continues on the next page...

Table 561. STCU2 parts (continued)

Part	Function
Fault interface	Performs the following tasks: • Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence • Sets the global recoverable or unrecoverable status flag, depending on the fault mapping for a given BIST • Manages the recoverable and unrecoverable fault lines to and from the FCCU module • Manages the set/clear injection mechanism provided by the FCCU module To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
Clock interface	Manages the internal and the BIST clock prescaler, the internal clock-gating power saving, and the wake-up clock feature
WDG FSM	Provides the following: • A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence • A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
Master FSM	Coordinates and schedules all of the operations performed during a BIST sequence
Loader Shifter FSM	Programs the BIST registers and reads back the data to be checked at the end of each test operation
LBIST interface	Provides the interface between the chip's LBIST engines and the STCU2 controllers
MBIST interface	Provides the interface between the MBIST controller and the STCU2 controllers

71.5 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration purposes via CPU. The module supports the following bus read operations:

- Word (32 bits) data read operations to any registers
- Any other operation is not supported.

Word, low and high half-words, byte operations are supported in write mode only:

- Write access is allowed by software only when CFG[WRP] is cleared. The default value of CFG[WRP] is cleared.
- Exceptions are the following read/write fields: CFG[WRP], ERR_STAT[UFSF] and ERR_STAT[RFSF].
- In all the other conditions, the write operations are not supported and all the STCU2 registers can be only read.
- STCU2 Configuration (CFG) should only be accessed in 32 bit (partial access not allowed).

The STCU2 module generates a transfer error in the following cases:

- Any read access to the registers after writing Key1 and before writing Key2 (in online) and before register write-access watchdog timer expires.

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when CFG[WRP] is set and the access is performed through software (internal peripheral interface). The exceptions are SKC register (for valid keys value and sequence) and INT_FLG register(interrupt flag) in which STCU2 does not assert transfer error.
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor, or test.

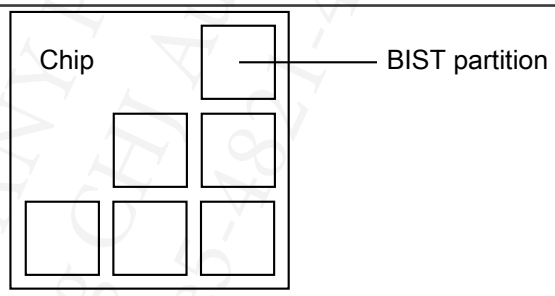
In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

71.6 BISTs and BIST partitions

71.6.1 Definition: BIST



A BIST is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

71.6.2 Definition: BIST partition

A BIST partition is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

71.6.3 Example: BIST partitions on a chip

This is an example of a chip with six BIST partitions:

71.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of BIST partitions:

Table 562. Types of BIST partitions

BIST partition type	Description
MBIST partition	An SRAM or ROM block
LBIST partition	One or more digital modules

71.7 BIST sequences

71.7.1 Definition: BIST sequence

A BIST sequence is a programmable series of one or more phases, each of which executes one or more individual BISTs.

71.7.2 STCU2 executes MBISTs before LBISTs

If a BIST sequence includes both MBISTs and LBISTs; STCU2 executes the MBISTs first.

71.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Table 563. Example: Single-phase BIST sequence

Phase	BIST executed
0	MBIST 16

71.7.4 Example: Multi-phase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Table 564. Example: Multi-phase BIST sequence

Phase	BISTs executed
0	MBISTs 7, 38
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

71.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of BIST sequences:

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-4848-8251-39013ab624c1

Table 565. Example: Types of BIST sequences

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.

71.7.6 Supported BIST sequences

NXP supports only a specific set of BIST sequences for this chip. For the list of supported BIST sequences, see the chip-specific STCU2 information.

71.8 STCU2 register descriptions

The STCU2 registers are listed in this section.

NOTE

Always write the reset value for the Reserved fields.

During online self-test, after the STCU2 registers are configured, they must not be overridden via internal peripheral system until the self-test is complete.

71.8.2 STCU2 Run Software (RUNSW)

Offset

Register	Offset
RUNSW	4h

Function

The RUNSW register defines the RUN bit to start the online self-testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when CFG[WRP] = 0.

Diagram

71.8.3 STCU2 SK Code (SKC)

Offset

Register	Offset
SKC	8h

Function

The SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers.

To unlock STCU2 access after the STCU2 asynchronous reset and at the end of the STCU2 run, the software (IPS bus) need to apply the following sequence:

- write the key1 into the SKC register
- write the key2 into the SKC register

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e54-821-48a8-b251-390d3ab924c1

Depending on the online test step, the two keys are different. Byte write operation is not allowed because the full key has to be recognized as one unit.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS is asserted. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined in the hard-coded WDG timeout, the STCU2 write access is locked and the WDG and register interface clocks are switched off. Also, in this case, to enable the write access to the STCU2 again and the WDG and register interface clocks, it is required to apply the sequence again. This hard-coded WDG counter starts decrementing its value right after POR is deasserted.

In case it is required to extend the STCU2 register access cycles before the hard-coded WDG timeout expires, Key1 and Key2 sequences need to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

The SKC register is not readable. The value 00000000h is always returned in case of read operation.

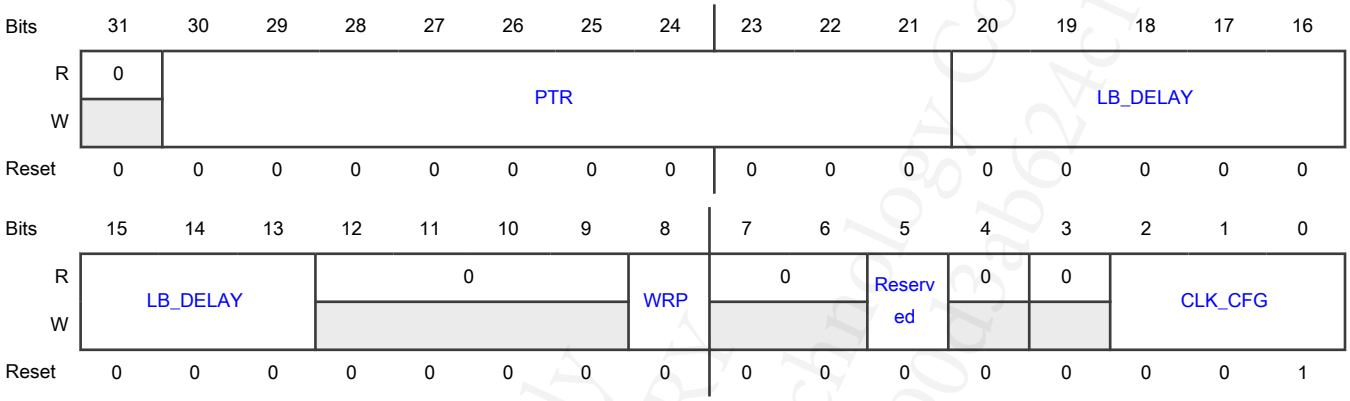
71.8.4 STCU2 Configuration (CFG)

Offset

Register	Offset
CFG	Ch



Function

The CFG register includes the global configuration of the STCU2 and can be updated in the online test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the online self-test case without restrictions.
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Diagram

Fields

Field	Function
31 —	Reserved
30-21 PTR	First LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled. See BIST scheduling for details. **NOTE** You can write to this field only when WRP = 0. 0h to (3Ch - 1): pointer to LBIST 00000080h to (00000080h + 06Eh - 1): pointer to MBIST 3FFh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU2 Error (ERR_STAT).
20-13 LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. The allowed delay time are these: 00h: No delay 01h: 1 x 16 STCU2 CORE_CLK cycles

Table continues on the next page...

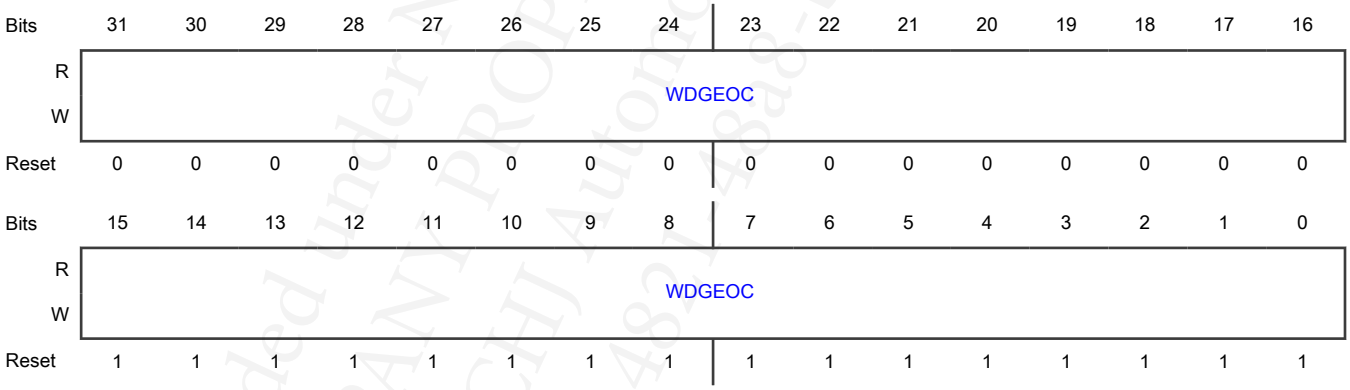
71.8.5 STCU2 Watchdog Granularity (WDG)

Offset

Register	Offset
WDG	14h



Function

The WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or endless conditions during the self-test procedure.

In case online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

Diagram

Fields

Field	Function
31-0 WDGEOC	Watchdog End of Count Timer This value has to be set to define the time budget related to the online self-test execution and check that everything is correctly working within this slot of time. The delay time slots that are allowed are as follows: 0000 0000h: 1 x 16 STCU2 CORE_CLK cycles

Table continues on the next page...

71.8.6 STCU2 Interrupt Flag (INT_FLG)

Offset

Register	Offset
INT_FLG	18h

Function

The INT_FLG register includes the MBISTand LBIST interrupt pending bits. These bits are effective during the online self-test phase and are managed only when the corresponding control bit in the RUNSW register (MBIE and LBIE) is enabled.

Diagram

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No interrupt is pending 1b - An interrupt, highlighting that the online execution of the concurrent scheduled MBIST is completed, is pending. Write 1 to clear the bit.
0 LBIFLG	LBIST Interrupt Flag 0b - No interrupt is pending. 1b - An interrupt, highlighting that the online execution of the concurrent scheduled LBIST is completed, is pending. Write 1 to clear the bit.

71.8.7 STCU2 Error (ERR_STAT)

Offset

Register	Offset
ERR_STAT	24h

Function

The ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the online self-testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

71.8.23 STCU2 MBIST Unrecoverable FM (MBUFM0)

Offset

Register	Offset
MBUFM0	18Ch

Function

This register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range 31:0.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

NOTE

The register reset value is chip-specific. See the chip-specific STCU2 information for reset values.

71.8.24 STCU2 MBIST Unrecoverable FM (MBUFM1)

Offset

Register	Offset
MBUFM1	190h

Function

This register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range 63:32.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

NOTE

The register reset value is chip-specific. See the chip-specific STCU2 information for reset values.

Field	Function
PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST orMBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure stops after the last BIST in the configuration chain is complete. See BIST scheduling for details. **NOTE** If the pointer is invalid and MBIST is scheduled to run concurrently than this invalid scenario is handled by watchdog timeout feature and corresponding watchdog timeout status bit will be updated in ERR_STAT[WDTOSW]. In this particular case ERR_STAT[INVPSW] will not be set. 0h to (3Ch - 1): pointer to LBIST 00000080h to (00000080h + 06Eh - 1): pointer to MBIST 3FFh: pointer to NIL. No next BIST execution. others: invalid pointer => an error is set into the STCU2 Error (ERR_STAT).
20 BSEL	BSEL BIST Select 0b - Selected BIST is not selected for execution. 1b - Selected BIST is selected for execution.
19-0 —	Reserved

71.9 Functional description

71.9.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the self-test operations and the other state machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

71.9.2 BIST scheduling

STCU2 is designed to program the parallel/serial execution of the MBIST or LBIST depending on the power, timing, and coverage constraints.

The mechanism used to provide this flexibility is a linked list of BIST descriptors where the starting pointer is defined in CFG[PTR]. The first LBIST is mapped on 0, the second on 1, and so on. A BIST descriptor identifies a LBIST or MBIST via an index that is associated with its control register (STCU2 LBIST Control (LB_CTRL0 - LB_CTRL59) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL109)). The first MBIST is mapped on (00000080h + 0), the second on (00000080h + 1), and so on. The additional pointers of the linked list are in LB_CTRL*n*[PTR] for LBIST *n* (where *n* is the selected LBIST) and MB_CTRL*m*[PTR] for MBIST *m* (where *m* is the selected MBIST) and must be populated depending on the selected run sequence. The additional fields

LB_CTRL[CSM] and MB_CTRL[CSM] provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list by setting the NIL pointer.

71.9.3 ABORT management

The STCU2 module provides online self test execution abort. When the abort is detected, the online self test operation stops running and the status of the currently running MBIST or LBIST is saved into the related registers to provide intermediate results that might be useful in case of debug or in case of concurrent run.

71.9.3.1 Hardware ABORT management

The STCU2 enters the hardware abort condition as a consequence of a functional reset which causes self test execution to abort.

When hardware abort is detected the bit ABORTHW of the ERR_STAT register is set. This flag allows the software to diagnose what has happened during the online self test execution run.

71.9.4 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

71.9.5 Watchdogs

The STCU2 implements different watchdogs to ensure that operations are finished in time.

71.9.5.1 BIST watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (WDG), to account for the overall execution time of the self test sequence. In case the selected LBISTs or MBISTs are not yet completed during assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

In case of multiple sequential run in the same online session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

71.9.5.2 Register write-access watchdog timer

As explained in the STCU2 SK Code (SKC):

- A key mechanism protects STCU2 registers during the self-test configuration phase by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write Key1 and Key2 sequences.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

The hardware watchdog timer is particularly useful in case CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

71.10 Use cases and limitations

For details on use cases and limitations, contact NXP sales representative.

71.11 Glossary

BIST	Built-in self-test

Chapter 72
Safety by Software (SBSW)

72.1 Introduction

The SBSW is a module that supports the "safety by software" approach in automotive safety applications.

It provides a fault detection mechanism to be used by safety-related applications via two distinct safety mechanisms. SBSW monitors the health of an application by performing the following functions:

- It checks application software results by comparing the outcome of redundant computations in a configured manner with respect to both the values and their temporal relationship.
- It monitors the execution process of an application by comparing the application's real-time progress state with the configured expected progress program flow.

72.1.1 Acronyms and abbreviations

Text	Description
AC	Application core
CPU	Central processing unit
FCCU	Fault collection and control unit
FSM	Finite-state machine
INTC	Interrupt controller
IP	Intellectual property
IRQ	Interrupt request
NCF	Noncritical fault
R	Read
RO	Read only
RW	Read/write
SW	Software
TC	TMWDP core
TCM	Tightly-coupled memory
TMC	Time-monitored comparator
TMWDP	Timed multi-watchdog processor
TMWDPI	TMWDP interface
W	Write
WO	Write only
W1C	Write 1 to clear

72.2 Block diagram

The following figure shows the top-level block diagram of SBSW:

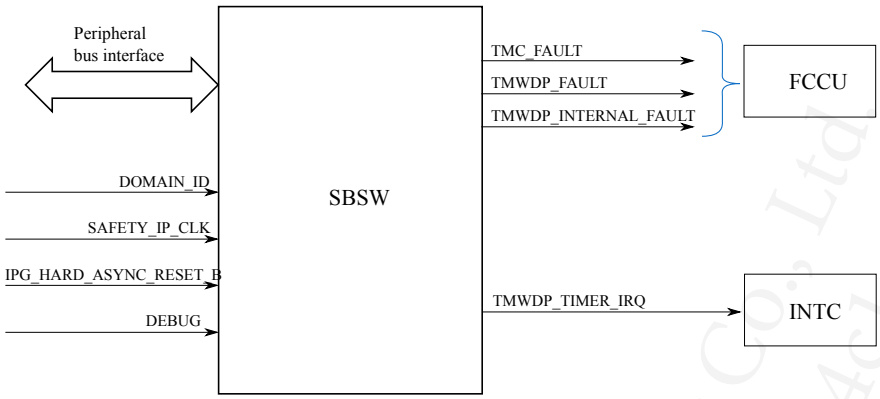

Figure 565. Top-level block diagram

The following figure shows the overall structure of the SBSW.

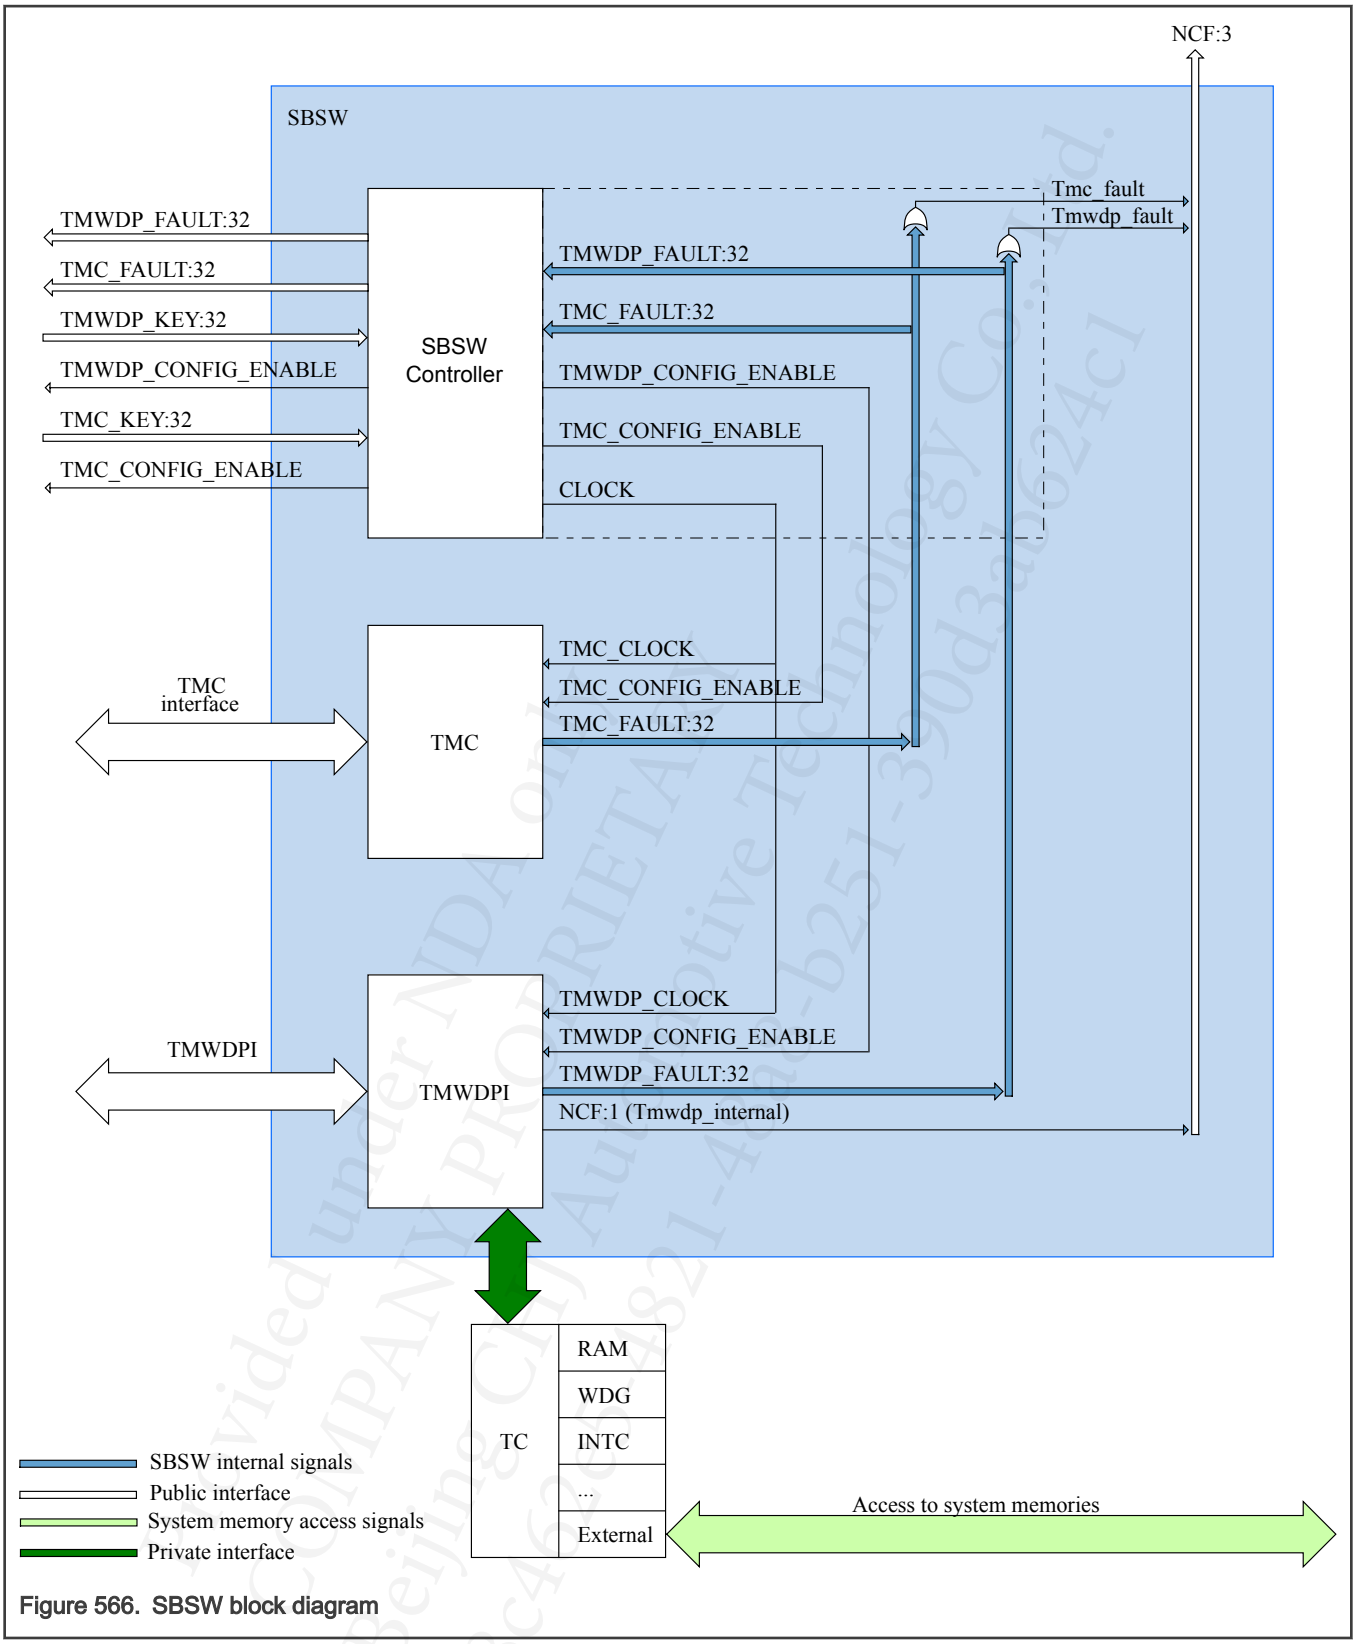

Figure 566. SBSW block diagram

The thin lines represent a single bit or signal, and the thick lines denote multiple-bit entities with names followed by colons and number of bits.

72.3 Signal descriptions

The table below describes the signals on the boundary of SBSW.

Table 566. Signal descriptions

Signal name	Direction	Description
Clock and reset		
SAFETY_IP_CLK	Input	SBSW has a single clock of 66.7 MHz, which is synchronous to the 133 MHz MODULE_CLK. The chip handles synchronization requirement of the clocks outside of the SBSW module.
IPG_HARD_ASYNC_RESET_B	Input	IP bus async functional reset
DEBUG	Input	SBSW enters the Debug mode when this signal is asserted high. The DEBUG_MODE[MODE] field configures the behavior of the SBSW when it is in the Debug mode.
DOMAIN_ID[3:0]	Input	These signals are used to distinguish whether the RW accesses are from TC or AC. If the value on this bus matches the value programmed in the TC_ID register, then RW accesses are from the TC, otherwise RW accesses are from the AC.
FCCU interface signals		
TMC_FAULT	Output	This signal is high when TMC detects a fault. The fault could be either because of false comparison or time violation.
TMWDP_FAULT	Output	This signal is high when TMWDP detects a fault. The fault could be either because of illegal transition or time violation in any automaton.
TMWDP_INTERNAL_FAULT	Output	This signal is high when TMWDP detects an error in the safety mechanism itself. The error could be either because of invalid configuration or an internal error.
INTC interface signals		
TMWDP_TIMER_IRQ	Output	This level interrupt is generated whenever the TMWDP timer reload expires.

72.4 Functional description

SBSW has three main functional blocks (or sub-modules):

- SBSW controller

- Array of TMCs
- TMWDPI

72.4.1 SBSW controller

The SBSW controller includes auxiliary parts of this module, and controls the operation of SBSW sub-modules (TMCs and TMWDPI), as shown in Figure 566. Some of the functions of the SBSW controller are as follows:

- Provides a locking/unlocking mechanism protecting configuration of the sub-modules.
- Provides the clock signals to the sub-modules.
- Provides aggregated fault outputs from the sub-modules.
- Generates NCF signals for FCCU to react.

SBSW controller protects sensitive configuration data by handling a locking/unlocking protocol. The unlocking mechanism is independent for each SBSW sub-module, using a dedicated register and a separate FSM implementing the protocol. You must unlock the individual sub-module's configuration before modifying it.

72.4.1.1 Unlocking/locking the TMC configuration

The following figure illustrates the unlocking protocol for the TMC.

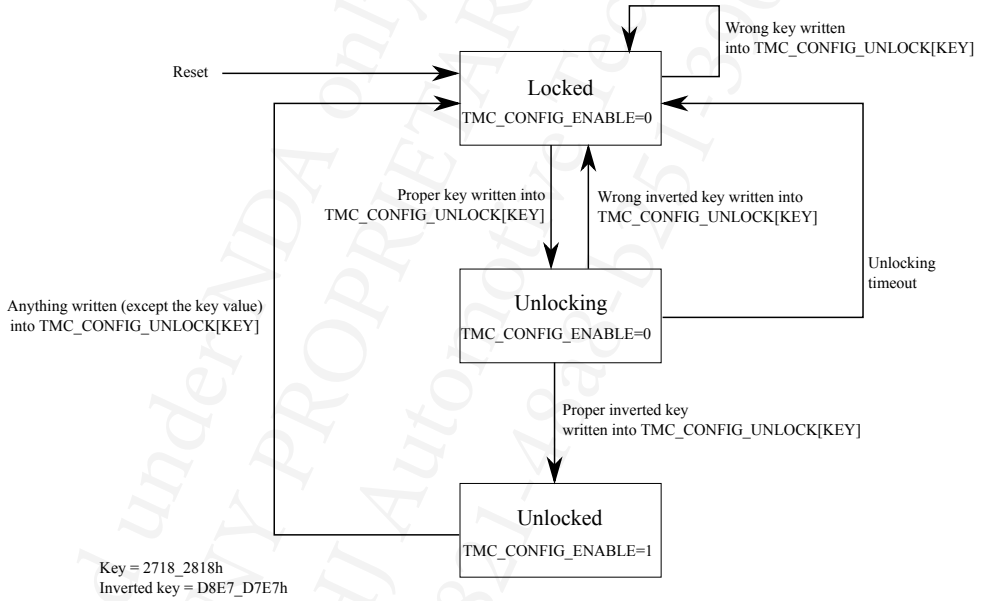

Figure 567. TMC configuration locking state diagram

To unlock the configuration, you must execute the following procedure by using the TMC_CONFIG_UNLOCK register:

1. Write a predefined key value (2718_2818h) to TMC_CONFIG_UNLOCK[KEY].
2. Write the inverted key value (D8E7_D7E7h) to TMC_CONFIG_UNLOCK[KEY] within a predefined timeout interval of 62 SAFETY_IP_CLK cycles.

On successful completion of the procedure described above, the SBSW controller unlocks the TMC configuration and asserts the TMC_CONFIG_ENABLE signal.

If you do not write the inverted key value within the predefined timeout, or if you write a wrong value, the SBSW controller aborts the unlocking operation.

After modifying the configuration, you must lock the TMC configuration by writing any value (except the unlocking key, 2718_2818h) into TMC_CONFIG_UNLOCK[KEY].

NOTE

Before locking the TMC configuration, you must ensure that it stays in the unlocked state for at least one SAFETY_IP_CLK cycle. You can ensure this, for example, by reading the TMC_CONFIG_STATUS[STATUS] field to see whether the TMC configuration unlocking procedure has succeeded.

A successful completion of step 1 (writing the predefined key value) reinitializes the counter and it starts decrementing. Successful completion of the step 2 (writing the inverted key value within a specified time) stops the counter. The counter also stops if the SBSW controller aborts the unlocking operation.

72.4.1.2 Unlocking/locking the TMWDP configuration

To unlock the configuration, you must execute the following procedure by using the TMWDP_CONFIG_UNLOCK register:

1. Write a predefined key value (3141_5926h) to TMWDP_CONFIG_UNLOCK[KEY].
2. Write the inverted key value (CEBE_A6D9h) to TMWDP_CONFIG_UNLOCK[KEY] within a predefined timeout interval of 62 SAFETY_IP_CLK cycles.

On successful completion of the procedure described above, the SBSW controller unlocks the TMWDP configuration and asserts the TMWDP_CONFIG_ENABLE signal.

If you do not write the inverted key value within the predefined timeout, or if you write a wrong value, the SBSW controller aborts the unlocking operation.

After modifying the configuration, you must lock the TMWDP configuration by writing any value (except the unlocking key, 3141_5926h) into TMWDP_CONFIG_UNLOCK[KEY].

NOTE

Before locking the TMWDP configuration, you must ensure that it stays in the unlocked state for at least one SAFETY_IP_CLK cycle. You can ensure this, for example, by reading the TMWDP_CONFIG_STATUS[STATUS] field to see whether the TMWDP configuration unlocking procedure has succeeded.

A successful completion of step 1 (writing the predefined key value) reinitializes the counter and it starts decrementing. Successful completion of the step 2 (writing the inverted key value within a specified time) stops the counter. The counter also stops if the SBSW controller aborts the unlocking operation.

72.4.2 TMC

TMC is an SBSW sub-module that:

- Compares results of two independent application software (SW) instances, SW1 and SW2
- Monitors the comparison timings
- Signals a fault if comparison does not succeed or timing violation occurs

This chip has 32 instances of TMC. Each instance is dedicated to a particular computation comparison. You can enable or disable a TMC instance by using the corresponding TMC_a_CONTROL register. The functionality of TMC is illustrated in the following figure:

Preliminary Proposal
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462b5-4821-48e8-9251-3901f3ab624c

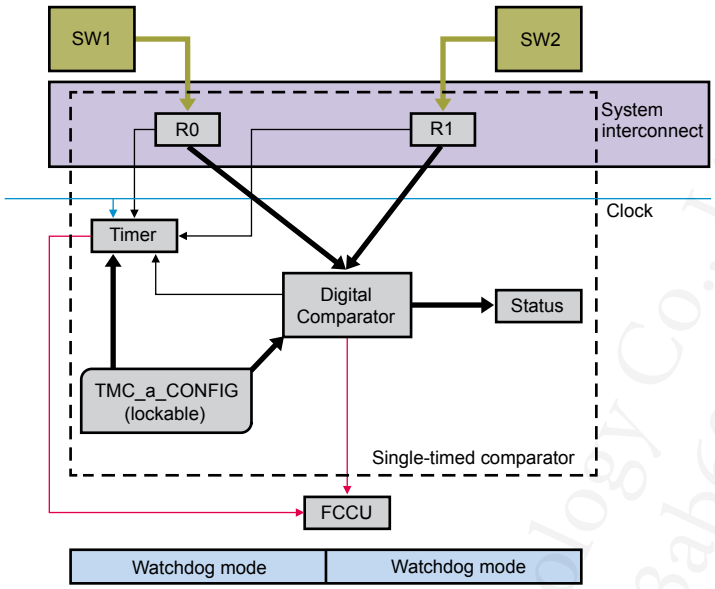

Figure 568. TMC functionality

There are two essential parts of a TMC:

- Digital comparator
- Timer

72.4.2.1 Digital comparator

The digital comparator performs a simple digital comparison (greater than, less than, or equal to) or a complex comparision (with distance value) of the values stored in R0 and R1 registers. The digital comparator signals a fault after any of the following cases:

- If the comparison does not succeed. You configure the comparison modes in the respective TMC configuration register by using TMC_a_CONFIG[COMPARE_MODE].
- If you overwrite either of the values programmed in R0 or R1 before the comparison.

You write the SW1 result in R0 by using TMC_a_R0[R0], and the SW2 result in R1 by using TMC_a_R1[R1].

NOTE

The core on which SW1 or SW2 executes is irrelevant.

The comparison occurs immediately after both R0 and R1 are written a value to compare. The comparison modes are:

- R0 == R1
- R0 > R1
- R0 < R1
- |R1 - R0| ≤ D, Distance

You program the value for Distance in TMC_a_DISTANCE[DISTANCE].

Often, you want to know whether a value (for example, from SW1) is within a certain range with respect to the other value. You can achieve this by comparing a calculation of |R1-R0| with a predefined distance value (D), |R1-R0| ≤ D.

72.4.2.2 Timer

The TMC monitors the comparisons (discussed in Digital comparator) by using a 32-bit count-down timer. Each TMC instance has its own dedicated timer. The TMC signals a fault if the timer expires without a comparison.

You configure a TMC instance by using TMC_a_CONFIG[TIMING_MODE] to run the corresponding timer in either of the following modes:

- **Watchdog mode:**

  The timer ensures that comparison occurs periodically within a specified time limit. If it does not, then TMC signals a fault. You specify the time limit in TMC_a_TIMEOUT[TIMEOUT].

  In this mode, the timer starts decrementing immediately after either of the following events:

  — TMC is enabled.

  — The comparison is complete (that is, when both R0 and R1 registers are written).

  The next comparison shall happen before the timer expires. After the comparison occurs, the timer is loaded again with the timeout value and it starts decrementing again.

- **Window mode:**

  The timer ensures that R0 and R1 registers are written within a specified time limit. If they are not, then TMC signals a fault. You specify the time limit in TMC_a_TIMEOUT[TIMEOUT].

  In this mode, the timer starts decrementing when either of the R0 or R1 register is written. The other register must be written before the timer expires.

The following figures illustrate both the modes. The DISABLED state is reachable from any other state (except from COMPARING); these transitions have been omitted for the sake of readability.

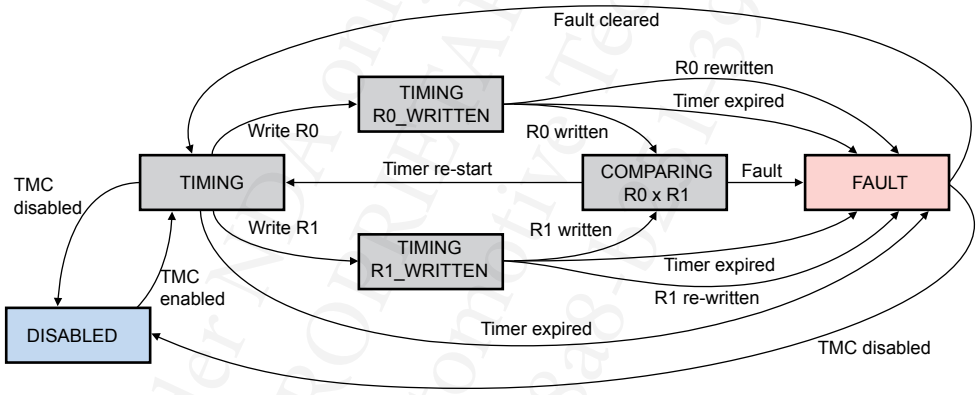

Figure 569. TMC in Watchdog mode

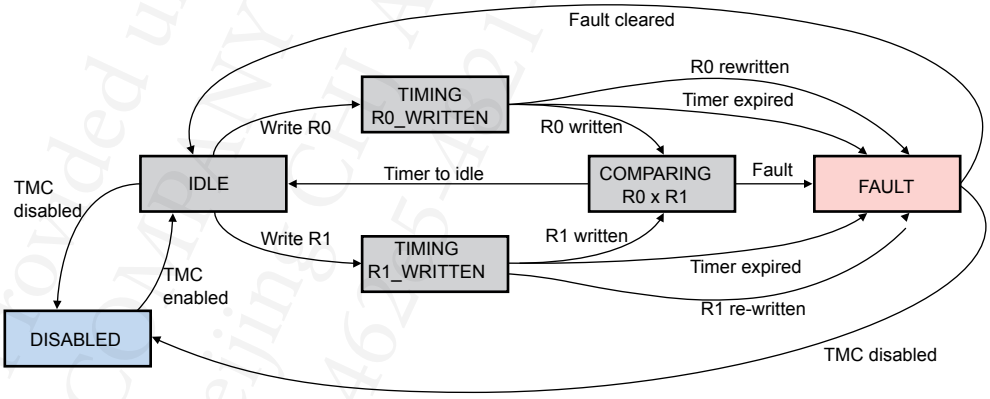

Figure 570. TMC in Window mode

See TMC Configuration (TMC_0_CONFIG - TMC_31_CONFIG) for the configuration registers, which you use to:

- Set the TMC behavior

- Set the TMC timeout value
- Enable a TMC instance

You may read the current value of the timer from TMC Timer (TMC_0_TIMER - TMC_31_TIMER), and the status of the respective TMC from TMC Fault Status (TMC_FAULT_STATUS).

72.4.2.3 Block diagram

The following figure is the top-level block diagram of the TMC array. Individual TMC_FAULT*n* signals merge to form the TMC_FAULT bus. All TMC instances share the TMC_CLOCK and TMC_CONFIG_ENABLE signals.

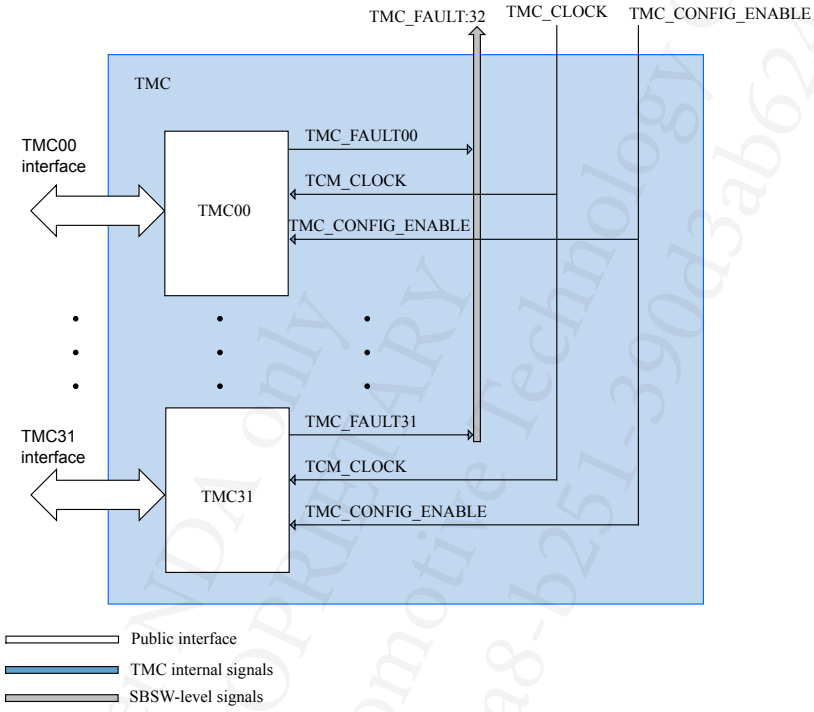

Figure 571. TMC block diagram

72.4.2.4 TMC states

You check the state of each TMC by using the corresponding TMC_a_STATUS register. Following are the possible states of a TMC:

- Timing: Indicates that the timer is currently running
- Idle: Indicates that the TMC is in an intermediate state—between enabling a TMC, and writing into R0 and R1
- R0 Written: Indicates that R0 is written
- R1 Written: Indicates that R1 is written
- Comparing: Indicates that both R0 and R1 were written and TMC is currently performing a comparison
- Fault: Indicates that TMC has detected a fault

There are four register fields determining the state of running of a TMC (see TMC Status (TMC_0_STATUS - TMC_31_STATUS)):

- R0_WRITTEN
- R1_WRITTEN
- FAULT

- OVERWRITTEN

The mapping between the TMC states and the flags are shown in the table below:

Table 567. TMC state mapping

Flags			States	
R0_Written	R1_Written	Fault	In Watchdog mode	In Window mode
0	0	00	Timing	Idle
1	0	00	R0 Written	R0 Written
0	1	00	R1 Written	R1 Written
1	1	00	Comparing	Comparing
0	0	01	Fault	Fault

72.4.2.5 TMC events

The TMC reports a fault on the following events:

- A false comparison fault is detected if the comparison result is not as configured.
- A timeout fault occurs if:
  - Both R0 and R1 are not written within the pre-configured time interval.
  - One of either R0 or R1 is rewritten before the other one is written.

A TMC reports a fault by asserting the TMC_FAULT*n* signal. These fault signals are aggregated by the module into a common status vector and presented to the SBSW controller. The controller is responsible for asserting the NCF signal to FCCU (via the TMC_FAULT signal). The TMC_FAULT*n* signal asserts the appropriate field in TMC_FAULT_STATUS[STATUSn] and stops the respective TMC timer. To learn whether the fault that a TMC instance reports is a false comparison or a timeout fault, see the respective field in TMC_a_STATUS[FAULT].

If the timer value is not configured properly (for example, if you specify a too small value because of design constraints), the timeout fault occurs almost immediately.

Use the following registers to analyze the details of a timeout:

- TMC_a_TIMEOUT[TIMEOUT] – To know the timeout value specified for the timer.
- TMC_a_TIMER[TIMER] – To know the current value of the timer and to calculate the remaining count before the expiration.

To clear the fault output:

- Disable the corresponding TMC instance.
- Clear the TMC_a_STATUS[FAULT] field which restarts the corresponding TMC instance. In this case, the comparator behaves exactly as if it were disabled and enabled immediately without any change in its configuration.

Clearing the fault output also eliminates contribution of the comparator to the TMC_FAULT signal. The TMC_FAULT NCF ceases when none of the TMCs reports any fault.

72.4.3 TMWDPI

TMWDPI is a sub-module of SBSW. It includes a set of registers that acts as a communication interface between the application software and the TMWDP. For details on the register interface, see TMWDPI registers.

The function of TMWDP is to monitor the execution of the application. You program a TMWDPI register to request for an application's execution progress state, and the TMWDP verifies the correctness of the execution progress. TMWDP also monitors that the application is reporting its execution progress in a timely fashion. For details on TMWDP, see TMWDP description.

72.4.3.1 TMWDP description

The TMWDP monitors the program flow using 32 timed finite state automata—timed state machines, and each state of an automaton is guarded by a specified time interval. The TMWDP ensures that a valid transition must take place within this time. A valid transition is a change in execution state of an application that matches the program flow configured in the respective automaton.

This algorithm for the TMWDP operation is implemented in firmware provided by NXP as a part of the SBSW software support package. The firmware runs on a dedicated core within the chip—TMWDP Core—hereafter referred to as the TC. The firmware is either loaded from the system memory to a local code RAM or executed directly from the system memory. In the latter case, the TMWDP firmware eventually ends up in the CPU cache. It completely fits typical code cache sizes.

Preliminary memory size estimates are as follows:

- 8 KB firmware
- 64 KB SRAM used for runtime data and a runtime copy of the TMWDP configuration

A TMWDP automaton reports the following faults:

- Time violation: TMWDP reports a time violation fault after either of the following two events:
  - If a valid transition does not complete within the time specified
  - If the application does not report change in its state for more than a specified time

  Each state of an automaton is guarded by a specified time interval.

  A TMWDP automaton reports this fault by asserting the TMWDP_FAULT*n* signal.
- Illegal transition: TMWDP reports an illegal transition fault if the application reports its transition to a state that does not immediately follow the current state. This is because the application program flow must match the flow in each automaton.

  A TMWDP reports this fault by asserting the TMWDP_FAULT signal.
- Internal error: TMWDP reports an internal error if the automaton could not process its algorithm timely.

  A TMWDP reports this fault by asserting the TMWDP_INTERNAL_FAULT signal.

The following figure is an example of the automaton program flow.

Legend:
S_n: Application states
$I(S_n)$: Maximum time before which the application must change its state
$T_n(g)$: Maximum time before which the given transition must occur

Figure 572. Timed automaton example

You statically generate the configuration for the TMWDP automata based on a particular application structure, stored in the application memory. You also pass the address of this application structure to the algorithm through the TMWDP_CONFIG_ADDR register. To prevent race conditions and common-cause faults during runtime, the TMWDP firmware copies the configuration data from the system memory to the local RAM during initialization.

A TMWDP timer, which is a hardware timer within SBSW, sends an interrupt (TMWDP_TIMER_IRQ signal) that executes the TMWDP algorithm periodically on TC. Only a single transition request is allowed per TMWDP timer period between the TMWDP algorithm runs.

72.4.3.2 Block diagram

The following figure is the top-level block diagram of TMWDP.

72.4.3.3 TMWDPI registers

The TMWDPI provides status indications concerning both TMWDP as a whole and each individual automaton.

The TMWDPI registers support the TMWDP algorithm to achieve a deterministic process of progress reporting. The register interface provides the following functionality:

- The application writes its state ID to the respective automaton register and the TMWDPI sets the written flag to indicate the automaton to process the request.
- The TMWDPI sets the overwritten flag if an application performs a new progress request while the written flag is set. Also, it does not write the new state ID to the respective automaton register.
- The TC reads the state ID and the flags from the progress request registers, and this also clears both the flags (written and overwritten).
- The TMWDPI performs arbitration when concurrent accesses are made by both the AC and TC. In general, write and read operations from both the cores are atomic.

The TMWDPI consists of the following register sets:

- **Configuration registers:**

  These registers are used for loading automata configuration and for enabling or disabling the entire TMWDP. These registers have write access privileges by the ACs, and are considered as input registers for the TMWDP. Write access to these registers is protected by the TMWDP_CONFIG_ENABLE signal from the SBSW controller. See Unlocking/locking the TMWDP configuration for details.

- **Status registers:**

  These registers report the status of the TMWDP as a whole.

- **Automaton registers:**

  These are the communication registers for the TMWDP. Each automaton has its own register for reporting progress of its corresponding application. Each write request to an automaton register is recorded by a write/overwrite detection logic. The TMWDP sets the written flag when an application performs a progress request, and it sets the overwritten flag when a new progress state is requested while the written flag is set. A TC read clears both the flags.

The configuration and status registers are common to the entire TMWDP sub-module.

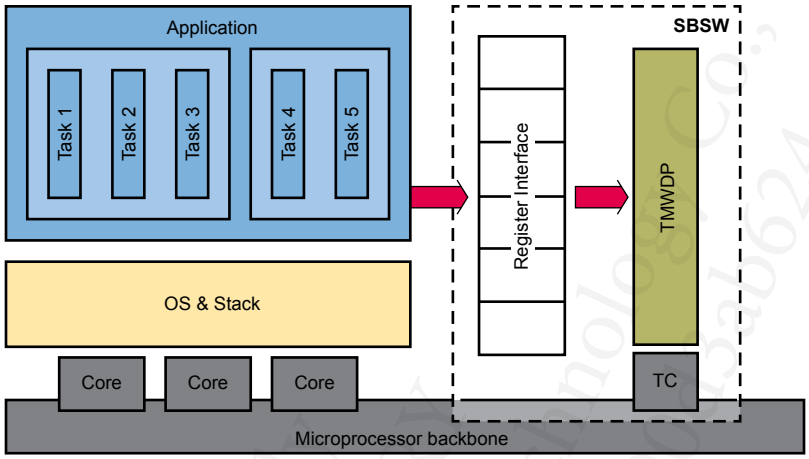

Figure 574. TMWDP register interface

All TMWDPI registers have two independent access ports (sides):

- The application side: accessed by the AC
- The internal side: manipulated by the dedicated TC exclusively

The access privileges are maintained by the SBSW controller.

72.4.3.4 TMWDP/TMWDPI events

The TMWDPI and the TMWDP algorithm report the following events:

- Invalid configuration data (invalid address, failed initialization or runtime consistency check)
- Internal issues (watchdog timeout, excessive runtime)
- Invalid transition request (wrong destination state ID, invalid automaton ID, more than one transition request per automaton in a TMWDP cycle)
- Timeout of an automaton

According to the status of individual automata, the TMWDPI maintains the corresponding bits of TMWDP_AUTOMATA_STATUS, TMWDP_AUTOMATA_ILLGL_TRANS, and TMWDP_AUTOMATA_TIME_VIOLATION as well as the status bits of each automaton application register. It also routes the aggregated fault vector to the SBSW controller.

When an automaton detects a fault or a timeout, it stops (AUT_a_STATUS[STATUS]=0). You need to reset the automaton to clear the error bits by requesting a transition to state 0 if the automaton is stopped.

72.4.4 SBSW interface summary

The SBSW exposes to the application:

- 32 instances (an array) of TMC with their own interface:
  - A configuration register and multiple status registers

  - Data registers R0 and R1
  - Timeout and timer registers
- Aggregated TMC fault register (32-bit wide)
- 32 state transition registers in the TMWDPI to mitigate a race condition bottleneck among AC and the TC executing the TMWDP firmware
- Aggregated TMWDP status and fault registers (32-bit wide; register width equals number of automata)
- A TMWDP configuration register
- A TMWDP status register
- Configuration locking mechanism

The SBSW module reports the faults detected by it to the FCCU through dedicated NCF lines.

72.5 Memory map and register definition

72.5.1 SBSW register descriptions

Only word (32-bit) accesses are allowed on all registers, and these registers can be read at any time.

Access to offset address 1Ch in the SBSW memory space does not result in a transfer error.

72.5.1.1 SBSW memory map

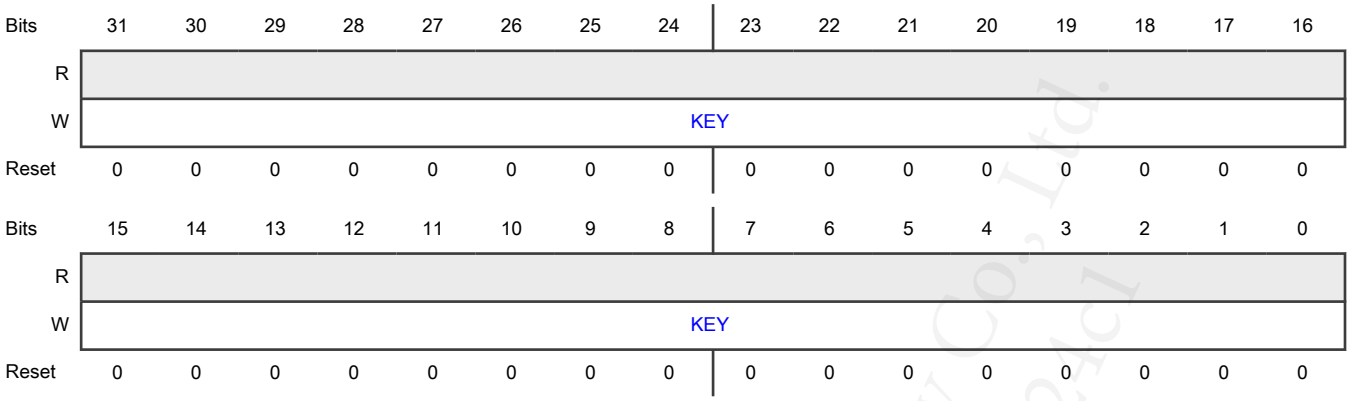
72.5.1.2 TMC Configuration Unlock (TMC_CONFIG_UNLOCK)

Offset

Register	Offset
TMC_CONFIG_UNLOCK	0h

Function

This register is used for locking and unlocking the TMC configuration. See Unlocking/locking the TMC configuration for the unlocking and locking procedures.



TMC configuration registers stay locked (that is, any write access is not permitted) by default or after functional reset (assertion of IPG_HARD_ASYNC_RESET_B signal).

NOTE

This register temporarily holds the key value and its bit-inverted value.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CXU Automotive Technology Co.,Ltd.
c8c462e5-4921-48a8-b251-3900abb6a1a1

Diagram

Fields

Field	Function
31-0 KEY	Key Write the key value (2718_2818h) and its inverted value (D8E7_D7E7h) in sequence within the pre-defined time interval (62 SAFETY_IP_CLK cycles) to unlock the TMC configuration. Writing any other value or a timeout (that is, writing the second value after 62 SAFETY_IP_CLK cycles) aborts the TMC configuration unlocking procedure.

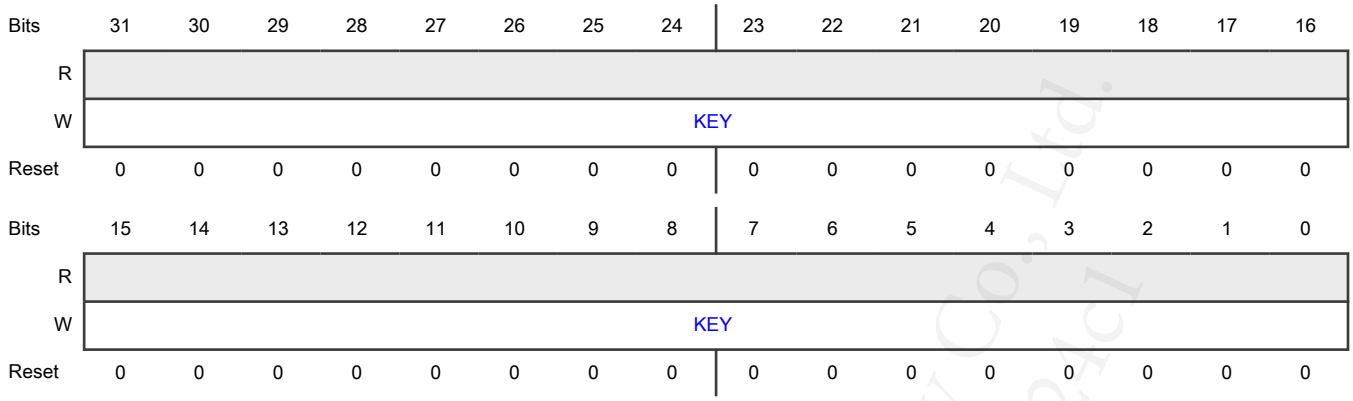
72.5.1.3 TMWDP Configuration Unlock (TMWDP_CONFIG_UNLOCK)

Offset

Register	Offset
TMWDP_CONFIG_UNLOCK	4h

Function

This register is used for locking and unlocking the TMWDP configuration. See Unlocking/locking the TMWDP configuration for the unlocking and locking procedures.



TMWDP configuration registers stay locked (that is, any write access is not permitted) by default or after functional reset (assertion of IPG_HARD_ASYNC_RESET_B signal).

NOTE

This register temporarily holds the key value and its bit-inverted value.

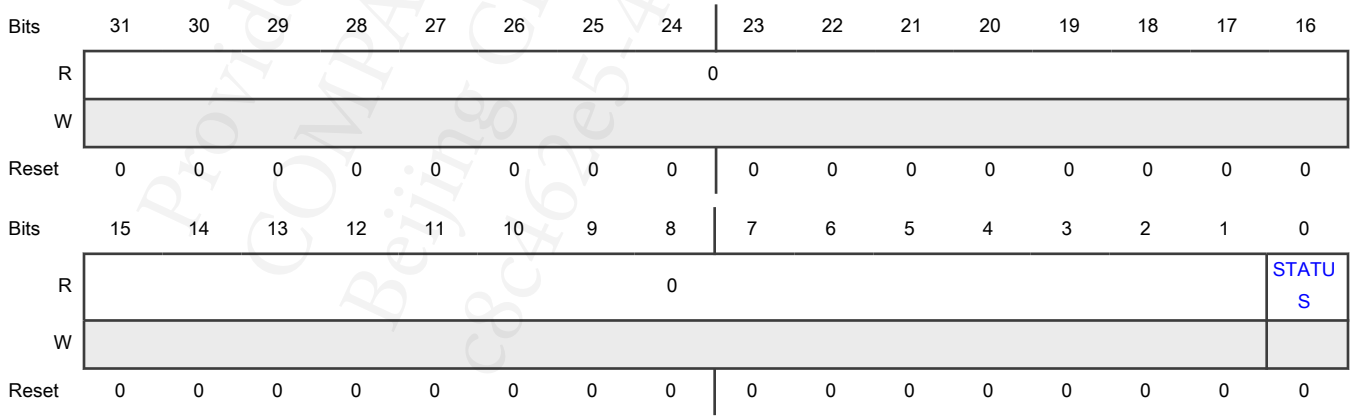
Provided under NDA of COMPANY PROPRIETARY Beijing CIU Automotive Technology Co., Ltd. c8c4626-4821-48a8-b251-3d8ab624c1

Diagram

Fields

Field	Function
31-0 KEY	Key Write the key value (3141_5926h) and its inverted value (CEBE_A6D9h) in sequence within the pre-defined time interval (62 SAFETY_IP_CLK cycles) to unlock the TMWDP configuration. Writing any other value or a timeout (that is, writing the second value after 62 SAFETY_IP_CLK cycles) aborts the TMWDP configuration unlocking procedure.

72.5.1.4 TMC Configuration Status (TMC_CONFIG_STATUS)



Offset

Register	Offset
TMC_CONFIG_STATUS	8h

Function

This register indicates the current status (locked or unlocked) of TMC configuration. You can configure the TMC only if the configuration is in the unlocked state. See Unlocking/locking the TMC configuration for the unlocking procedure.

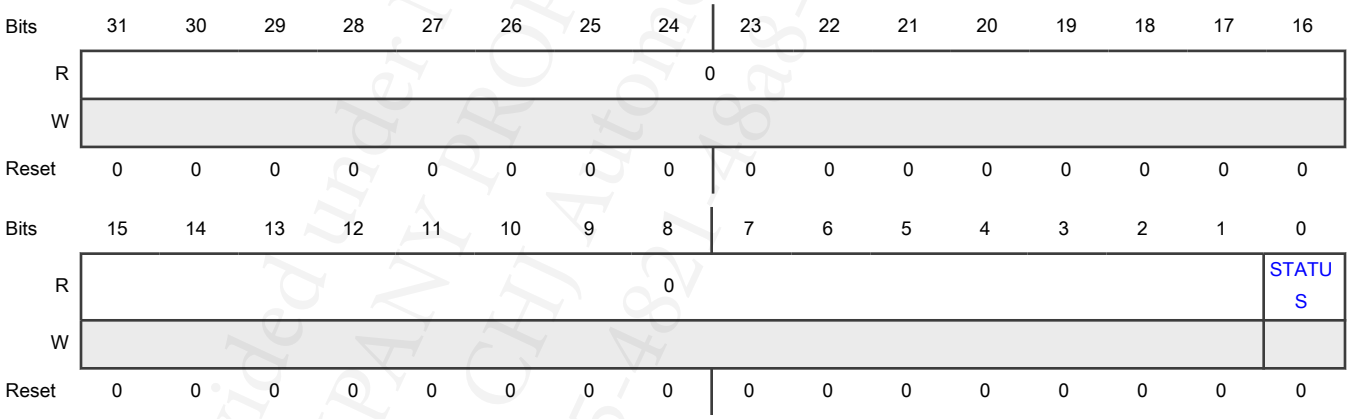
Diagram

Provided under NDA of COMPANY PROPRIETARY Beijing CHJ Automotive Technology Co., Ltd. c8c462e5-482-48a8-b251-3d8ab624c1

Fields

Field	Function
31-1 —	Reserved
0 STATUS	Status This bit indicates the state of TMC configuration. 0b - Locked 1b - Unlocked

72.5.1.5 TMWDP Configuration Status (TMWDP_CONFIG_STATUS)



Offset

Register	Offset
TMWDP_CONFIG_STATUS	Ch

Function

This register indicates the current status (locked or unlocked) of TMWDP configuration. You can configure the TMWDP only if the configuration is in the unlocked state. See Unlocking/locking the TMWDP configuration for the unlocking procedure.

Diagram

Fields

Field	Function

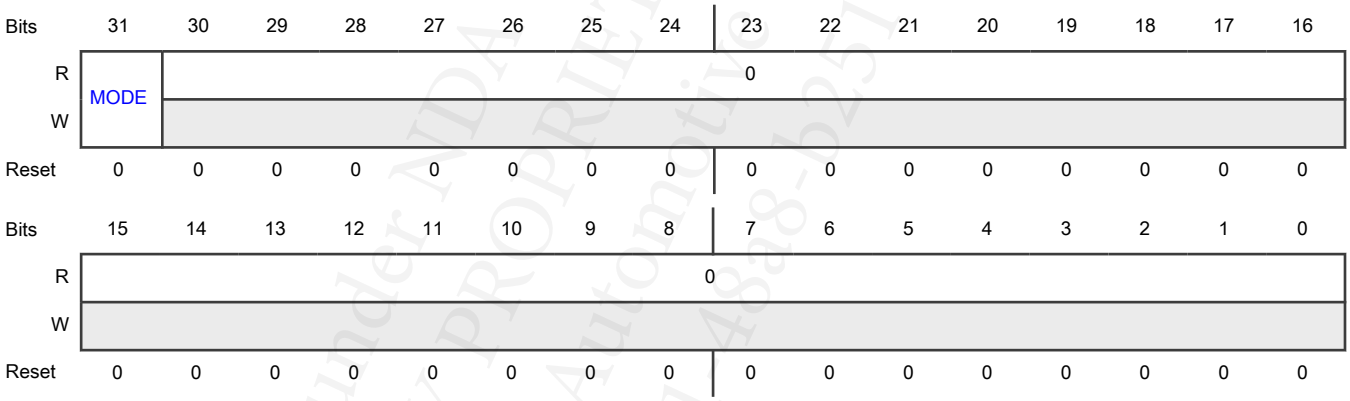
0 STATUS	Status This bit indicates the state of TMWDP configuration. 0b - Locked 1b - Unlocked

72.5.1.6 Debug Mode (DEBUG_MODE)



Offset

Register	Offset
DEBUG_MODE	10h

Function

This register is used for configuring the behavior of the SBSW when the chip is in the Debug mode.

Diagram

Fields

Field	Function
31 MODE	Mode 0b - Debug mode does not affect the SBSW behavior. 1b - All counters/timers within the SBSW stop in the Debug mode. The list of counters comprises of two unlocking timers in the controller, one timer in each TMC instance, and the other timer in the TMWDPI.

Fields

Field	Function
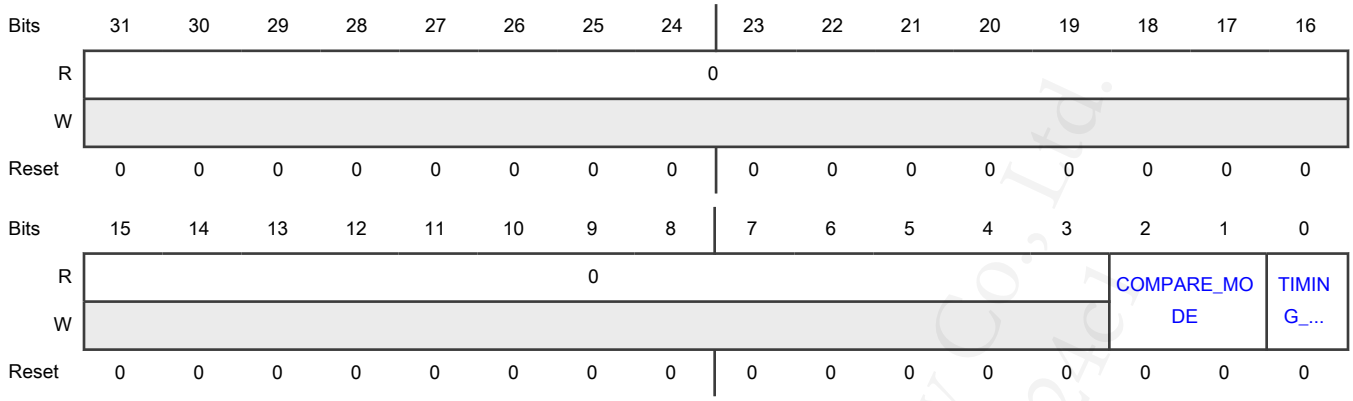
31-0 STATUSn	Status n This field indicates whether the corresponding TMWDP automaton instance (n) has detected a fault. A TMWDP automaton reports a fault by asserting the TMWDP_FAULT*n* signal. 0b - Fault is not detected. 1b - Fault is detected.

72.5.1.9 TMC Configuration (TMC_0_CONFIG - TMC_31_CONFIG)

Offset

For a = 0 to 31:



Register	Offset
TMC_a_CONFIG	20h + (a × 20h)

Function

This register is used for configuring the TMC timing and the comparison modes.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-30d3ab624

Diagram

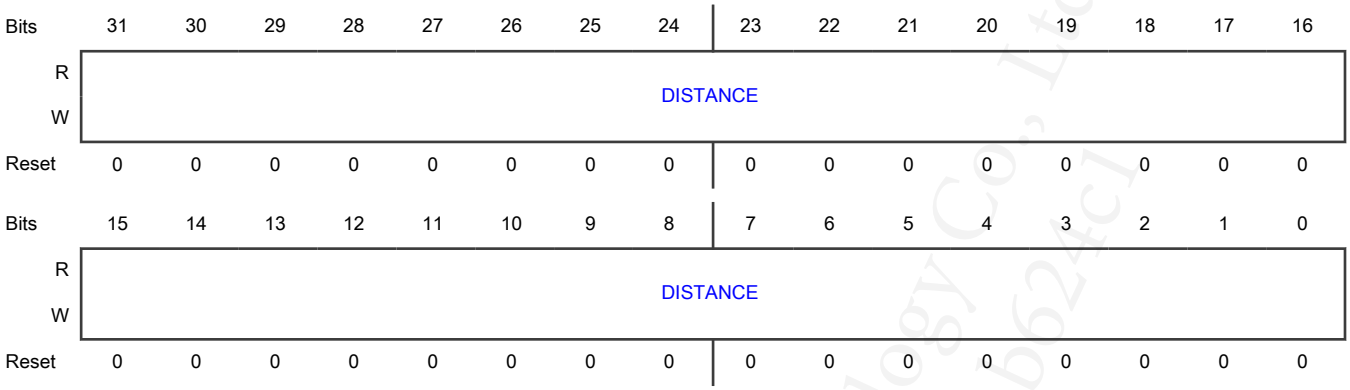
Fields

Field	Function
31-3 —	Reserved
2-1 COMPARE_MODE	Compare mode Select one of the following modes. **NOTE** You program the value for Distance (D) in TMC_a_DISTANCE[DISTANCE]. 00b - (R0 == R1) 01b - (R0 < R1) 10b - (R0 > R1) 11b - (|R1 – R0| ≤ D)
0 TIMING_MODE	Timing mode Select one of the following modes. 0b - Watchdog Mode 1b - Window Mode

72.5.1.10 TMC Distance (TMC_0_DISTANCE - TMC_31_DISTANCE)

Offset

For a = 0 to 31:



Register	Offset
TMC_a_DISTANCE	24h + (a × 20h)

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab62402

Function

See TMC_a_DISTANCE[DISTANCE].

Diagram

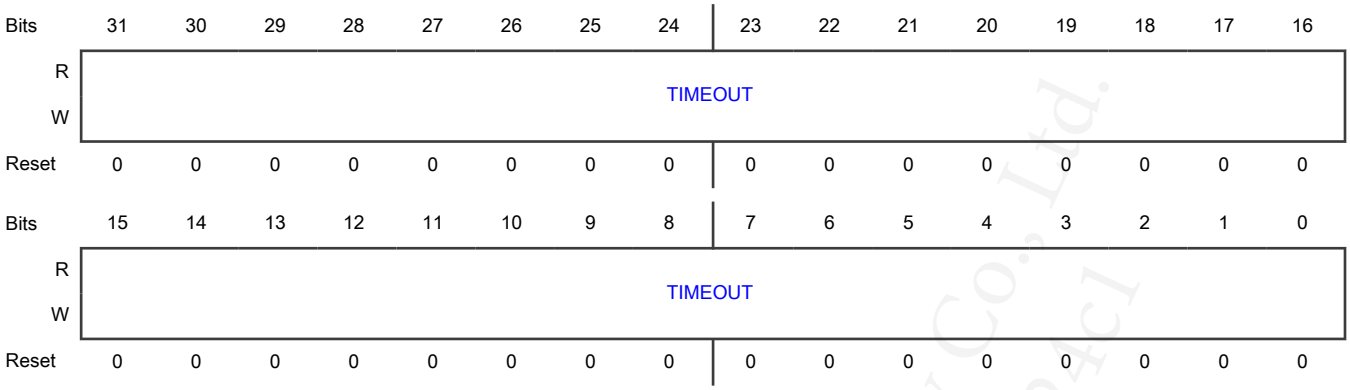
Fields

Field	Function
31-0 DISTANCE	Distance value You configure the maximum distance between the R0 and R1 values for comparison. **NOTE** Distance is a 32-bit unsigned value.

72.5.1.11 TMC Timeout (TMC_0_TIMEOUT - TMC_31_TIMEOUT)

Offset

For a = 0 to 31:



Register	Offset
TMC_a_TIMEOUT	28h + (a × 20h)

Function

See TMC_a_TIMEOUT[TIMEOUT].

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b521-390d3ab624c1

Diagram

Fields

Field	Function
31-0 TIMEOUT	Timeout interval Functioning of this field varies with the timer modes. You select the timer mode using the TMC_a_CONFIG[TIMING_MODE] field. In Watchdog mode, you use this field to configure the timeout interval in which the timer periodically compares the values written to the R0 and R1 registers . In Window mode, you use this field to configure the timeout interval within which the R0 and R1 registers must be written. **NOTE** Each unit represents one tick of SAFETY_IP_CLK cycle (15 ns). See Timer for more information about the timer modes.

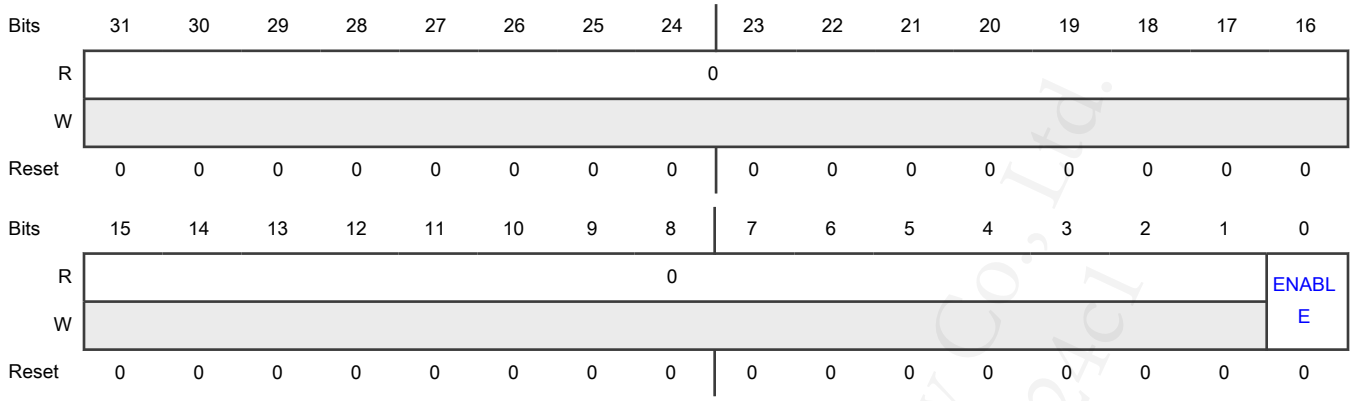
72.5.1.12 TMC Control (TMC_0_CONTROL - TMC_31_CONTROL)

Offset

For a = 0 to 31:

Register	Offset
TMC_a_CONTROL	2Ch + (a × 20h)

Function



This register is used for enabling and disabling the corresponding TMC instance. For proper functioning of the TMC, enable the TMC_a_CONTROL[ENABLE] field only after configuring the corresponding TMC (by using TMC_a_CONFIG, TMC_a_DISTANCE and TMC_a_TIMEOUT).

NOTE

Clear the corresponding TMC_a_STATUS[FAULT] field (by writing 11b to it) before enabling the TMC instance.

Provided under NDA

c8c46e54-82f4-48a8-b251-390d3ab624c1

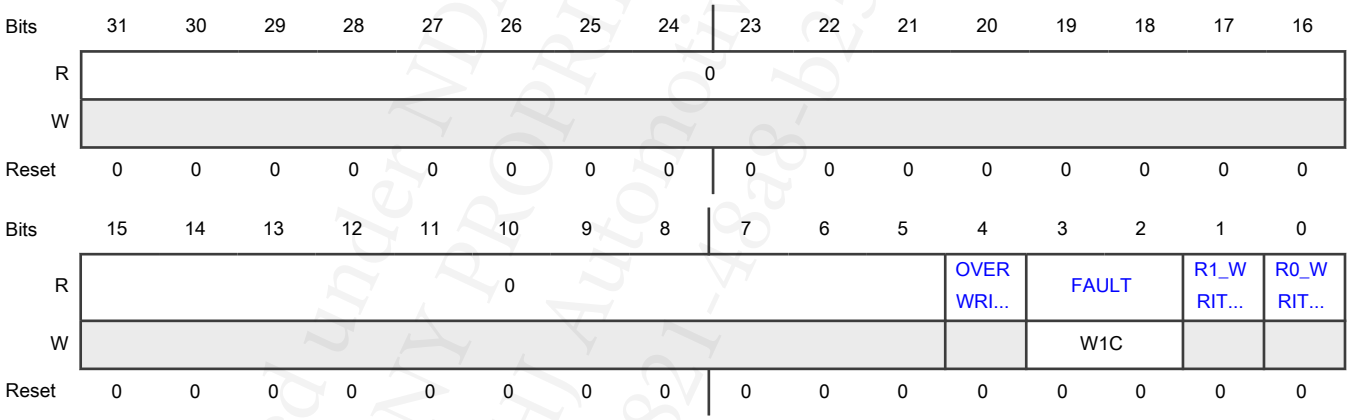
Fields

Field	Function
31-0 R1	R1 data value Write the TMC's R1 data value for comparison.

72.5.1.15 TMC Status (TMC_0_STATUS - TMC_31_STATUS)

Offset

For a = 0 to 31:



Register	Offset
TMC_a_STATUS	38h + (a × 20h)

Function

This register indicates the current state of the corresponding TMC.

When the second register is written and the comparison succeeds, the TMC immediately enters its initial state ("Timing" or "Idle"). Otherwise, it first transitions to "Comparing" state and then to "Fault" state with successive clock pulses. Thus, the TMC_a_STATUS[FAULT] field is updated one clock cycle after the last data write is complete.

Diagram

Fields

Field	Function
31-5 —	Reserved
4 OVERWRITTEN	Overwritten Indicates whether timeout has occurred because R0 or R1 was written more than one time during a single TMC cycle

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You can also learn whether the timeout that has occurred is real (because of timer elapse) or not (because of R0/R1 overwritten) from the value of TMC_a_TIMER[TIMER]. **NOTE** You clear this field by clearing the TMC_a_STATUS[FAULT] field. 0b - Neither R0 nor R1 is overwritten. 1b - R0 or R1 is overwritten.
3-2 FAULT	Fault indicator Indicates the cause if the corresponding TMC has detected a fault. **NOTE** When you clear this field (by writing 11b), the other three fields in this register are also cleared (OVERWRITTEN, R0_WRITTEN, and R1_WRITTEN). 00b - No fault 01b - False comparison 10b - Timeout or overwritten R0/R1
1 R1_WRITTEN	R1 written Indicates whether R1 data value has been written to TMC_a_R1[R1] **NOTE** A successful comparison clears this field automatically. In case of a fault, you must clear TMC_a_STATUS[FAULT] to clear this field. 0b - R1 has not been written in the current cycle. 1b - TMC is in the Timing state.
0 R0_WRITTEN	R0 written Indicates whether R0 data value has been written to TMC_a_R0[R0] **NOTE** A successful comparison clears this field automatically. In case of a fault, you must clear TMC_a_STATUS[FAULT] to clear this field. 0b - R0 has not been written in the current cycle. 1b - TMC is in the Timing state.

72.5.1.16 TMC Timer (TMC_0_TIMER - TMC_31_TIMER)

Offset

Field	Function
31-0 STATUSn	Status n Indicates whether the corresponding TMWDP automaton instance (n) has detected a time violation 0b - Automaton has not detected a time violation. 1b - Automaton has detected a time violation.

72.5.1.23 TMWDP Automaton Status (AUT_0_STATUS - AUT_31_STATUS)

Offset

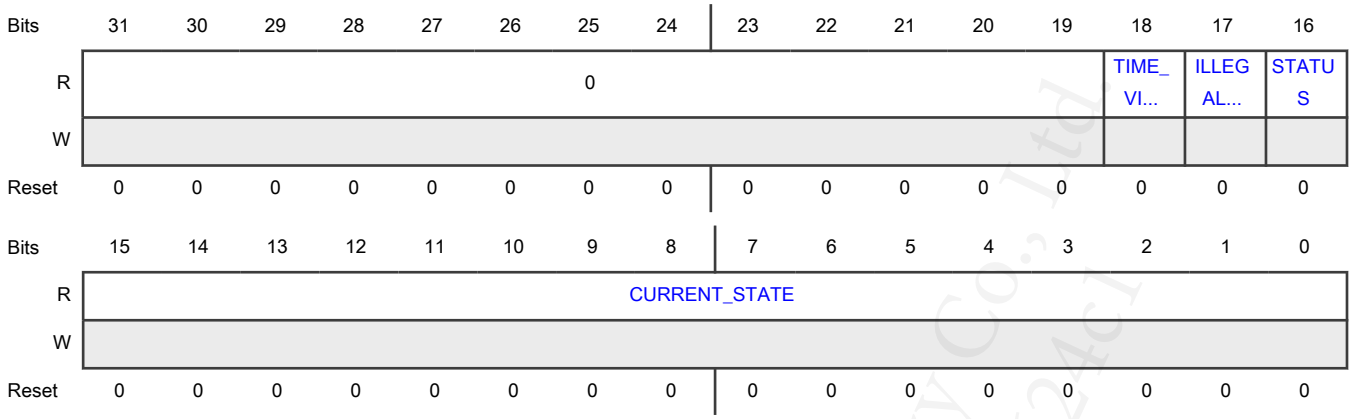
For a = 0 to 31:

Register	Offset
AUT_a_STATUS	450h + (a × 8h)

Function

This register indicates the status of the corresponding TMWDP automaton.

Following are the four types of status that it captures:



- Current state
- Running or stopped status
- Illegal transition fault status
- Time violation fault status

NOTE

This register is RO for the AC and RW for the TC.

Printed under NDA only
COMPANY PROPRIETARY
Beijing C-J Automotive Technology Co., Ltd.

Diagram

Fields

Field	Function
31-19 —	Reserved
18 TIME_VIOLATION	Time violation Indicates whether the corresponding automaton has detected a time violation 0b - Time violation is not detected. 1b - Time violation is detected.
17 ILLEGAL_TRANSITION	Illegal transition Indicates whether the corresponding automaton has detected an illegal transition 0b - Illegal transition is not detected. 1b - Illegal transition is detected.
16 STATUS	Automaton status Indicates whether the corresponding automaton is running or has stopped (initial or fault) 0b - Stopped (initial or fault state) 1b - Running state
15-0 CURRENT_STATE	Automaton current state Indicates the state ID of the corresponding automaton (any integer value from 0 to 65535).

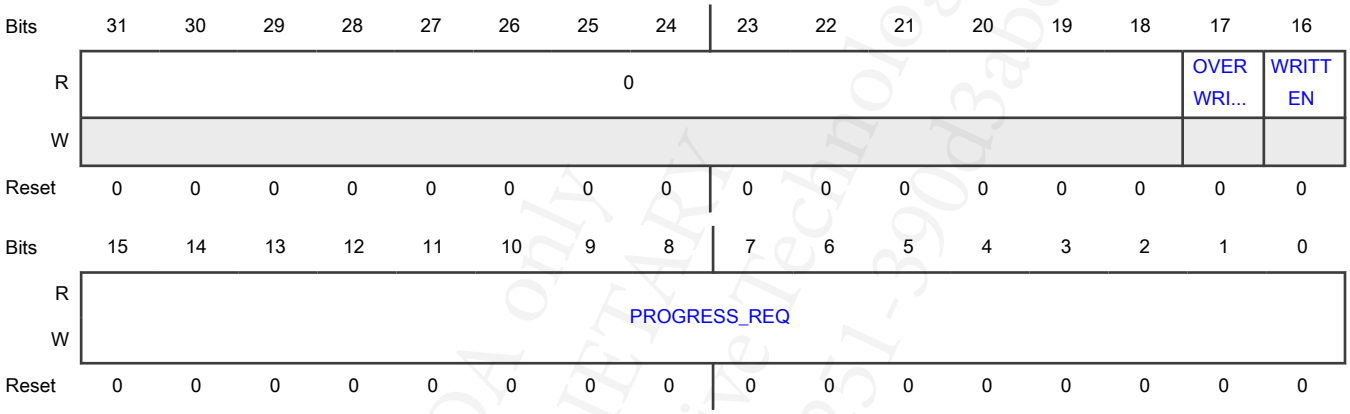
72.5.1.24 TMWDP Automaton Progress Request (AUT_0_PRGS_REQ - AUT_31_PRGS_REQ)

Offset

For a = 0 to 31:

Provided to NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c42e_482_48a8_b251_390a3ab624c1

Register	Offset
AUT_a_PRGS_REQ	454h + (a × 8h)



Function

This register is used as a communication channel between the application, which reports its progress by successively writing its state IDs, and the SBSW firmware running on TC, which reads and processes these requests.

NOTE

This register is RW for the AC and RO for the TC. When TC reads this register, the TMWDPI sets the WRITTEN and OVERWRITTEN fields to 0.

Diagram

Fields

Field	Function
31-18 —	Reserved
17 OVERWRITTEN	Overwritten Indicates whether the PROGRESS_REQ field has been written more than one time after the TMWDP last serviced this field **NOTE** When the TC reads this field, the TMWDPI sets this field to 0. 0b - PROGRESS_REQ field is not overwritten. 1b - PROGRESS_REQ field is overwritten.
16 WRITTEN	Written Indicates whether the PROGRESS_REQ field has been written after the TMWDP last serviced this field

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the TC reads this field, the TMWDPI sets this field to 0. 0b - PROGRESS_REQ field is not written. 1b - PROGRESS_REQ field is written.
15-0 PROGRESS_REQ	Application progress request You use this field to request an application to report its progress state.

72.5.1.25 TMWDP Core Domain ID (TC_ID)

Offset

Register	Offset
TC_ID	FFCh

Function

This register is used to set the TC domain ID. You can write to this register only one time after reset.

The TC boot initializes this register. You can read this register at any time. SBSW controller compares the domain ID value with the value on the sideband signal of the IPS interface, and the comparison result determines the core that performs the read or write operation. If the values match, the TC initiates the operation, otherwise the AC initiates the operation.

Chapter 73
Error Injection Module (EIM)

73.1 Chip-specific EIM information

73.1.1 EIM instances

The following table summarizes the features of EIM instances on this chip.

Table 568. EIM instance summary

EIM instance	Number of used memory channels	Targets
ACP_EIM	31	Memory arrays for: • SRAM controllers • eDMA controllers • Cortex-M7 cores Comparison signals used by RCCU regarding lockstep operation of: • eDMA controllers • Cortex-M7 cores • Cortex-A53 cores • GIC-500
EIM_0	1	Memory arrays for: • Cortex-A53 cores • GIC-500
EIM_1	2	Memory arrays for QuadSPI
EIM_2	6	Memory arrays for SerDes subsystem
EIM_3	4	Memory arrays for DDR subsystem

73.1.2 ACP_EIM channel assignments

Each EIM channel corresponds to a specific target. The EIM instance can inject errors on access for two types of targets:

- Memory arrays: errors on accesses to the memory data bits and checkbits
- Comparison signals used by the RCCU: errors on data bits

It is recommended that the error injection configuration is enabled when the target is in quiescent state.

The following table shows details about the channel assignments and corresponding targets.

- In the EIM programming model, each channel has a set of EICHD*n*_WORD registers for injecting errors. This table correlates the WORD register bits with target bits.
- EIM channels 0–27 inject errors on memory arrays. Writing 1 to a WORD register bit causes the controller of the corresponding memory array to generate an error event.
- EIM channels 28–30 inject errors into comparison signals used by the RCCU. Writing 1 to any combination of these WORD bits triggers RCCU alarms.

— For the mapping of RCCU alarms to EIM channel bits, see Table 570.

— Each RCCU alarm corresponds to an FCCU fault.

Table 569. EICHD*n*_WORD register targets

Channel	Target	Data bits	Checkbits	Error injection path
0	SRAM controller 1 bank1–0	Bank1 bits 63–32: WORD1[31:0] Bank1 bits 31–0: WORD2[31:0]	Bank1 bits 7–0: WORD0[31:24]	Read

73.1.3 EIM_0 channel assignments

The single channel of the EIM_0 instance can inject errors on accesses to the two LSBs of target memory arrays.

The following table shows the assigned targets for channel 0.

- In the EIM programming model, channel 0 has a set of EICHD0_WORD registers for injecting errors.
- The table maps the two LSBs of each target to a pair of EICHD0_WORD register bits.

To inject a single-bit error on a target, write 1 to one of the two corresponding EICHD0_WORD bits. To inject a multi-bit error on a target, write 11b to the the pair of EICHD0_WORD data bits.

Table 571. Targets for the EIM_0 EICHD0_WORD registers

Target: two LSBs only	EICHD0_WORD data bits	Error injection path
Cortex-A53 cluster 0 core 0 data "dirty" RAM	WORD8[1:0]	Write
Cortex-A53 cluster 0 core 0 data cache tag bank0	WORD8[3:2]	Write
Cortex-A53 cluster 0 core 0 data cache tag bank1	WORD8[5:4]	Write
Cortex-A53 cluster 0 core 0 data cache tag bank2	WORD8[7:6]	Write
Cortex-A53 cluster 0 core 0 data cache tag bank3	WORD8[9:8]	Write
Cortex-A53 cluster 0 core 0 instruction cache data bank0 high bits	WORD8[11:10]	Write

73.1.4 EIM_1 channel assignments

The EIM_1 instance channels can inject errors on accesses to data bits of its target memory arrays.

The following table shows the channel assignments and corresponding targets.

- In the EIM programming model, each channel has a set of EICHD*n*_WORD registers for injecting errors.
- The table maps the targets to their corresponding WORD register bits.

To cause a memory array controller to generate an error event, write 1 to the designated WORD register bit.

Table 572. Targets for the EIM_1 EICHD*n*_WORD registers

73.1.7 Constraints to use EIM on A53 cache memories

Cortex-A53 processor protects against the soft errors in the cache memories upon detection of a single-bit ECC error. In such an event, the A53 processor attempts to correct the data and update the memory, then read the line to confirm the correction. In the case of a hard error, such as the persistent injection by the EIM, until cleared by the Software, the processor might enter into a continuous livelock loop. Thus, care must be taken when using EIM to inject errors in the A53 processor cache memories to narrow the scope of any such safety diagnostic software. Here are the steps for this:

1. Clear all cache

```
ca53_invalidate_icache_all();
```

```
ca53_flush_dcache_all();
```

2. Read data into cache

```
/*Start Performance Monitoring*/
```

```
ca53_api_start_pmu();
```

3. Enable EIM

```
ca53_eim_enable(ECC_TYPE[L1_ECC_REGIONS[i]].ECC_TARGET, ECC_TYPE[L1_ECC_REGIONS[i]].OFFSET,
A53_single_bit_error, L1_ECC_Channel);
```

4. Read from cache

```
data32 = *(volatile uint32_t*)(addr);
```

Read/Writes Data into Cache with error

```
for(n=addr; n>(addr+size);n=n+4){*(volatile uint32_t*)(n + 0x1000) = *(volatile uint32_t*)(n);}
```

5. Disable EIM

```
ca53_eim_disable(ECC_TYPE[L1_ECC_REGIONS[i]].ECC_TARGET, ECC_TYPE[L1_ECC_REGIONS[i]].OFFSET,
A53_single_bit_error, L1_ECC_Channel);
```

Enable and program EIM to inject A53 cache memory error, then a single cacheline can be read to induce ECC reaction. Then, disable EIM. Reading more than one cacheline with EIM error injection active can lead to A53 livelock scenario. For details on the A53 processor livelock behavior, see ARM Cortex-A53 MPCore Processor Technical Reference Manual.

73.2 Chip-specific EIM information

73.2.1 EIM instances

73.3 Introduction

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of internal memories (for example, system RAM, cache RAMs, and peripheral memories). See the chip-specific EIM information to determine which functional safety features are supported by this method.

73.3.1 Overview

EIM provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

NOTE

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

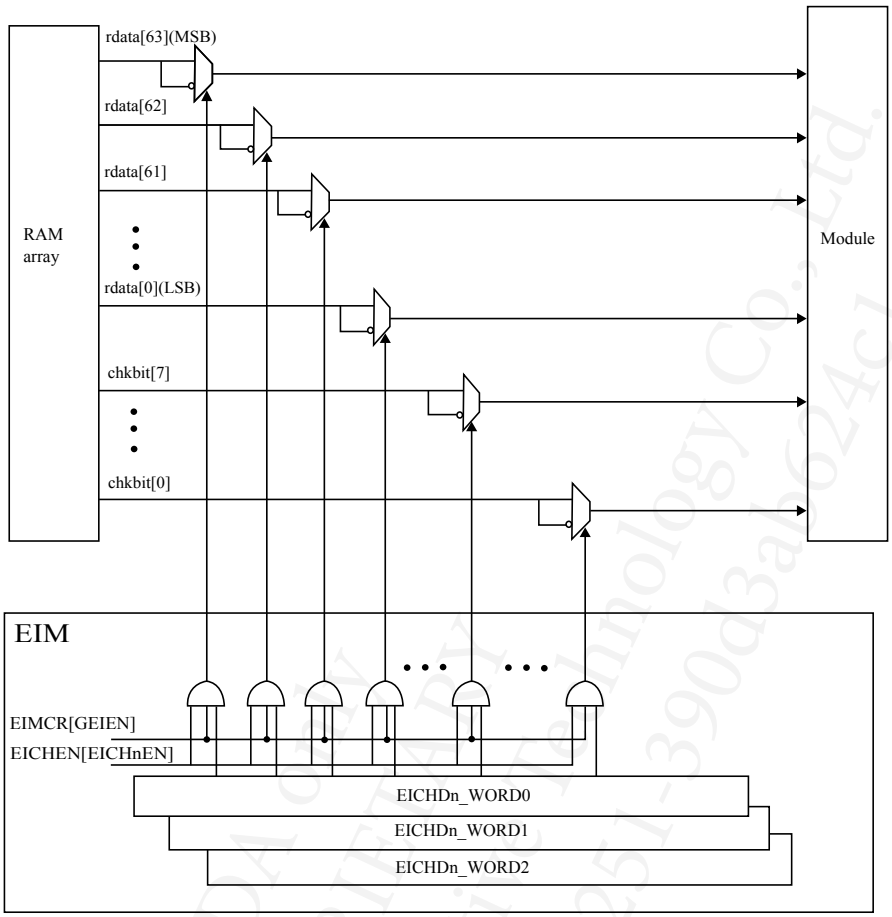

Figure 575. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

73.3.2 Features

The EIM includes these features:

- Supports 31 error injection channels
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

73.4 EIM register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 576. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

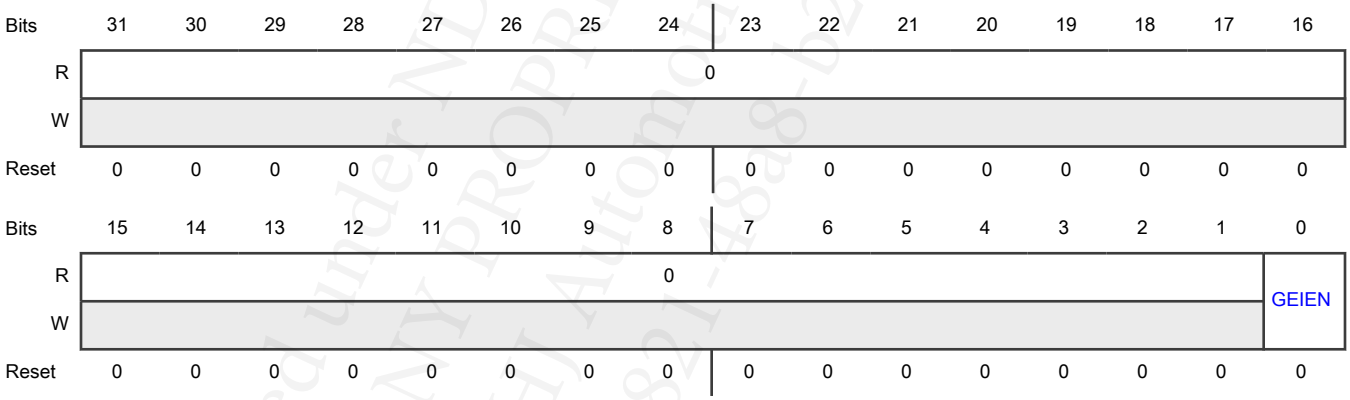
73.4.2 Error Injection Module Configuration Register (EIMCR)



Offset

Register	Offset
EIMCR	0h

Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

Diagram

Fields

Field	Function
31-1 —	Reserved
0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset.

73.4.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Diagram

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 2 1b - Error injection is enabled on Error Injection Channel 2
28 EICH3EN	Error Injection Channel 3 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 3 1b - Error injection is enabled on Error Injection Channel 3
27 EICH4EN	Error Injection Channel 4 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection.

EICHD4_WORD0	200h
EICHD5_WORD0	240h
EICHD6_WORD0	280h
EICHD7_WORD0	2C0h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[31:0] (32 bits wide), CHKBIT_MASK[31] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

Function

The ninth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B28_31DATA_MASK correspond to bytes 28–31 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

EICHD24_WORD1	704h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.5 EIM_0 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

Error injection channel descriptor: DATA_MASK details

The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 578. Error injection channel descriptor: DATA_MASK details

Diagram

Fields

Field	Function
31-1 —	Reserved
0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

73.6.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Provided under NDA only

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

EICHD14_WORD1	484h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.7 EIM_2 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 582. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	256	255-224	223-192	191-160
1	256	255-224	223-192	191-160
2	256	255-224	223-192	191-160
3	256	255-224	223-192	191-160
4	256	255-224	223-192	191-160
5	256	255-224	223-192	191-160

Table 583. DATA_MASK bit: Channel-word mapping

Channel	Specific bits of DATA_MASK in

0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

73.7.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 2 1b - Error injection is enabled on Error Injection Channel 2
28 EICH3EN	Error Injection Channel 3 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

Table continues on the next page...

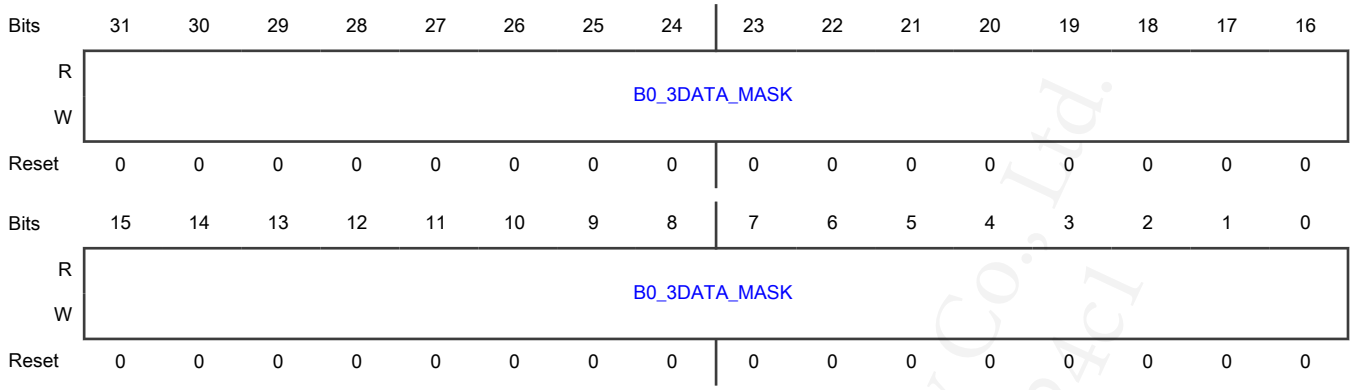
73.7.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD5_WORD1)

Offset



Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h
EICHD4_WORD1	204h
EICHD5_WORD1	244h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Provided under NDA only

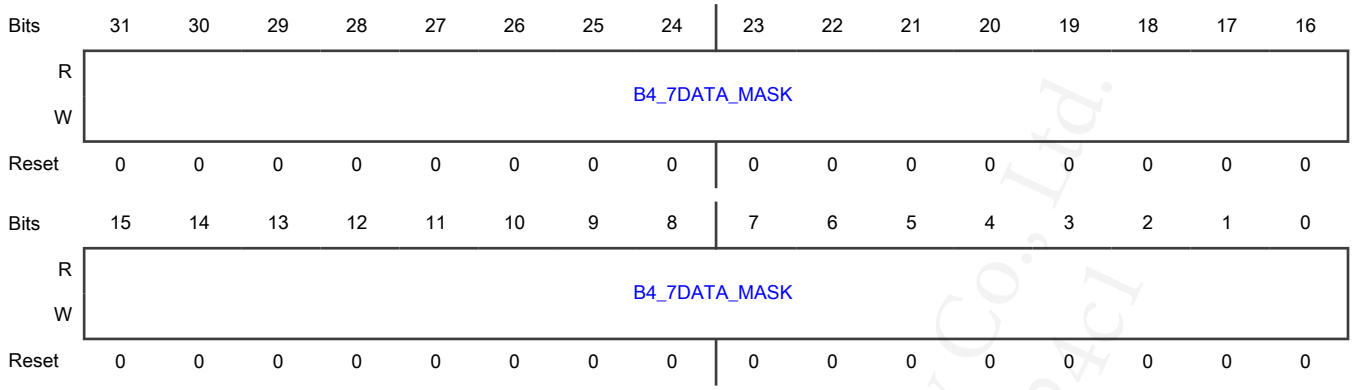
Diagram

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.7.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD5_WORD2)



Offset

Register	Offset
EICHD0_WORD2	108h
EICHD1_WORD2	148h
EICHD2_WORD2	188h
EICHD3_WORD2	1C8h
EICHD4_WORD2	208h
EICHD5_WORD2	248h

Function

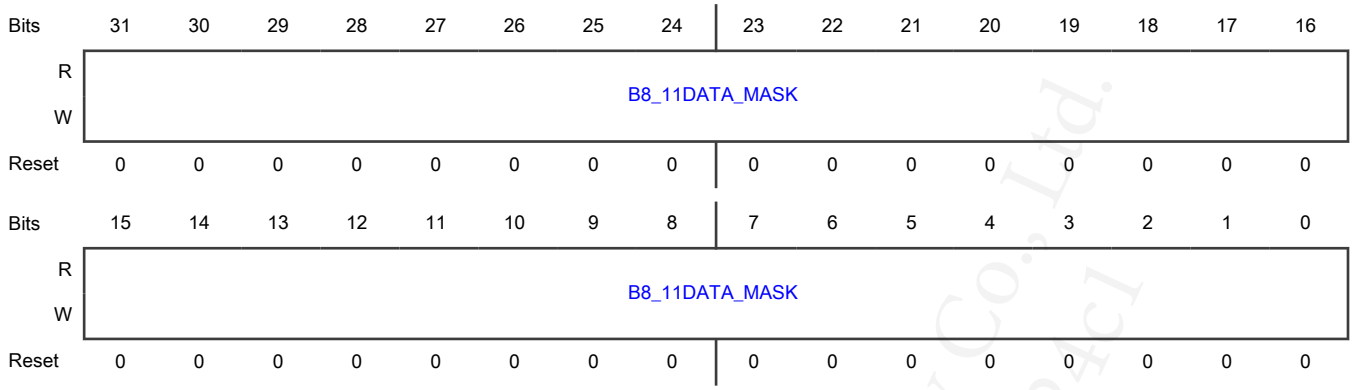
The third word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B4_7DATA_MASK correspond to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B4_7DATA_MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B4_7DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 4-7 on the read data bus is inverted.

73.7.6 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD5_WORD3)



Offset

Register	Offset
EICHD0_WORD3	10Ch
EICHD1_WORD3	14Ch
EICHD2_WORD3	18Ch
EICHD3_WORD3	1CCh
EICHD4_WORD3	20Ch
EICHD5_WORD3	24Ch

Function

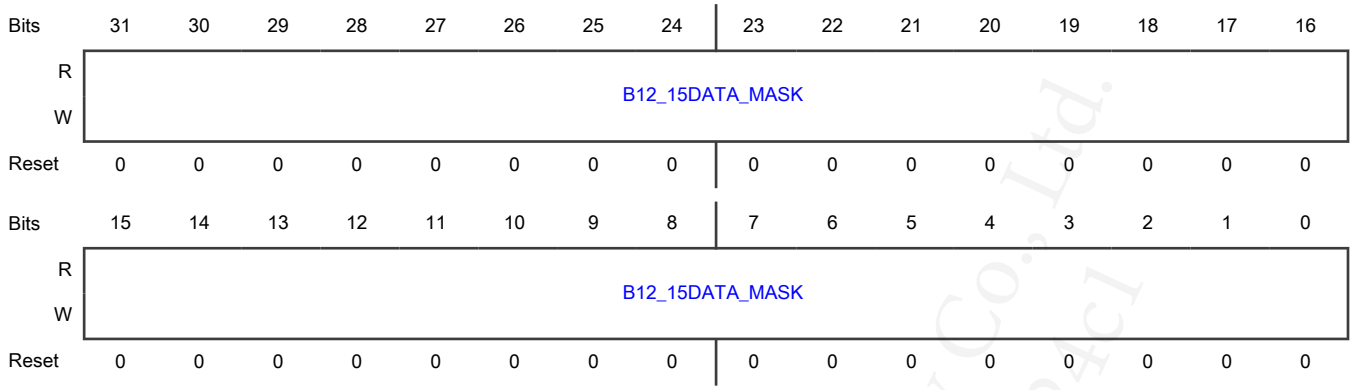
The fourth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B8_11DATA_MASK correspond to bytes 8–11 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B8_11DATA_MASK	Data Mask Bytes 8-11 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B8_11DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 8-11 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 8-11 on the read data bus is inverted.

73.7.7 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD5_WORD4)



Offset

Register	Offset
EICHD0_WORD4	110h
EICHD1_WORD4	150h
EICHD2_WORD4	190h
EICHD3_WORD4	1D0h
EICHD4_WORD4	210h
EICHD5_WORD4	250h

Function

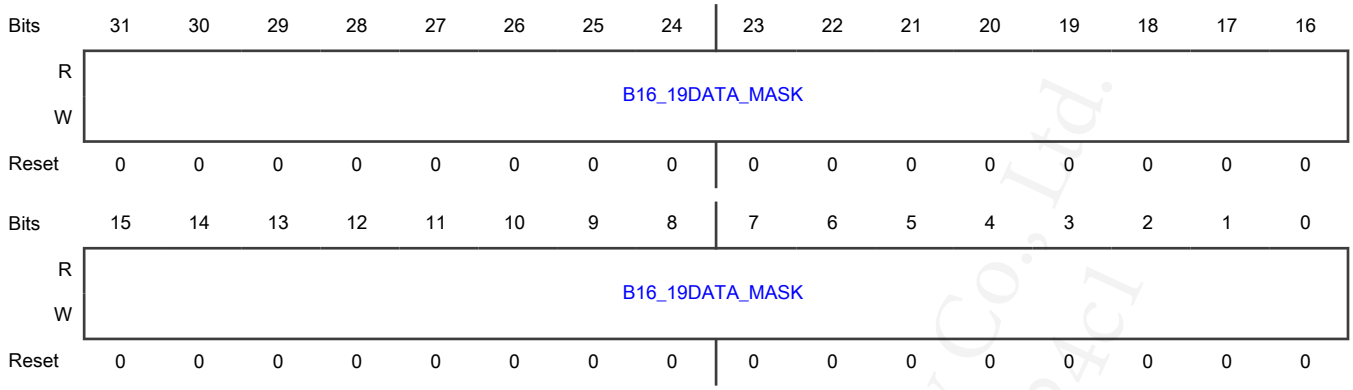
The fifth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B12_15DATA_MASK correspond to bytes 12–15 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B12_15DATA_MASK	Data Mask Bytes 12-15 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B12_15DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 12-15 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 12-15 on the read data bus is inverted.

73.7.8 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD5_WORD5)



Offset

Register	Offset
EICHD0_WORD5	114h
EICHD1_WORD5	154h
EICHD2_WORD5	194h
EICHD3_WORD5	1D4h
EICHD4_WORD5	214h
EICHD5_WORD5	254h

Function

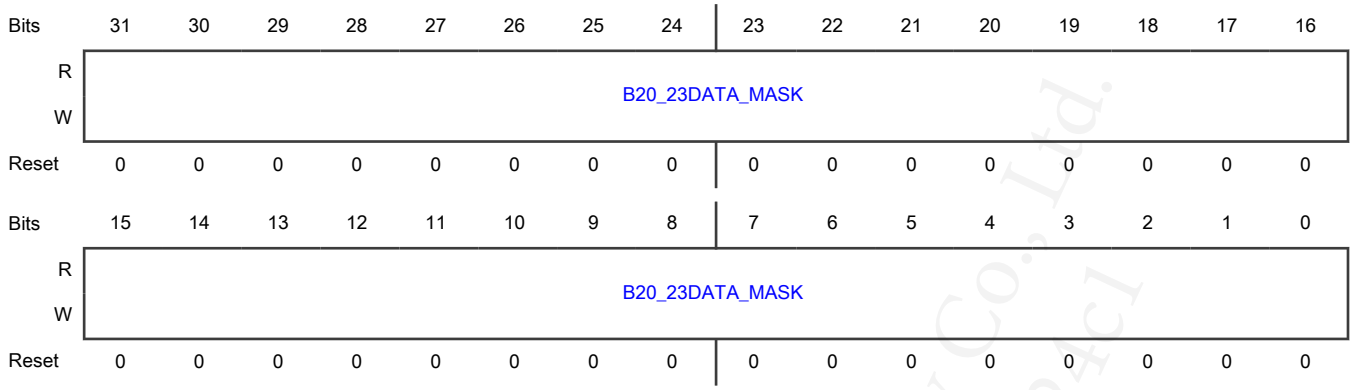
The sixth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B16_19DATA_MASK correspond to bytes 16–19 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B16_19DATA_MASK	Data Mask Bytes 16-19 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B16_19DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 16-19 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 16-19 on the read data bus is inverted.

73.7.9 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD5_WORD6)



Offset

Register	Offset
EICHD0_WORD6	118h
EICHD1_WORD6	158h
EICHD2_WORD6	198h
EICHD3_WORD6	1D8h
EICHD4_WORD6	218h
EICHD5_WORD6	258h

Function

The seventh word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B20_23DATA_MASK correspond to bytes 20–23 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B20_23DATA_MASK	Data Mask Bytes 20-23 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B20_23DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 20-23 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 20-23 on the read data bus is inverted.

EICHD5_WORD8	260h

Function

The ninth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B28_31DATA_MASK correspond to bytes 28–31 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B28_31DATA_MASK	Data Mask Bytes 28-31 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B28_31DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 28-31 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 28-31 on the read data bus is inverted.

73.8 EIM_3 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.

— Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 584. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	256	255-224	223-192	191-160
1	256	255-224	223-192	191-160
2	256	255-224	223-192	191-160
3	256	255-224	223-192	191-160

Table 585. DATA_MASK bit: Channel-word mapping

Channel	Specific bits of DATA_MASK in				
	WORD4	WORD5	WORD6	WORD7	WORD8
0	159-128	127-96	95-64	63-32	31-0
1	159-128	127-96	95-64	63-32	31-0

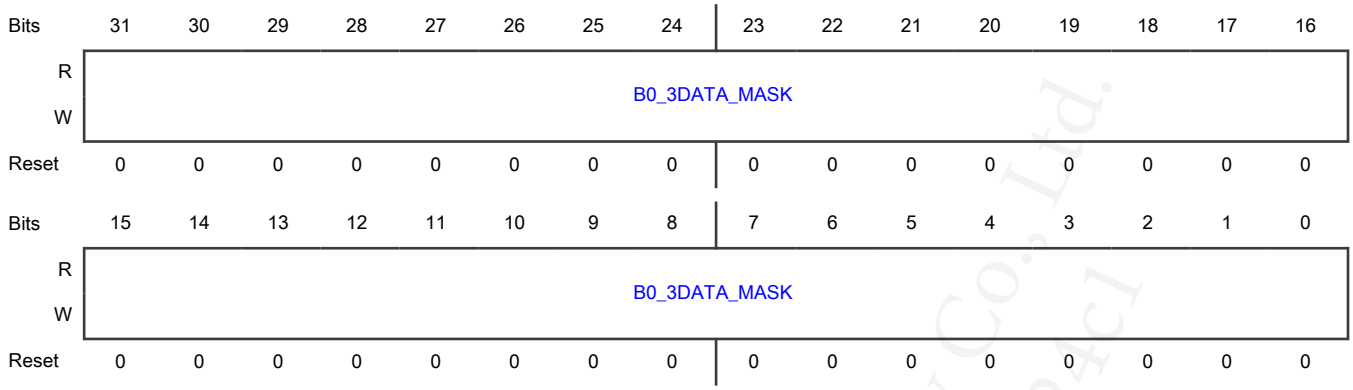
73.8.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD3_WORD1)

Offset



Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

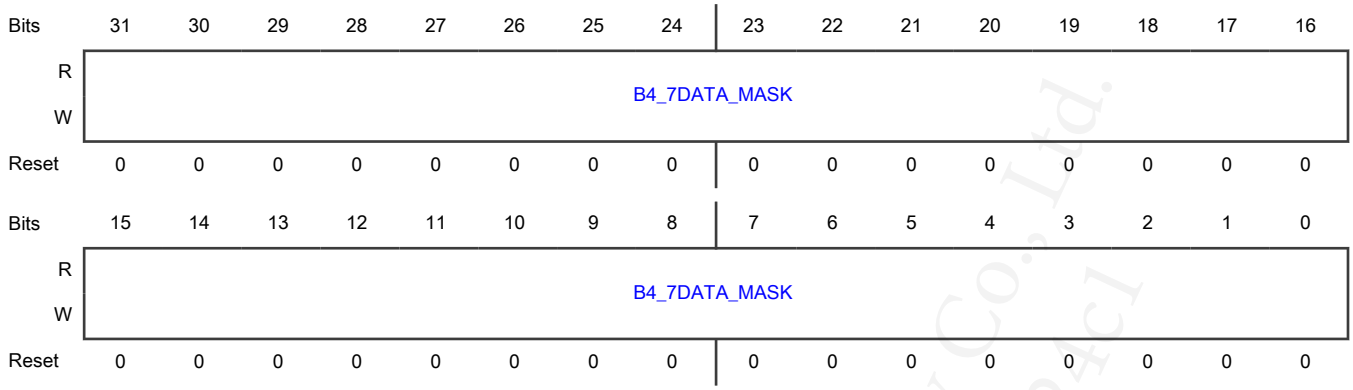
Provided under NDA only
COMPANY PROPRIETARY
Bosch Chassis Systems Control (CHJ) Automotive Technology Co., Ltd.
c8c2e54821-48a8-b251-390d3ab624c1

Diagram

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.8.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD3_WORD2)



Offset

Register	Offset
EICHD0_WORD2	108h
EICHD1_WORD2	148h
EICHD2_WORD2	188h
EICHD3_WORD2	1C8h

Function

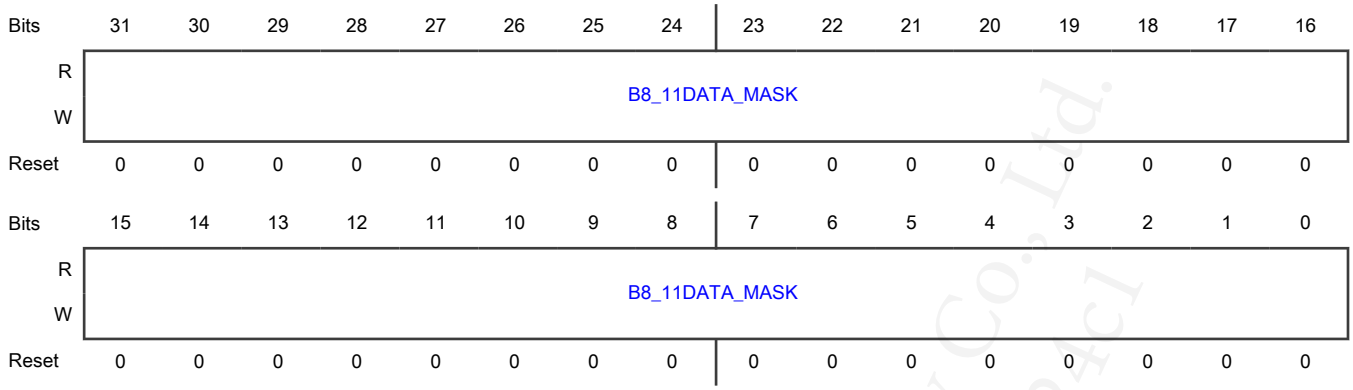
The third word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B4_7DATA_MASK correspond to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B4_7DATA_MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B4_7DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 4-7 on the read data bus is inverted.

73.8.6 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD3_WORD3)



Offset

Register	Offset
EICHD0_WORD3	10Ch
EICHD1_WORD3	14Ch
EICHD2_WORD3	18Ch
EICHD3_WORD3	1CCh

Function

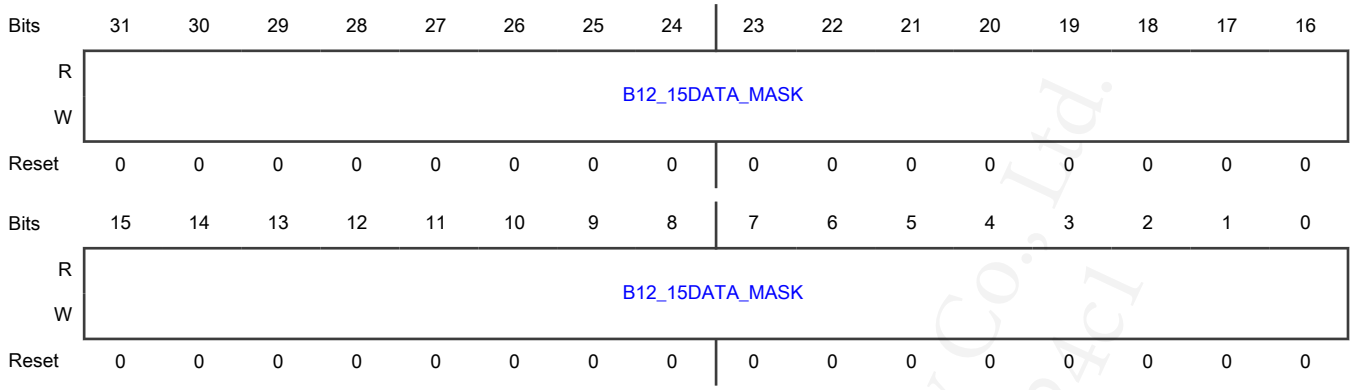
The fourth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B8_11DATA_MASK correspond to bytes 8–11 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B8_11DATA_MASK	Data Mask Bytes 8-11 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B8_11DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 8-11 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 8-11 on the read data bus is inverted.

73.8.7 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD3_WORD4)



Offset

Register	Offset
EICHD0_WORD4	110h
EICHD1_WORD4	150h
EICHD2_WORD4	190h
EICHD3_WORD4	1D0h

Function

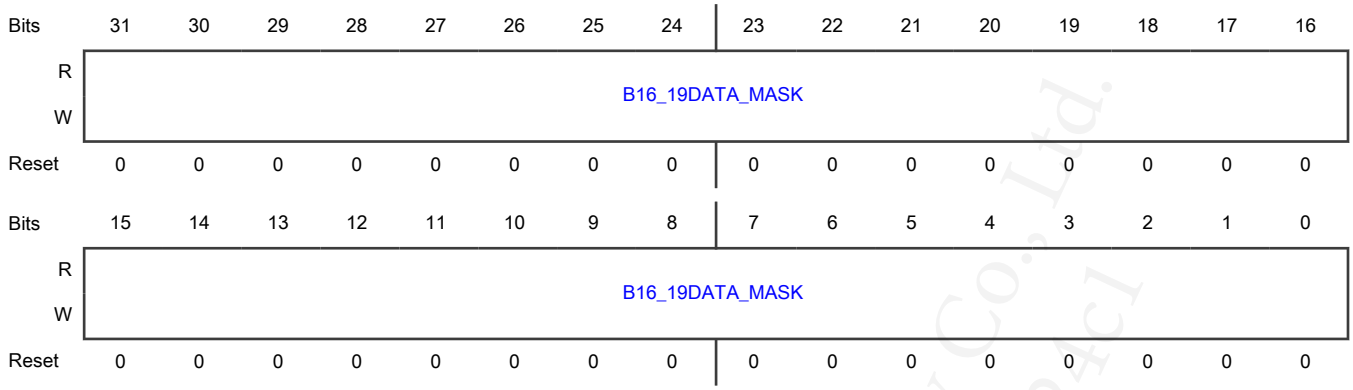
The fifth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B12_15DATA_MASK correspond to bytes 12–15 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B12_15DATA_MASK	Data Mask Bytes 12-15 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B12_15DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 12-15 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 12-15 on the read data bus is inverted.

73.8.8 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD3_WORD5)



Offset

Register	Offset
EICHD0_WORD5	114h
EICHD1_WORD5	154h
EICHD2_WORD5	194h
EICHD3_WORD5	1D4h

Function

The sixth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B16_19DATA_MASK correspond to bytes 16–19 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

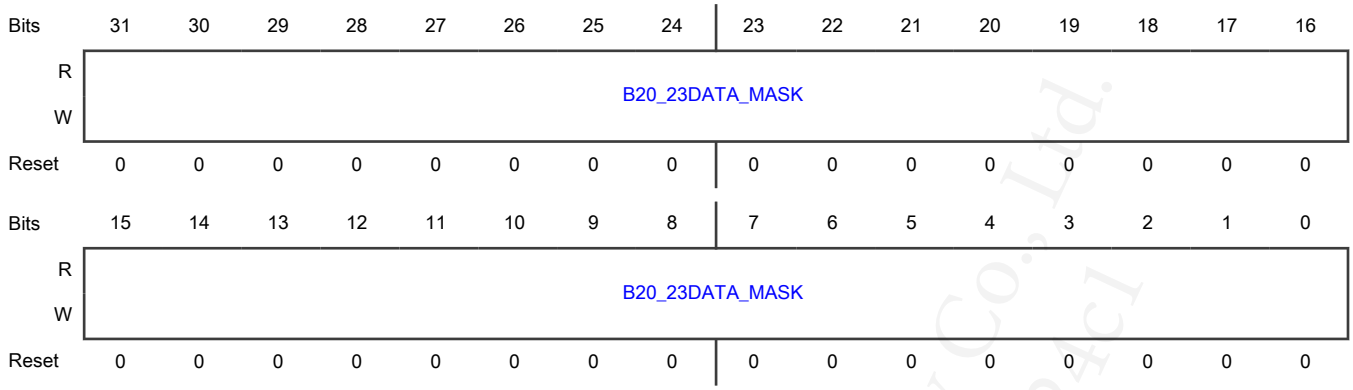
Diagram

Fields

Field	Function
31-0 B16_19DATA_MASK	Data Mask Bytes 16-19 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B16_19DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 16-19 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 16-19 on the read data bus is inverted.

73.8.9 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD3_WORD6)

Offset



Register	Offset
EICHD0_WORD6	118h
EICHD1_WORD6	158h
EICHD2_WORD6	198h
EICHD3_WORD6	1D8h

Function

The seventh word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B20_23DATA_MASK correspond to bytes 20–23 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

EICHD3_WORD7	1DCh

Function

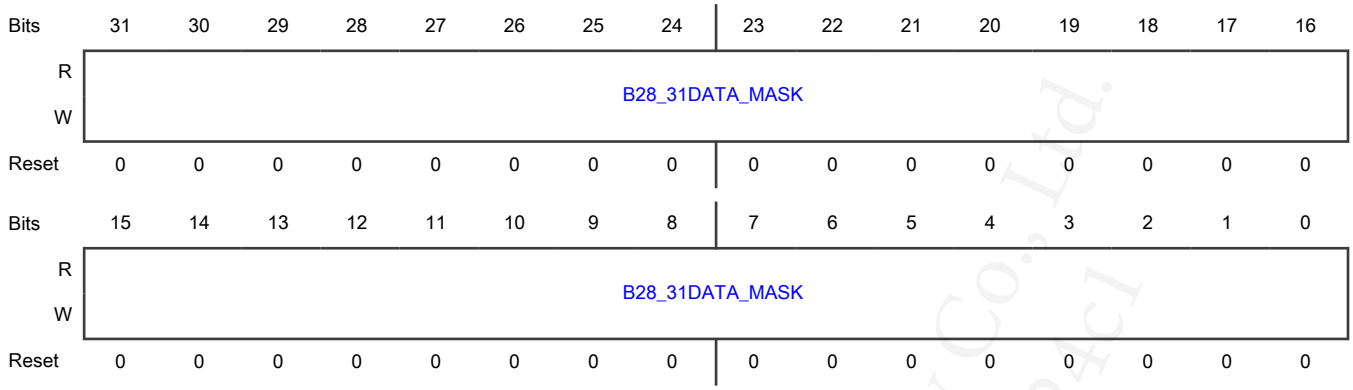
The eighth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B24_27DATA_MASK correspond to bytes 24–27 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B24_27DATA_MASK	Data Mask Bytes 24-27 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B24_27DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 24-27 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 24-27 on the read data bus is inverted.

73.8.11 Error Injection Channel Descriptor n, Word8 (EICHD0_WORD8 - EICHD3_WORD8)



Offset

Register	Offset
EICHD0_WORD8	120h
EICHD1_WORD8	160h
EICHD2_WORD8	1A0h
EICHD3_WORD8	1E0h

Function

The ninth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B28_31DATA_MASK correspond to bytes 28–31 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B28_31DATA_MASK	Data Mask Bytes 28-31 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B28_31DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 28-31 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 28-31 on the read data bus is inverted.

73.9 EIM_LLCE register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model. Unused words are not documented.

— Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1-3 (EICHD*n*_WORD1-3), if present, define the data mask. Word2 and Word3 are present only when required by the total width of the channel's data mask. See Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following table shows the total width of DATA_MASK and the distribution of its bits across the WORD registers.

Table 586. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	32	31-0	—	—
1	32	31-0	—	—
3	32	31-0	—	—
4	32	31-0	—	—
5	32	31-0	—	—
6	32	31-0	—	—

25 EICH6EN	Error Injection Channel 6 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 6 1b - Error injection is enabled on Error Injection Channel 6

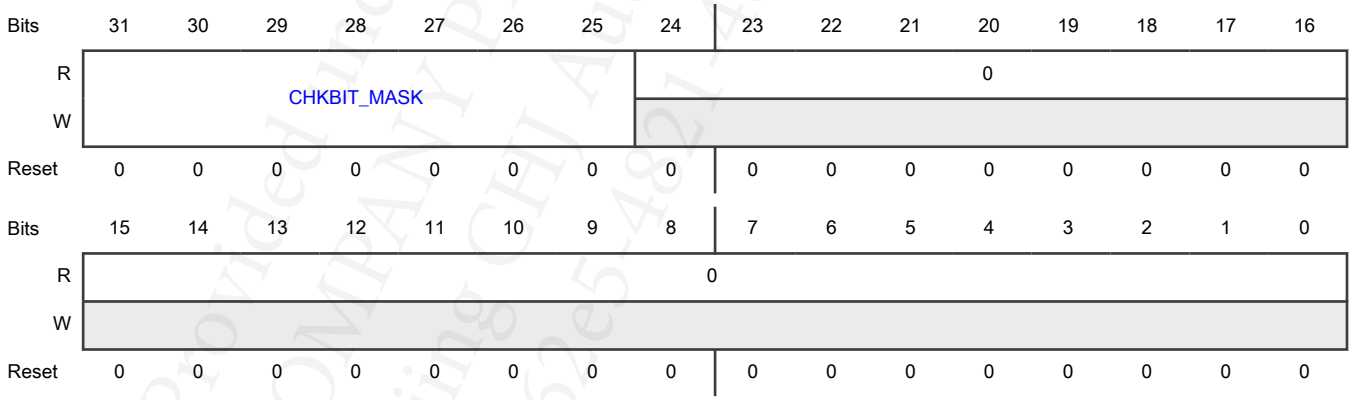
73.9.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD6_WORD0)



Offset

Register	Offset
EICHD0_WORD0	100h
EICHD1_WORD0	140h
EICHD3_WORD0	1C0h
EICHD4_WORD0	200h
EICHD5_WORD0	240h
EICHD6_WORD0	280h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

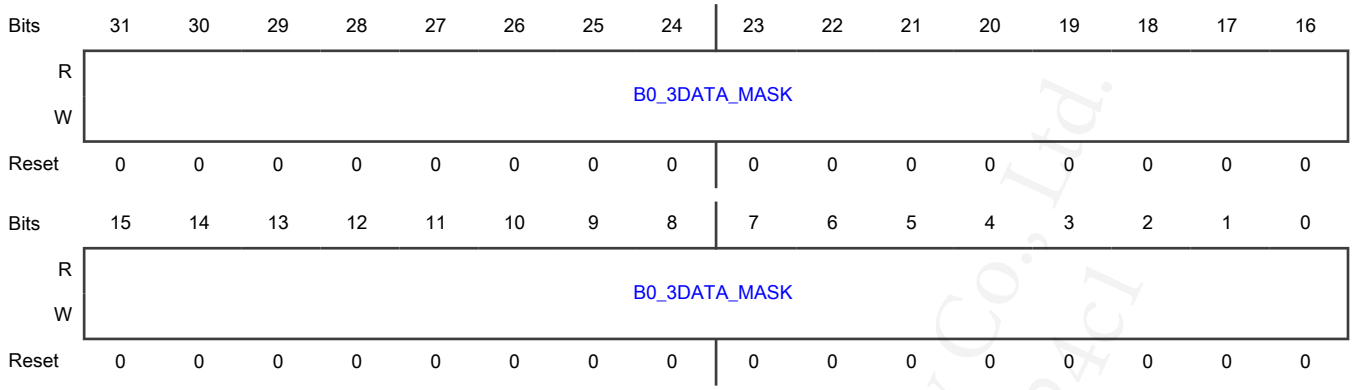
Fields

Field	Function
31-25 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[6:0] (7 bits wide), CHKBIT_MASK[6] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
24-0 —	Reserved

73.9.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD6_WORD1)

Offset



Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD3_WORD1	1C4h
EICHD4_WORD1	204h
EICHD5_WORD1	244h
EICHD6_WORD1	284h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.10 EIM_MISC register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.

— Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

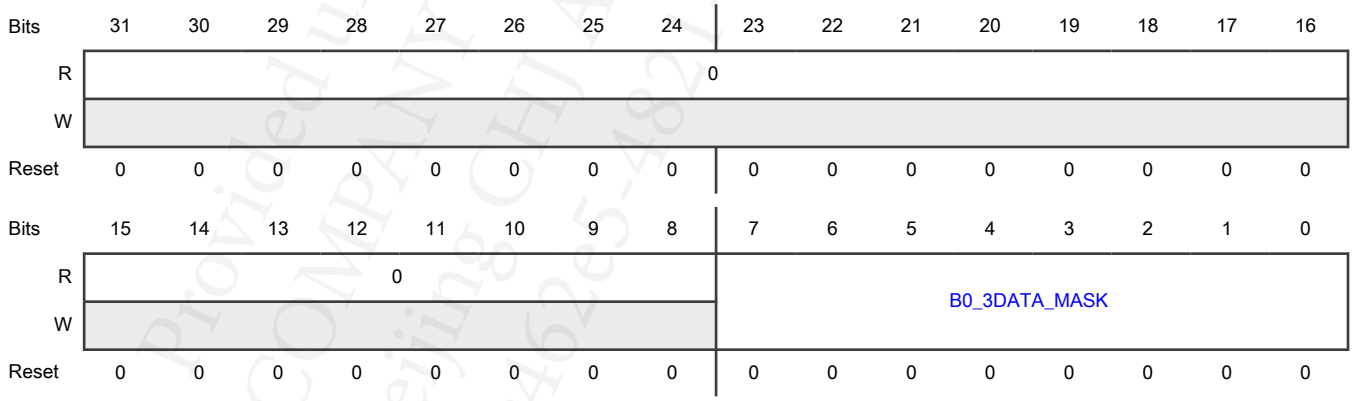
73.10.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD4_WORD1)



Offset

Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h
EICHD4_WORD1	204h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

73.11 EIM_PFE0 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 589. Error injection channel descriptor: DATA_MASK details

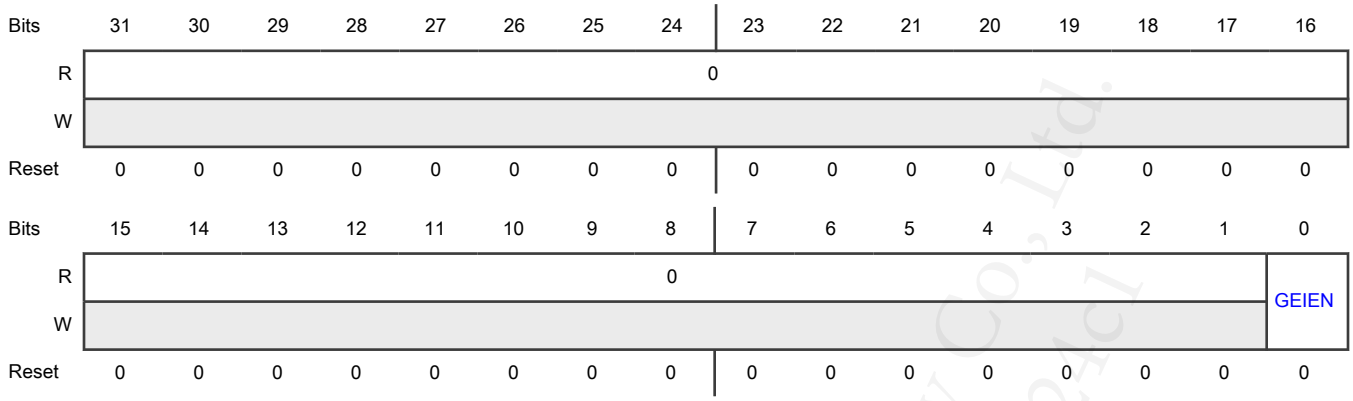
73.11.2 Error Injection Module Configuration Register (EIMCR)

Offset



Register	Offset
EIMCR	0h

Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

Provided under NXP SEMICONDUCTORS COMPANY CONFIDENTIAL Beijing CHIPHOME Technology Co., Ltd. c84625-48124 2020-09-08 08:04:51

Fields

Field	Function
31-1 —	Reserved
0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

73.11.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Provided under NDA only

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

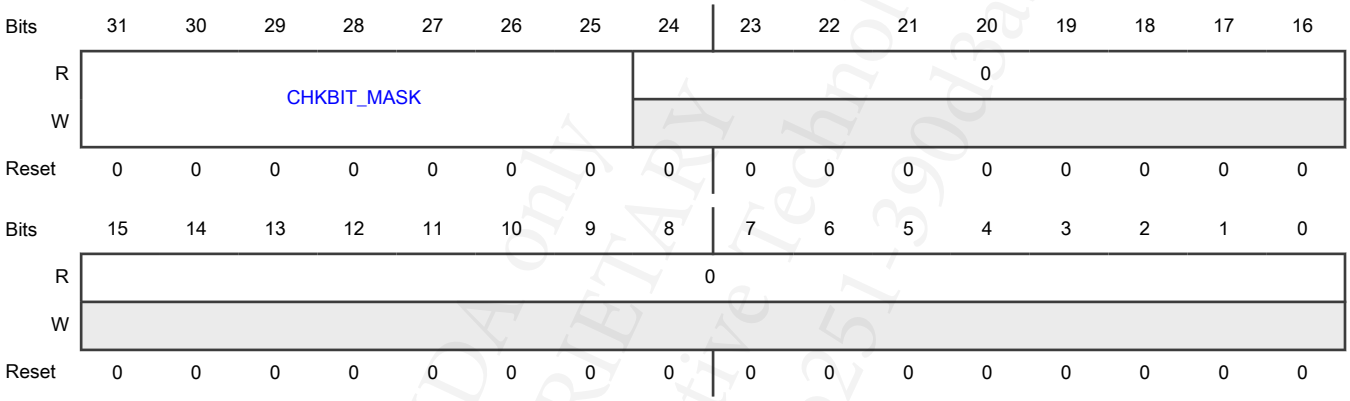
2 EICH29EN	Error Injection Channel 29 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 29 1b - Error injection is enabled on Error Injection Channel 29
1 EICH30EN	Error Injection Channel 30 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 30 1b - Error injection is enabled on Error Injection Channel 30
0 EICH31EN	Error Injection Channel 31 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 31 1b - Error injection is enabled on Error Injection Channel 31

73.11.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)



Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-25 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[6:0] (7 bits wide), CHKBIT_MASK[6] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

31-25 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[6:0] (7 bits wide), CHKBIT_MASK[6] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
24-0 —	Reserved

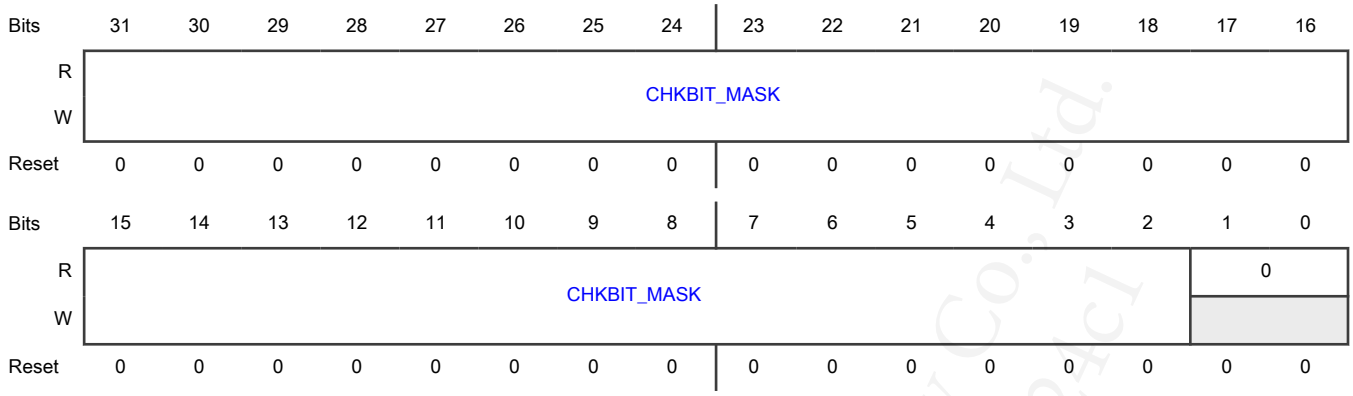
73.11.24 Error Injection Channel Descriptor 13, Word0 (EICHD13_WORD0)



Offset

Register	Offset
EICHD13_WORD0	440h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-2 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[29:0] (30 bits wide), CHKBIT_MASK[29] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

Fields

Field	Function
31-12 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[19:0] (20 bits wide), CHKBIT_MASK[19] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
11-0 —	Reserved

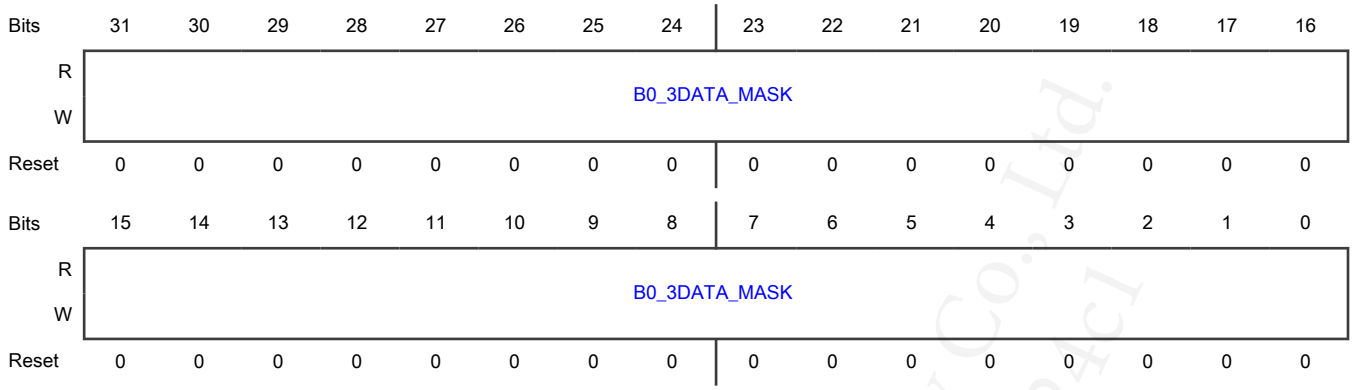
73.11.46 Error Injection Channel Descriptor n, Word1 (EICHD30_WORD1 - EICHD31_WORD1)



Offset

Register	Offset
EICHD30_WORD1	884h
EICHD31_WORD1	8C4h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.12 EIM_PFE1 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.

— Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 591. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 2 1b - Error injection is enabled on Error Injection Channel 2
28 EICH3EN	Error Injection Channel 3 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

73.12.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

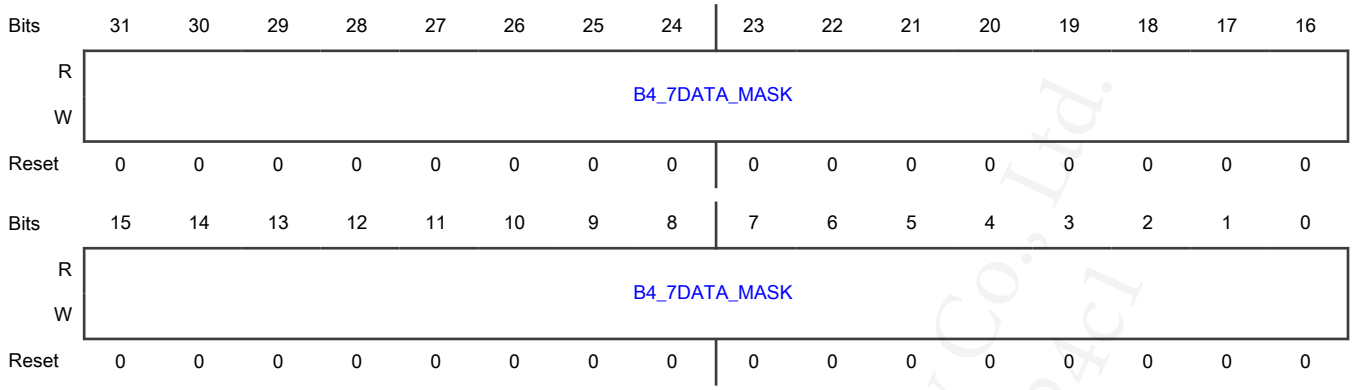
15-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.12.8 Error Injection Channel Descriptor n, Word2 (EICHD1_WORD2 - EICHD14_WORD2)

Offset



Register	Offset
EICHD1_WORD2	148h
EICHD6_WORD2	288h
EICHD12_WORD2	408h
EICHD13_WORD2	448h
EICHD14_WORD2	488h

Function

The third word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B4_7DATA_MASK correspond to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

73.13 EIM_PFE2 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 593. Error injection channel descriptor: DATA_MASK details

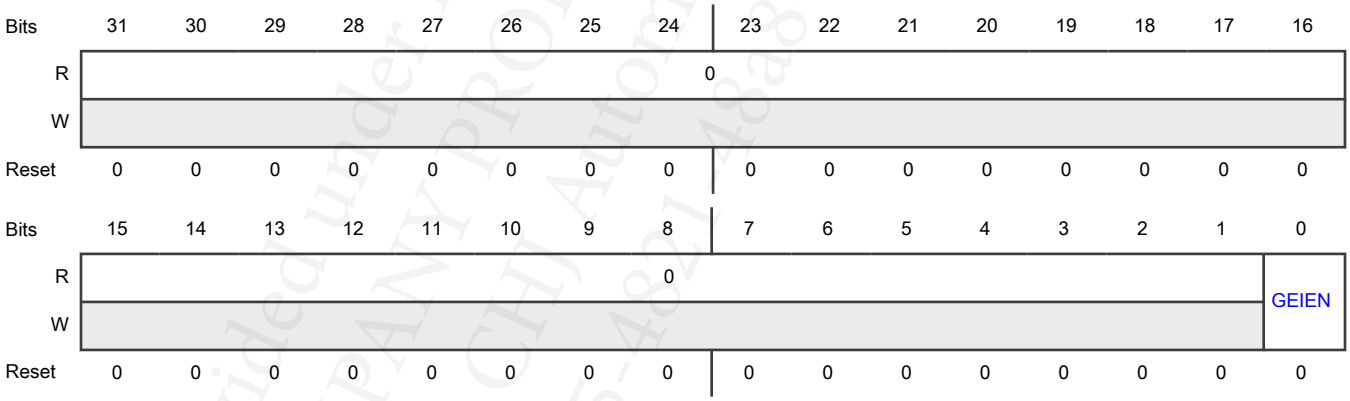
73.13.2 Error Injection Module Configuration Register (EIMCR)



Offset

Register	Offset
EIMCR	0h

Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

Diagram

Fields

0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

73.13.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 26 1b - Error injection is enabled on Error Injection Channel 26
4 EICH27EN	Error Injection Channel 27 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 27 1b - Error injection is enabled on Error Injection Channel 27
3 EICH28EN	Error Injection Channel 28 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 28 1b - Error injection is enabled on Error Injection Channel 28
2 EICH29EN	Error Injection Channel 29 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

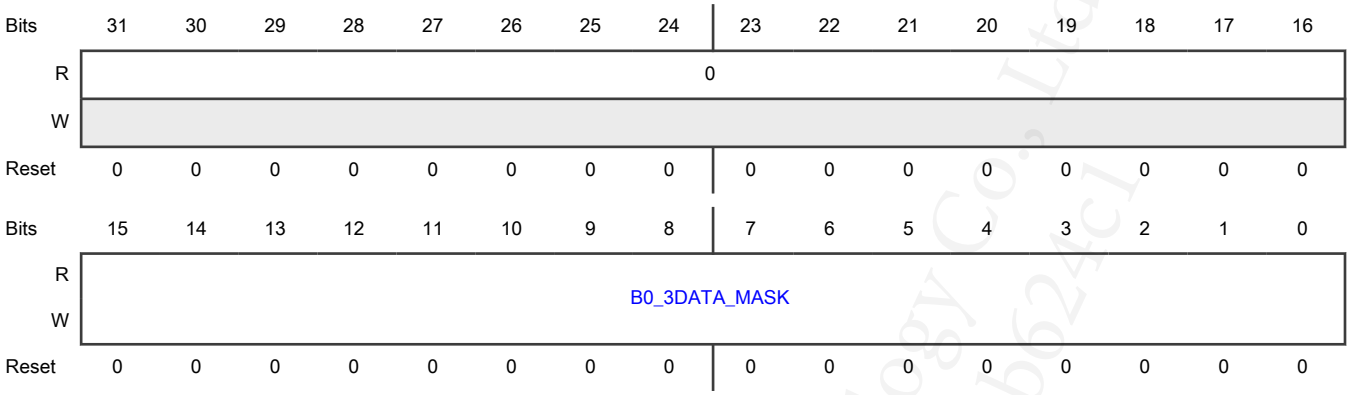
Field	Function
	Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 29 1b - Error injection is enabled on Error Injection Channel 29
1 EICH30EN	Error Injection Channel 30 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 30 1b - Error injection is enabled on Error Injection Channel 30
0 EICH31EN	Error Injection Channel 31 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 31 1b - Error injection is enabled on Error Injection Channel 31

73.13.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD3_WORD1)

Offset



Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target

RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

Diagram

Fields

Field	Function
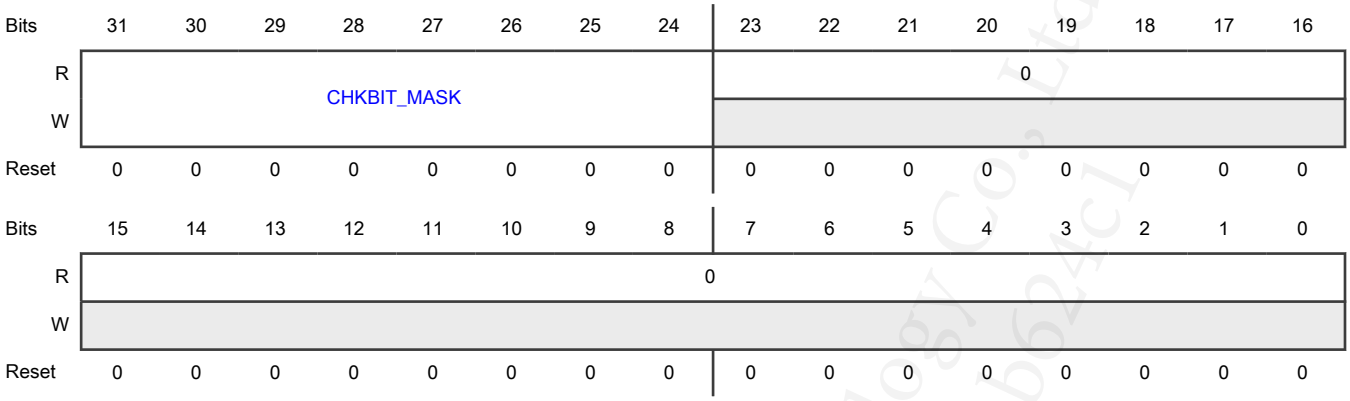
31-0 B28_31DATA_MASK	Data Mask Bytes 28-31 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For the specific DATA_MASK bits to which B28_31DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 28-31 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 28-31 on the read data bus is inverted.

73.13.23 Error Injection Channel Descriptor n, Word0 (EICHD23_WORD0 - EICHD30_WORD0)

Offset



Register	Offset
EICHD23_WORD0	6C0h
EICHD24_WORD0	700h
EICHD25_WORD0	740h
EICHD26_WORD0	780h
EICHD27_WORD0	7C0h
EICHD28_WORD0	800h
EICHD29_WORD0	840h
EICHD30_WORD0	880h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or

remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

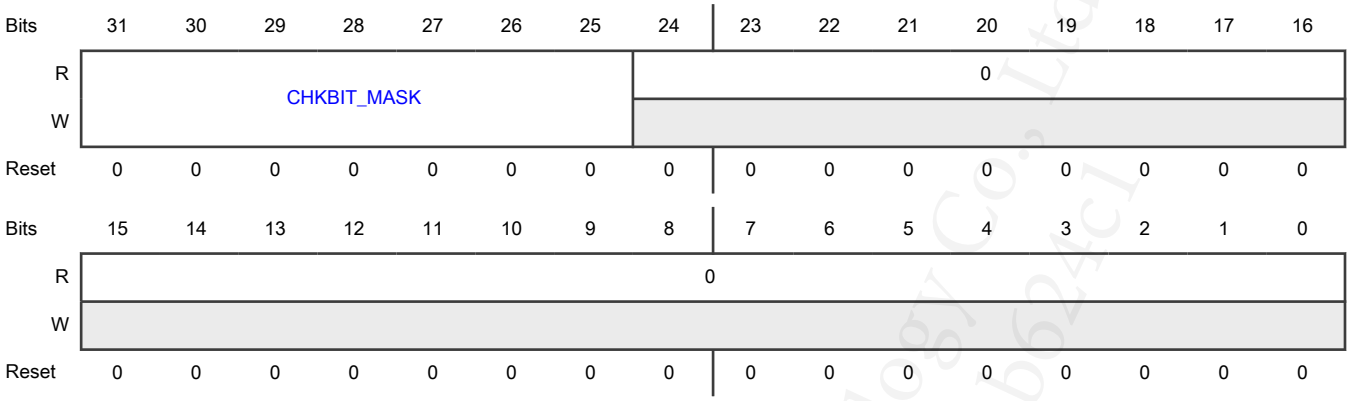
Diagram

Fields

Field	Function
31-24 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
23-0 —	Reserved

73.13.24 Error Injection Channel Descriptor 31, Word0 (EICHD31_WORD0)

Offset



Register	Offset
EICHD31_WORD0	8C0h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or

remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

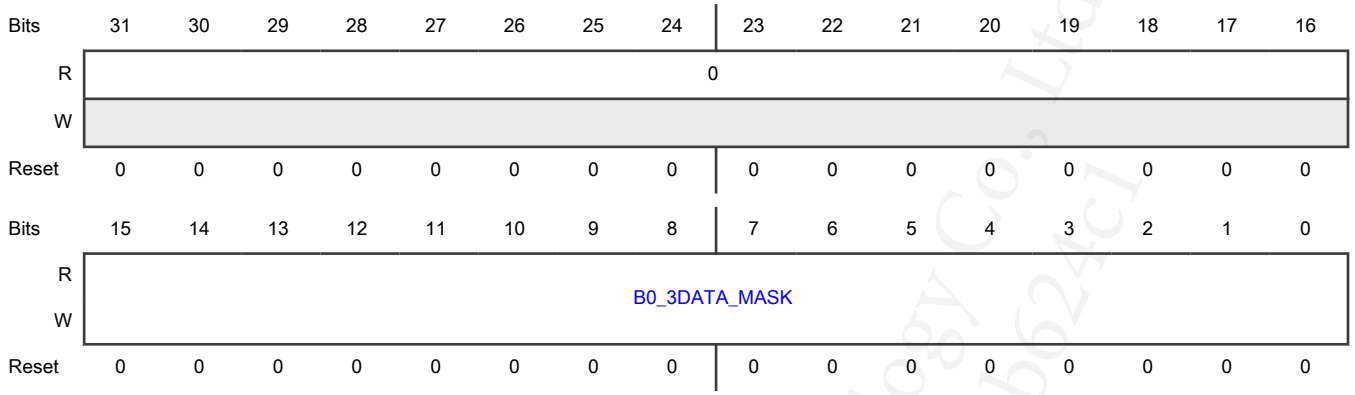
73.13.25 Error Injection Channel Descriptor 31, Word1 (EICHD31_WORD1)

Offset



Register	Offset
EICHD31_WORD1	8C4h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target

RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.14 EIM_PFE3 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 595. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3

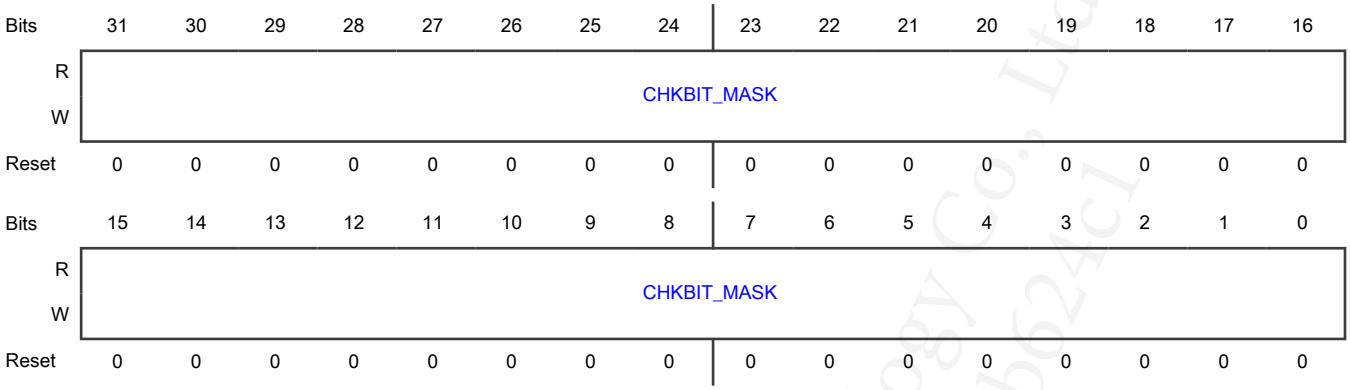
73.14.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

Offset



Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or

remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[31:0] (32 bits wide), CHKBIT_MASK[31] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

Function

The sixth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B16_19DATA_MASK correspond to bytes 16–19 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

73.15 EIM_PFE4 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model. Unused words are not documented.

— Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1-3 (EICHD*n*_WORD1-3), if present, define the data mask. Word2 and Word3 are present only when required by the total width of the channel's data mask. See Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following table shows the total width of DATA_MASK and the distribution of its bits across the WORD registers.

Table 597. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

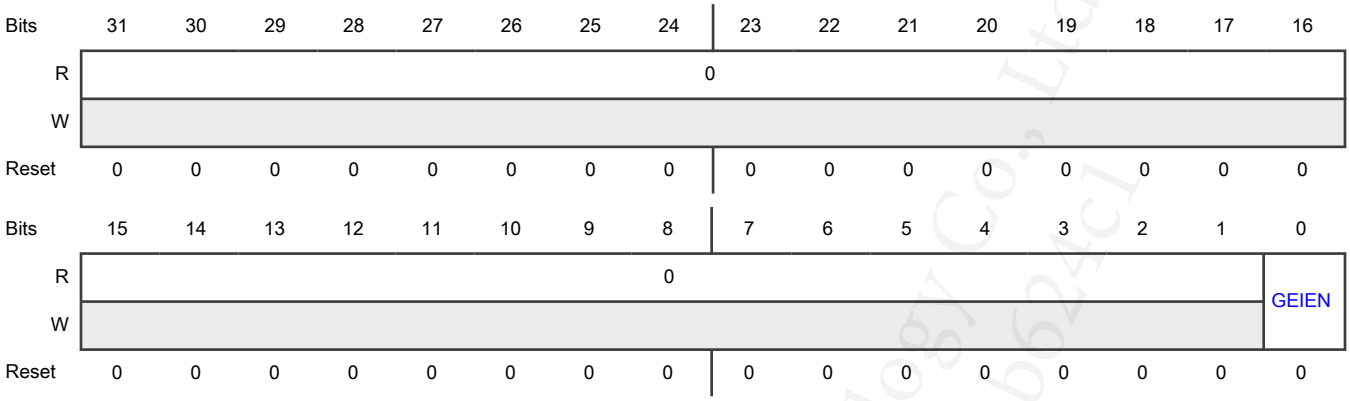
73.15.2 Error Injection Module Configuration Register (EIMCR)



Offset

Register	Offset
EIMCR	0h

Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

Diagram

Fields

Field	Function
31-1 —	Reserved
0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

73.15.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Provided under NDA only

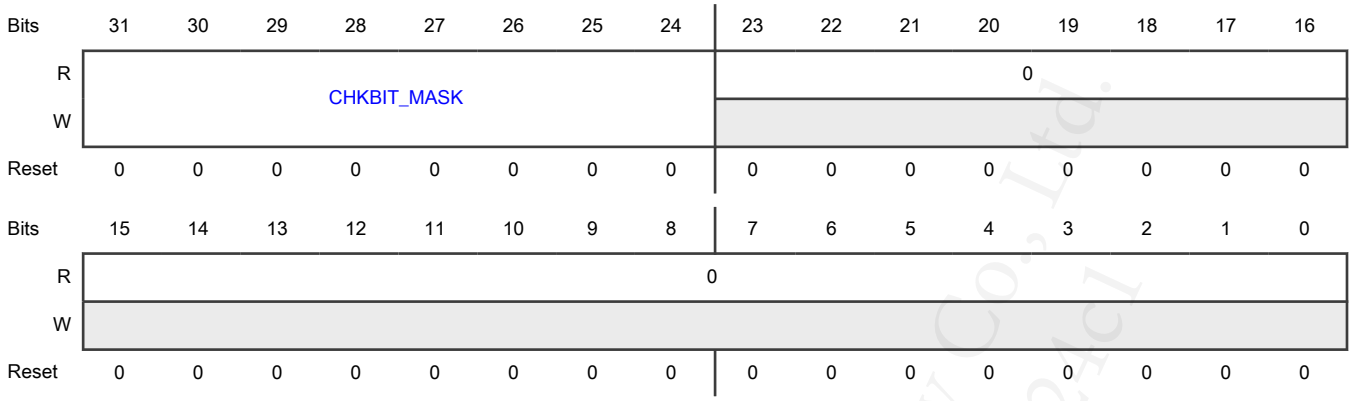
73.15.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

Offset



Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Provided under NDA only

Diagram

Fields

Field	Function
31-24 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

23-0 —	Reserved

73.16 EIM_PFE5 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

73.16.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 2 1b - Error injection is enabled on Error Injection Channel 2
28 EICH3EN	Error Injection Channel 3 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

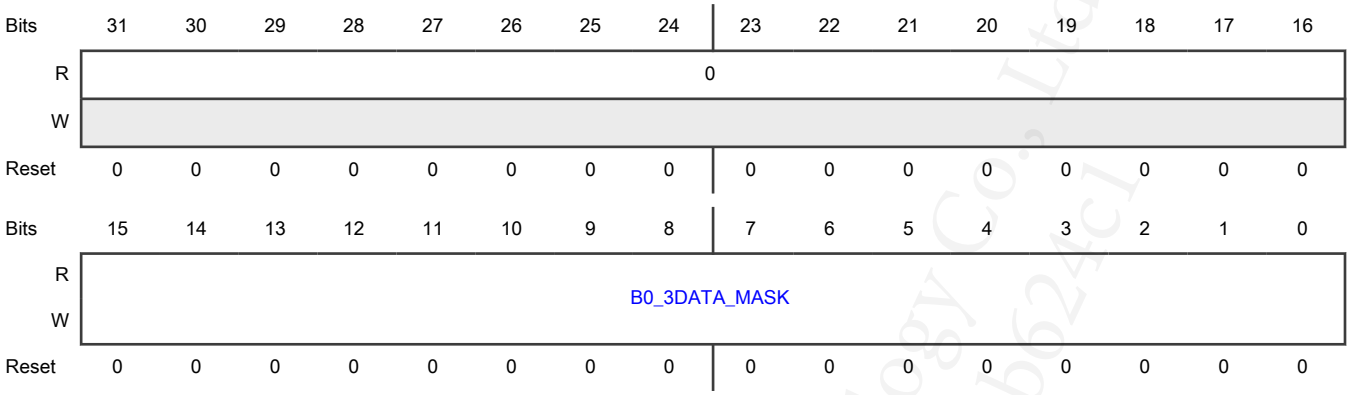
73.16.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD1_WORD1)

Offset



Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target

RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.16.5 Error Injection Channel Descriptor n, Word1 (EICHD2_WORD1 - EICHD3_WORD1)

Offset

Register	Offset
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Function

The fifth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B12_15DATA_MASK correspond to bytes 12–15 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

73.17 EIM_PFE6 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model. Unused words are not documented.

— Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1-3 (EICHD*n*_WORD1-3), if present, define the data mask. Word2 and Word3 are present only when required by the total width of the channel's data mask. See Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following table shows the total width of DATA_MASK and the distribution of its bits across the WORD registers.

Table 600. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	32	31-0	—	—
1	32	31-0	—	—

EICHD1_WORD1	144h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

73.18 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c5c46e25-8187-48a8-b251-390d3ab64c1

- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 31 error injection channels. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 575 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

Chapter 74
Cyclic Redundancy Check (CRC) Unit

74.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied to the final CRC signature. Each context can be configured with one of the four hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

74.2 Main features

- Peripheral bus interface
- Three contexts for the concurrent CRC computation are supported
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- Four hard-wired polynomials
  - CRC-8 VDA CAN
  - CRC-16-CCITT
  - CRC-32 ITU-T V.42 (see note below)
  - CRC-8-H2F AUTOSAR polynomial
- Support for byte, halfword, or word width of the input data stream

NOTE

Although the CRC-32 ITU-T V.42 polynomial is used for CRC generation, the generation algorithm MISR differs from the one used by the IEEE 802.3 standard.

74.3 Block diagram

See the following figure for an overview of the CRC module. See Main features for number of contexts in this module.

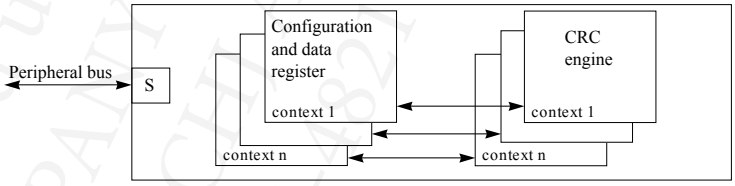

Figure 576. CRC top-level diagram

74.4 External signal description

The CRC module does not generate any external signals.

74.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped to the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:

- User
- Supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_ CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_ CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

NOTE

High-level code must be written in a way to realize byte-, halfword-, and word-wide writes on the assembler code level. Any endianness problem faced can be corrected by appropriate configuration of CRC_CFG[SWAP_BYTEWISE] and CRC_CFG[SWAP_BITWISE].

Fields

Field	Function
31-0 OUTP	Final CRC signature This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation.

74.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided that can consist a mix of data formats (byte, halfword and word), which allows writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem), where *n* is less or equal to the number of contexts.

The standard generator polynomials are provided in Figure 577, Figure 578, and Figure 579 for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8+x^4+x^3+x^2+1$$

$$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

Figure 579. CRC-32 (ITU-T V.42 protocol)

$$x^5+x^3+x^2+x+1$$

Figure 580. CRC-8-H2F (AUTOSAR 4.0 protocol)

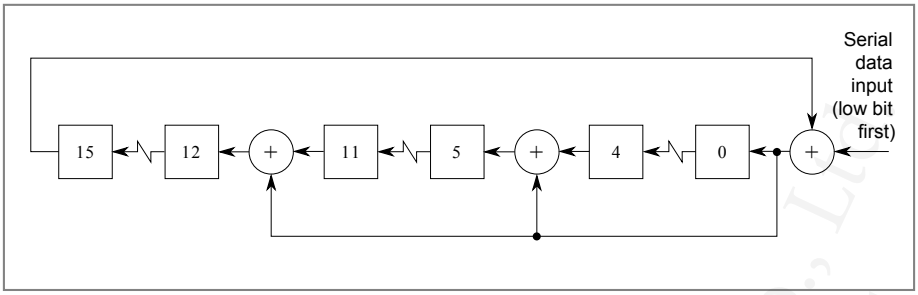

Figure 581. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in Figure 581 for CRC-CCITT. Note that, conceptually, the least-significant or "right-most" bit shown in Input Register is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, and so on.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart provided in Figure 582.

74.7 Use cases

74.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for these types of data transfer—mem2mem, periph2mem, and mem2periph—the following sequence, as shown in Figure 583, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

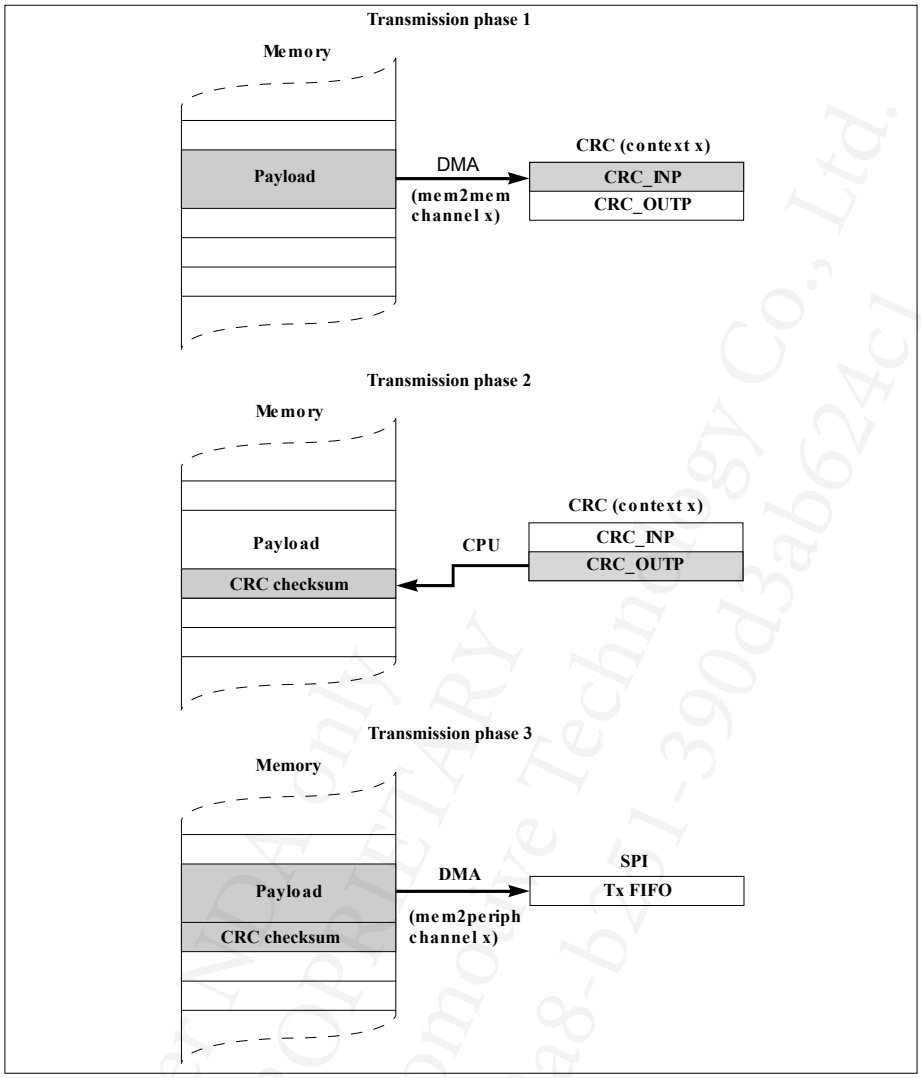

Figure 583. DMA-CRC transmission sequence

74.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the ITU-T V.42 standard, the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16, the user needs to set the SWAP_BITWISE bit.

NOTE

The below results and examples are for **littleEndian** format.

74.7.2.1 Configuration Register values

The configuration register values that must be set for all the hard wired polynomials are as below:

Table 601. Configuration Register values

Bit Field	[31:6]	5	4	3	2	1	0	Hex Value
	RESERVED	SWAP_BYTEWISE	SWAP_BITWISE	POLY		SWAP	INV	
CRC - 16 CCITT	0	0	1	0	0	0	0	0x10
CRC - 32	0	1	0	0	1	1	1	0x27
CRC - 8	0	0	1	1	0	0	1	0x19
CRC - 8 H2F	0	0	1	1	1	0	1	0x1D

74.7.2.2 Current Status Register initial values

The initial values for the Current Status Register that must be set for all the hard wired polynomials are as below:

Table 602. Current Status Register initial values

Bit Field	[31:0]
CRC - 16 CCITT	0x0000_FFFF
CRC - 32	0xFFFF_FFFF
CRC - 8	0x0000_00FF
CRC - 8 H2F	0x0000_00FF

74.7.2.3 Examples of input data and expected output data

Some examples of input data and expected output data are as below:

Table 603. Examples of input data and expected output data

Polynomial	Initial value (CSTAT)	Input data	Output data
CRC - 16 CCITT	0x0000_FFFF	0xA1B2C3D4	0x4063

Chapter 75
Debug

75.1 Introduction

This chapter describes the debug and trace features of this chip. The debug and trace architecture is based on Arm® CoreSight™ architecture. See the Arm CoreSight architecture specification (available in References) for details.

The Arm Cortex M7 and Cortex A53 core-clusters support the debug and trace features described in their Technical Reference Manual (TRM) (available in References). In addition, the debug architecture includes NoC debug and trace modules. These debug components are accessible via the Arm DAP controller-based architecture. The DAP controller works in parallel with the system JTAG Controller (JTAGC). The DAP controller and the JTAGC share the JTAG port and JTAG instruction set.

The debug structure consists of up to three sections. There is a "system" component and Accelerator components. The "system" components are similar on different MCUs in the same family and include the primary cores debug interfaces, the chip level debug interfaces and chip level trace interfaces. The Accelerator components include the debug and trace circuits necessary for any application specific accelerators required for the different application spaces that the MCU supports. These vary from MCU to MCU and could include only trace components.

75.2 Block diagram

75.3 Glossary

This section provides a list of terms used in this chapter.

Table 604. Glossary and acronyms

Term	Definition
ACTIVE_HIGH	Names for signals that are active-high. These are shown in uppercase without an overbar. Signals that are active-high. These are referred as asserted when they are logic 1 and negated when they are logic 0.
ACTIVE_LOW	A bar over a signal name indicates that the signal is active-low. Active-low signals are referred as asserted when they are logic 0 and negated when they are logic 1.
AHB	System Interconnect
APBIC	System Debug APB Interconnect (APBIC)
Asserted	A signal that is asserted in its active state. An active-low signal changes from logic level one to logic level zero when asserted and an active-high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits
Customer	The end user of an SoC design or chip
DAP	Debug Access Port
Double word	Two words, or 64-bits
ECT	Embedded Cross Trigger
ETF	Embedded CoreSight Funnels

Table continues on the next page...

Table 604. Glossary and acronyms (continued)

Term	Definition
JDC	JTAG Data Communication
JTAGC	JTAG Controller
Logic level one	The voltage corresponding to boolean set to true (1)
Logic level zero	The voltage corresponding to boolean set to false (0)
MDM_AP	Miscellaneous Debug Module Access Port
MIC	Manufacturer identity code
Negated	A signal that is negated in its inactive state. An active-low signal changes from logic level zero to logic level one when negated and an active-high signal changes from logic level one to logic level zero.
PIN	Part identification number
Set	To set a bit or bits means to establish logic level one on the bit or bits
SIP	System-In-a-Package
TAP	Test and Debug Access Port
TPIU	Trace Port Interface Unit

75.4 Features

The debug and trace features are as follows:

- Debug control
  - Via IEEE 1149.1 compliant JTAG interface
- Test control
  - Via IEEE 1149.1 compliant JTAG interface
  - Uses IEEE 1149.6 extension to IEEE 1149.1
- Trace interfaces
  - Aurora-based 10-pin Trace port interface
    - Four (8-pin) LVDS trace ports output
    - 2-pin LVDS reference clock input (AURORA_EXT_CLK)
  - Capability to trace to internal system RAM via Arm ETR interface
- Debug security
  - JTAG/DAP interface that controls all debug features and is gated by the HSE using the HSE JDC (JTAG Data Communication) module
  - Security modes as described in the security chapter
- Debugging and run control
  - Stop, start, break/watchpoints
  - Each Cortex A53 supports full six hardware breakpoints and four watchpoints
  - Each Cortex M7 supports eight instruction comparators and a watchpoint unit supporting four watchpoints
- Trace

Provided under NDA on behalf of NXP
COMPANY PROPRIETARY
Beijing CATI Automotive Technology Co., Ltd.
8c462e5-491-48a8-b251-390d5ab64d1

  - Trace data routed through funnels and replicators and output via one of following output streams:
    - Four lanes LVDS at 2.5 GHz to 5 GHz High Speed Serial Trace Port (HSSTP)
    - ETR to route data to system memory—this module connects to a port on NoC and allows writing data to system RAM or external DRAM
- Trace source
  - Cortex A53
    - ETM providing instruction trace
    - ITM, time-stamping and diagnostic information

NOTE

A53 ITM does not support global timestamp but a 21 bit local timestamp.

    - 16 KB + 16 KB local ETF RAM (8 KB for each A53 core)
  - Cortex M7
    - ETM-M7 providing instruction and data trace
    - ITM providing DWT, time-stamping, and diagnostic information
    - 8 KB local ETF RAM per M7 core
    - Trace output through the TPIU to the Aurora Trace Port, with 8 KB local ETF RAM per M7 core
  - NoC
    - Provides visibility of data transactions triggered by CPUs that do not support data trace and non-CPU masters
    - Provides trace capability of accesses to DDR memory
- Cross-triggering
  - Controls run-control of cores based on other cores (for example, breakpoint reached on Cortex-M7 can optionally halt execution of Cortex-A53 and vice versa)
  - Matrix includes connections to
    - All Cortex A53 CPUs
    - All Cortex M7 CPUs
    - NoC trace sources
- Ability to view and modify all memory-mapped areas that are not otherwise blocked
  - System bus debug access port
- Performance monitoring of cores
  - PMU implemented on each Cortex A53 core
- Safety
  - Supports monitoring of debug signals to avoid common mode faults
  - Allows checking of erroneous activation of debugging (especially if intrusive, for example a CPU entering debug state)
- Timestamps
  - Generates timestamp bus for distribution to the trace sources
  - 48-bit binary timestamp bus
  - Clocked by XBAR_CLK

Provided under NDA only

75.5 Debug

75.5.1 Test and Debug Access Port (TAP) connectivity

This device has two JTAG controllers sharing the common JTAG port of the device, Arm DAP's JTAG-DP and System JTAG Controller JTAGC. Both JTAG-DP and JTAGC have an IR length of eight and are connected to the JTAG port in an overlay scheme. The System JTAG Controller, JTAGC, also supports the device's test interface.

75.5.2 Debug Access Port (DAP) TAP

The Debug Access Port (DAP) is a standard Arm component. DAP provides multiple master driving ports, all accessible and controlled through a single external interface port, to provide system-wide debug.

DAP Instruction Register (DAP IR) overlays with the system JTAG controller IR (JTAGC IR). DAP instructions are listed in the following table. DAP uses five instructions, but because BYPASS is identical to the JTAGC BYPASS, it is not shown.

Table 605. Arm DAP IR codes

Code	DAP IR
1111_1000b	ABORT
1111_1010b	DPACC
1111_1011b	APACC
1111_1110b	IDCODE

DAP offers AXI, AHB, and APB master interfaces to access system buses. It also exports the internal DAP bus to extend the access ports. For more information on DAP TAP, see the Arm Debug Interface Architecture Specification (available in References) for details.

AXI AP provides the debugger access to all memory and registers in the system memory map. The XRDC controls system access. The APB_AP allows access to all CoreSight components except Cortex-M7 components.

A core can access the debug components of another core through a DAPMUX to the bus interconnect.

The exported DAP bus hosts AHB_AP (part of Cortex-M7) and the Miscellaneous Debug Module Access Port (MDM_AP). The MDM_AP hosts system level JTAG status and control registers (see MDM_AP register descriptions) which can be used for cross-triggering, synchronized debug, and other miscellaneous control and status functions.

For accessing any APB-mapped Debug modules, APB_AP uses an APSEL value of 1h. Table 609 and Table 610 describe the access addresses of APB-mapped Debug modules.

The value of DAP SELECT[APSEL], the SELECT register of SWJ-DP, selects the access ports in the DAP. APSEL decoding is shown in the following table.

Table 606. DAP APSEL decode

APSEL (SELECT[31:24])	APBIC base address (access from debugger)	System memory address (access from cores)	Selection	Identification register (IDR) value
00h	0000_0000h	51D0_0000h	AXI_AP to system bus	4477_0004h
01h	0100_0000h	51D0_0100h	APB_AP to all APB mapped Debug modules (for example Cortex-A53, watchpoints, trace funnels)	5477_0002h

Table continues on the next page...

75.5.3 System JTAG Controller (JTAGC)

The JTAGC connects in parallel with the Arm TAP controller (JTAG DP of Arm DAP). The IR length is 8-bits. The JTAGC IR codes overlay the Arm DAP controller IR codes. The DAP uses four instructions and the remaining are used by JTAGC. The outputs of the TAPs (TDO) are multiplexed based on the IR code selected. This chip is fully JTAG-compliant and appears to the JTAG chain as a single TAP.

The following table gives the IR codes for the JTAGC. The instructions used by Arm DAP TAP are shown in Table 605.

Table 607. JTAG instructions for JTAGC

Code	JTAGC IR
0000_0000b	IDCODE
0000_0001b	CENSOR_CTRL
0000_0010b	SAMPLE-PRELOAD
0000_0011b	SAMPLE

75.5.3.1 Chip JTAG ID

Each chip in the S32 family includes a unique JTAG ID. This includes changing of the JTAG ID when instantiated with different die in a System-In-a-Package (SIP). This following table shows the JTAGC ID for this chip.

Table 608. JTAG ID

Chip	Part revision number (PRN)	Design center (DC)	Part identification number (PIN)	Manufacturer identity code (MIC)	IDCODE ID	JTAG ID
S32G275A	0	20h (32d)	301h (769d)	Eh (14d)	1	1830_101Dh

75.5.3.2 JTAG Data Communication (JDC) module

JDC allows access to two 32-bit data registers by JTAG interface and by software running on one of the CPUs in the chip. These registers exchange data between an internal CPU and an external debug tool.

75.6 APB memory map

The debug registers are accessed via the APB-AP bus. The table below shows all the addresses for the CoreSight APB components. In addition, all APB registers are accessible from the processing cores (assuming access permission is enabled). This table also shows the addressing for accessing the DAP components via the memory interface.

Arm CoreSight APB_AP ROM auto-discovery method cannot be used for identifying the APB components in the system since some components, specifically the NoC does not provide the standard CoreSight component and peripheral ID register. For details, see following table.

NoC debug registers are reset by a destructive reset. However, they cannot be accessed while functional reset is asserted. In addition, trace packets cannot be accessed during functional reset.

Table 609. APB component mapping

Debug APB component		APBIC base address (access from debugger)	System memory map base address (access from cores)	Slot size	APB_AP0 slot number
	APB_AP ROM Table	F8h	510000F8h	4 KB	APBIC base

1. See the Accelerator subsection (if required).

For debug access, subtract 5100_0000h from the CPU system access register memory map addresses.

75.6.1 S32G accelerator debug APB memory map

This section describes the debug features implemented in the Accelerator portion of the MCU. The Accelerator consists of the Low Latency Communication Engine (LLCE), a second PCIe_1, and an Ethernet packet Forwarding Engine (PFE). The table below describes the address map of the additional modules.

Table 610. S32G accelerator APB component mapping

1. Access from cores.

75.7 Trace

75.7.1 Trace modules and connectivity

The trace subsystem combines trace data from all internal clients that generate trace information. The trace subsystem has a 32-bit TPIU.

The following figure shows the trace architecture.

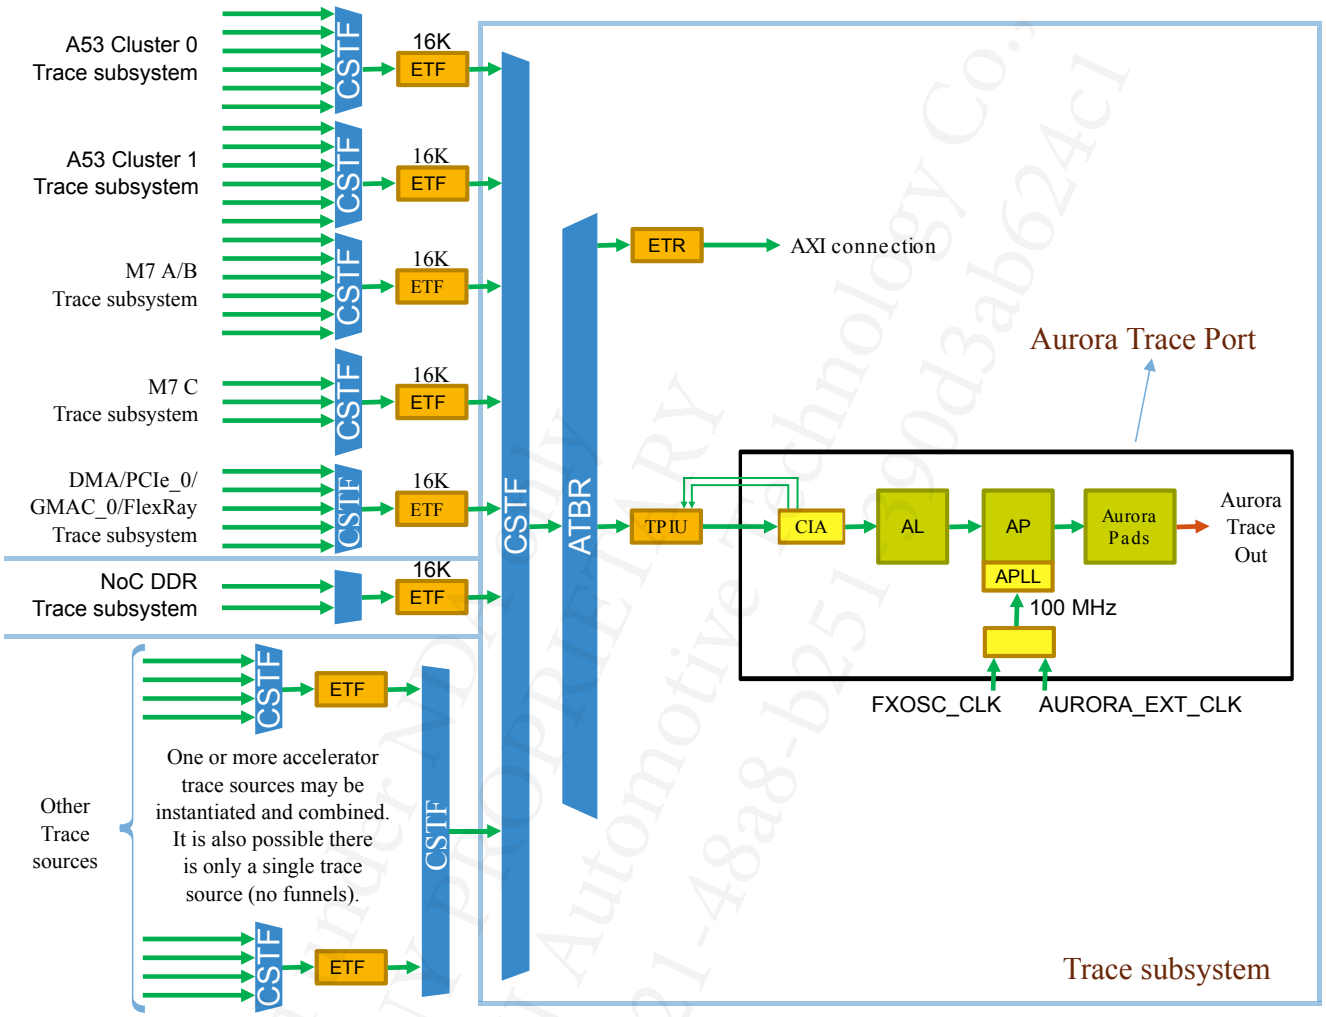

Figure 586. Trace bus connectivity

Table 611. Trace subsystem components

Component	Name
APLL	Aurora PLL
ATB	Advanced Trace Bus
ATBR	ATB Replicator
CIA	CoreSight Interface Adapter (CoreSight to Aurora Interface)
CSTF	CoreSight Trace Funnel

Table continues on the next page...

Table 611. Trace subsystem components (continued)

Component	Name
Debug APB	Debug Advanced Peripheral Bus
ETF	Embedded Trace FIFO
ETR	Embedded Trace Router
AL	Trace Aurora Link
AP	Trace Aurora Physical Interface
TPIU	Trace Port Interface Unit

Multiple options for trace output allow parallel tracing. The trace information can be read from the trace interface or the DAP interface. The traces can be alternatively read out from ETF at slow speeds via APB AP. Additionally, the trace can be written into system RAM via the ETR and you can read it later.

The sizes of the ETFs are shown in the following table.

Table 612. ETF sizes

ETF	Size
ETF 0	16 Kbytes
ETF1	16 Kbytes
ETF2	16 Kbytes
ETF3	16 Kbytes
ETF4	16 Kbytes
ETF5	16 Kbytes

The MDM_AP Control register implements bits to over-ride the speed control from some of the trace sinks (ETR, and TPIU). The complete trace pipeline bandwidth is limited by the slowest sink component. The default settings of these bits allow for maximum bandwidth for the TPIU to trace to the Aurora Trace Port (ATP). When tracing to memory (if supported), these bits may need to be changed.

Table 613. Trace output overrides

Trace destination	SWO_Override	ETR_Override	TPIU_Override
TPIU/Aurora	1	1	0
ETR to memory	1	0	1

The trace sources of the chip are the cores and their related modules. Trace information can be monitored in NoC for some master and slave interfaces. Trace funnels exist for all possible trace clients. For details of the various components in the trace bus connectivity, see the Arm CoreSight Components TRM (available in References) for details.

75.7.1.1 S32G accelerator trace modules and connectivity

Accelerator modules contain several trace sources. These include the NoC observers (discussed in the next section) and the LLCE HTM0 and HTM1 modules from LLCE. Description on the HTMs and the buses they monitor can be found in the LLCE chapter of the Reference Manual. All modules are configured via the debug APB interface using the base addresses defined in the memory map.

The following diagram shows the accelerator trace architecture.

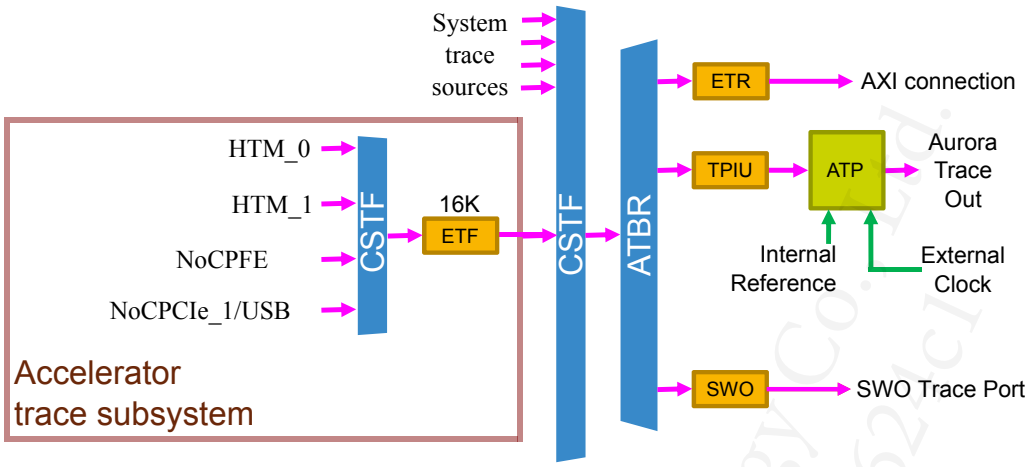

Figure 587. S32G accelerator trace architecture

75.7.2 Trace assignments

The embedded CoreSight Funnels (ETF) combine trace information from multiple clients into a single stream of trace data. The following table shows the CoreSight funnel input assignments.

Table 614. CoreSight funnel assignments

Instance name	Port assignment
Funnel0 (CSTF0)	s0: Cortex-A53a ETM0

75.7.2.1 S32G accelerator trace assignments

The S32G includes a single CoreSight Trace Funnel (CSTF) in the Accelerator debug circuitry. This funnel feeds an Embedded Trace FIFO (ETF) that connects to the system trace funnel. The trace clients are connected as shown in the following table.

Table 615. S32G accelerator trace funnels assignments

Instance name	Port assignment
ACCR_CSTF	s0: PCIe_1 NoC observer (PCIe_1 and USB)

75.8 Embedded Cross Trigger (ECT)

ECT allows for multicore run-control and trace cross-triggering, such as synchronous stop-start for all cores or trigger trace on a trigger event from another core or IP. See the *CoreSight Components Technical Reference Manual* (available in References) for detailed information on ECT.

ECT architecture involves CTMs and CTIs. The CTIs provide cross-triggering interface between the cores and other debug and trace modules. The channels of these CTIs are interconnected using CTMs, as shown in the following figure.

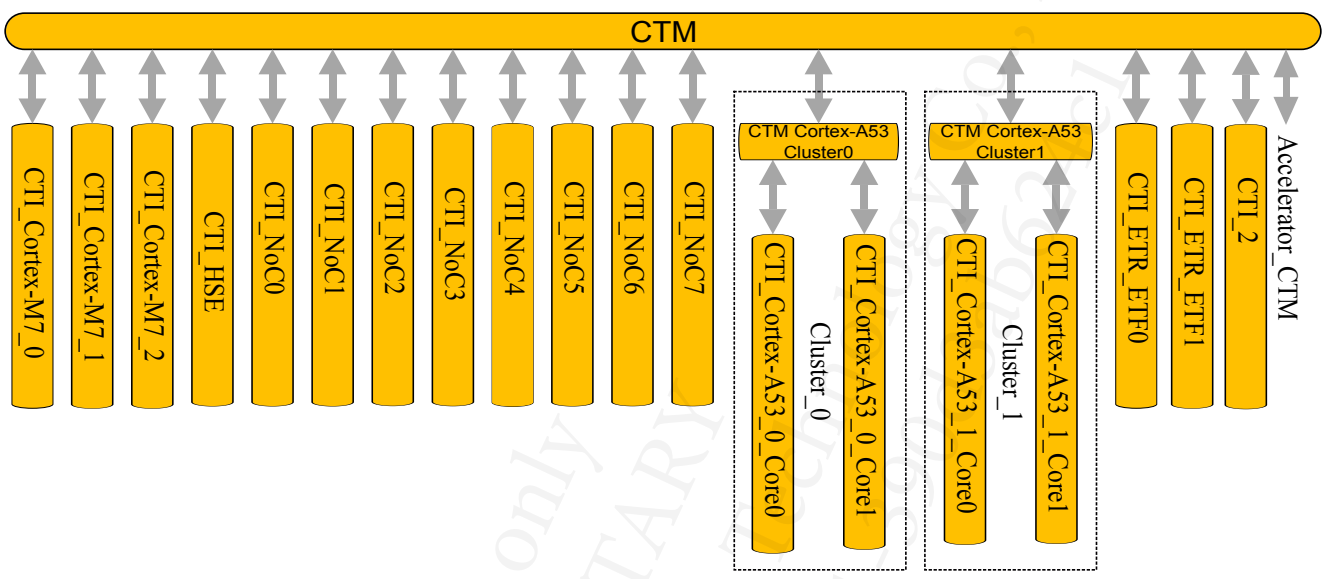

Figure 588. ECT

75.8.1 CTI assignments

The following table shows the connections of the CTI channels.

Table 616. CTI assignments

CTI instance	Trigger number	Trigger in	Trigger out
CTI_Cortex-M7_0	7	Cortex-M7_0 ETM event output3	Cortex-M7_0 processor restart
	6	Cortex-M7_0 ETM event output2	Cortex-M7_0 ETM event input3
	5	Cortex-M7_0 ETM event output1	Cortex-M7_0 ETM event input2
	4	Cortex-M7_0 ETM event output0	Cortex-M7_0 ETM event input1
	3	Cortex-M7_0 DWT comparator output2	Cortex-M7_0 ETM event input0
	2	Cortex-M7_0 DWT comparator output1	Cortex-M7_0 interrupt request 1
	1	Cortex-M7_0 DWT comparator output0	Cortex-M7_0 interrupt request 0
	0	Cortex-M7_0 processor halted	Cortex-M7_0 process debug request
CTI_Cortex-M7_1	7	Cortex-M7_1 ETM event output3	Cortex-M7_1 processor restart
	6	Cortex-M7_1 ETM event output2	Cortex-M7_1 ETM event input3
	5	Cortex-M7_1 ETM event output1	Cortex-M7_1 ETM event input2

75.8.1.1 S32G accelerator subsystem CTI assignments

Additional cross-triggering inputs and outputs are connected to the accelerator subsystem. These allow cross-triggering to/from the LLCE, USB trace, PCIe_1 trace, and the PFE trace clients. Each Probe in NoC provides up to eight Trigger Outputs (TrigOut) and provides eight Trigger Inputs (TrigIn), but only the two (Least Significant bits 1:0) are used. The others are not used or available.

75.9 NoC trace

The system NoC provides all bus interconnectivity between initiators (masters) and targets (slaves). Trace features implemented in NoC allow bus transactions to be observed. NoC contains probes that monitor the buses, and these probes feed data to an observer. NoC generates STPv2 messages and transports the messages on the Arm Trace Bus as 64-bit cells. Trace packets are compliant with the AMBA3 ATB Protocol Specification 1.0.

Two kinds of probes are implemented: packet probes (requesters and responders) and transaction probes. Packet probes have these features:

- Runtime programmable selection of packet probe points
- Runtime programmable filtering for packet tracing
  - Four filters available on each probe
- Recording of traffic and link statistics
- Event counting of signals external to NoC
  - Eight 16-bit counters on each probe

— Counters can be cascaded for additional range

- Generation of trace or statistic packets, or both, for the observation network
- 32 bytes of buffers on each probe
- Optional timestamping of packets
- Most probes support intrusive (stalls upstream processing to avoid overflows) and spy (do not stall, discards data to avoid overflows) modes, however, some probes support only spy mode (see table below)

The following figure shows the high-level hierarchy of the NoC observers.

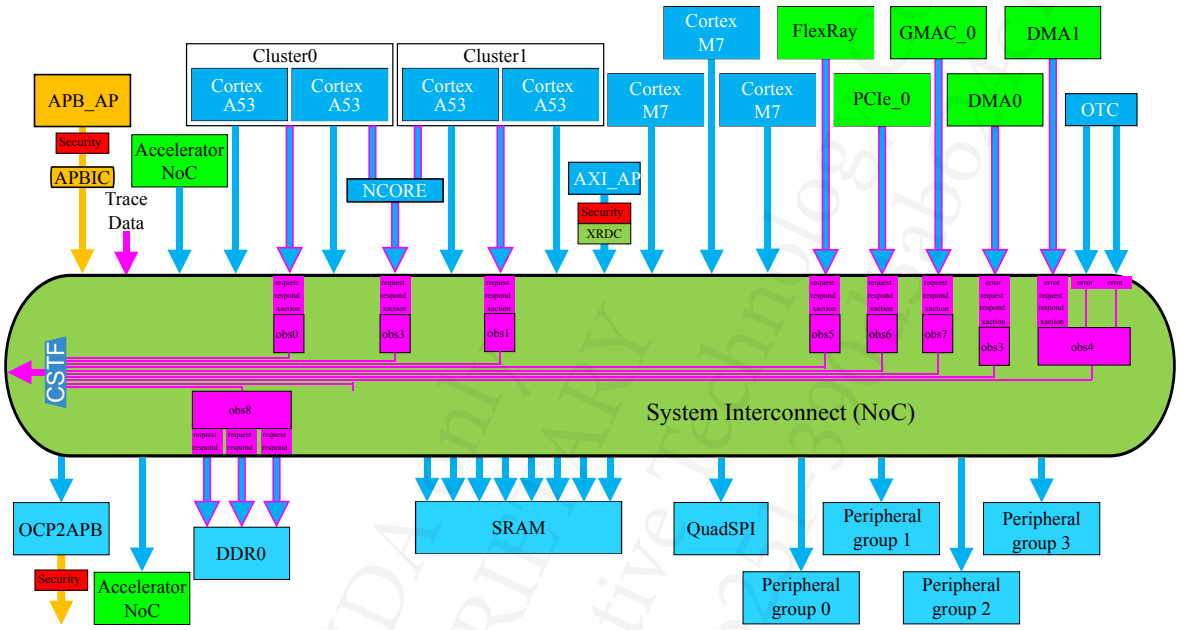

Figure 590. NoC connections

This figure also shows the points at which trace observers/probes can monitor the bus activities. The type of observability is shown in the following table.

Table 618. NoC observation network

Observer	Buffer size	Probe	Probe ID	Probe point	Probe type	Trace modes supported
A53 Cluster 0 non-coherent data access bus (Obs0)	256 bytes 4 packets	a53_cluster0_noncoh_req_probe	0	Data Request	Packet	Intrusive, Spy

m_pfe_HIF3				

The debug parameters for system NoC are provided in the following table.

Table 621. Debug parameters for system NoC

Probe	Type	Observer	Mode	Probe ID	# Filter	Allow filter on user	Allow filter on enabled bytes	Transaction profiling	Statistics collection	# Statistics counters
pcie_req_probe	packets	pcie	intrusive	0	2	True	True	False	True	8
pcie_resp_probe	packets	pcie	intrusive	1	2	True	True	False	True	8
ppfe_DDRreq_probe	packets	pcie	intrusive	2	2	True	True	False	True	8
pfe_DDRresp_probe	packets	pcie	intrusive	3	2	True	True	False	True	8
pfe_HIF02_req_probe	packets	pfe	intrusive	4	2	True	True	False	True	8
pfe_HIF02_resp_probe	packets	pfe	intrusive	5	2	True	True	False	True	8
pfe_HIF13Utilreq_probe	packets	pfe	intrusive	6	2	True	True	False	True	8
pfe_HIFT13Utilresp_probe	packets	pfe	intrusive	7	2	True	True	False	True	8
usb_probe	packets	pcie	spy	8	2	True	True	False	True	8

All probes are defined as packet probes except for the USB probe, which is defined as a spy probe. Each probe has four filters associated with them that can be used to filter when a trace packet is generated. All probes also include eight statistic counters that can be used to count various events and a 48-bit CoreSight timestamp. The debug registers to control the probes and observers are programmable via the accelerator NoC's m_debug_apb master port. Probes can be configured to be intrusive or non-intrusive. When intrusive mode is set to 1, no packets are dropped from trace. Back pressure will be applied on the functional data path if the trace FIFOs get full. If intrusive mode is set to 0, no back pressure is applied and it's then possible to lose trace data if the trace FIFOs get full. Details on the registers can be found in the NoC chapter.

The following diagram shows the connectivity between the probes and the observers.

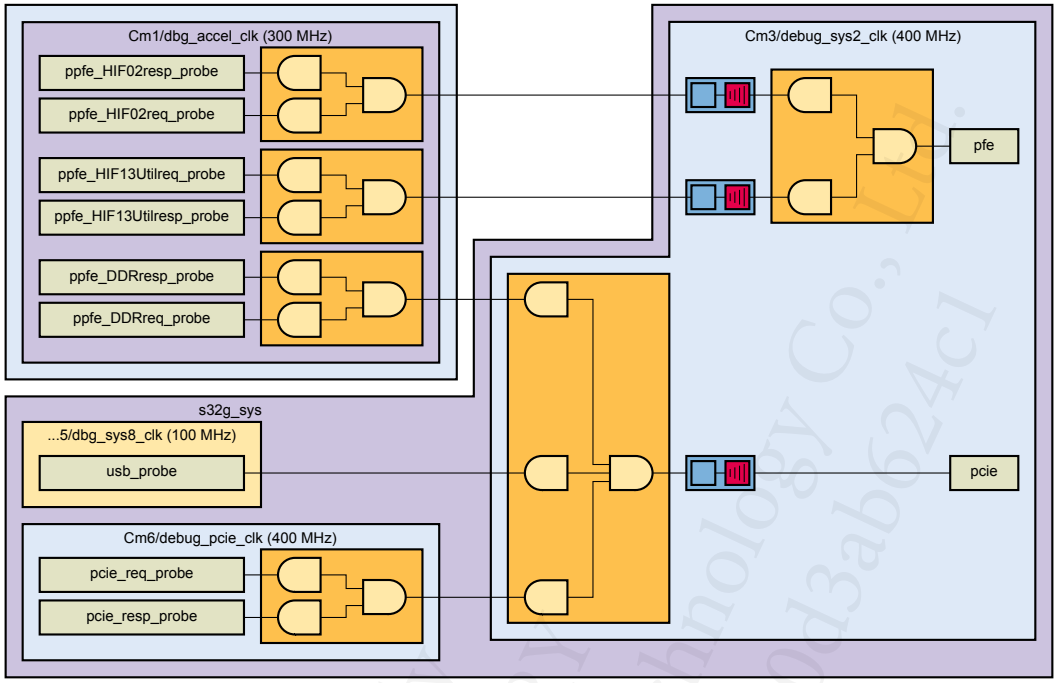

Figure 591. S32G accelerator NoC probe topology

NOTE

Probe buffers may overflow when setting "payload_en=1" and "intrusive_mode=0". When setting intrusive_mode to 1, buffers will not overflow, but backpressure will be applied to the data path so as not to lose trace information.

75.9.2 Observability

75.9.2.1 Concepts

The technology that allows activity within NoC interconnects to be observed and reported, provides the following services:

- Error detection, logging, and reporting
- Packet tracing
- Traffic or link statistics computation
- Transaction latency profiling
- Events or statistics reporting to the system via industry standard third-party interface, MIPI® STPv2 over the Arm® ATB Coresight™ trace interface

To provide these services, NoC technology uses task-specific probes placed on probe points located in the datapath topology. Traced packets and observed events are gathered by observers that can issue interrupts and forward detailed data to the supported third-party interfaces.

75.9.2.1.1 Packet and transaction probes

NoC packet probes provide the following features:

- Run-time programmable selection of packet probe points for probes connected to multiple points
- Run-time programmable filtering for packet tracing
- Recording of traffic and link statistics
- Event counting of signals external to NoC

- Generation of trace or statistic packets, or both, for the observation network
- Optional time stamping of packets

NoC transaction probes provide the following features:

- Run-time programmable selection of transaction probe points
- Transaction profiling in terms of latency or number of pending transactions
- Event counting of signals external to the NoC
- Generation of statistic packets for the observation network
- Optional time stamping of packets

NoC error probes detect packets in error and forward them to the associated observer via the observation network. The error packets are recorded by error loggers in the observer. An error logger can be programmed to assert an output signal when an error packet is received. The signal can be used as a system interrupt. Observers can contain one or more loggers and associated interrupt signals, each dedicated to specific error codes or error security levels.

By default, a new error can only be logged when the previous one is cleared by proper register access. If an error probe reports new errors and the associated logger is already full, then subsequent errors are dropped. Alternatively, the error logger can be programmed to queue up error packets and only accept them once the currently logged error has been cleared.

75.9.2.1.2 Observers

Data collected by the certain NoC probes can be transferred to NoC observer units via the observation network.

Observers can be connected to NoCs via an ATB™ interface, with MIPI STPv2 encapsulation and time stamping. Collected data can be forwarded either to an off-chip interface, or on-chip storage buffer for analysis by an on-chip debugger.

75.9.2.1.2.1 Time stamping probed events

The timestamp is added to the observation packet, regardless of whether the probe is configured for tracing or statistic collection.

The timestamp remains attached to the observation packet until the packet reaches the observer. This timestamp value is extracted and the difference between the current timestamp and the previous timestamp value, which was sent in the STPv2 stream, is calculated. This delta value is appended to the first STPv2 packet embedding the ATB packet.

75.9.2.2 Operation

75.9.2.2.1 Logging errors

75.9.2.2.1.1 Reconstructing transaction addresses

75.9.2.2.1.1.1 Calculating initiator – target transaction addresses

Once the initiator–target mapping associated with the logged packet has been identified, the complete transaction address, either from the perspective of the initiator or the target, can be calculated.

75.9.2.2.1.1.1.1 Initiator transaction address

From the perspective of the initiator, calculate InitAddr by:

```
InitAddr = Init localAddress | Addr
```

where:

- Addr – Logged packet transport address Addr given in register ErrLog3 and, additionally, ErrLog4, in the case where the address exceeds 32 bits
- Init localAddress – Value from the identified initiator-target mapping in subsection "Aperture values” of the structure information file

75.9.2.2.1.1.1.2 Target transaction address

The transaction address from the perspective of the target, calculate TargAddr by:

```
TargAddr = Targ localAddress | Addr
```

Where the definitions of the terms are the same as used for calculating the initiator transaction address (see Initiator transaction address).

75.9.2.2.2 Tracing packets

75.9.2.2.2.1 Basic packet tracing

To trace packets, the packet probe must be programmed as follows:

1. Set field TraceEn of register MainCtl to 1 to enable forwarding of traced packets to the connected observer. Optionally set field PayloadEn of register MainCtl to 1 if the packet payload should be included in the trace
2. Set register TracePortSel to the value corresponding to the probe point of interest
3. Set field GlobalEn of register CfgCtl to 1
4. Set register FilterLut to -1 (all bits set)

NOTE

A lookup table acts as a simple gate when there are no filters.

After competing the programming sequence above, filters must be configured (see Filtering packets).

75.9.2.2.2.2 Filtering packets

Each packet probe supports up to four packet filters.

The following list comprises the complete set of filter registers, where the value for filter *n* ranges from 0 to 3.

- Filters_N_RouteIdBase
- Filters_N_Status
- Filters_N_RouteIdMask
- Filters_N_Length
- Filters_N_AddrBase_Low
- Filters_N_Urgency
- Filters_N_AddrBase_High
- Filters_N_UserBase
- Filters_N_WindowSize
- Filters_N_UserMask
- Filters_N_UserBaseHigh
- Filters_N_UserMaskHigh
- Filters_N_Opcode

75.9.2.2.2.2.1 Filtering on an address range

Packets which target a given address range of a specific mapping may be filtered by programming the set of filter registers.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c12e5-4821-48a8-b231-39d3ab624c1

Table 622. Packet filtering registers

Register	Value
Filters_N_RouteIdBase	RouteId subfields Initflow, TargFlow, and TargSubRange.
Filters_N_RouteIdMask	Set bits to 1 if RouteId fields are to be used by filter.
Filters_N_AddrBase_Low/ High	Address offset from initiator or target local address.
Filters_N_WindowSize	Log_2 of address range.

75.9.2.2.2.2.2 Selecting packets based on packet opcode

Packets can be selected based on the opcode field (Opc) in the packet header using register Filters_N_Opcode. In the following example, the filter is required to select all packets with Opc equal to RD and all packets belonging to a locked sequence.

Program the register fields of Filters_N_Opcode as shown in Table 623.

Table 623. Packet filtering registers

Field name	Setting
RdEn	1
LockEn	1

The other register fields are set to 0. Figure 592 shows a sequence of packets with the resulting filter hits.

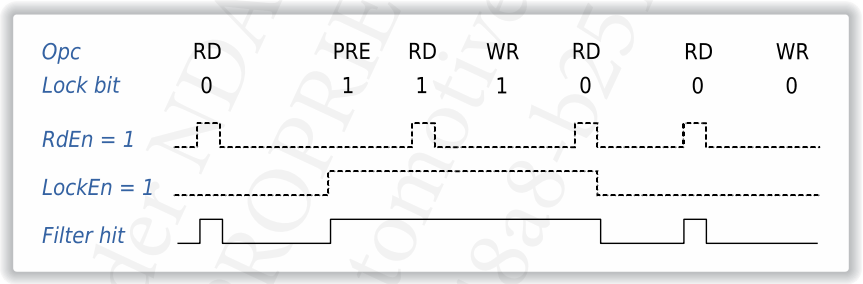

Figure 592. Sequence of packets

75.9.2.2.2.2.3 Excluding packet header fields from filter criteria

To ignore a specific packet header field in the filter, set its associated register with the value in shown Table 624.

Table 624. Excluding packet header field register settings

Register name	Setting
Filters_N_RouteIdMask	0
Filters_N_WindowSize	-1[1]
Filters_N_Opcode	Fh
Filters_N_Status	3h
Filters_N_Length	Fh

Table continues on the next page...

Table 624. Excluding packet header field register settings (continued)

Register name	Setting
Filters_N_Urgency	0
Filters_N_UserMask (if present)	0
Filters_N_UserMaskHigh (if present)	0

1. Setting register Filters_N_WindowSize to –1 programs the filter to accept packets which target anywhere in the full address range supported by the transport network. Hence the address is effectively excluded from the filter criteria.

75.9.2.2.2.2.4 Tracing all packets

If it is required to trace all packets, then the probe's filtering function must be programmed as follows:

1. Program one of the filters to accept all packet header field values. Set the filter registers to the values given in the table in the preceding section "Excluding packet header fields from filter criteria"
2. Program register FilterLut to select the output of filter programmed in the previous step

75.9.2.2.2.3 Tracing error packets

Error packets, that is packets with header field Status set to ERR, are not traced by default. To include error packets in the trace output, write MainCtl[ErrEn] = 1 and MainCtl[ErrEn] = 1.

75.9.2.2.2.4 Combining filters

A look-up table (LUT) is instantiated in the probe, which allows a hit to be generated on any logical combination of packet filters. The logic function is programmed via register FilterLut. The value programmed in the register corresponds to the truth table applied on the filter outputs.

For example, with two filters F0 and F1, sixteen possible functions can be defined, a subset of which is shown in the following table.

Table 625. Example subset of sixteen possible functions

Filter hit			Required filter combination					
F1	F0		F0	F1	F1 & F0	F1 | F0	F1 ^ F0	~F0
0	**0**		0	0	0	0	0	1
0	**1**		1	0	0	1	1	0
1	**0**		0	1	0	1	1	1
1	**1**		1	1	1	1	0	0
			Value to program in FilterLut					
			Ah	Ch	8h	Eh	6h	5h

NOTE

In this example, setting register FilterLut to Fh will generate a LUT hit for any combination of filter hits, effectively bypassing the filters.

75.9.2.2.2.5 Configuring and managing trace alarm events

Trace alarm events can be separately enabled, recorded, and cleared using registers TraceAlarmEn, TraceAlarmStatus, and TraceAlarmClr respectively. In each register, a dedicated bit is associated with each filter hit; the MSB is associated with the LUT hit.

The trace alarm logic can be configured to drive output signal TraceAlarm if one or more trace alarm events are recorded in register TraceAlarmStatus. Signal TraceAlarm can be used directly as an interrupt source, or can be routed through a sideband manager.

To use the trace alarm feature:

1. Enable hits from selected filters 0 to (nFilter – 1) to generate a trace alarm by setting register TraceAlarmEn bits 0 to (nFilter – 1) to 1.
   - Optionally, enable LUT hits to generate a trace alarm by setting the MSB of TraceAlarmEn.
2. Set field AlarmEn to 1 in register MainCtl in order to activate signal TraceAlarm when a trace alarm occurs.

If TraceAlarm is asserted, the interrupt service routine should:

1. Identify the source or sources of the trace alarm by reading register TraceAlarmStatus.
2. Clear the source or sources of the trace alarm by setting the corresponding bits to 1 in register TraceAlarmClr. Signal TraceAlarm deasserts when all bits in TraceAlarmStatus have been cleared.

75.9.2.2.3 Collecting statistics

75.9.2.2.3.1 Counting packets over fixed period

The following programming sequence counts packets at a given probe point using statistic counter 0:

1. Set field StatEn to 1 in register MainCtl
2. Set register Counters_0_PortSel to the value corresponding to the probe point of interest
3. Set register Counters_0_Src to 6h (PKT) to count packets
4. Specify the period during which the packets should be counted by setting register StatPeriod to: log2 (interval expressed in number of probe clock cycles)
5. Set field GlobalEn of register CfgCtl to 1 to enable packet counting

Once time $2^{StatPeriod}$ has elapsed, the number of packets counted is dumped to the observer.

75.9.2.2.3.2 Counting filtered packets over fixed period

The following programming sequence counts hits from packet filter 2 using statistic counter 0:

NOTE

The important distinction between this sequence and the one in a related programming example (see Counting packets over fixed period) is that the probe port is selected using register TracePortSel rather than Counters_0_PortSel

1. Set field StatEn to 1 in register MainCtl
2. Set register TracePortSel to the value corresponding to the probe port of interest
3. Set register Counters_0_Src to 0xE (FILT2) to count packets from filter 2
4. Specify the period during which the packets should be counted by setting register StatPeriod to: log2(interval expressed in number of probe clock cycles)
5. Set field GlobalEn of register CfgCtl to 1 to enable packet counting

Once time $2^{StatPeriod}$ has elapsed, the number of filtered packets counted is dumped to the observer.

75.9.2.2.4 Transaction profiling operation

The programming sequence examples in this section constitute, for a given category of use cases, the obligatory base from which to develop sequences to handle specific needs within the category.

75.9.2.2.4.1 Measuring latency

The following example of a run-time programming sequence shows how a transaction probe can be used to measure transaction latency.

The measurement specification is:

- For init0, monitor delays for read transactions only
- For init1, monitor delays for read and write transactions

75.9.2.2.4.2 Programming the packet probe statistics subsystem

The statistics counters in the packet probe unit of the transaction probe must be programmed to count the delay events recorded by the transaction profiler unit.

1. Map the five delay event bins, associated with transactions issued by init0, from the transaction profiler unit to statistics counters in the packet probe unit by programming the following registers:
   - Counters_0_Src = 20h => Counts the number of transactions from init0 with a delay between 0 and 1
   - Counters_1_Src = 21h => Counts the number of transactions from init0 with a delay between 2 and 4
   - Counters_2_Src = 22h => Counts the number of transactions from init0 with a delay between 5 and 9
   - Counters_3_Src = 23h => Counts the number of transactions from init0 with a delay between 10 and 99
   - Counters_4_Src = 24h => Counts the number of transactions from init0 with a delay greater than 100
2. Map the five delay event bins, associated with transactions issued by init1, from the transaction profiler unit to statistics counters in the packet probe unit by programming the following registers:
   - Counters_5_Src = 25h => Counts the number of transactions from init1 with a delay between 0 and 1
   - Counters_6_Src = 26h => Counts the number of transactions from init1 with a delay between 2 and 4
   - Counters_7_Src = 27h => Counts the number of transactions from init1 with a delay between 5 and 9
   - Counters_8_Src = 28h => Counts the number of transactions from init1 with a delay between 10 and 99
   - Counters_9_Src = 29h => Counts the number of transactions from init1 with a delay greater than 100
3. Set register StatPeriod to $\log_2$(period), that is, the period during which delay events should be counted before being sent to the observer
4. Set field StatEn of register MainCtl to 1 to enable the statistics counters to count delay events

75.9.2.2.4.3 Enabling the transaction probe

1. Set field GlobalEn of register CfgCtl to 1 to enable the statistics counters
2. Set register En to 1 to enable the transaction profiling counters

75.9.2.2.4.4 Programming the init0 NIU transaction filter

1. Set register Mode to 1 to set the delay mode to latency
2. Set field RdEn of register Opcode to 1 to monitor read transactions only

75.9.2.2.4.5 Programming the init1 NIU transaction filter

1. Set register Mode to 1 to set the delay mode to latency
2. Set fields RdEn and WrEn of register Opcode both to 1 to monitor read and write transactions

75.9.2.2.5 Activating observer debug output

75.9.2.2.5.1 STPv2 interface

The observers generate STPv2 formatted trace packets. To enable trace output, the following registers must be programmed.

1. Specify the required period between STP synchronization sequences in register AsyncPeriod. Ensure that the value of AsyncPeriod is large enough to allow STPv2 cells, encapsulating Trace / Statistic Packets, to be inserted in between STPv2 synchronization sequences
2. Ensure that register STPv2En is set to 1 to enable the STPv2 interface
3. Set register AtbId to a value that is unique not only within the NoC but also within the debug system
4. Set register AtbEn to 1 to enable the ATB function

75.9.2.3 Technical reference

NoC observability technology comprises two principle components: observation probes and observer units.

The section provides detailed technical reference information for these components, along with the NoC packet format description needed to analyze error logs and packet trace information.

75.9.2.3.1 Observation probes

This section provides the detailed technical reference information for the NoC Observability technology collectively called observation probe units.

75.9.2.3.1.1 Packet probe

The NoC packet probe unit collects trace and statistics data. The unit can be used in conjunction with the NoC transaction profiler unit to create a transaction probe.

75.9.2.3.1.1.1 Packet probe features

The unit has the following main features:

- Support for any transport packet format and serialization
- Trace mode with programmable packet filters
- Optional packet payload tracing
- Programmable flow-control modes: Overflow Management and Intrusive
- Statistics can be collected and sent to an observer either periodically or after manual triggering
- Alarms on both trace filters and statistics counters
- Optional time stamping of probed events

75.9.2.3.1.2 Overflow flow-control for tracing

When not using Intrusive Mode (see register field IntrusiveMode of register MainCtl), an overflow packet is added after the stalled packet(s), which reports how many observation packets have been lost.

This Overflow packet has the following format:

- Opc = WR, Status = ERR

- Debug = (probeId, Urgency= 0, Mod=1)
- RouteId = RouteID of the packet that triggered the overflow
- Addr[8:0] = number of lost or uncompleted observation packets, minus one
- Len: 0 if no payload lost; 1 otherwise
- Lock = Addr[8:0] = Security = User = 0

In case of payload overflow, the current packet is completed according to its type; then an overflow packet is also sent:

- Write request packets are fully completed with the correct number of words, all having null Data and BE
- A single data word with null data that terminates the tracing of the read payload for that transaction completes Read response and Read continuous packets

75.9.2.3.1.3 Transaction filter

The NoC transaction filter unit uses programmable criteria to select request and response events.

The unit is integrated into the NIU and is connected to the NIU generic-to-transport unit. More than one transaction filter can be connected to a NoC transaction profiler unit.

75.9.2.3.1.4 Transaction profiler

The NoC transaction profiler unit receives events from one or more transaction filters and organizes them into histogram bins, defined by programmable thresholds.

The unit is connected to a standard Packet Probe via the unit external event input ports.

75.9.2.3.2 Observers

This section provides detailed technical reference information for the NoC Observability technology Observer unit.

75.9.2.3.2.1 Error logging

Errors that occur in packets observed by probes can be logged.

75.9.2.3.2.1.1 Features

- Error filtering can be based on selected error codes, user and security flags and sideband signals
- An optional fault interrupt can be asserted on an error
- Can be used in conjunction with trace probe filtering to monitor a specific port

75.9.2.3.2.1.2 NoC error codes

The following table lists all error codes that are relevant to NoC interconnect operation.

Table 626. NoC error codes

Code	Value	Source	Type
SLV	0	Target	Target error detected by slave
DEC	1	Initiator NIU	Address decode error
UNS	2	Target NIU	Unsupported request
DISC	3	Power disconnect	Disconnected target or domain

Table continues on the next page...

Table 626. NoC error codes (continued)

Code	Value	Source	Type
SEC	4	Initiator NIU or firewall	Security violation
HIDE	5	Firewall	Hidden security violation, reported as ok to initiator
TMO	6	Target NIU	Timeout
RSV	7	None	Reserved

75.9.2.3.2.2 STPv2 stream generation

The NoC STPv2 adapter in the observer encapsulates ATB packets and generates synchronization sequences to provide a MIPI-STPv2 compliant STP stream. Time stamps can optionally be included in the stream.

75.9.2.3.2.2.1 Features

- Compliant with AMBA®-3 ATB and MIPI® STPv2 specifications
- Supports ATB data widths from 8 to 64 bits
- Supports STPv2 opcodes ASYNC, VERSION, NULL, NULL_TS, D64, D64MTS, and MERR
- Synchronization sequence generation with optional time stamp
- Encapsulation of probe time stamps
- Supports all time stamp length encodings

NOTE

For details, see MIPI® Alliance Specification for System Trace Protocol (STP), version 2.00.01, 24 February 2010.-STPv2 specification.

75.9.2.3.2.2.2 Synchronization sequence generation

The synchronization sequence permits the SoC debug system to identify the STPv2 packet boundary. A time stamp can be optionally inserted in the sequence to which the SoC debug system may resynchronize itself.

The synchronization sequence is sent when one of the following events occurs:

- After a reset
- On the rising edge of input signal SyncReq
- When the number of clock cycles since the last synchronization sequence is between 2AsyncPeriod and 223 inclusive, and register AsyncPeriod is greater than 0

NOTE

The synchronization sequences are inserted instead of ATB synchronization cells.

The STPv2 adapter can issue synchronization sequences either with or without time stamps. The examples in figures that follow are represented according to the following key.

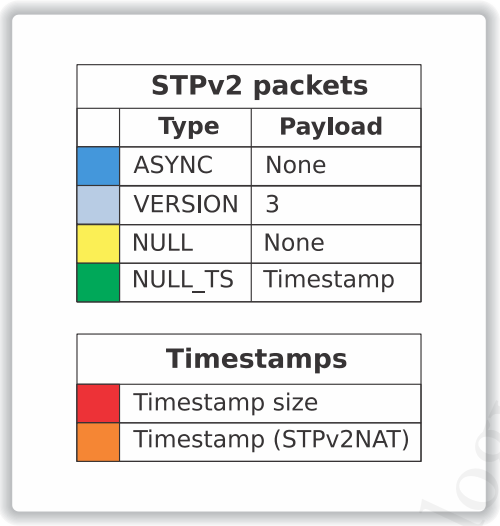

Figure 593. STPv2 synchronization sequence key

75.9.2.3.2.2.2.1 STPv2 synchronization sequence without timestamp

Synchronization sequences are sent without a timestamp when the observer STPv2 parameter wTimeStamp is set to 0. In this case, the sequence comprises the STPv2 packets ASYNC and VERSION, as well as NULL packets for padding. Such a sequence is shown in the following figure.

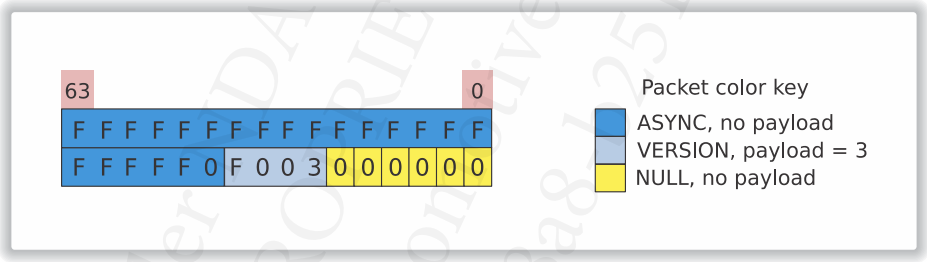

Figure 594. STPv2 synchronization sequence without timestamp

NOTE

The sequence in the figure assumes a data width of 64 for the ATB debug port, as set by parameter wData (Specification: Interface: Observation: debugOutput).

75.9.2.3.2.2.2.2 STPv2 synchronization sequence with timestamp

If wTimeStamp is greater than zero, synchronization sequences are sent with time stamps. The sequence comprises the STPv2 packets ASYNC, VERSION, NULL, and NULL_TS. The time stamp value, received on observer input signal TimeStamp and extended to 64 bits, is sent in the payload of NULL_TS.

The synchronization sequence with time stamp is shown in the following figure.

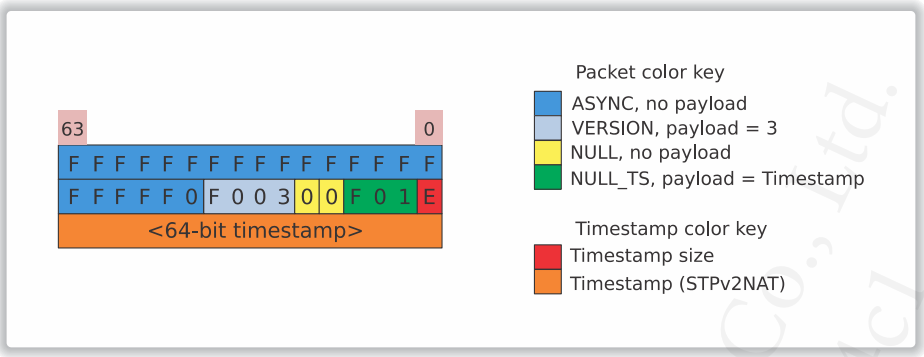

Figure 595. STPv2 synchronization sequence with timestamp

In the figure:

- Regardless of the width of the time stamp, specified by wTimeStamp, the time stamp is extended to 64 bits
- All 16 nibbles of the time stamp are significant, indicated by the time stamp size nibble being set to Eh
- The protocol version is set to 3 in the payload of packet VERSION. This indicates that the time stamp is encoded using the uncompressed STPv2NAT format

75.9.2.3.2.2.3 Encapsulation of ATB packets

The STPv2 adapter encapsulates 64–bit ATB cells into the payload of 64–bit STPv2 data packets. The first ATB cell of an observation packet is encapsulated into a D64MTS STPv2 packet; D64 STPv2 packets are used for subsequent cells of the same observation packet. If observer parameter wTimeStamp is set to a value greater than 0, a Timestamp Size nibble and the time stamp are appended to the D64MTS packet. If wTimeStamp is 0, only the Timestamp Size nibble, set to a value of 0, is appended.

If an overflow packet is received by the observer, an MERR STPv2 packet is sent, indicating an STPv2 master error, prior to the encapsulation of the probed data into D64MTS and D64 packets.

75.9.2.3.2.2.3.1 Timestamp compression

When wTimeStamp is greater than 0, the number of bits sent in the Timestamp field of D64MTS packets depends on the difference between the time stamp from the current observation packet and the previous time stamp value sent in the STPv2 stream. The previous time stamp may be either itself the time stamp of the previous observation packet or the absolute time stamp sent in an STPv2 synchronization sequence.

Only nibbles which are different between the current and previous time stamps are sent, left-aligned, in the Timestamp field of the D64MTS packet. The field is preceded by a Timestamp Size nibble, which indicates the field size, in nibbles. The encoding of TimeStamp Size is defined in Section 7.2 of MIPI STP specification version 2.00.01.

The following table shows several examples of time stamp compression values.

Table 627. Timestamp compression values

Timestamp value		STP timestampe	
Previous	Current	Timpstamp size	Compressed timestamp
0000_0000_1111_2222h	0000_0000_1111_2222h	0	—
0000_0000_1111_2222h	0000_0000_1111_2234h	2	34h
0000_0000_1234_5678h	0000_0000_1254_5601h	6	545601h
0123_0000_0000_0000h	0226_0000_0002_0030h	16[1]	0226_0000_0002_0030h
0000_0000_0012_3459h	0000_0000_0012_3457h	1	7h[2]

1. The Timestamp Size nibble is encoded for 16 nibbles even though only 15 nibbles are different because there is no encoding for 15 (see MIPI STP specification).
2. It is possible for the time stamp value of the packet being processed to be less than the time stamp of the previous packet. This can occur if an observation packet, which has an earlier time stamp than a packet from another probe, is delayed due to buffering in the observation network.

75.9.2.3.2.3 Observer registers

Observer functions, such as error logging, ATB formatting, and STPv2 encapsulation, are run-time programmable via registers. For a given function, in addition to the specific registers for that function, the register set includes standard identification registers.

See APB memory map.

See "Memory maps/register definitions" in this document for reset values of registers.

75.9.2.3.2.3.1 Error logging registers

Registers related to error logging are summarized in the following table.

Address offset	Name	Type	Retention
0008h	FaultEn	Control	Yes
000Ch	ErrVld	Status	No
0010h	ErrClr	Pulse	No
0014h	ErrLog0	Status	No
0018h	ErrLog1	Status	No
001Ch	ErrLog2	Status	No
0020h	ErrLog3	Status	No
0024h	ErrLog4	Status	No
0028h	ErrLog5	Status	No
002Ch	ErrLog6	Status	No
0030h	ErrLog7	Status	No
0034h	ErrLog8	Status	No
0038h	StallEn	Control	Yes

75.9.2.3.2.3.1.1 FaultEn

When 1-bit register FaultEn is set to 1, error reporting signal Fault is enabled and asserted when register ErrVld is 1. When FaultEn is cleared to 0, signal Fault is driven to 0.

- Bit – (0)

Related signals:

- Fault

75.9.2.3.2.3.1.2 ErrVld

Register ErrVld indicates that the ErrLog registers contain valid error information.

- Bit – (0)

75.9.2.3.2.3.1.3 ErrLog0

Register ErrLog0 logs fields from the NoC packet transport protocol header of the logged packet.

The MSB field indicates the transport protocol version number.

The following table shows the field assignments. All other bits are reserved and read as 0.

Table 628. ErrLog0 field assignments

Bit range	Field name	Type	Access
0	Lock	Status	Read only
4:1	Opc	Status	Read only
10:8	ErrCode	Status	Read only
27:16	Len	Status	Read only
31	Format	Status	Read only

75.9.2.3.2.3.1.3.1 Lock

Register field Lock contains the packet header bit Lock.

75.9.2.3.2.3.1.3.2 Opc

Register field Opc contains the packet header field Opc.

75.9.2.3.2.3.1.3.3 Len1

Register field Len1 contains the packet header field Len1.

75.9.2.3.2.3.1.3.4 ErrCode

Register field ErrCode contains the packet header field ErrCode.

If the packet field does not exist, the register field contains 0.

75.9.2.3.2.3.1.3.5 Format

Register field Format specifies the version of the NoC packet transport protocol.

75.9.2.3.2.3.1.4 ErrLog1

Register Errlog1 contains the least significant part of the NoC packet transport protocol packet header field RouteId of the logged error. Up to 32 bits will be stored, depending on the width of RouteId. The field is right-aligned in the register, and unused bits are read as 0.

The RouteId value can be used to identify the initiator–target mapping associated with the logged error, in order to calculate the complete address.

When decoding RouteId sub-field SeqId, bit index 0 corresponds to the value for packet header field Opc when:

- The transaction comes from an interface with a protocol, such as AHB, AXI, or AMBA, that allows response disorder based on transaction opcodes.
- The NoC supports other interface protocols that do not.

A description of the sub-fields comprising RouteId is provided in related reference documentation.

- Type – Status

75.9.2.3.2.3.1.5 ErrLog2

Provided under NDA only
COMPANY PROPRIETARY
Beijing CIU Automotive Technology Co., Ltd.
c8c2e2c2-482-48a8-b251-390d3ab624c1

Register Errlog2 contains the most significant part of the NoC packet transport protocol packet header field RouteId of the logged error. Up to 16 MSBs of RouteId are stored, depending on the width of RouteId. The field is right-aligned in the register, and unused bits are read as 0.

The RouteId value can be used to identify the initiator–target mapping associated with the logged error, in order to calculate the complete address.

A description of the sub-fields comprising RouteId is provided in related reference documentation.

This register is only present if the width of RouteId is greater than 32 bits.

- Type – Status

75.9.2.3.2.3.1.6 ErrLog3

Register Errlog3 contains the least significant part of the NoC packet transport protocol packet header field Addr of the logged error. Up to 32 bits will be stored, depending on the width of Addr. The field is right-aligned in the register and unused bits are read as 0.

Because ErrLog3 only contains the transport address offset within the particular mapped region, its value must be used in conjunction with the local addresses of the initiator–target mapping, in order to reconstitute the complete transaction address. The mapping is identified using RouteId, logged in ErrLog1 and optionally ErrLog2.

75.9.2.3.2.3.1.7 ErrLog4

Register Errlog4 contains the most significant part of the NoC packet transport protocol packet header field Addr of the logged error. Up to 16 MSBs of Addr are stored, depending on the width of Addr. The field is right-aligned in the register and unused bits are read as 0.

Because ErrLog4 only contains the transport address offset within the particular mapped region, its value, concatenated with ErrLog3, must be used in conjunction with the local addresses of the initiator–target mapping in order to reconstitute the complete transaction address. The mapping is identified using RouteId, logged in ErrLog1, and optionally, ErrLog2.

This register is only present if the width of Addr is greater than 32 bits.

75.9.2.3.2.3.1.8 ErrLog5

Register Errlog5 contains the least significant part of the NoC packet transport protocol packet header field User of the logged error.

Up to 32 bits will be stored, depending on the width of User. The field is right-aligned in the register, and unused bits are read as 0.

75.9.2.3.2.3.1.9 ErrLog6

Register Errlog6 contains the midrange part of field User contained in the packet header of the packet transport protocol. Bit User (32) up to bit User (63) will be stored, depending on the width of User. The field is right-aligned in the register, and unused bits are read as 0.

The register is present only if the width of User is greater than 32 bits.

75.9.2.3.2.3.1.10 ErrLog7

Register Errlog7 contains the NoC packet transport protocol packet header field Security of the logged error. The field is right-aligned in the register and unused bits are read as 0.

75.9.2.3.2.3.1.11 ErrLog8

Register Errlog8 contains the most significant part of the NoC packet transport protocol packet header field User of the logged error. Bits User(64) up to User(95) are stored, depending on the width of User. The field is right-aligned in the register, and unused bits are read as 0.

The register is present only if the width of User is greater than 64 bits.

75.9.2.3.2.3.1.12 StallEn

Register StallEn controls the stall mode of the NoC error logger.

When set to 1, error packets (status = ERR) are stalled, that is, queued at the input to the error logger. The packets are only passed into the error logger once the currently logged error packet has been cleared by setting register ErrClr to 1.

When set to 0, only the first error packet is stored in the error logger. Subsequent error packets are lost.

NOTE

The number of error packets which may be queued is 4.

75.9.2.3.2.3.2 ATB endpoints registers

Registers which are used to control the ATB endpoint are summarized in the following table.

Address offset	Name	Type	Retention	Width
0008h	AtbId	Control	Yes	7 bits
000Ch	AtbEn	Control	Yes	1 bit
0010h	SyncPeriod	Control	Yes	3 bits (4:0)

75.9.2.3.2.3.2.1 AtbId

Register AtbId sets the ATB identifier of the observer. The identifier is carried on signal ATId.

Each observer within the NoC must have a unique ID value. The value is used along with probe IDs to identify probes.

NOTE

Values 00h and 70h to 7Fh are reserved for Arm® CoreSight™ debug systems.

75.9.2.3.2.3.2.2 AtbEn

When AtbEn = 1, register AtbEn enables ATB output.

NOTE

Writing AtbEn = 0 is equivalent to a power disconnect on the affected socket: the current transmission of an ATB packet is completed before the ATB output is disabled.

75.9.2.3.2.3.2.3 SyncPeriod

Register SyncPeriod sets the period, in terms of the number of ATB cells sent, between insertion of ATB synchronization cells.

The following table summarizes the relationship between SyncPeriod and the delay between synchronization cells.

Table 629. SyncPeriod and delay between synchronization cells

SyncPeriod value	Period of sync cell insertion
0	No sync cell insertion
1...2	8
3...22	$2^{(SyncPeriod + 1)}$
23...31	Not supported

SyncPeriod is not present when setting parameter debugOutput of the observer to STPv2, since ATB synchronization cells are not generated when using the STPv2 adapter.

75.9.2.3.2.3.3 STPv2 encapsulation registers

Registers relative to STPv2 encapsulation are summarized in the following table.

Address offset	Name	Type	Retention	Width
0008h	AsyncPeriod	Control	Yes	5 bits (4:0)
000Ch	STPv2En	Control	Yes	1 bit (bit 0)

SyncPeriod is not present when setting parameter debugOutput of the observer to STPv2, since ATB synchronization cells are not generated when using the STPv2 adapter.

75.9.2.3.2.3.3.1 AsyncPeriod

Register AsyncPeriod defines the period, in observer clock cycles, between transmission of STPv2 synchronization sequences.

The following table summarizes the relationship between AsyncPeriod and the delay between synchronization sequences.

Table 630. AsyncPeriod and delay between synchronization cells

AsyncPeriod value	Period between synchronization sequences
0	No sync sequence inserted due to AsyncPeriod
1...22	$2^{(SyncPeriod + 1)}$
23...31	2^{23}

SyncPeriod is not present when setting parameter debugOutput of the observer to STPv2, since ATB synchronization cells are not generated when using the STPv2 adapter.

75.9.2.3.2.3.3.2 STPV2En

When STPV2En = 1, register STPV2En enables the STPv2 output.

When STPV2En = 0, the observer debug interface is disabled: neither STPv2 packets nor synchronization sequences are sent.

By default, the reset value is 1 so that STPv2 stream generation is enabled. If it should be enabled explicitly by software, the reset value can be changed to 0 by setting its parameter rstVal (Structure: Parameters: Control Setting).

NOTE

Writing STPv2En =0 has an equivalent effect to a power disconnect on this interface: the STPv2 encapsulation and transmission of an ATB packet will be completed before the observer debug output is disabled.

75.10 Debug and trace under functional reset

Cores Cortex-M7_0, Cortex-M7_1, Cortex-M7_2 and Cortex-M7_HSE under main reset domain support debug and trace over Functional reset.

Cores Cortex-A53_A0, Cortex-A53_A1, Cortex-A53_B0, and Cortex-A53_B1 which are under software resettable domain support retention of debug and trace configuration over functional reset. This is achieved only when Bit[7] (DBG_RST_MSK_0a) of the DEBUG_CONTROL register (see the SRC chapter for details) is set before giving functional reset to the chip. This bit masks debug resets of the cores from functional reset imitating *Cluster cold reset with debug active* as per Cortex A53 Technical Reference Manual (available in References).

Bit DBG_RST_MSK_0a must only be set after enabling Cortex-A53 partition (See "Software Reset Partition Turn-On Flow Chart" in Reset chapter for details).

Under functional reset, trace from Cortex-A53 cores are not available.

NOC probes and observers support only retention of debug configurations under functional reset.

The LLCE's M0-3 cores support debug and trace over functional reset by asserting Bit[8] (DBG_RST_MSK_1a) of the DEBUG_CONTROL register. The CoreSight AHB_APs are on the destructive reset and thus not cleared by a functional reset.

Also, the accelerator related CoreSight debug components (accelerator CTIs, ETF, etc) are on the destructive reset and thus will not be affected by a functional reset. Likewise, the accelerator NoC debug and QoS registers will have their values retained during a functional reset and can only be cleared by a software write to each register or a destructive reset event.

NOTE

Note only debug register access is allowed while functional reset is asserted, trace is not available.

75.11 MDM_AP register descriptions

The debugger has access to the status and control elements implemented as registers in MDM_AP. APSEL (6h) selects the MDM_AP on the Debug Access Port (DAP). These registers provide additional control and status information for typical debug, cross-triggering, and run-control scenarios. The status register fields also provide a way for the debugger to get the updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

The MDM_AP is accessible as Debug Access Port (see Debug Access Port (DAP) TAP). The MDM_AP registers are listed in the following table and detailed information about the registers is provided in the following sections.

Certain modules have a Debug mode (IPG DEBUG) that freezes the module when the cores enter Debug mode. If you want to detach dependency of a particular core's Debug mode on entry of modules into Debug mode, then you must write a 1 to the corresponding Cortex_**n**_IP_DBGDIS field in MDM_AP IP_DBG registers. MDM_AP IP_DBG register pertains to Cortex_**n**_IP_DBG registers in memory map. The following table shows the modules that depend on the core's debug state.

Table 631. Dependency of modules on the core's debug

Module	Affected by

CONTROL	4h

Function

A system destructive reset in this register allows the debugger to give the destructive reset to the system. The debugger also loses connection with the system with this reset. A system functional reset in this register allows the debugger to hold the system in functional reset.

75.12 Debug resets

The debug subsystem receives the following sources of reset:

- POR reset the complete debug logic.
- JCOMP pin resets the TAP modules (JTAGC and SWJ-DP).
- Debug reset (CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register) is not used.

Conversely, the debug subsystem can generate a system reset using these mechanisms:

- System destructive reset in the MDM AP control register that allows the debugger to give the destructive reset to the system. The debugger loses connection with the system with this reset.
- System functional reset in the MDM AP control register that allows the debugger to hold the system in functional reset.

To program various debug registers, the functional clocks must be enabled. All debug and trace components must be on Destructive Reset.

75.13 Security

The Hardware Security Engine (HSE):

- Provides chip security

- Controls access to the chip's debug featurese)

Authentication by HSE must be complete before handshake using CDBGPWRUPREQ and CDBGPRWUPACK via SWJ-DP.

75.13.1 Arm authentication signals

Authentication interface aims to restrict access to debug and trace functionality by controlling the Arm debug authentication signals. (For more details on these signals, see CoreSight v2.0 Architecture Specification). The Arm authentication signals are shown in the following table.

Table 632. Arm authentication signals

Control signal name	Meaning
DBGEN	Invasive debug enable
NIDEN	Non invasive debug enable
SPIDEN	Secure invasive debug enable
SPNIDEN	Secure non-invasive debug enable

For information on control, see DAP enable control register.

75.13.2 Security fuses

HSE offers a range of security levels and blocks the access to debug based on eFuse configuration and authentication.

75.14 Programming checklists

75.14.1 JTAG switching sequence

75.14.2 FCCU considerations

The Fault Collection and Control Unit (FCCU) monitors whether a core enters Debug mode while in normal operation. This fault is monitored on NCF[59].

In case of self-hosted debug, it is recommended that CONTROL[MSK_DBG_FAULT] must be asserted before entering Debug mode. This will mask NCF[59] and no fault is triggered to FCCU.

75.14.3 Lockstep considerations

In Lockstep mode, the two Cortex-A53 clusters operate in the delayed lockstep configuration, that is, core0 of cluster0 (Cortex-A53 A0) is in Lockstep mode with core0 of cluster1 (Cortex-A53 B0) and similarly for core1 (Cortex-A53 A1 and Cortex-A53 B1). Only cluster0 is available in the system for the debugger while cluster1 works as a checker or redundant module. The debug configurations of cluster1 and its cores must not be programmed in this mode, as when cluster 0 (Cortex-A53 A0 or Cortex-A53 A1) is in Debug mode, the other lockstep core also enters in Debug mode without any software intervention. Therefore, the trace is generated by both the clusters observable on the ATB bus.

75.15 Pin interface

A summary of the number of functional and power pins for the debug interface is shown in the following table.

Table 633. Pin Interface

Pin type	Pins	Number of pins (balls)[1]	Nominal voltage
Functional JTAG	JCOMP, TCK, TMS, TDI, TDO	5 (only TDI and TDO can be multiplexed with GPIO or other functions)	3.3 V, 5 V
Functional Aurora (high-speed serial trace)	AUR_TX*x*_p, AUR_TX*x*_n	10 (8 LVDS outputs, 2 LVDS clock inputs)	—
	AUR_RX_CLK_p, AUR_RX_CLK_n		—
Power	VDD_LV_PLL_AUR	1	0.8 V
	VDD_HV_PLL_AUR	1	1.8 V
	VDD_IO_AUR	1 to 2	1.8 V
Ground	VSS	Shared with common chip VSS pins	0 V

1. The terms pins and balls are used interchangeably. Some chip packages have pins and some packages have balls.

75.15.1 Debug port pin descriptions

Table 634. Debug port pins

Pin name	JTAG debug port		Internal pullup/down
	Type	Description	
JCOMP	I	JCOMP pin	Pulldown
TMS	I	JTAG test mode selection (TMS)	Pullup
TCK/SWCLK	I	JTAG test clock (TCK)	Pulldown
TDI	I	JTAG test data input (TDI)	Pullup
TDO	O	JTAG test data output (TDO)	NC

75.15.2 Trace port pin descriptions

This chip generates the trace via the Trace Port Interface Unit (TPIU) that transmits the trace data out of the MCU over a high-speed serial - Aurora trace port. The trace port consists of Aurora reference clock (AUR_CLK_p and AUR_CLK_n) input port and four pairs of LVDS TXn[3:0] ports for trace output.

Table 635. Trace port pins

Pin name	Type	Description	Internal pullup/down
AUR_TX0_p	O	Aurora Transmit lane 0 positive	NC
AUR_TX0_n	O	Aurora Transmit lane 0 negative	NC
AUR_TX1_p	O	Aurora Transmit lane 1 positive	NC
AUR_TX1_n	O	Aurora Transmit lane 1 negative	NC
AUR_TX2_p	O	Aurora Transmit lane 2 positive	NC
AUR_TX2_n	O	Aurora Transmit lane 2 negative	NC
AUR_TX3_p	O	Aurora Transmit lane 3 positive	NC

Table continues on the next page...

Table 635. Trace port pins (continued)

Pin name	Type	Description	Internal pullup/down
AUR_TX3_n	O	Aurora Transmit lane 3 negative	NC
AUR_CLK_p	I	Aurora reference Clock input	NC
AUR_CLK_n	I	Aurora reference Clock input	NC

NOTE

The RX pins are by default floating and not pulled inside. An internal active pulldown exists only when you enable RX via software (IBE).

The Aurora PLL (AURORA_EXT_CLK) uses the 100 MHz clock input clock (AURORA_REF_CLK) as reference.

Table 636. Aurora transmit frequencies

Clock multiplier	Transmit data frequency
25	2.5 Gbps
30	3.0 Gbps
34	3.4 Gbps
40	4.0 Gbps
50	5.0 Gbps

75.16 Timestamp distribution network

The timestamp distribution network uses CoreSight timestamp components to generate a 48-bit timestamp value for the trace sources as shown in the following diagram. The CoreSight Timestamp generator generates a 64-bit counter value, but only the least significant 48 bits are distributed to the trace sources. A 7-bit narrow timestamp is derived from the 48-bit timestamp and distributed to the trace client, where a decoder regenerates the 48-bit timestamp. The generator must be programmed. The programming details can be found in Arm CoreSight Components TRM (available in References).

The following figure shows the configuration of the accelerator timestamp network that is outside of the system core circuitry.

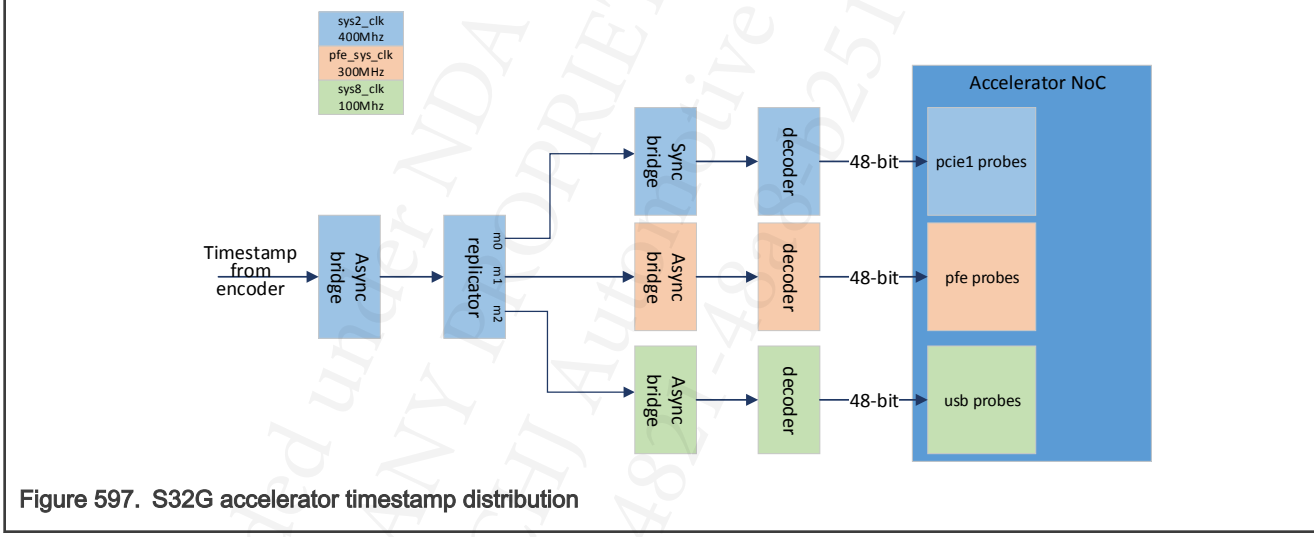

Figure 597. S32G accelerator timestamp distribution

75.17 Low power debug

The device supports debug through Standby mode, to allow the tool to finish operations and the device to transmit all pending trace messages before the device goes into Standby mode. The following sequence achieves low power debug:

1. Set the MDM AP WIR_ENABLE register bit[0] to 1 to notify the device that debug through standby is required.
2. When the device is ready to enter Standby mode, standby is held off until all trace messages have been transmitted from the device.
3. While exiting Standby mode, initialize debug registers, then set the MDM AP WIR_RELEASE register bit[0] to 1 to lift the device out of functional reset.

Chapter 76
JTAG Controller (JTAGC)

76.1 Chip-specific JTAGC information

76.1.1 JTAGC device identification register

For the JTAGC device identification values in this chip, see the "Device JTAG ID" section in the Debug Subsystem chapter.

76.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

76.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

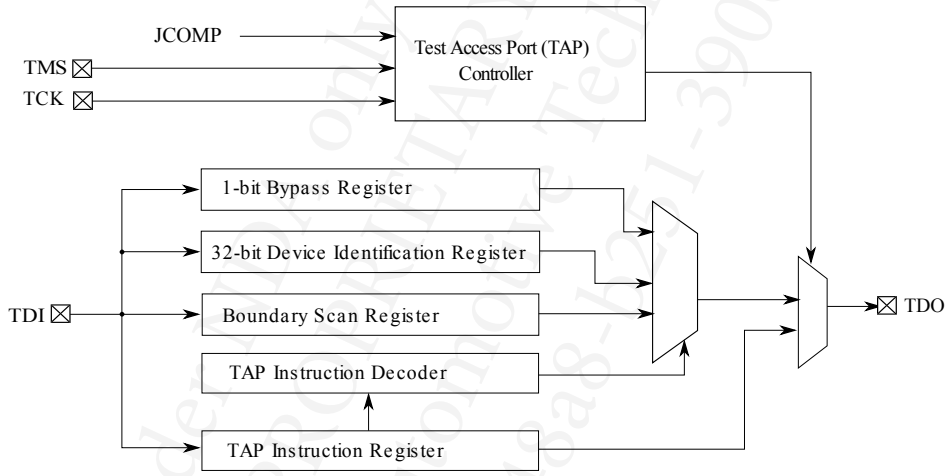

Figure 598. JTAG (IEEE 1149.1) block diagram

76.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

76.2.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

76.2.3.1 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- JCOMP is negated
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

76.2.3.2 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE, and SAMPLE/PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

76.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

76.3 External signal description

The JTAGC consists of a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 637. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup
JCOMP	Input	JTAG compliancy	Weak pulldown

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

76.3.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

76.3.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

76.3.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

76.3.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

76.3.5 JCOMP JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding—otherwise the JTAGC TAP controller remains in reset.

76.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

76.4.1 Instruction register

The JTAGC block uses a 8-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the

Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

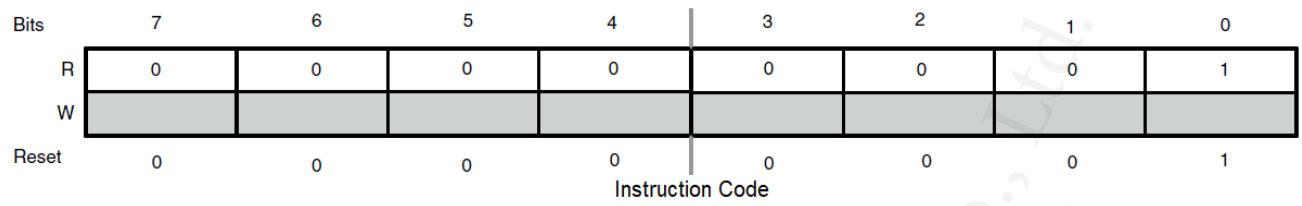

Figure 599. Instruction register

76.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

76.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

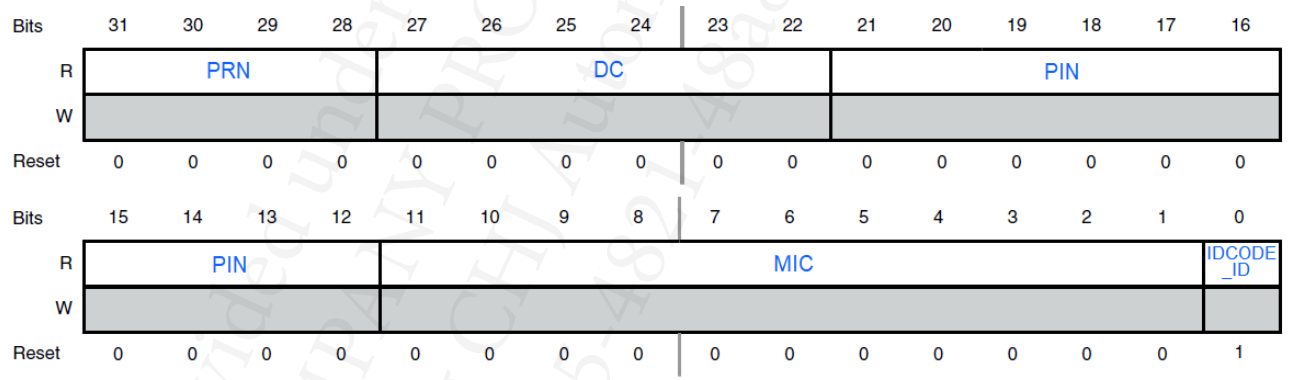

Figure 600. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 638. Device identification register field descriptions

Field	Function
PRN	Part revision number Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

76.4.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

76.5 Functional description

This section explains the JTAGC functional description.

76.5.1 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

76.5.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions, see ACCESS_AUX_x instructions .

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

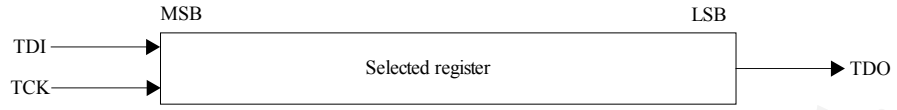

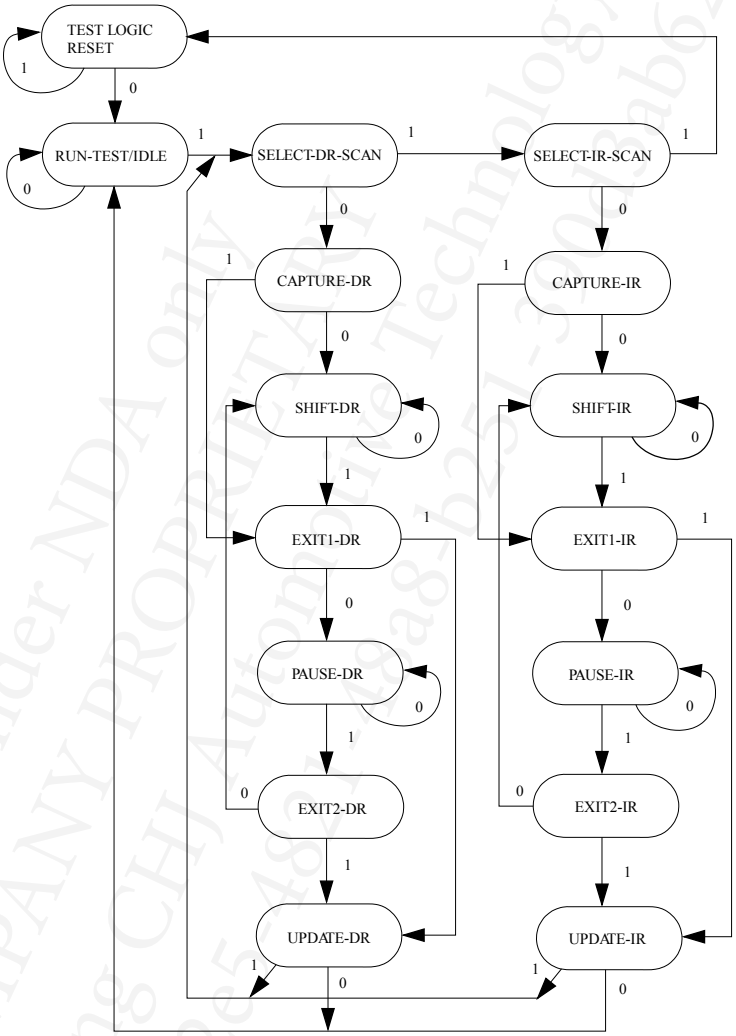

Figure 601. Shifting data through a register

76.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 602. IEEE 1149.1-2001 TAP controller finite state machine

76.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

76.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

76.5.4 JTAGC block instructions

The JTAGC implements instructions defined in IEEE 1149.1-2001. See the chip-specific JTAGC information for the JTAGC instructions implemented on this chip. See the IEEE 1149.1-2001 standard for additional information. All undefined opcodes are reserved.

76.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

76.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

76.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

76.5.4.4 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

76.5.4.5 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

76.5.4.6 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

76.5.4.7 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers.

When this instruction is loaded, control of the JTAG pins is transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins.

The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE when they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

76.5.4.8 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

76.5.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

76.6 Initialization/application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

Chapter 77
JTAG Data Communication (JDC)

77.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory-mapped register space and an external tool that accesses the JTAG port.

77.2 Overview

The JDC module consists of:

- IPS-accessible registers
- JTAG-accessible registers
- Associated logic to coordinate movement of data from one register domain to another

The JDC implements the following IPS data registers, occupying separate memory space:

- 1 32-bit memory mapped register that can be read or written via IPS (JTAG Output Data Register (JOUT_IPS)), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 1 32-bit memory mapped register that can only be read via IPS (JTAG Input Data Register (JIN_IPS)), and whose contents are loaded from a JTAG register (JIN).

JDC indicates when:

- New data has been shifted in via the JTAG port and is ready to be read from the JTAG Input Data Register (JIN_IPS) register
- New data has been written to the JTAG Output Data Register (JOUT_IPS) register and is ready to be read via the JTAG port

A Module Status Register (MSR) captures the state of these flags and also provides the flags to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

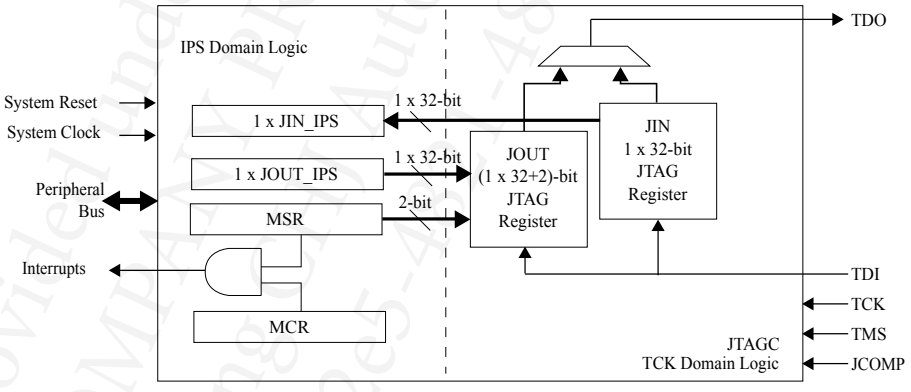

Figure 603. JDC block diagram

77.3 Signal description

JDC signals are listed in the following table.

Table 639. Signal properties

Name	Function	I/O	Reset
TCK	Test clock input	I	—
TMS	Test mode select	I	0
TDI	Test data in	I	0
JCOMP	JTAG compliance pin	I	0
TDO	Test data out	O	HiZ

77.4 JDC register descriptions

The following sections describe the implemented 32-bit registers. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

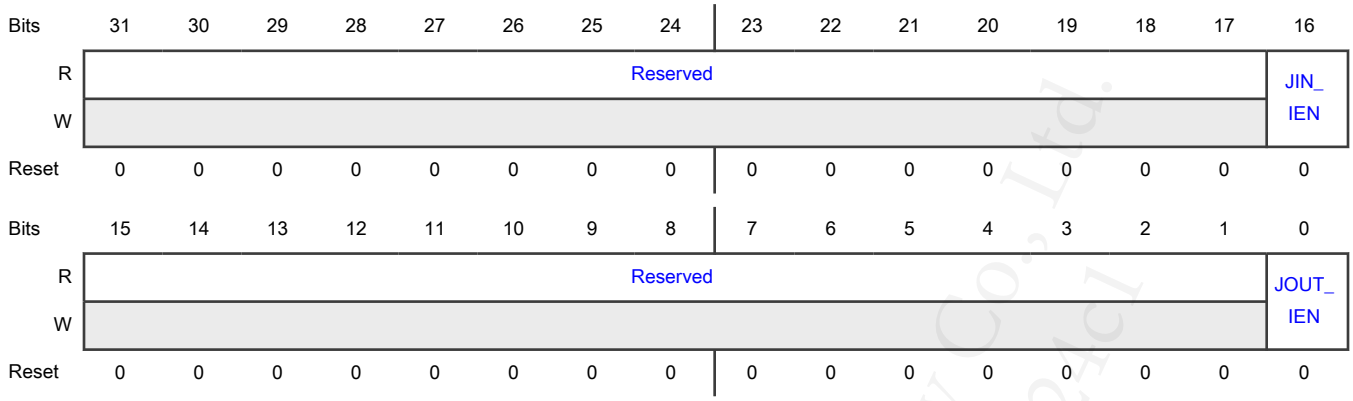
77.4.1 JDC memory map

JDC base address: 402F_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	0000_0000h
4h	Module Status Register (MSR)	32	W1C	0000_0000h
8h	JTAG Output Data Register (JOUT_IPS)	32	RW	0000_0000h
Ch	JTAG Input Data Register (JIN_IPS)	32	RO	0000_0000h

77.4.2 Module Configuration Register (MCR)

Offset



Register	Offset
MCR	0h

Function

The MCR enables the interrupt outputs of the JDC. This register is reset by system functional reset.

77.5 Non-memory-mapped register definition

The JDC also implements two JTAG accessible registers that are not memory-mapped. One JTAG register shifts in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register plus ready status from the MSR, to be shifted out via the JTAG port.

77.5.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system power-on reset and JTAG reset. The reset value of the JOUT register is 0. The following figure shows the format of the JOUT register.

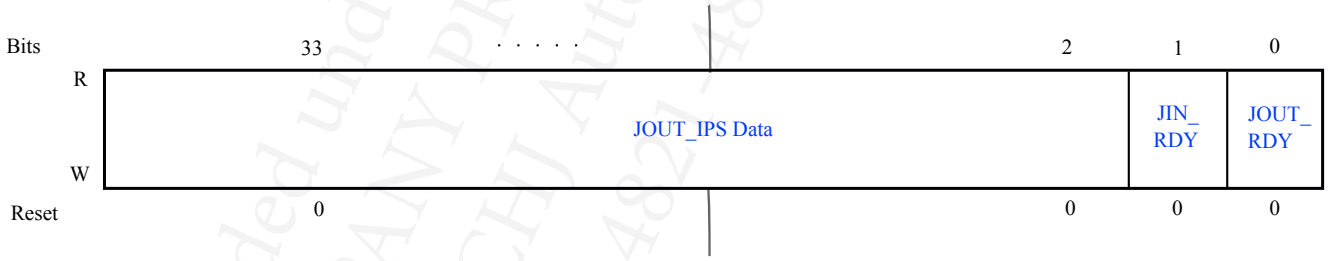

Figure 604. JOUT

The JOUT register is described in the following table.

Table 640. JOUT JTAG register field descriptions

JOUT_RDY	JOUT_RDY State of JOUT_RDY bit from MSR

77.5.2 JTAG input data register (JIN)

The external tool writes data to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JDC later captures JIN data in the JIN_IPS register to be read via IPS. This register is reset by system power-on reset and JTAG reset. The reset value of the JIN register is 0. The following figure shows the format of the JIN register.

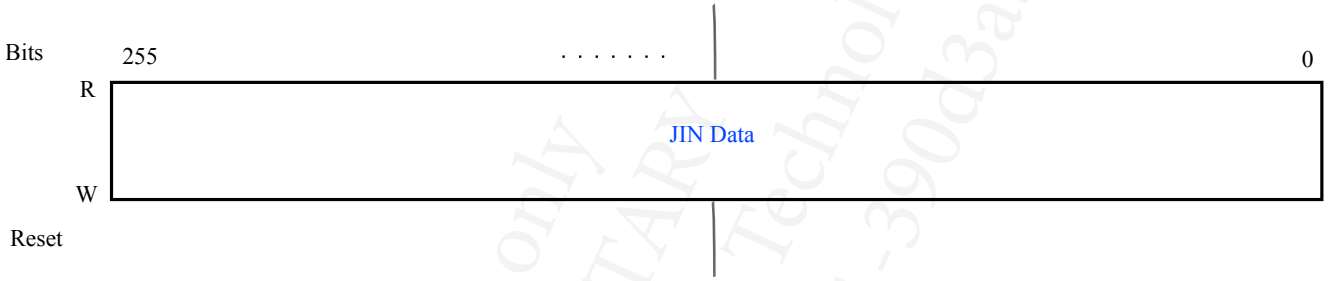

Figure 605. JIN

The JIN register is described in the following table.

Table 641. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

77.6 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data in memory-mapped register that can be accessed via IPS. It also provides the ability to capture data written to memory-mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described here.

- Software write to the JOUT_IPS register:
  1. The JDC sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port.
  2. The MSR reflects the state of the JOUT_RDY bit.
  3. The JDC also captures the state of the JOUT_RDY bit in the JOUT register.
  4. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data.
  5. The JDC clears the JOUT_RDY flag bit upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction.

6. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.

- JTAG write to the JIN register via execution of the JIN_WRITE JTAG instruction:
  1. The JDC updates the contents of the JIN_IPS register upon exit of the Update-DR state.
  2. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS.
  3. The MSR register reflects the state of the JIN_RDY bit.
  4. The JDC also captures the state of the JIN_RDY bit in the JOUT register.
  5. The JDC clears the JIN_RDY flag bit upon software read of the JIN_IPS register.
  6. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

77.6.1 JTAG register access

See the JTAGC documentation for information on how to access the JTAG registers.

77.6.1.1 JDC block instructions

The JDC block implements the instructions listed in Table 642. This section gives an overview of each instruction. All undefined opcodes are reserved.

Table 642. JTAG instructions

Instruction	Code[4:0]	Instruction summary
Reserved	00001	Factory debug reserved.
JOUT_READ	00010	Selects JOUT data register. The JDC captures data from JOUT_IPS into JOUT data register upon entry to Capture-DR state when JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. The JDC captures data from JIN into JIN_IPS upon exit of Update-DR state when JIN_WRITE is active.
BYPASS[1]	11111	Selects bypass register for data operations.
Reserved	All other opcodes	Decoded to select bypass register.

1. This is an IEEE 1149.1-2001 defined instruction. See the IEEE 1149.1-2001 standard for more details.

77.7 Secure challenge/response connection procedure

A summary of how the JDC can be used to interact with a security module to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.

6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.
7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The security module can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

For details related to the lifecycle stage at which this process is performed, see the "Hardware Security Engine (HSE_B)" chapter.

Chapter 78
Aurora Trace Port (ATP) Subsystem

78.1 Introduction

The Aurora protocol is used to send debug information over a high-speed serial link. A high-speed serial link using the Aurora protocol is ideally suited to provide high speed trace debug support because it is a light-weight protocol with 80% efficiency based on an open standard developed by Xilinx Corporation. The Aurora protocol increases internal visibility and debug capability by providing higher trace throughput up to 20 Gbps at 5 GHz with four data lanes. With the Aurora interface, each data lane only takes two pins per differential output pair (positive and negative).

The Aurora Trace Port (ATP) subsystem is a part of the debug subsystem in Arm-based SOCs. ATP uses Xilinx Aurora 8B/10B protocol to send data off-chip. The control of the ATP subsystem is through the Debug Access Port (DAP) and Advanced Peripheral Bus (APB) interface. The data path of the ATP communicates with Arm cores through the Trace Port Interface Unit (TPIU) module. ATP has dedicated 4 KB address space and the address bus can be controlled and monitored. Access to ATP registers is through the Serial Wire JTAG Debug Port (SWJ-DP). Interaction of ATP with DAP and TPIU is shown in the following figure.

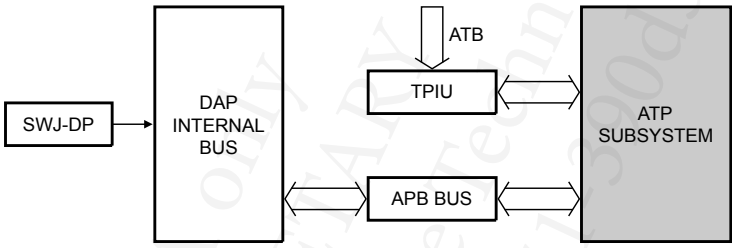

Figure 606. ATP subsystem overall debug interface

ATP subsystem has control and data paths. The control path consists of register configuration of all the internal modules, most of these registers are write and readable. The DAP sends the APB interface signals along with the select line to ATP. Users configure registers using dedicated 4 KB address space. The data path of ATP takes 32-bit data from TPIU module and ATP provides the gated clock of Aurora PHY output Clock (Aurora Clock, PLL output Clock / 10) to control the data flow of TPIU.

78.1.1 Features

ATP supports these features:

- Xilinx Aurora Protocol 8B/10B Specification V2.3 compliance
- Simplex mode with static (timer-based) channel training
- 0, 2 or 4 Aurora lane configuration
- Up to 5 Gbps bandwidth for each lane
- Arm compliance registers
- Configurable clock compensation
- Aurora PLL frequencies 2.5, 3, 3.4, 4, and 5 Gbps can be configured by using register configuration (PLLDIV).
- The Aurora PLL generates 5GHz clock using LVDS input reference clock of 100MHz.

The PLL does not detect loss of reference clock. If the clock stops after the PLL achieves lock, PLLDIG continues to indicate the lock status.

78.2 External signal description

The table below describes the port connections of ATP subsystem.

Direction	Width	Port name	Port details	Domain
output	1	AUR_TX0_PAD_N	Aurora TX data output - LVDS	-
output	1	AUR_TX0_PAD_P	Aurora TX data output - LVDS	-

78.3 Overview

The ATP subsystem supports high-speed trace output and transmits high bandwidth data off-chip from the SoC Arm debug infrastructure using an add-on to the TPIU parallel interface. This ensures complete reuse of existing Arm IP.

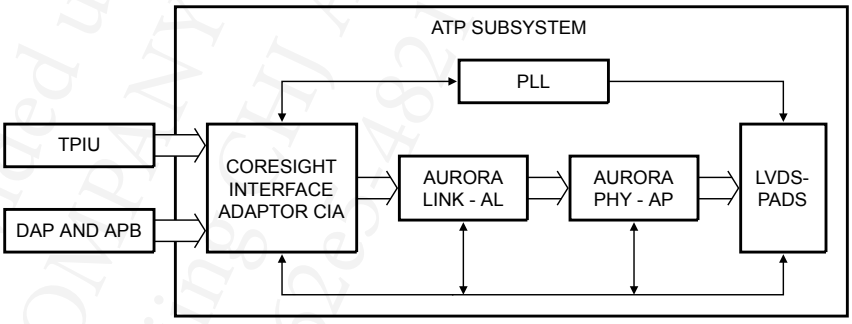

Figure 607. ATP subsystem modules and interface

The ATP subsystem consist of five modules:

Table 643. ATP subsystem modules

Module	Description
CoreSight Interface Adaptor (CIA)	CIA interacts with Trace Port Interface Unit (TPIU) and APB interface bus. CIA takes trace data from TPIU, converts it to the required format for Aurora Link (AL), and generates all the required intermediate signals. CIA interface with APB is connected for register configuration of ATP and it controls and reads the status of various registers of the ATP subsystem. CIA also controls the clock for TPIU. Therefore, there are no additional signals to control the data flow of TPIU and clock gating is used to throttle the data.
Aurora Link (AL)	AL communicates with the CIA and Aurora PHY (AP). AL receives 64-bit format data from CIA, implements Aurora 8B/10B protocol, and appends CRC based on user selection. Based on the number of lanes configured at AL, the data is sent to AP on the corresponding lanes.
Aurora PHY (AP)	AP interacts with AL and LVDS pads. AP receives the Aurora 8B/10B format segregated data from the AL and performs all the operations required to transfer the data off-chip. APs major function is to convert parallel data to serial data at 1:10 clock rate and to transfer data on to the LVDS pads.
Aurora PLL	Aurora PLL module generates the clock for the Aurora sub-system (AURORA_CLK) up to 5 GHz by taking the input reference clock (AURORA_EXT_CLK) of 100 MHz. The Aurora high-speed clock is used to send the data off-chip. The Aurora PLL is configurable using register settings.
Aurora LVDS pads	Aurora pads are high-speed supporting pads. They are LVDS differential pair pads and each supports up to 5 GHz per lane. These pads receive the data from AP and controlled by CIA.

78.4 ATP register descriptions

ATP subsystem registers configure the AL, AP, Aurora PLL, Aurora LVDS IO pads, and CIA.

All registers and fields which are marked reserved when written with values other than reset values could lead to unpredictable hardware behavior. Read values of reserved/bits registers can be ignored.

78.4.1 ATP memory map

Fields

Field	Function
31 —	Reserved
30-25 —	Reserved
24-22 —	Reserved
21-16 ODIV1	PLL Output Division Factor 1 This field is the output frequency divider for raw AURORA_CLK PLL clock. 000000b - Divide by 1 000001b - Divide by 1 000010b - Divide by 2 000011b - Divide by 3

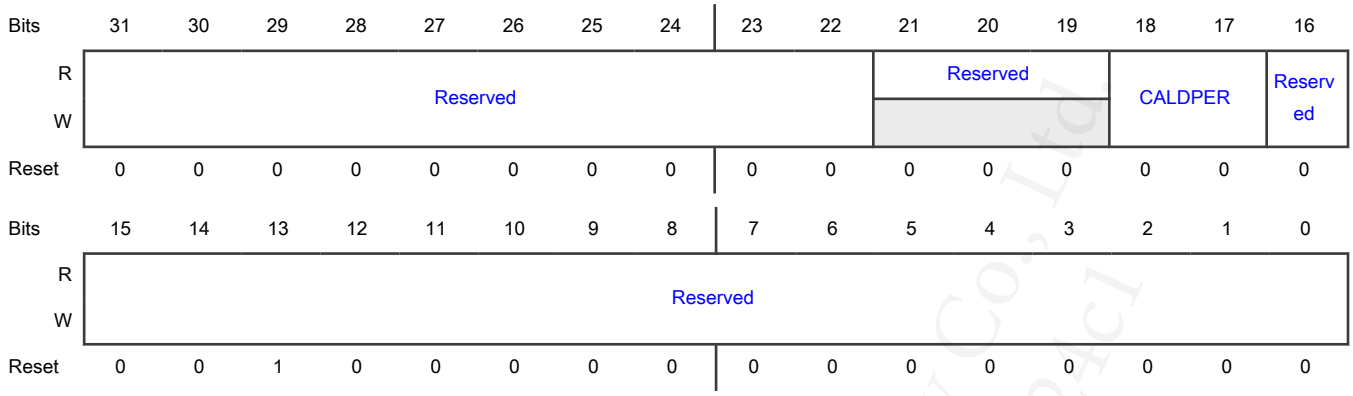
Table continues on the next page...

Table continued from the previous page...

Field	Function
	000100b - Divide by 4 111111b - Divide by 63
15 —	Reserved
14-12 RDIV	PLL Input Clock Predivider This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. 000b - Divide by 1 001b - Divide by 1 010b - Divide by 2 011b - Divide by 3 100b - Divide by 4 101b - Divide by 5 110b - Divide by 6 111b - Divide by 7
11-8 —	Reserved
7-0 MFID	PLL Multiplication Factor Integer Divider This field controls the value of the divider in the feedback loop. The value specified by MFID establishes the multiplication factor applied to the reference frequency. Divider value = MFID, where MFID has the range 10...150 (Ah...96h). All other values are reserved. AURORA_CLK = (MFID × 2 × RefClock) / (RDIV × ODIV1) where the RefClock is determined by PLLCKMUX[REFCLKSEL] setting.

78.4.5 PLL Calibration 2 (PLLCAL_2)

Offset



Register	Offset
PLLCAL_2	18h

Function

This offset register consists of PLL Calibration-2 Registers.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

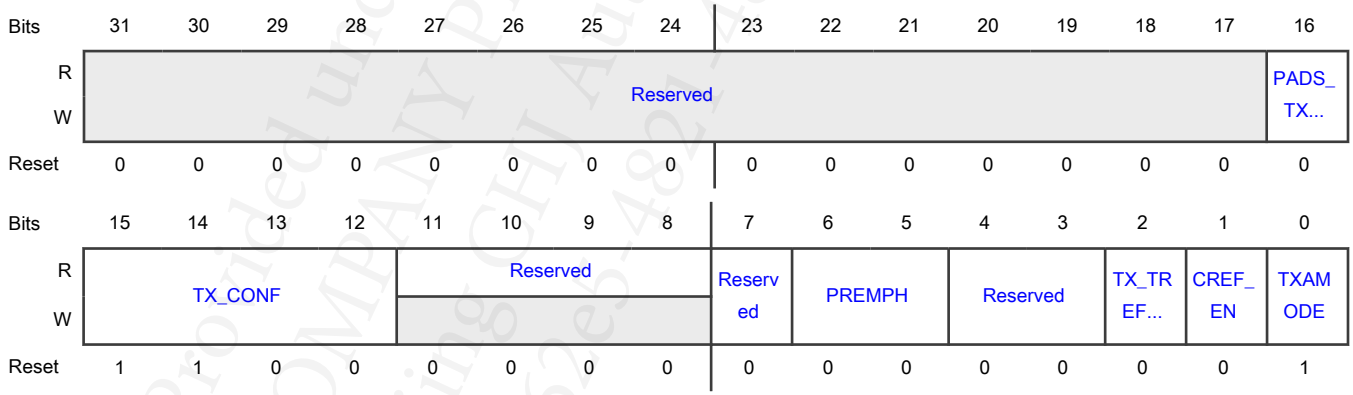
78.4.10 LVDS TX IO Configuration (LVDSTX)



Offset

Register	Offset
LVDSTX	440h

Function

This register controls the Aurora LVDS TX pads.

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c467e5-4821-48a8-b251-390d3ab624c1

Fields

Field	Function
31-17 —	Reserved
16 PADS_TX_CONF_EN	PADS TX Configuration Enable Enables or disables the TX_CONF field to select the transmitter output stage current drive. The value of this field defaults to 0 that uses the transmit configuration from the fuse. This value is configured in the chip for optimum settings. You may require to override the internal default settings on early silicon, or if settings other than the default are needed in special circumstances. 0b - PADS TX configuration disabled 1b - PADS TX configuration enabled
15-12 TX_CONF	LVDS PADS TX Control Configuration Controls the drive current of transmitter output. Each enabled bit of this field adds approximately 16% drive. Typically, a setting of 1100 generates a 10mA drive, which is optimal for impedance matching. Setting the current to too high can lead to a higher inter-symbol interference (ISI) and a low setting can lead to impedance mismatch or reflections. See the following table for bit settings and their corresponding ballpark values.
11-8 —	Reserved
7 —	Reserved
6-5 PREMPH	Pre-Emphasis Configuration If enabled, adds up to 3 dB gain in differential swing, with 0b11 being the highest gain setting. However, in addition to increasing the differential signal height, the signal jitter could increase by approximately 5 to 10 ps.
4-3 —	Reserved

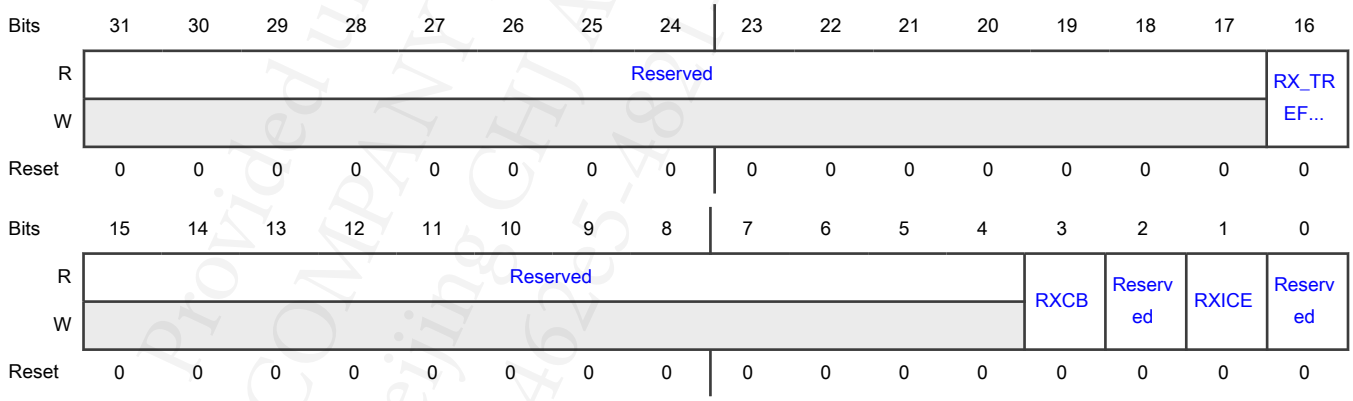
Bit setting	Drive current
0b0000	7 mA
0b1000	8.5 mA
0b1100	10 mA
0b1110	11.5 mA
0b1111	13 mA

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 TX_TREF_EN	TX LVDS Termination Reference Enable This field enables the internal 100 Ω termination. 0b - Disable 1b - Enable
1 CREF_EN	Current Reference Enable This field enables the current reference control signal. 0b - Disable 1b - Enable
0 TXAMODE	TX Aurora pad mode enable 0b - Disable 1b - Enable

78.4.11 LVDS RX IO Configuration (LVDSRX)



Offset

Register	Offset
LVDSRX	444h

Function

This register has configuration details of the LVDS Receiver to receive the Aurora PLL reference clock from an external source.

Diagram

Field	Function
31-0 DEVAFF1	Value of this field is set to 0x24.

78.4.20 Lock Access Register (LAR)

Offset

Register	Offset
LAR	FB0h

Function

This register is used to enable write access to device registers. A write of 0xC5ACCE55 to this register enables further write access to this device. An invalid write has the affect of removing write access. This is applicable only for core access. For debug mode this is invalid. This is write only register.

Provided under NDA only

78.5 Functional description

78.5.1 CoreSight interface adaptor

The trace input interface to the ATP matches the output signals from the TPIU. The CoreSight Interface Adaptor (CIA) receives the data in TPIU standard format and stores it in an internal FIFO. The FIFO stored data is formatted as per the Aurora protocol and sent to AL.

The CIA consist of the logic to establish the connection between the TPIU and the AL. The CIA includes TPIU interface, buffer, AL formatter, APB to IPS conversion, memory mapping and configurations.

78.5.1.1 CIA functional blocks

The CIA consists of five functional modules:

- TPIU interface module
- Buffer management module
- AL interface module
- Register configuration module
- Clock gating module

The CIA block level overview and interface are shown in the following figure.

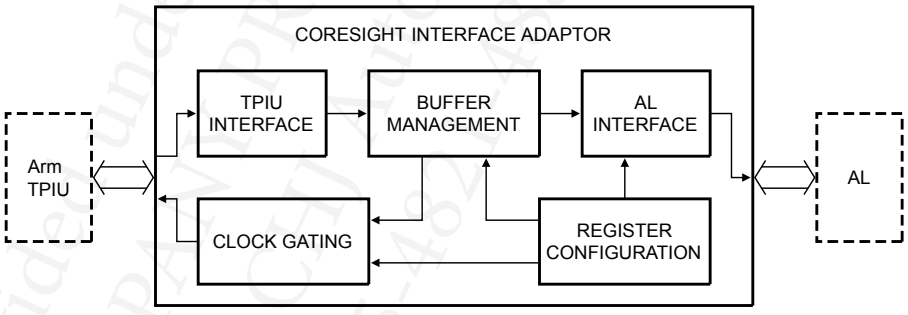

Figure 608. CIA functional blocks

The CIA block supports bit/byte reversal feature. CIAC[DBYTER] and CIAC[DBITR] are used in conjunction to implement the reversal feature as specified in the following table.

Table 644. Reversal feature

DBITR	DBYTER	output_DATA (31:0)
1	0	TPIU_DATA – (24:31)(16:23)(8:15)(0:7)

Table continues on the next page...

Table 644. Reversal feature (continued)

DBITR	DBYTER	output_DATA (31:0)
1	1	TPIU_DATA – (0:7)(8:15)(16:23)(24:31)
0	1	TPIU_DATA – (7:0)(15:8)(23:16)(31:24)
For rest of the combination		TPIU_DATA (31:0)

If TPIU_DATA (31:0) is input data from TPIU to ATP, then output_DATA (31:0) is output to the pads.

78.5.1.2 TPIU interface module

TPIU Interface Module (TIM) interfaces with Arm-TPIU, takes the data, and sends it to a buffer. TPIU trace clock input (TRACECLKIN) is provided by CIA clock gating module. Trace data is collected by considering gated clock and clock enable. As per TPIU configuration, each clock is provided by gated clock. TPIU gives 32-bit data on negative edge of the clock provide by CIA clock gating module. The data is sampled with the continuous 500 MHz clock. TIM takes 32-bit data and every alternate clock cycle of enable, it combines the data to make a 64-bit block of data. TIM generates write enable pulse of one clock period and gives the enable pulse to buffer management module. The buffer management module writes this data into the FIFO.

78.5.1.3 Buffer management module

Buffer Management Module (BMM) maintains the CIA FIFO and generates the signals related to AL internal FIFO. CIA FIFO receives the data and write enable signal from TPIU interface module and read enable and read data from AL interface module, these modules consider full and empty status flags before generating corresponding signals. AL FIFO status is maintained based on 8-credit flow, it increments with tx_valid generated by NIM and decrements with data_accept which is given by AL as received data acknowledgement.

78.5.1.4 AL interface module

AL Interface Module (AIM) interfaces with AL IP. AIM takes data from buffer management module and converts it into an AL compatible format and passes it to AL. AIM continuously polls the AL ready signal and whenever the AL is ready, AIM sends data and corresponding tx_valid signal. Before sending valid pulse, AIM reads data from FIFO and sends FIFO read pulse. To generate this AIM needs to satisfy these conditions:

- AL Aurora ready signal should be active.
- AL 8-credit FIFO should not be in almost full condition.
- CIA 8 depth internal FIFO should not be in almost empty condition.

These FIFO signals are managed by buffer management module. Ready and data accept signals are directly received from AL. It also generated start of the frame SOF and end of the frame EOF signals based on the Aurora frame length configured by user. It is programmable up to 8192.

78.5.1.5 Register configuration module

CIA module manages the register configuration required for ATP. It configure the registers of AL, AP, PLL and PADS. To configure these registers, CIA has APB interface. It takes the data over APB, then it convert the APB signals to IPS format. It decodes the corresponding register value from IPS interface and then it gives the value to the corresponding IP port.

78.5.1.6 Clock gating module

CIA interact with the Arm-TPIU in the SOC Arm debug infrastructure. TPIU uses 32-bit wide data path to send data to CIA. CIA provides 500 MHz gated clock to TPIU-TRACECLKIN port, same is used by TPIU to send the data. This clock is the output of clock gate (CG). This clock gating is required to back pressure TPIU as it does not have any control signals or mechanism to control the TPIU output data. To avoid the data loss of TPIU, the TRACECLKIN clock throttling implemented by non-continuous trace clock to Arm-TPIU.

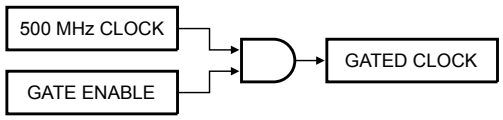

Figure 609. CIA clock gating

This clock gating is implemented when the CG override and CG by-pass are not active. If CG override is active, then the 500 MHz clock in not gated, and is continuously given to TPIU.

78.5.2 Aurora link

The Aurora Link (AL) consists of the logic required for Aurora protocol 8B/10B and to implement the connection up to the physical-layer SerDes and transceivers. The AL includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. The following figure details the AL flow:

- Debug data in the frame format from multiple clients is collected by the TPIU.
- Debug data is framed by CIA as per AL requirement.
- Messages are packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine (APE), which performs all the logical layer functions and flow control.
- Data from the APE is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug. The number of lanes for the AL is configurable as 0, 2 or 4 lanes.
- ALC also performs the PCS functions of the link. The PCS drives the Aurora Physical (AP) interface. The AP, in conjunction with the AL, supports one-way simplex high-speed serial communication with an external debugger.

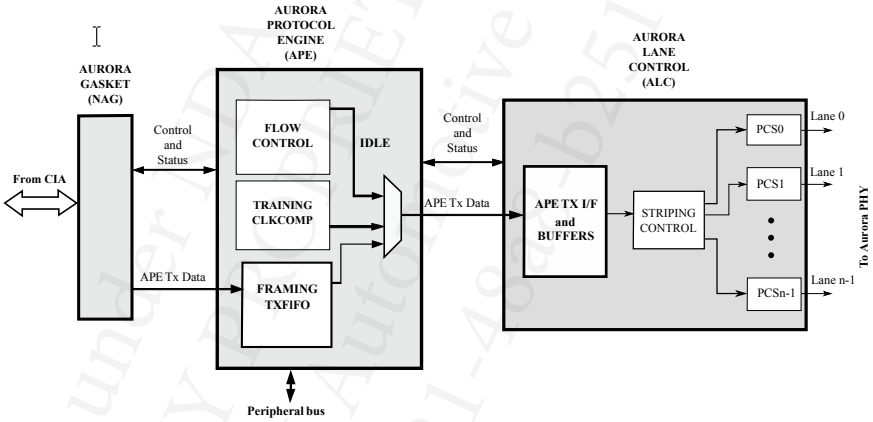

Figure 610. AL block diagram

78.5.2.1 AL functional blocks

During normal operation, the CIA reads data from TPIU and pushes data into the AL at a sufficiently high rate to ensure that the link does not become data-starved even in its highest-bandwidth configuration (4 lanes operating at 5 GHz). The AL three main blocks then perform the buffering, domain-crossing, data-packaging, and protocol translations to prepare the data stream for transmission through the AP. The work is divided as follows:

- CIA Interface (AG): The CIA and Aurora Gasket use a credit/debit interface to send data over a (possibly) multiple-stage connection, with the CIA pushing data out whenever possible and the gasket informing the CIA whenever it makes space available.
- Platform/AP Domain Crossing (AG): The logic on the AP side of the link is synchronous with the AP block and clocked by the Aurora PLL transmit/receive clocks, when the logic on the CIA side is on the platform clock domain. The AG performs this domain crossing in both directions.

- Link Training (APE): The core contains the state machines and timers that control the link training procedure.
- Aurora Protocol Engine (APE): As described in the Aurora Protocol specification, native flow-control (NFC), clock-compensation, and data framing are performed by the Aurora core.
- Cyclic Redundancy Check (APE): The core performs the CRC encoding/decoding on each transmitted/received frame.
- Data Striping (ALC): The ALC stripes the data stream from the Aurora core across all available lanes in two-byte chunks. This requires resizing and repackaging the data based on the debug port configuration.
- Channel Bonding (ALC): As part of the training procedure, the ALC aligns the data streams from different lanes to ensure that the received data stream is correctly aligned across the lanes.
- 8B/10B encoding/decoding (ALC): The protocol converter contains the 8B/10B encode and decode engines for the PCS layer of the three protocols.
- Receive data elastic buffer (ALC): The protocol converter buffers the raw incoming data stream.
- Data Alignment (ALC): As part of the training procedure, the incoming serial data stream must be partitioned into discrete characters. The protocol converter determines where the character boundary is and aligns each lane accordingly. The AL supports 2 and 4 TX lane configurations.

78.5.2.2 AL link training

The Aurora link training procedure is divided into three stages:

Table 645. Aurora link training stages

Stage	Description
Lane alignment	Each transmitter sends a sequence consisting of data and comma characters. The receive side must analyze the incoming serial data stream and determine the character boundaries by attempting to detect commas.
Channel bonding	Each transmitter simultaneously sends a series of idle sequences, which include the /A/ character. The receive side checks to see if it sees the /A/ on every lane on the same cycle, skewing the lanes as necessary to bring them into alignment.
Channel verification	Each transmitter simultaneously sends the verification sequence (/V/) on all lanes, imbedded in a series of idles. If the receive side detects the sequence on all lanes at the same cycle, the channel is brought up.

78.5.2.3 AL static training

The AL only supports static training. The AL performs static training using programmable timers to determine how long to stay in each stage of the training process. There is no communication between the channel partners as to training status. Rather each partner sends the align/bond/verify sequence for a set amount of time that it is assumes is sufficient for the receive side to complete the training stage.

To enable static training, program the counters in the AL Training Control (ALTC)) and then set the STE bit. This resets the channel and initiates the training routine. The time spent in each stage can range from 16 to 3072 cycles. When a counter times out, a counter timeout signal is asserted to the APE to prompt it to move to the next stage.

Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to stay in align, bond, or verify until unset. This allows a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the SOC side to the next stage.

During the Aurora training sequence, the AL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

78.5.2.4 AL transmission procedure

The CIA generates user protocol data units (PDU) to form a frame of data. The boundaries of the frame are indicated by assertion of SOF and EOF signals. The frame of data is transmitted on the Aurora channel as a channel PDU according to the following procedure:

- CRC calculation
- Padding
- Encapsulation with channel PDU delimiters
- Clock compensation

The AL calculates CRC for each frame of data according to the CRC-16 polynomial:

$$G(x) = x^{16} + x^{15} + x^2 + 1$$

When enabled, two octets of CRC information are inserted into each frame.

The Aurora channel requires that all transmissions contain an even number of symbols. In this implementation, the data is generated 8 bytes at a time and the CRC information is encoded into two bytes, therefore padding is unnecessary. Padding is therefore not supported by the APE for transmission. Received data, however, may contain pad characters and the APE processes them according to the protocol specification.

After the CRC octets are added, the frame is encapsulated with ordered sets which delimit the beginning and end of the channel PDU for identification by the channel partner. The SCP and ECP ordered sets are used to indicate start-of-channel and end-of-channel, respectively. If more than 7424 symbol pairs have been sent after the last clock compensation sequence, a new clock compensation sequence is immediately inserted into the data flow. A clock compensation sequence consists of 12 pairs of the /CC/ ordered set, and its periodic insertion allows the AL to tolerate small clock rate-differences between the transmitter and receiver.

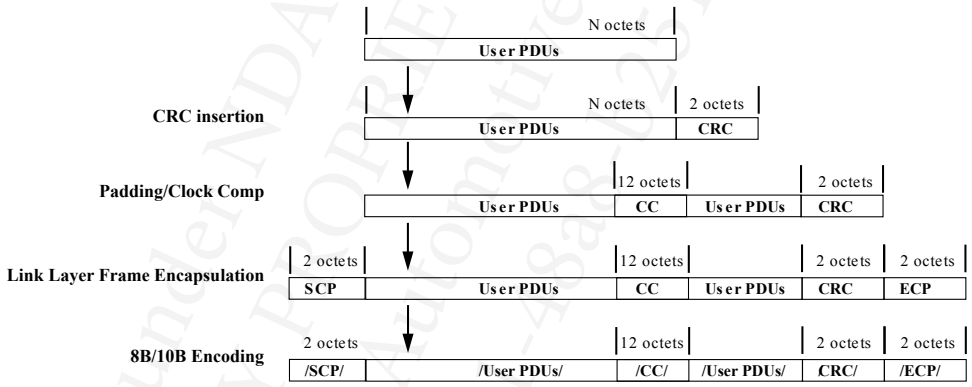

Figure 611. AL transmission procedure

78.5.2.5 AL clock compensation considerations

The Aurora Protocol specification describes clock compensation as a means for the link to compensate for clock rate differences between the transmitter and receiver. The specification requires that a clock compensation be inserted at a minimum every 10,000 symbol pairs. This allows the link to accommodate up to a 200 ppm difference in clock rates. The ALGC[CCOEN] field sets the default clock compensation time-out at 7424 cycles. However, due to the fact that the AL is restricted to only inserting clock compensation sequences after an end-of-frame, it may not be possible to always meet the Aurora specification requirement.

Because the CIA always operates in framed mode, there is one scenario that can prevent an adequate number of clock compensation sequences from being generated: the sparse data case. In the sparse data case, there are long periods of time when no data is flowing through the link; no data means no frames. The AL could end up transmitting idles for an undetermined number of cycles when waiting for the CIA to provide new data. However, a user can get around this problem by insuring that the CIA always has at least some minimal amount of data to send. In extreme sparse data cases where clock compensation

is required, the receiver could reset the CIA or use a periodic watchpoint to force data transmission, and therefore force and end-of-frame to complete clock compensation.

78.5.3 Aurora PHY

The Aurora PHY (AP), in conjunction with the AL, supports one way simplex high-speed serial communication with an external debugger. Configuration settings in the ATP configuration register specify the AP and AL lane configuration. The AL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the AP for transmission. The AP receives 8B/10B encoded data from the AL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.

Each AP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the AL on the rising edge of the AL clock (AL clock = AURORA_CLK / 10). Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called lane alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

78.5.3.1 AP modes of operation

The operating mode of the AP is determined by the device control signals. Functional operation is enabled by the CIA.

Table 646. AP modes of operation

Mode	Description
Reset	During Reset all internal AP resources are reset, all output ports are disabled, and all inputs are ignored. Because there is no device clock domain logic in the AP itself, the AP is unaffected by device system reset. Depending on the AP configuration settings, the AP may activate upon exiting Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.
Link training	Before beginning trace output mode operation, the AL must go through a training process to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds after the link powers up, and must complete successfully before data transmission can occur. The AL initializes and trains the Aurora link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the AL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The AP is not directly aware of the link training operation, because it merely transmits the data presented to it by the AL.
Transmit	During trace output operation, it is the responsibility of the CIA to push data into the AL at a sufficiently high rate to ensure that the link does not become data-starved. The AL and AP support up to four transmit lanes. The Aurora encapsulated data is modified by the AL to ensure the appropriate number of symbols are transmitted through the AP.

78.5.3.2 AP functional blocks

High-level descriptions of the operation of the AP and its main functional blocks are given in the following table.

Table 647. AP functional blocks

Block	Description
Data symbol character accumulator	The data symbol character accumulator portion of the AP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit AL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the AL clock and presents the 10-bit quantity to the serializer at the appropriate times.
Serializer	The serializer portion of the AP for each lane takes the data captured by that lane's data symbol character accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate. Figure 612 shows a high level timing diagram that demonstrates the operation of the serializer for a AP lane, where S0 - S9 represents a 10-bit symbol, S10 - S19 represent the next symbol, and so on. The 5 GHz pll_clk is the AURORA_CLK.

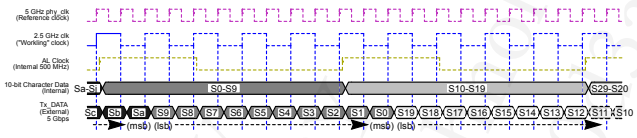

Figure 612. Serializer timing diagram

78.5.4 Aurora PLL

The Aurora PLL module provides the clocks required for ATP subsystem. The overall clock flow of ATP using Aurora PLL is shown in the following figure.

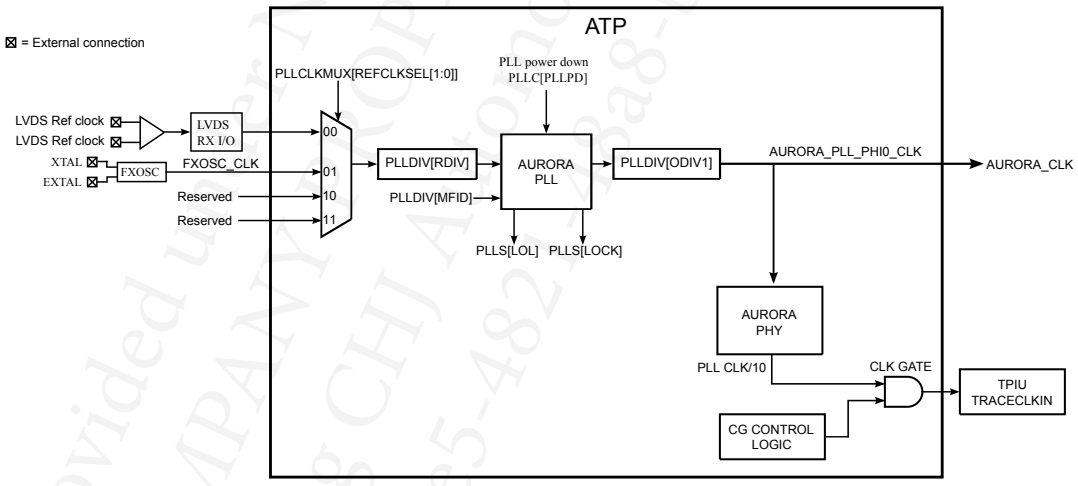

Figure 613. ATP clock flow functional block diagram

78.5.4.1 PLL clock configuration

See the following figures and the corresponding register configuration that determine the relationship between VCO frequency (f_{VCO}) and PLL reference frequency.

- When PLLDIV[RDIV] is 0:

$$f_{pll\_VCO} = f_{pll\_ref} \times (PLLDIV[MFI] \times 2)$$

Figure 614. PLL VCO frequency when PLLDIV[RDIV] is 0

- When PLLDV[RDIV] is not 0:

$$f_{pll\_VCO} = \frac{f_{pll\_ref}}{PLLDIV[RDIV]} \times (PLLDIV[MFI] \times 2)$$

Figure 615. PLL VCO frequency when PLLDIV[RDIV] is not 0

See the following figure and the corresponding register configuration that determine the relationship between reference and PLL_PHI*n* output frequencies.

$$f_{pll\_phi} = \frac{f_{VCO}}{PLLDIV[ODIV1]}$$

Figure 616. PLL PHI output frequency

When configuring the PLL, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of the PLL (see this chip's data sheet for frequency limits).

NOTE

The PLL must be disabled by writing PLLC[PLLPD] = 1 before any PLL configuration or input clock are modified.

NOTE

The PLL must be disabled by writing PLLC[PLLPD] = 1 for at least 5 µs before enabling the PLL (writing PLLC[PLLPD] = 0).

The recommended procedure to program the PLL and engage normal mode is shown in Initialization sequence.

78.6 Initialization sequence

The ATP initialization sequence is described as follows:

1. Aurora IO configuration:
    a. Configure the ATP lock key: Write C5AC_CE55h to LAR[KEY] in core access mode only.
    b. Write 1 to LVDSRX[RXICE], LVDSRX[RXCB], and LVDSRX[RX_TREF_EN].

       You must ensure that there is no termination on the PCB because Aurora is AC coupled.
    c. Write 1 to LVDSTX[TXAMODE] and LVDSTX[CREF_EN].
    d. Wait for 1 µs.
    e. Write 1 to LVDSTXOBE[OBETX1], LVDSTXOBE[OBETX2], LVDSTXOBE[OBETX3], and LVDSTX[TX_TREF_EN].

       You must:
       - Ensure that the aforementioned fields are enabled together.
       - Avoid writing 1 to LVDSTX[TX_TREF_EN] and 0 to any of the OBETX fields of LVDS TX OBE Configuration (LVDSTXOBE).

       This enables the source or dual termination scheme for LVDS Tx pads for a better jitter performance.

       If the board design has losses and you have a smaller eye height, you can keep LVDSTX[TX_TREF_EN] = 0 to improve the eye height.

In case of high board loss, you can write 11b to LVDSTX[PREMPH] to get faster slew rates and increased eye height at the cost of additional power consumption.

2. Clock output to TPIU had been muxed with FIRC (after reset de-assertion) to complete auto-discovery. Before configuring PLL, switch from default FIRC clock to PLL output (PLL CLK/10). Steps to switch:
    a. Set CIA Control register bit[29] to 1b1.
    b. Set CIA Control register bit[28] to 1b1.
    c. Set CIA Control register bit[29] to 1b0.
3. Aurora PLL configuration:
    a. Before configuring PLL, connect LVDS RX IO to 100MHz clock.
    b. Wait 6 µs to reset the analog PLL.
    c. Configure PLL divider
        - Configure PLL Divider (PLLDIV) Register: Address = 0x008, Configure MFID, RDIV and ODIV1.
        - Configure PLL Calibration 2 (PLLCAL_2) Register: Address = 0x018, Configure CALDPER.
    d. Configure PLL reference clock
        - Configure PLL Clock MUX (PLLCKMUX): Address = 0x020, Configure reference clock for PLL(REFCLKSEL).
    e. Configure PLL power down
        - Configure PLL Control (PLLC) Register: Address = 0x000, Configure PLLPD.
    f. Wait for PLL to lock
        - Wait 150 µs or
        - Wait for PLL Status (PLLS) register: Address = 0x004, LOCK Status bit set to 1b1.
4. ATP CIA configuration:
    a. Configure CIA Control Registers
        - Configure CIA Control (CIAC): Address = 0x480, Configure number of lanes (NUM_LANE) and TPIU Control mode (TPIUCM).
5. Aurora PHY configuration:
    a. Configure APHY enable
        - Aurora Trace Port Enable (ATPE): Address = 0x488 : Configure Aurora PHY (APHYEN).
        - Wait 1 µs to complete training.

NOTE

MISR calculations start four cycles after the APMISR[AP_MISR_START] time, and MISR calculations stop four cycles after the APMISR[AP_MISR_STOP] time.

6. Aurora Link configuration:
    a. Configure Aurora Link Control register
        - Configure AL General Control (ALGC): Address = 0x308 , CRC Enable (CRCEN) and Clock Compensation Selection (CCOEN).
        - In case of training failure, configure AL Training Control (ALTC): Address = 0x30C , AHD (Align), BHD (Bond) and VHD (Verify).
7. Aurora enable configuration:
    a. Configure ATP enable

- Aurora Trace Port Enable (ATPE): Address = 0x488 : Configure Aurora Trace Port Enable (ATPEN).

Appendix A
Revision History

A.1 About_This_Manual module changes

• Made editorial changes.
• In Conventions, changed "Notes, cautions, and warnings" to Notes and cautions. • In Notes and cautions: — Deleted the definition for warnings (which are now deprecated). — Provided new definitions for notes and cautions.
• Added Editorial changes.
• Description of 'MOD.REG' is added in Typographic notation

A.2 Introduction changes

• In the Feature comparison table, revised the PCI express (PCIe) and SERDES rows for S32G234M. • In the Feature comparison table, removed DDR4 reference and added DDR3L reference.
• Revised the Overview section.
• In the Block Diagram, removed the DDR4 reference and added DDR3L reference.
• S32G274A is replaced with S32G2. This is a global change and implemented throughout this document and the excels embedded in this document.

A.3 Arm modules changes

• Added a point, "The MPU contains support for up to 16 regions." in Cortex-M7 core introduction
• Fixed the formatting issues of the image, "Figure 7" to ensure that it appears in the doc

A.4 FlexNoC module changes

No substantial content changes.

A.5 Chip-specific Ncore information changes

No substantial content changes.

A.6 Ncore module changes

• Added a statement about full-word access for all the registers in Ncore memory space, in Memory map and register definition.

A.7 MCM module changes

• Added reference for Arm Cortex-M7 technical reference manual in Interrupt Status and Control (ISCR) and Core Platform Control (CPCR).
• In Introduction added note "MCM is accessible using the Private Peripheral Bus of Cortex-M7".

A.8 A53_CLUSTER_GPR module changes

• In GPR08 (GPR08), for Warm Reset Status Of Core* Of Cluster* bits, updated the bit field value for 0 and 1 from "0b - Reset request completed and 1b - Reset in progress" to "0 - Reset in progress and 1 - Reset request completed".

A.9 CM7_CLUSTER_GPR module changes

No substantial content changes.

A.10 Chip-specific eDMA information changes

No substantial content changes.

A.11 eDMA3 module changes

• Added glossary. • Removed 'otherwise, a configuration error is reported' from TCDn_BITER_ELINKYES[BITER] and TCDn_BITER_ELINKNO[BITER]. • Fixed xref issue in Lockstep. • In Figure 22 replaced ACTIVE and DONE with EEOP and ESDA.
• In Testing for minor loop completion splitted the table heading for CHn_CSR and TCDn_CSR fields.
• In TCDn_NBYTES_MLOFFNO replaced TCDn word 2 with correct register (TCDn_BYTES_MLOFFNO/ TCDn_BYTES_MLOFFYES). • In TCDn_NBYTES_MLOFFYES replaced TCDn_NBYTES_™* with correct register (TCDn_BYTES_MLOFFNO/ TCDn_BYTES_MLOFFYES).

A.12 DMA_CRC module changes

No substantial content changes.

A.13 Chip-specific DMAMUX information changes

No substantial content changes.

A.14 DMAMUX module changes

• Updated the section Enabling and configuring sources, and added comments to the code lines.

- Removed the word "for example" from the phrase "for example PIT" in the sections DMA channels with periodic triggering capability, and Modes of operation.
- Minor editorial changes throughout.

A.15 Chip-specific XRDC information changes

- In Table 48, updated from Input from master to Input from master(0):
  - XRDC_MDAC8, XRDC_MDAC9, XRDC_MDAC10
- In Table 49, updated from DRAM0_COHERENT(0) to DRAM0_A53(0).
- In Table 49, updated from M7_TCM_0(0), M7_TCM_1(1), and M7_TCM_2(2) to M7_TCM_0(0), M7_TCM_1(0), and M7_TCM_2(0) for MRC11.
- In MDAC configurations, added a note, "Input DID is 0 for all masters except DMA MDAC which takes input from DMA."

A.16 XRDC module changes

- Added Glossary
- Added 'It also clears the corresponding field in DERRLOC*n* register.' in DERR_W3_*n* register description.

A.17 Application Extension-Specific SIUL2 Changes

No substantial content changes.

A.18 SIUL2 module changes

- In the MSCR and IMCR register descriptions, modified figure titles.
- In the DISR0[EIFn] field description descriptions, removed reference to "DMA request" for inapplicable field instances.
- In IREER0[IREE*n*] and IFEER0[IFEE*n*] field descriptions, corrected references to "DISR0[EIFRn]" to "DISR0[EIFn]".

A.19 SEMA42 module changes

- Added glossary.

A.20 SRC module changes

- Removed the references of cjtag from DEBUG_CONTROL[DEBUG_CLK_DISABLE]

Provided under NDA ONLY
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c42e54-8218-4848-b251-90d3a6f04c1

A.21 S32G_MAIN_GPR module changes

• Enhanced the description of the PCIE_TOGGLE register.
• Removed the CLKOUT_PAD_CTRL_REG register.
• In the the Generic Control 1 register, added a note, "In addition to programming the MC_CGM_2 to select the correct SerDes clocks, setting this bit to 1 is mandatory for SGMII mode."

A.22 S32G_STDBY_GPR module changes

No substantial content changes.

A.23 REG_PROT module changes

• Updated the #unique_4595 section — REG_PROT is a protection module that is located between the module under protection and the peripheral interface. — Writes to these protected address locations are locked using a Soft Lock Bit Register (SLBRn). Any access to address locations in the module under protection is restricted if their corresponding Soft lock fields in a Soft Lock Bit Register (SLBRn) are 1. — The configured soft-lock fields can also be write-restricted by using GCR[HLB]. When GCR[HLB]=1, you cannot write to the softlock fields. • Updated the #unique_4596 section — Write accesses for the module under protection can be restricted to the supervisor mode only. — Modules with their register slot size occupying 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory map and register definition. — Multiple ways are present to set the lock bits. • Updated the #unique_4597 section — This section provides a detailed description of the memory map of a module using register protection with instantiating a REG_PROT wrapper. — The resulting memory space is divided into four areas. Memory locations within Area 1 and Area 2 are a part of the module under protection. Area 3 and Area 4 are a part of REG_PROT. — See the Offset column to know the exact location of the GCR register. • Updated the #unique_4598 section — The register protection size can be. — The addresses that are protected and the register protection size depends on the chip and/or module. — If an address is unprotected, the corresponding SLBRn[SLBm] bit is always 0, regardless of what the software writes to that field. • Updated the #unique_4599 section. • Updated the #unique_4600 section. • Updated the #unique_4601 section.

Table continues on the next page...

- Updated the chapter for the following points:
  - SLBn to SLB*n*
  - SLBR*n*(SLB*m*) to SLBR*n*[SLB*m*]
  - Area to Area#
  - SLBR*n*[SLBR*m*] to SLBR*n*[SLB*m*]
  - See the REG_PROT sheet attached to this document to See the REG_PROT details file attached to this document.
- Updated the definition of PROT_MEM in #unique_4602 from "Memory protection size" to "Integration parameter that specifies the size of the module register slot protected".
- Removed the phrase, "Only a write to the mirror-module space can change a lock field to 1. Reading the mirror-module space does not change the lock fields." from the end of #unique_4599 section.
- Added a phrase, "Note that reading area #2 does not affect soft lock bits." in #unique_4599 section.
- Added the #unique_4603 back to the map and removed the definition of Module register (MR) from the #unique_4602 section.

- Switched the order of bullet points in #unique_4604 section.
- Added the phrase, "The following shows an example with PROT_MEM = 8 KB where SLBs are modified using area #2." and updated from "0Ch and 0Dh" to "000Ch and 000Dh" in #unique_4599 section.
- Added a phrase, "The PROT_MEM size varies per chips." in #unique_4597 section.

A.24 Chip-specific [S32G] information changes

- Added a topic Enabling wakeup pads
- Updated the note in Pull control of wake-up pads
- Added a note in Asynchronous wake-up sources for various modes.
- In the Wakeup/Interrupt Pull Enable Register (WIPUER_WIPDER) section, added a note " Enabling pull-ups on the wake-up pins during the Standby mode will increase the overall standby power consumption."

A.25 WKPU module changes

No substantial content changes.

A.26 Clocking changes

- In section Input clock pins corrected table alignment. No content change.
- In section SIRC corrected "POR_WDG" to "POR_WDOG".
- In section PLL SSCG Setup modified sentence before bullet for clarification.

- In section PLL corrected "HSE" to "HSE_H".

- In section PFE_MAC_0 clocking overview moved CMU_FC_46 to monitor PFE_MAC_0_TX_DIV_CLK in the diagram.

Table continues on the next page...

• In section Clock input sources Table 105 changed the CMU_FC_46 monitored clock to PFE_MAC_0_TX_DIV_CLK.
• Removed section "Built-In Self-Test configuration".
• In sections PFE_MAC_0 clocking overview and Application clock source options added SERDES_1_LANE_0_TX_CLK clock to MC_CGM2 Clock mux1 Selector.
• In section Peripheral-related clock overview corrected diagram by adding a DIV at mux 15 output between the GMAC_0_REF_CLK and GMAC_0_REF_DIV_CLK connections.

A.27 MC_CGM module changes

• Updated the description of MUX_n_DIV_UPD_STAT[DIV_STAT] field. • Updated the description of the "PCFS Step Duration" register. • Added section: Glossary.
• In Software-controlled clock multiplexer, updated the first sentence of the second bullet in the note. • Added following note at the end of the sections: Hardware-controlled clock multiplexer and Software-controlled clock multiplexer: The above flowchart steps can be preceded by points 1 and 3 below ...

A.28 DFS module changes

No substantial content changes.

A.29 PLLDIG module changes

• In section Modes of operation, added title to figure.
• In section Block diagram added description that number of output dividers can vary with the module instance.
• In PLLCAL2 register section corrected ULKCTL field description.

A.30 FXOSC module changes

• In section Initialization information subsection Initializing FXOSC: — Modified first bullet in first NOTE to clarify it is referring to the default mode when the module is enabled. — Added step to set EOCV and moved the content of the "Calculating EOCV" subsection to be part of this procedure. — Added step to confirm that the clock is stable.
• In section Initialization information: — Removed step "Configure inputs needed for FXOSC". — Removed first bullet in first NOTE on the default mode when OSC_BYP and COMP_EN fields are not set.
• In CTRL[GM_SEL] field description NOTE:

Preliminary Information
COMPANY CONFIDENTIAL

— Modified bullet on GM_SEL = 0 to apply to Crystal mode and Differential Bypass mode. — Replaced description on configuration of this field with a reference to the Initialization information section. • In section Initialization information: — Modified GM_SEL configuration description to provide guidance for each mode. — Modified NOTE bullet on GM_SEL = 0 to apply to Crystal mode and Differential Bypass mode.

A.31 Reset changes

• In Reset changes added a bullet "Boot configuration pins" and a note "To allow the boot configuration pins to be properly sampled, you must ensure that the corresponding I/O power supplies are within their specified ranges. If this is not the case, the reset sequence is not prevented from completing, but could lead to an incorrect boot".
• Removed the reference of cJTAG from the chapter.

A.32 Chip-specific MC_RGM information changes

No substantial content changes.

A.33 MC_RGM module changes

• Removed the section: PAD tristate interface. • Added section: RESET_B pin assertion and pin safe state control. • Added note in ERCTRL[ERASSERT].
• Changed the "Warning" to "Note" in Functional Event Reset Disable Register (FERD).

A.34 Boot changes

• In BootROM impact on module registers' reset values — Added a note.
• Updated Table 163.
• Changed the IVT offset for SD/MMC/eMMC entry from "0h" to "1000h" in Table 127. • In Functional description removed the note "By default, the boot ROM is configured for a flash-memory size of 1 MB. If you need to prepare an image greater than 1 MB, you must reconfigure the flash-memory size using a QuadSPI configuration parameter".
• In PHY identification and configuration: — Removed three from the text "BootROM maintains a list of RGMII PHYs against which these PHYIDn registers are compared". — Changed 2.5 seconds to 5 seconds in the texts "BootROM expects PHYs to start Autonegotiation after every reset and wait for autonegotiation to complete within 5 seconds" and in the first bullet "Autonegotiation fails within 5 seconds".

Table continues on the next page...

- Thoroughly updated Ethernet boot.

- In Functional description:
  - In Table 170 added the text "BootROM uses BOOT_CFG/RCON based values, table 170, for configuring QSPI controller for applying successful initial configuration" in the QuadSPI initial configuration description.
  - In Table 170 changed the changed the settings of RCON/BOOT_CFG1[30:29] for 00 and 10 to Reserved.
- In Table 173 updated the description of DLL_AUTO_UPD_EN, DLL_SLV_UPD_EN and DLL_BYPASS_EN.

- In Table 173, changed DLL_SLV_UPD_EN to Reserved.

A.35 Power management changes

- In NCSPD configuration changed the text from "Not mapped to any monitor for S32G274A" to "Not mapped to any monitor for the chip".
- In Use case: Interfacing to external PMIC changed the text from "For interfacing to the PMIC, see S32G274A Hardware Design Guidelines" to "For interfacing to the PMIC, see the chip Hardware Design Guidelines".
- In Standby mode exit changed the text from "For more information on Standby mode exit sequence, refer to section 10 of S32G274A data sheet" to "For more information on Standby mode exit sequence, refer to the chip data sheet".

- Safety context for PMIC WDOG :
  - In "sequence of steps" list, revised "After power supplies reach correct normal operation", step for clarity.
  - Updated Deep Fail-Safe mode description for clarity.

- In the Wake-up pin pullup/pulldown control during Run and Standby modes section, added a note "It is not valid to configure the wake-up pad from SIUL2 and write zero to WKUP_PUS[WKUP_PU_OVERRIDE] of the S32G_STBY_GPR before entering the Standby mode."

- In NCSPD configuration, changed NCSPD6 to Reserved.

- In Static Voltage Scaling (SVS), changed the bullet text to:
  - DIE_PROCESS[1:0] = 01b, SVS mode 1
  - DIE_PROCESS[1:0] = 10b, SVS mode 2
  - DIE_PROCESS[1:0] = 11b, SVS mode 3
- In Static Voltage Scaling (SVS), added text "For more information on power domain SVS voltage levels, see the “Operating Conditions" section of the chip data sheet".

- In NCSPD configuration, for NCSPD8 changed the supply name from VDD_HV_PLL_DDR0 to VDD_LV_PLL_DDR0.

A.36 Chip-specific MC_ME information changes

- In MC_ME partition 1 mapping:
  - For MC_ME_PRTN1_CORE0_STAT[CCS], mentioned "Used for" column as "CA53 cluster0 core0/1".
  - For MC_ME_PRTN1_CORE0_ADDR[ADDR], mentioned "Used for" column as "Performance mode - CA53 cluster0 core0 Lockstep mode - shared control for core0 of CA53 cluster0 and cluster1"

- For MC_ME_PRTN1_CORE1_ADDR[ADDR], mentioned "Used for" column as "Performance mode - CA53 cluster0 core1 Lockstep mode - shared control for core1 of CA53 cluster0 and cluster1"
- For MC_ME_PRTN1_CORE2_STAT[CCS], mentioned "Used for" column as "CA53 cluster1 core0/1"
- For MC_ME_PRTN1_CORE2_STAT[WFI], mentioned "Used for" column as "CA53 cluster1 core0"
- For MC_ME_PRTN1_CORE3_STAT[WFI], mentioned "Used for" column as "CA53 cluster1 core1"

A.37 MC_ME module changes

- Updated the section: Glossary.

A.38 MC_PCU changes

- Updated the first sentence of the third paragraph in Introduction.

A.39 Chip-specific PMC information changes

No substantial content changes.

A.40 PMC module changes

No substantial content changes.

A.41 Chip-specific [S32G] information changes

- Created a new chip-specific section SRAMC registers topic.

A.42 SRAMC module changes

- Updated "SRAMC register descriptions" section. Added information regarding generation of transfer errors.
- Removed 'hardware initialization' related content in Features.
- updated Latency of read and write accesses to remove content related to "2-cycle Resp".

A.43 DDR module changes

- Added a new section as Performance signals/counters
- Updated the description of CSV
- Updated the description of reg_par_poison_en

Printed under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4626-480-18a8-b251-390d3ab624c1

A.44 DDR_GPR module changes

• raq_split_0, raq_split_1, raq_split_2, raqr_push_0, raqr_push_1, raqr_push_2, raqr_pop_0, raqr_pop_1, and raqr_pop_2 are hidden in Configuration 5 (DDR_Config_5)
• From: 000b RD_N (RD data for non-ECC region), 001b RD_E (RD data for ECC region), 000b WD_N (WR data for non-ECC region), and 001b WD_E (WR Data for ECC region) To: 000b RD_N (RD data for non protected region), 001b RD_E (RD data for protected region), 000b WD_N (WR data for non protected region), and 001b WD_E (WR data for protected region) in Configuration 3 (DDR_Config_3)

A.45 Chip-specific QuadSPI changes

• Added a new limitation, "It is required that the application must rely on the FCCU fault for the ECC error handling by writing '0' to the QuadSPI RSER[CRCBIE] and RSER[CRCAIE]. In cases where FCCU is not configured (for example, in the customer bootloader), these fields must be enabled" in QuadSPI limitations
• In the Chip-specific feature configuration section, added a note.

A.46 QuadSPI module changes

• Glossary table added.
• Editorial update in "Internally generated DQS" section. Changed "QuadSPI chip-specific information" to "Chip-specific QuadSPI information". • Updated TX buffer operation. Updated the statement that talks about the interrupt generated by TBUFF field.
• Updated Driving external signals - Updated description of "Dummy".
• Updated decimal notation format in Programmable sequence engine and Address scheme.
• Removed the section "Internally generated DQS". • Added a new section Pad loopback, and removed the existing section "Pad loopback DQS".
• Updates in DLLCRA and DLLCRB register — Added DLLRES field — SLV_DLY_FINE field at position 5 is now removed • Updated programming sequence for DLL auto update mode in DLL and delay chain usage.

A.47 uSDHC module changes

• Changed the size of bit TUNING_CTRL[TUNING_START_TAP] from 7 to 6. • Added a new bit, TUNING_CTRL[DIS_CMD_CHK_FOR_STD_TUNING] .
• Added Command Queue Register Map from 100h to 15Ch in uSDHC register descriptions
• Corrected the reset value of Command Queuing Capabilities (CQCAP) and Command Queuing Send Status Configuration 1 (CQSSC1) as 0x0000_310A and 0x0001_1000

Table continues on the next page...

• Corrected from "<cmd_index> & 0x3f) >> 24;" to "<cmd_index> & 0x3f) << 24;" in Command send & response receive basic operation
• In DLL_CTRL[DLL_CTRL_SLV_DLY_TARGET0], added a note, "For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.". • In STROBE_DLL_CTRL[STROBE_DLL_CTRL_SLV_DLY_TARGET], added a note, "For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK/16.".

A.48 Chip-specific STM information changes

No substantial content changes.

A.49 STM module changes

No substantial content changes.

A.50 Chip-specific SWT information changes

No substantial content changes.

A.51 SWT module changes

• Added "soft" to the title of Avoid accidental soft unlock. • In that topic, changed "generator can include the unlock keys for soft lock" to "generator includes the unlock keys for soft lock".

A.52 Chip-specific PIT information changes

No substantial content changes.

A.53 PIT_RTI module changes

• In Example configuration for the Lifetime Timer, removed the sentence "The timer is a downcounter".

A.54 Chip-specific FTM information changes

• In FTM instances, updated Quadrature decoder filter to Quadrature decoder.

A.55 FTM module changes

No substantial content changes.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462548-1481-48a8-b251-390d3ab624c1

A.56 RTC module changes

No substantial content changes.

A.57 I²C module changes

• Revised Divider and hold values.

A.58 Chip-specific GMAC changes

No substantial content changes.

A.59 PFE module changes

No substantial content changes.

A.60 Chip-specific FlexRay information changes

No substantial content changes.

A.61 FlexRay module changes

• Made editorial changes.
• Made editorial changes.
• Made editorial changes.
• Made editorial changes.

A.62 LINFlexD module changes

No substantial content changes.

A.63 Chip-specific SPI information changes

No substantial content changes.

A.64 Chip-specific FlexCAN information changes

No substantial content changes.

A.65 FlexCAN module changes

• Added new instruction to initialization sequence in FlexCAN initialization sequence.

Table continues on the next page...

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
e8c46265-4821-48a8-b251-390d3ab624c1

• Fixed problem in note explaining maximum range value in Detection and correction of memory errors. • Created Glossary and added links to it from multiple topics.
• In FlexCAN initialization sequence changed "The FlexCAN module may be reset in three ways" to "You can reset FlexCAN in the following ways."
• In Error and Status 1 register (ESR1), added the following text to all read-only error-flag fields: "After a read operation, the field's value clears to 0." • Made editorial changes.
• Made editorial changes.

A.66 S32G CAN Timestamp changes

No substantial content changes.

A.67 Chip-specific SerDes information changes

• Added Unexpected behavior when enabling error injection in DMA Channel context memories of SerDes
• In SerDes subsystem working modes, a note about S32G234M.
• Added Converting nonsecure accesses to secure accesses.

A.68 SERDES_GPR module changes

No substantial content changes.

A.69 LLCE module

• Changed CAN instances to BCAN. • Added high-level block diagram. • Added FIFO interrupts • Added Core-to-Core module • Added Interrupts and status

A.70 Chip-specific USBOTG changes

• Added a new chip-specific section SBUSCFG[AHBBRST] field reset value topic.

A.71 USBOTG module changes

• Editorial changes • In Host mode events, corrected "PORTSC1[WKDC]" to be "PORTSC1[WKDS]"

Table continues on the next page...

• Editorial changes
• Added a new field - CR[UCMALLBE] • Updated "PID Code" description in qTD token. • Removed mention of TTCTRL register from Asynchronous transaction scheduling and buffer management and Operational registers. • Removed mention of CTRLDSSEGMENT register from FSTN back path link pointer . • Changed occurrences of EPCR register throughout the chapter to ENDPTCTRL register. • Updated field descriptions for the following. Updates are only to refer to the correct fields from the text: — OTGSC[DPIS] — USBMODE[SDIS] — ENDPTSTAT[ETBR] — USBSTS[UEI] — ENDPTCOMPLETE[ETCE] — ENDPTCOMPLETE[ERCE] — ENDPTCTRLn • Updated QH. • Updated Halting a QH.
• Updated field description for CR[PWRFLT] and CR[PWRFLTDF].

A.72 Chip-specific CTU changes

• Added, "Throughout the CTU chapter, ADC_0 is referred to as ADC A (ADC_A). Throughout the CTU chapter, ADC_1 is referred to as ADC B (ADC_B)" in CTU connections.

A.73 CTU module changes

No substantial content changes.

A.74 Chip-specific ADC information changes

No substantial content changes.

A.75 SAR_ADC module changes

• In STAW0R[THRH], added bandgap value information. • In STAW0R[THRL], added bandgap value information.
• In Introduction, corrected the formatting of "12-bit resolution".

Preliminary NDA only
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.
c8c42e5-4821-48a8-b251-390d3ab6240

A.76 Chip-specific TMU information changes

No substantial content changes.

A.77 TMU changes

• In Initialization information, changed from "For the last four calibration points (12-15), there are per-part trims that you need to apply. You must read these fields in the appropriate Shadow register of OCOTP—SHADOW38[EFUSES4:0], SHADOW38[EFUSES10:6],SHADOW38[EFUSES16:12], and SHADOW38[EFUSES 22:18]." changed to "For the last four calibration points (12-15), there are per-part trims that you need to apply. You must read these OCOTP fields (in the appropriate shadow register): CFG_DAC_TRIM_0, CFG_DAC_TRIM_1, CFG_DAC_TRIM_2, and CFG_DAC_TRIM_3."
• Added Table 534 to show how the eight flags are mapped to the two TMU outputs. • In Figure 543, added the single "interrupts" arrow to two signals (for example. alarm / critical alarm). • In Figure 543, removed the ADC output bitwidth "9".
• Updated the description of TCMCFG[DEMA] and TCMCFG[OCM]: — Added a note, "This field should be set to 1 for the normal TMU monitor operation. For details on initialization, see Initialization information." — Removed the description of bit field values for 0 and 1
• For the TCMCFG register: — Added a note, "The values for OCS, OCM, DEMA, DFDRCTC, and CLKDIV are chip-specific. See the "Chip-specific TMU section" for the required settings." — Updated the DAC_OFFSET reset value as undefined.

A.78 Security changes

No substantial content changes.

A.79 Chip-specific MU information changes

No substantial content changes.

A.80 MU changes

No substantial content changes.

A.81 OCOTP Controller module changes

• Added a new statement to Fuse ECC as "The OCOTP implements 7-bit ECC for every 32-bit ECC-protected eFuse word."
• A new table is added to show the OCOTP memory address space assignments - Table 546.

Posted under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
ca4605-4821-48a8-b251-390c3ab624

A.82 FBXC module changes

No substantial content changes.

A.83 Safety changes

No substantial content changes.

A.84 Chip-specific ERM information changes

• In Memory error event sources and captured information, for SRAMC 0 and SRAMC1 under ERM PER, added a footnote, "The status must be cleared from SRAM Controller (SRAMC) before clearing the ERM status for SRAMC".

A.85 ERM module changes

• Added section: Glossary. • Updated the register names to show actual error "number" instead of showing generic "n".
• Updated the Overview section. • Changed the ordering bullets in Features. • From Features, replaced the term "ECC" with "error" in points 1 and 3. • In Initialization, updated the first sentence as follows: For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory. • In Features, updated the last bullet as follows: Recording the count value of the number of corrected error events • Removed the following sentence from the "ERM register descriptions": The ERM provides an IPS programming model mapped to an on-platform peripheral slot. • Removed the term "IPS" from the following statement in "ERM register descriptions": Any of the following attempted references to the programming model generates an error termination

A.86 FCCU chip-specific changes

No substantial content changes.

A.87 FCCU module changes

• Glossary table added.
• In Introduction, replaced the term "hardware channel" with "hardware interface", moved all features from this section to Features section. • In FCCU submodules, for the HNSHK blocks submodule, clarified the clock names as "CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)" • In Signals, replaced column heading "Active level" with "Sensitivity", added "NCF" as "Programmable". • In Definitions, removed the term "edge-triggered".

Table continues on the next page...

- In FSM description, removed a paragraph, "Consider the case... has IRQ enabled.
- In FCCU state diagram, replaced the term "Any fault pending" with "pending fault (unmasked AND timeout enabled)".
- In EOUT interface, removed the table, "FCCU error pin behavior on state transitions" and text associated with it.
- In , Bi-Stable protocol , updated the terms "Normal phase" with "Non-faulty" and "Error phase" with "Faulty phase".
- Added footnote in the reset value of EINOUT[EINn]".
- In CFG register bit value at different events, replaced the table with a sentence, "In this chip, there are no events that affect the bits in the configuration register."

- In Features, re-arranged the "Lockable configuration" bullet, added sub-bullets in it.
- Removed all occurrences of "Dual-Rail" and "Time-Switching" modes from the chapter.
  - Updated CFG[SM] field as “reserved”.
- In CFG[FOM], removed the note, "In the Test modes, ...input/outputs with CLKSAFE."

- Removed the section, "Fault signal flow".

A.88 Chip-specific CMU_FC information changes

No substantial content changes.

A.89 Chip-specific CMU_FM information changes

No substantial content changes.

A.90 SELFTEST_GPR module changes

No substantial content changes.

A.91 SELFTEST_GPR_TOP module changes

No substantial content changes.

A.92 Chip-specific STCU2 information changes

- In Indicating fault state during the main reset domain self-test, Replaced, "When MC_RGM's ERCTRL[ERASSERT] field is programmed to 1 during the main reset domain self-test, along with RESET_B assertion, it also results into FCCU EOUT pins indicating the fault state" with "The Software must program the MC_RGM's ERCTRL[ERASSERT] field to 1b prior to initiating the main reset domain self-test. This results in the RESET_B pin being asserted, the FCCU EOUT pins indicating the fault state, and all other pins being put into their default state as indicated by the "Pad State During Main Reset Domain Selftest" column of the "Misc With Pin Controls" tab of IOMUX sheet".

- In STCU2 BIST start (BSTART) register description, added the field description of the register
- In Self-test programming sequence, added, "instructions for the configurations when the selftest is executed on the software resettable domain followed by the selftest run on the main reset domain, or software resettable domain."

- For LBIST28, updated the value from Reserved to NOC_Internal in STCU2 LBIST mapping

A.93 STCU2 module changes

• Added section: Glossary.
• In Main features, replaced "IPS" with "System", clarified BIST related feature, removed the term "ITF" and removed the feature, "LB_MISRELSWn[MISRESWx].... software". • Removed the term "TCK" throughout the content. • In Figure 564, removed "MC Reset" and removed extraneous terms "Kern 1 and Kern 2" from the "Fault interfaces". • In Peripheral bus interface, replaced the term, "Any other operation (such as free byte enables) has to be avoided" with "Any other operation (such as byte enable) is not supported." • In CFG[PTR], LB_CTRL[PTR], MB_CTRL[PTR] field maps, replaced "LBIST" with "NLBIST" and "MBIST" with "NMCUT" actual parameter values. • In CFG[CLK_CFG], corrected field map description: "sys_clk1" with "sys_clk/1", "sys_clk2" with "sys_clk/ 2" and so on • In field map, clarified PLL unlock as PLL unlock (loss-of-clock) • In MBSSW[MBSSWn], — updated the term "Online status of MBISTs" with "Online status of MBISTn" — updated the term "NMCUT BIST with "MBIST" • In ALGOSEL and BSTART register description, added a sentence to see "Chip-specific STCU2 information" for details. • In BIST scheduling, updated MBIST mapping in hex format and removed the reference to "Use cases and limitations" section.
In Glossary: • Rearranged the entries in alphabetical order. • Changed definitions to sentence case. • Changed "self test" to "self-test".
• Removed extraneous bracket from 3Ch and updated 06Eh value to all caps in CFG[PTR], LB_CTRL[PTR], MB_CTRL[PTR].
• In STCU2 LBIST Control (LB_CTRL0 - LB_CTRL59), updated access of field [7] to "RW" (was "RO"). • Made clarifications in the Peripheral bus interface about the write access. • In the CFG[PTR], added "others: invalid pointer...STCU2 Error (ERR_STAT)." • In BIST scheduling, added a sentence, "A BIST descriptor identifies...control register (STCU2 LBIST Control (LB_CTRL0 - LB_CTRL59) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL109))".

A.94 SBSW module changes

• Updated the description for SAFETY_IP_CLK in Signal descriptions. • Added title to the table in Signal descriptions. • Replaced all references of SBSW clock with SAFETY_IP_CLK in the chapter. • Added information in "SBSW register descriptions" about the offset address (1Ch) in the SBSW memory space on which accesses does not result in transfer error.

A.95 Chip-specific EIM information changes

- In the EIM instances, updated SerDes_1 to PCIe_1.

A.96 EIM changes

- Added section: Glossary
- In Introduction, updated the second sentence.
- Removed the term "IPS" from the first sentence of "EIM register descriptions".

- Updated the register names to show actual Error Injection Channel Descriptor "number" instead of showing generic "n".
- Removed the term "IPS" from the chapter.
- Updated the Introduction.

- Added following content in the Overview.

A.97 CRC module changes

No substantial content changes.

A.98 Chip-specific JTAGC information changes

No substantial content changes.

A.99 JTAGC module changes

- Fixed shared review rejected comments and glossary added.
- Made editorial changes.

- Shared review comments incorporated.

A.100 CJTAG module changes

No substantial content changes.

A.101 ATP module changes

No substantial content changes.

A.102 JDC module changes

- In Secure challenge/response connection procedure added statement "For details related to the lifecycle stage at which this process is performed, see the "Hardware Security Engine (HSE_B)" chapter."
