Contents

Chapter 1 About This Manual 91
1.1 Audience 91
1.2 Organization 91
1.2.1 Attachments 91
1.3 Module descriptions 91
1.3.1 Chip-specific information that clarifies content in the same chapter 92
1.3.2 Chip-specific information that refers to a different chapter 93
1.4 Register descriptions 94
1.5 Conventions 95
1.5.1 Notes and cautions 95
1.5.2 Numbering systems 95
1.5.3 Typographic notation 95
1.5.4 Special terms 96
1.6 Editorial changes 97

Chapter 2 Introduction 98
2.1 Overview 98
2.2 Applications 98
2.3 Block diagram 98
2.4 Module functional categories 99
2.5 Feature comparison 101

Chapter 3 Memory Map 105
3.1 Introduction 105

Chapter 4 Signal Description 106
4.1 IOMUX and signal details 106

Chapter 5 Arm Modules 107
5.1 Core complex platform components 107
5.2 Cortex-A53 cluster complex 107
5.2.1 Arm Cortex-A53 MPCore 107
5.2.2 Arm CoreLink Generic Interrupt Controller (GIC-500) 109
5.3 Operation details 112
5.3.1 Operation mode 112
5.3.2 Booting Cortex-A53 cores in 32-bit mode 112
5.3.3 Cluster clock gating 112
5.3.4 Cortex-A53 system counter 113
5.3.5 Cortex-A53 system error interrupt 113
5.3.6 Cortex-A53 wake-up from WFE 113
5.3.7 Cortex-A53 PMUEVENT bus signals observation 113
5.3.7.1 PMUEVENT observer register descriptions 114
5.3.7.1.1 PMUEVENTOBSERVER memory map 114
5.3.7.1.2 PMUEVENT Observer Control Register (CTL0 - CTL29) 114
5.3.7.1.3 PMUEVENT Observer Status Register (STAT0 - STAT29) 116
5.3.8 Cortex-A53/GIC500 lockstep operation 116
5.3.9 Cortex-M7 lockstep operation 119

5.4 Cortex-M7 overview....120
5.4.1 Cortex-M7 core introduction....120
5.4.1.1 Buses, interconnects, and interfaces....120
5.4.2 Debug facilities....121

Chapter 6 NoC Subsystem....122
6.1 Introduction....122
6.2 Functional description....122
6.2.1 Observability....122
6.2.1.1 Concepts....122
6.2.1.1.1 Packet and transaction probes....122
6.2.1.1.2 Observers....123
6.2.1.2 Operation....123
6.2.1.2.1 Logging errors....123
6.2.1.2.2 Tracing packets....124
6.2.1.2.3 Collecting statistics....127
6.2.1.2.4 Transaction profiling operation....128
6.2.1.2.5 Activating observer debug output....129
6.2.1.3 Technical reference....129
6.2.1.3.1 Observation probes....129
6.2.1.3.2 Observers....130
6.2.2 QoS....138
6.2.2.1 Concepts....138
6.2.2.1.1 QoS generators....138
6.2.2.2 Programming....139
6.2.2.2.1 Programming QoS generators....139
6.2.3 Resilience features....142
6.2.3.1 Fault aggregation and reporting....142
6.2.3.1.1 Unit fault aggregation and reporting....142
6.2.3.1.2 Fault controller....143

Chapter 7 Ncore....147
7.1 Chip-specific Ncore information....147
7.1.1 Ncore interface units....147
7.2 Introduction....147
7.3 Features....147
7.4 Block diagram....148
7.5 Signal description....148
7.6 Functional description....148
7.6.1 Caches and cache coherency....148
7.6.2 Ncore agents....148
7.6.3 Ncore interfaces....149
7.6.3.1 Coherent agent interface (CAI)....149
7.6.3.2 Coherent memory interface (CMI)....150
7.6.3.3 Non coherent bridge (NCB)....150
7.6.3.4 Directory....150
7.6.3.4.1 Snoop filter....150
7.6.4 Transport interconnect....151
7.6.5 Storage protection....151
7.6.5.1 Error types....152
7.6.6 Resiliency....152
7.6.6.1 Component logic duplication....153
7.6.6.2 Fault controller....154

7.6.6.3 BIST sequence 154
7.6.7 Coherent read/write transactions 155
7.6.7.1 Coherent read transactions 155
7.6.7.2 Coherent write transactions 155
7.7 Reset and initialization 155
7.7.1 CAI initialization 156
7.7.2 CMI initialization 156
7.7.3 NCB initialization 156
7.7.4 Directory initialization 156
7.7.5 Discovery routine 157
7.8 Maintenance operations 157
7.8.1 Snoop filter maintenance 158
7.9 Power management 159
7.9.1 CAI power management 160
7.9.1.1 Isolated power state 160
7.9.2 NCB power management 161
7.9.3 CMI power management 161
7.9.4 Directory power management 162
7.10 Memory map and register definition 162
7.10.1 Coherent agent interface unit (CAIU) register descriptions 162
7.10.1.1 CAIU memory map 162
7.10.1.2 CAIU Transaction Control (CAIUTC) 163
7.10.1.3 CAIU Transaction Activity (CAIUTA) 163
7.10.1.4 CAIU Correctable Error Control (CAIUCEC) 164
7.10.1.5 CAIU Correctable Error Status (CAIUCES) 165
7.10.1.6 CAIU Correctable Error Location Register 0 (CAIUCELR0) 167
7.10.1.7 CAIU Correctable Error Location Register 1 (CAIUCELR1) 168
7.10.1.8 CAIU Correctable Error Status Alias (CAIUCESA) 168
7.10.1.9 CAIU Uncorrectable Error Control (CAIUUEC) 170
7.10.1.10 CAIU Uncorrectable Error Status (CAIUUES) 171
7.10.1.11 CAIU Uncorrectable Error Location Register 0 (CAIUUELR0) 172
7.10.1.12 CAIU Uncorrectable Error Location Register 1 (CAIUUELR1) 173
7.10.1.13 CAIU Uncorrectable Error Status Alias (CAIUUESA) 174
7.10.1.14 CAIU Identification (CAIUID) 175
7.10.2 Non-coherent bridge unit (NCBU) register descriptions 177
7.10.2.1 NCBU memory map 177
7.10.2.2 NCBU Transaction Control (NCBUTC) 177
7.10.2.3 NCBU Transaction Activity (NCBUTA) 178
7.10.2.4 NCBU Correctable Error Control (NCBUCEC) 179
7.10.2.5 NCBU Correctable Error Status (NCBUCES) 180
7.10.2.6 NCBU Correctable Error Location Register 0 (NCBUCELR0) 182
7.10.2.7 NCBU Correctable Error Location Register 1 (NCBUCELR1) 183
7.10.2.8 NCBU Correctable Error Status Alias (NCBUCESA) 183
7.10.2.9 NCBU Uncorrectable Error Control (NCBUUEC) 185
7.10.2.10 NCBU Uncorrectable Error Status (NCBUUES) 186
7.10.2.11 NCBU Uncorrectable Error Location Register 0 (NCBUUELR0) 187
7.10.2.12 NCBU Uncorrectable Error Location Register 1 (NCBUUELR1) 188
7.10.2.13 NCBU Uncorrectable Error Status Alias (NCBUUESA) 189
7.10.2.14 NCBU Identification Register (NCBUID) 190
7.10.3 Directory unit (DIRU) register descriptions 192
7.10.3.1 DIRU memory map 192
7.10.3.2 DIRU Transaction Activity (DIRUTA) 192
7.10.3.3 DIRU Snoop Filtering Enable (DIRUSFE) 193
7.10.3.4 DIRU Caching Agent Snoop Enable (DIRUCASE0) 194
7.10.3.5 DIRU Caching Agent Snoop Activity (DIRUCASA0) 195

7.10.3.6 DIRU Snoop Filter Maintenance Control (DIRUSFMC)..... 195
7.10.3.7 DIRU Snoop Filter Maintenance Activity (DIRUSFMA)..... 197
7.10.3.8 DIRU Snoop Filter Maintenance Location Register 0 (DIRUSFMLR0)..... 197
7.10.3.9 DIRU Snoop Filter Maintenance Location Register 1 (DIRUSFMLR1)..... 198
7.10.3.10 DIRU Correctable Error Control (DIRUCEC)..... 199
7.10.3.11 DIRU Correctable Error Status (DIRUCES)..... 200
7.10.3.12 DIRU Correctable Error Location Register 0 (DIRUCELR0)..... 202
7.10.3.13 DIRU Correctable Error Location Register 1 (DIRUCELR1)..... 203
7.10.3.14 DIRU Correctable Error Status Alias (DIRUCESA)..... 204
7.10.3.15 DIRU Uncorrectable Error Control (DIRUUEC)..... 205
7.10.3.16 DIRU Uncorrectable Error Status (DIRUUES)..... 206
7.10.3.17 DIRU Uncorrectable Error Location Register 0 (DIRUUELR0)..... 208
7.10.3.18 DIRU Uncorrectable Error Location Register 1 (DIRUUELR1)..... 209
7.10.3.19 DIRU Uncorrectable Error Status Alias (DIRUUESA)..... 210
7.10.3.20 DIRU Identification Register (DIRUID)..... 212
7.10.4 Coherent memory interface unit (CMIU) register descriptions..... 212
7.10.4.1 CMIU memory map..... 212
7.10.4.2 CMIU Transaction Activity (CMIUTA)..... 213
7.10.4.3 CMIU Correctable Error Control (CMIUCEC)..... 214
7.10.4.4 CMIU Correctable Error Status (CMIUCES)..... 215
7.10.4.5 CMIU Correctable Error Location Register 0 (CMIUCELR0)..... 216
7.10.4.6 CMIU Correctable Error Location Register 1 (CMIUCELR1)..... 217
7.10.4.7 CMIU Correctable Error Status Alias (CMIUCESA)..... 218
7.10.4.8 CMIU Uncorrectable Error Control (CMIUUEC)..... 219
7.10.4.9 CMIU Uncorrectable Error Status (CMIUUES)..... 220
7.10.4.10 CMIU Uncorrectable Error Location Register 0 (CMIUUELR0)..... 222
7.10.4.11 CMIU Uncorrectable Error Location Register 1 (CMIUUELR1)..... 223
7.10.4.12 CMIU Uncorrectable Error Status Alias (CMIUUESA)..... 223
7.10.4.13 CMIU Identification Register (CMIUID)..... 225
7.10.5 Coherent subsystem (CSR) register descriptions..... 226
7.10.5.1 CSR memory map..... 226
7.10.5.2 Coherent Subsystem ACE DVM Snoop Enable (CSADSE0)..... 227
7.10.5.3 Coherent Subsystem ACE DVM Snoop Activity (CSADSA)..... 227
7.10.5.4 Coherent Subsystem Correctable Error Interrupt Status (CSCEIS0 - CSCEIS3)..... 228
7.10.5.5 Coherent Subsystem Correctable Error Interrupt Status (CSCEIS4 - CSCEIS6)..... 229
7.10.5.6 Coherent Subsystem Uncorrectable Error Interrupt Status (CSUEIS0 - CSUEIS3)..... 230
7.10.5.7 Coherent Subsystem Uncorrectable Error Interrupt Status (CSUEIS4 - CSUEIS6)..... 231
7.10.5.8 Coherent Subsystem Snoop Filter Identification (CSSFIDR0)..... 232
7.10.5.9 Coherent Subsystem Snoop Filter Identification (CSSFIDR1 - CSSFIDR31)..... 233
7.10.5.10 Coherent Subsystem Unit Identification (CSUID)..... 234
7.10.5.11 Coherent Subsystem Identification (CSID)..... 236
7.10.6 CCTI fault controller register descriptions..... 236
7.10.6.1 CCTI_fault_ctrl memory map..... 237
7.10.6.2 Core ID (COREID)..... 237
7.10.6.3 Revision ID (REVISIONID)..... 238
7.10.6.4 Mission Fault 0 (MISSION_FAULT0)..... 239
7.10.6.5 Mission Fault 1 (MISSION_FAULT1)..... 240
7.10.6.6 Mission Fault 2 (MISSION_FAULT2)..... 241
7.10.6.7 Mission Fault 3 (MISSION_FAULT3)..... 241
7.10.6.8 Latent Fault 0 (LATENT_FAULT0)..... 242
7.10.6.9 Latent Fault 1 (LATENT_FAULT1)..... 243
7.10.6.10 Latent Fault 2 (LATENT_FAULT2)..... 244
7.10.6.11 Latent Fault 3 (LATENT_FAULT3)..... 245
7.10.6.12 Faults (FAULTS)..... 245
7.10.6.13 Interrupt Enable (INTEN)..... 246

7.10.6.14 Interrupt Clear (INTCLR)....247
7.10.6.15 BIST Control (BISTCTL)....248
7.10.6.16 BIST Done (BIST_DONE)....249
7.10.6.17 BIST Timeout 1 (BIST_TO1)....250
7.10.6.18 BIST Timeout 2 (BIST_TO2)....251
7.10.7 Functional safety controller (FSC) register descriptions....251
7.10.7.1 FSC memory map....251
7.10.7.2 FSC BIST Control (SCBISTC)....252
7.10.7.3 FSC BIST Activity (SCBISTA)....252
7.10.7.4 FSC Correctable Errors Threshold (SCCETH)....254
7.10.7.5 FSC Latent Fault (SCLF0)....254
7.10.7.6 FSC Mission Fault (SCMF0)....255
7.10.7.7 FSC Correctable Error Threshold Fault (SCCETHF0)....256

Chapter 8 Miscellaneous System Control Module (MSCM)....258
8.1 Introduction....258
8.1.1 Features....258
8.2 Memory map and register definition....258
8.2.1 Core configuration registers....258
8.2.2 Shared peripheral interrupt (SPI) routing....259
8.2.3 MSCM register descriptions....259
8.2.3.1 MSCM memory map....259
8.2.3.2 Processor X Type Register (CPXTYPE)....264
8.2.3.3 Processor X Number Register (CPXNUM)....265
8.2.3.4 Processor X Revision Register (CPXREV)....266
8.2.3.5 Processor X Configuration 0 Register (CPXCFG0)....267
8.2.3.6 Processor X Configuration 1 Register (CPXCFG1)....269
8.2.3.7 Processor X Configuration 2 Register (CPXCFG2)....270
8.2.3.8 Processor X Configuration 3 Register (CPXCFG3)....272
8.2.3.9 Processor Type Register (CP0TYPE - CP6TYPE)....274
8.2.3.10 Processor Number Register (CP0NUM - CP6NUM)....276
8.2.3.11 Processor Count Register (CP0REV - CP6REV)....277
8.2.3.12 Processor Configuration 0 Register (CP0CFG0 - CP6CFG0)....279
8.2.3.13 Processor Configuration 1 Register (CP0CFG1 - CP6CFG1)....281
8.2.3.14 Processor Configuration 2 Register (CP0CFG2 - CP6CFG2)....283
8.2.3.15 Processor Configuration 3 Register (CP0CFG3 - CP6CFG3)....285
8.2.3.16 Interrupt Router CPa Interruptb Status Register (IRCP0ISR0 - IRCP6ISR2)....288
8.2.3.17 Interrupt Router CPa Interruptb Generation Register (IRCP0IGR0 - IRCP6IGR2)....290
8.2.3.18 Interrupt Router CPa Interruptb Status Register (IRCP0ISR3 - IRCP6ISR4)....291
8.2.3.19 Interrupt Router CPn Interruptx Generation Register (IRCP0IGR3 - IRCP6IGR3)....294
8.2.3.20 Interrupt Router CPn Interruptx Generation Register (IRCP0IGR4 - IRCP6IGR4)....296
8.2.3.21 Interrupt Router Configuration Register (IRCPCFG)....298
8.2.3.22 Interrupt Router Non-Maskable Interrupt Control Register (IRNMIC)....300
8.2.3.23 Interrupt Router Shared Peripheral Routing Control Register (IRSPRC0 - IRSPRC239)....301
8.3 Functional description....302
8.3.1 MSI routing....303
8.3.1.1 Core-to-core MSIs....304
8.3.1.2 PCIe-to-core MSIs....304
8.3.2 Interrupt steering and semaphores....304
8.3.2.1 Interrupt handling overview....304
8.3.2.2 MSCM interrupt router functional description....305

Chapter 9 Miscellaneous Control Module (MCM)....306

9.1 Introduction....306
9.1.1 Features....306
9.2 Memory map/register descriptions....306
9.2.1 MCM register descriptions....306
9.2.1.1 MCM memory map....306
9.2.1.2 SoC-defined Platform Revision (PLREV)....307
9.2.1.3 Processor Core Type (PCT)....307
9.2.1.4 Core Platform Control (CPCR)....308
9.2.1.5 Interrupt Status and Control (ISCR)....309
9.2.1.6 Local Memory Descriptor 0 (LMEM_DESC_0)....312
9.2.1.7 Local Memory Descriptor a (LMEM_DESC_1 - LMEM_DESC_2)....315
9.2.1.8 Local Memory Descriptor 3 (LMEM_DESC_3)....317
9.2.1.9 Local Memory Descriptor 4 (LMEM_DESC_4)....320
9.3 Functional description....322
9.3.1 Interrupts....322
9.4 Glossary....322

Chapter 10 A53 Cluster General Purpose Registers (A53_GPR)....323
10.1 Introduction....323
10.2 Technical reference....323
10.3 A53_CLUSTER_GPR register descriptions....323
10.3.1 A53_CLUSTER_GPR memory map....323
10.3.2 GPR00 (GPR00)....324
10.3.3 GPR01 (GPR01)....326
10.3.4 GPR06 (GPR06)....328
10.3.5 GPR07 (GPR07)....329
10.3.6 GPR08 (GPR08)....330
10.3.7 GPR09 (GPR09)....333
10.3.8 Cluster0 Core0 CPUMERRSR High (GPR10)....334
10.3.9 Cluster0 Core0 CPUMERRSR Low (GPR11)....335
10.3.10 Cluster0 Core1 CPUMERRSR High (GPR12)....336
10.3.11 Cluster0 Core1 CPUMERRSR Low (GPR13)....336
10.3.12 Cluster1 Core0 CPUMERRSR High (GPR14)....337
10.3.13 Cluster1 Core0 CPUMERRSR Low (GPR15)....338
10.3.14 Cluster1 Core1 CPUMERRSR High (GPR16)....339
10.3.15 Cluster1 Core1 CPUMERRSR Low (GPR17)....339
10.3.16 Cluster0 L2MERRSR High (GPR18)....340
10.3.17 Cluster0 L2MERRSR Low (GPR19)....341
10.3.18 Cluster1 L2MERRSR High (GPR20)....342
10.3.19 GPR21 (GPR21)....342

Chapter 11 Cortex-M7 Cluster General Purpose Registers (CM7_GPR)....344
11.1 Introduction....344
11.2 CM7_CLUSTER_GPR register descriptions....344
11.2.1 CM7_CLUSTER_GPR memory map....344
11.2.2 Cortex-M7 GPR0 (CORTEXM7_GPR0)....344

Chapter 12 Enhanced Direct Memory Access (eDMA)....346
12.1 Chip-specific eDMA information....346
12.1.1 eDMA instances....346
12.1.2 ECC support....346
12.1.3 eDMA bandwidth management....346

12.2 Introduction....346
12.2.1 eDMA system block diagram....347
12.2.2 Block parts....347
12.2.3 Features....348
12.3 Modes of operation....349
12.4 Memory map/register definition....349
12.4.1 DMA MP register descriptions....350
12.4.1.1 MP memory map....350
12.4.1.2 Management Page Control (CSR)....351
12.4.1.3 Management Page Error Status (ES)....354
12.4.1.4 Management Page Interrupt Request Status (INT)....356
12.4.1.5 Management Page Hardware Request Status (HRS)....357
12.4.1.6 Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)....358
12.4.2 DMA TCD register descriptions....359
12.4.2.1 TCD memory map....359
12.4.2.2 Channel Control and Status (CH0_CSR - CH31_CSR)....360
12.4.2.3 Channel Error Status (CH0_ES - CH31_ES)....362
12.4.2.4 Channel Interrupt Status (CH0_INT - CH31_INT)....364
12.4.2.5 Channel System Bus (CH0_SBR - CH31_SBR)....365
12.4.2.6 Channel Priority (CH0_PRI - CH31_PRI)....367
12.4.2.7 TCD Source Address (TCD0_SADDR - TCD31_SADDR)....368
12.4.2.8 TCD Signed Source Address Offset (TCD0_SOFF - TCD31_SOFF)....369
12.4.2.9 TCD Transfer Attributes (TCD0_ATTR - TCD31_ATTR)....370
12.4.2.10 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD31_NBYTES_MLOFFNO)....371
12.4.2.11 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD31_NBYTES_MLOFFYES)....372
12.4.2.12 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD31_SLAST_SDA)....374
12.4.2.13 TCD Destination Address (TCD0_DADDR - TCD31_DADDR)....375
12.4.2.14 TCD Signed Destination Address Offset (TCD0_DOFF - TCD31_DOFF)....376
12.4.2.15 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO)....377
12.4.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES)....378
12.4.2.17 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD31_DLAST_SGA)....379
12.4.2.18 TCD Control and Status (TCD0_CSR - TCD31_CSR)....380
12.4.2.19 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD31_BITER_ELINKNO)....383
12.4.2.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD31_BITER_ELINKYES)....384
12.5 Functional description....385
12.5.1 eDMA basic data flow....386
12.5.2 Fault reporting and handling....388
12.5.3 Channel preemption....389
12.6 Initialization/application information....389
12.6.1 eDMA initialization....389
12.6.2 eDMA arbitration....391
12.6.3 Programming errors....393
12.6.4 Arbitration mode considerations....393
12.6.4.1 Fixed group arbitration, fixed channel arbitration....393
12.6.4.2 Fixed group arbitration, round-robin channel arbitration....393
12.6.5 Performing DMA transfers....393
12.6.5.1 Single request....393

12.6.5.2 Multiple requests....394
12.6.5.3 Using the modulo feature....395
12.6.6 Monitoring transfer descriptor status....396
12.6.6.1 Testing for minor loop completion....396
12.6.6.2 Reading the transfer descriptors of active channels....397
12.6.6.3 Checking channel preemption status....397
12.6.7 Channel linking....397
12.6.8 Dynamic programming....398
12.6.8.1 Dynamically changing the channel priority....398
12.6.8.2 Dynamic channel linking....398
12.6.8.3 Dynamic scatter/gather....399
12.6.8.3.1 Method 1 (channel not using major loop channel linking)....399
12.6.8.3.2 Method 2 (channel using major loop channel linking)....400
12.6.9 Lockstep....400
12.6.10 Suspend/resume a DMA channel with active hardware service requests....401
12.6.10.1 Suspend an active DMA channel....401
12.6.10.2 Resume a DMA channel....402
12.7 Glossary....402

Chapter 13 DMA CRC Module (DMA_CRC)....403
13.1 Introduction....403
13.1.1 Block diagram....403
13.1.2 Features....403
13.1.3 Mode of operation....404
13.2 DMA_CRC register descriptions....404
13.2.1 DMA_CRC memory map....404
13.2.2 Global Enable CRC Register (GEC)....405
13.2.3 CRC Control Register (CTL0 - CTL7)....406
13.2.4 Initial CRC Value Register (ICRC0 - ICRC7)....409
13.2.5 Final CRC Value Register (FCRC0 - FCRC7)....410
13.3 Functional description....410

Chapter 14 Direct Memory Access Multiplexer (DMAMUX)....412
14.1 Chip-specific DMAMUX information....412
14.1.1 DMAMUX-to-eDMA channel mapping....412
14.2 Introduction....412
14.2.1 Overview....412
14.2.2 Features....413
14.2.3 Modes of operation....413
14.3 Memory map/register definition....413
14.3.1 DMAMUX register descriptions....413
14.3.1.1 DMAMUX memory map....413
14.3.1.2 Channel Configuration register (CHCFG0 - CHCFG15)....414
14.4 Functional description....415
14.4.1 DMA channels with periodic triggering capability....416
14.4.2 DMA channels with no triggering capability....417
14.4.3 Always-enabled DMA sources....417
14.5 Initialization/application information....418
14.5.1 Reset....418
14.5.2 Enabling and configuring sources....418

Chapter 15 Extended Resource Domain Controller (XRDC)....422

15.1 Chip-specific XRDC_0 information.....422
15.1.1 XRDC instances.....422
15.1.2 XRDC_0 submodule configurations.....422
15.1.2.1 MDAC configurations.....422
15.1.2.2 MRC configurations.....423
15.1.2.3 PAC configurations.....424
15.1.3 XRDC_0 MRCs and SRAM interleaving.....425
15.1.4 XRDC_1 Introduction.....425
15.2 Introduction.....426
15.2.1 Features.....426
15.2.2 Block diagram.....427
15.2.3 Modes of operation.....428
15.3 External signal description.....428
15.4 Memory map register definition.....428
15.4.1 XRDC_0 register descriptions.....429
15.4.1.1 XRDC_0 memory map.....429
15.4.1.2 Control (CR).....468
15.4.1.3 Hardware Configuration 0 (HWCFG0).....469
15.4.1.4 Hardware Configuration 1 (HWCFG1).....470
15.4.1.5 Hardware Configuration 2 (HWCFG2).....471
15.4.1.6 Master Domain Assignment Configuration (MDACFG0 - MDACFG21).....472
15.4.1.7 Memory Region Configuration (MRCFG0 - MRCFG13).....474
15.4.1.8 Domain Error Location (DERRLOC0 - DERRLOC7).....475
15.4.1.9 Domain Error Word0 (DERR_W0_0 - DERR_W0_19).....477
15.4.1.10 Domain Error Word1 (DERR_W1_0 - DERR_W1_19).....478
15.4.1.11 Domain Error Word2 (DERR_W2_0 - DERR_W2_19).....481
15.4.1.12 Domain Error Word3 (DERR_W3_0 - DERR_W3_19).....482
15.4.1.13 Process Identifier (PID0 - PID18).....484
15.4.1.14 Master Domain Assignment (MDA_W0_0_DFMT0 - MDA_W7_18_DFMT0).....487
15.4.1.15 Master Domain Assignment (MDA_W0_2_DFMT1 - MDA_W0_21_DFMT1).....492
15.4.1.16 Peripheral Domain Access Control (PDAC_W0_0 - PDAC_W0_408).....494
15.4.1.17 Peripheral Domain Access Control (PDAC_W1_0 - PDAC_W1_408).....496
15.4.1.18 Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_223).....497
15.4.1.19 Memory Region Descriptor (MRGD_W1_0 - MRGD_W1_223).....498
15.4.1.20 Memory Region Descriptor (MRGD_W2_0 - MRGD_W2_223).....499
15.4.1.21 Memory Region Descriptor (MRGD_W3_0 - MRGD_W3_223).....501
15.4.2 XRDC_1 register descriptions.....502
15.4.2.1 XRDC_1 memory map.....502
15.4.2.2 Control (CR).....509
15.4.2.3 Hardware Configuration 0 (HWCFG0).....511
15.4.2.4 Hardware Configuration 1 (HWCFG1).....512
15.4.2.5 Hardware Configuration 2 (HWCFG2).....513
15.4.2.6 Master Domain Assignment Configuration (MDACFG0 - MDACFG7).....514
15.4.2.7 Memory Region Configuration (MRCFG0 - MRCFG5).....515
15.4.2.8 Domain Error Location (DERRLOC0 - DERRLOC7).....516
15.4.2.9 Domain Error Word0 (DERR_W0_0 - DERR_W0_16).....518
15.4.2.10 Domain Error Word1 (DERR_W1_0 - DERR_W1_16).....519
15.4.2.11 Domain Error Word2 (DERR_W2_0 - DERR_W2_16).....521
15.4.2.12 Domain Error Word3 (DERR_W3_0 - DERR_W3_16).....522
15.4.2.13 Master Domain Assignment (MDA_W0_0_DFMT1 - MDA_W0_7_DFMT1).....524
15.4.2.14 Peripheral Domain Access Control (PDAC_W0_0 - PDAC_W0_15).....526
15.4.2.15 Peripheral Domain Access Control (PDAC_W1_0 - PDAC_W1_15).....528
15.4.2.16 Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_83).....529
15.4.2.17 Memory Region Descriptor (MRGD_W1_0 - MRGD_W1_83).....530
15.4.2.18 Memory Region Descriptor (MRGD_W2_0 - MRGD_W2_83).....531

15.4.2.19 Memory Region Descriptor (MRGD_W3_0 - MRGD_W3_83)....533
15.5 Functional description....534
15.5.1 Manager (MGR)....534
15.5.2 Master domain assignment controller (MDAC)....534
15.5.3 D*x*ACP evaluation....535
15.5.4 Hardware semaphores and dynamic access rights....536
15.5.5 Memory region controller (MRC)....536
15.5.5.1 Memory region descriptor hit determination....537
15.5.5.2 Memory region D*x*ACP evaluation....537
15.5.5.3 MRC C code description....538
15.5.6 Peripheral access controller (PAC)....540
15.6 Initialization information....541
15.7 Application information....542
15.7.1 Master domain assignments....542
15.7.2 Cache coherency interconnect (CCI)....542
15.7.3 Memory region descriptor management....544
15.7.4 Domain error capture management....544
15.8 Glossary....545

Chapter 16 System Integration Unit Lite2 (SIUL2)....546
16.1 Chip-specific SIUL2 information....546
16.1.1 SIUL2 memory map....546
16.1.2 Register configuration....546
16.1.3 Interrupts and DMA requests....546
16.1.4 MIDR1 and MIDR2 Reset Values....546
16.2 Introduction....547
16.2.1 Overview....547
16.2.2 Features....548
16.3 SIUL2_0 register descriptions....548
16.3.1 SIUL2_0 memory map....549
16.3.2 SIUL2 MCU ID Register #1 (MIDR1)....559
16.3.3 SIUL2 MCU ID Register #2 (MIDR2)....560
16.3.4 SIUL2 DMA/Interrupt Status Flag Register0 (DISR0)....563
16.3.5 SIUL2 DMA/Interrupt Request Enable Register0 (DIRER0)....567
16.3.6 SIUL2 DMA/Interrupt Request Select Register0 (DIRSR0)....571
16.3.7 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (IREER0)....575
16.3.8 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (IFEER0)....578
16.3.9 SIUL2 Interrupt Filter Enable Register 0 (IFER0)....581
16.3.10 SIUL2 Interrupt Filter Maximum Counter Register (IFMCR0 - IFMCR11)....585
16.3.11 SIUL2 Interrupt Filter Clock Prescaler Register (IFCPR)....586
16.3.12 SIUL2 Multiplexed Signal Configuration Register (MSCR0 - MSCR101)....586
16.3.13 SIUL2 Input Multiplexed Signal Configuration Register (IMCR0 - IMCR83)....590
16.3.14 SIUL2 GPIO Pad Data Output Register (GPDO0 - GPDO101)....594
16.3.15 SIUL2 GPIO Pad Data Input Register (GPDI0 - GPDI101)....598
16.3.16 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO0 - PGPDO5)....602
16.3.17 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO6)....604
16.3.18 SIUL2 Parallel GPIO Pad Data In Register (PGPDI0 - PGPDI5)....606
16.3.19 SIUL2 Parallel GPIO Pad Data In Register (PGPDI6)....608
16.3.20 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO0 - MPGPDO5)....610
16.3.21 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO6)....615
16.4 SIUL2_1 register descriptions....618
16.4.1 SIUL2_1 memory map....619
16.4.2 SIUL2 MCU ID Register #1 (MIDR1)....633
16.4.3 SIUL2 MCU ID Register #2 (MIDR2)....635

16.4.4 SIUL2 DMA/Interrupt Status Flag Register0 (DISR0)..... 637
16.4.5 SIUL2 DMA/Interrupt Request Enable Register0 (DIRER0)..... 643
16.4.6 SIUL2 DMA/Interrupt Request Select Register0 (DIRSR0)..... 648
16.4.7 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (IREER0)..... 654
16.4.8 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (IFEER0)..... 658
16.4.9 SIUL2 Interrupt Filter Enable Register 0 (IFER0)..... 661
16.4.10 SIUL2 Interrupt Filter Maximum Counter Register (IFMCR0 - IFMCR31)..... 665
16.4.11 SIUL2 Interrupt Filter Clock Prescaler Register (IFCPR)..... 666
16.4.12 SIUL2 Multiplexed Signal Configuration Register (MSCR112 - MSCR190)..... 667
16.4.13 SIUL2 Input Multiplexed Signal Configuration Register (IMCR119 - IMCR495)..... 672
16.4.14 SIUL2 GPIO Pad Data Output Register (GPDO115 - GPDO188)..... 679
16.4.15 SIUL2 GPIO Pad Data Input Register (GPDI115 - GPDI188)..... 682
16.4.16 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO7)..... 684
16.4.17 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO9)..... 686
16.4.18 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO11)..... 688
16.4.19 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO10)..... 690
16.4.20 SIUL2 Parallel GPIO Pad Data In Register (PGPDI7)..... 692
16.4.21 SIUL2 Parallel GPIO Pad Data In Register (PGPDI9)..... 694
16.4.22 SIUL2 Parallel GPIO Pad Data In Register (PGPDI11)..... 696
16.4.23 SIUL2 Parallel GPIO Pad Data In Register (PGPDI10)..... 698
16.4.24 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO7)..... 700
16.4.25 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO9 - MPGPDO10)..... 704
16.4.26 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO11)..... 708
16.5 Functional description..... 712
16.5.1 Pad Control..... 712
16.5.2 General Purpose Input and Output pads (GPIO)..... 712
16.5.3 External interrupts/DMA requests (REQ Pins)..... 713
16.5.3.1 External interrupt initialization..... 713
16.5.3.2 External interrupt management..... 714
16.5.3.3 External interrupt request..... 714
16.5.3.4 DMA requests..... 715

Chapter 17 Semaphores2 (SEMA42)..... 716
17.1 Introduction..... 716
17.1.1 Multi-core programming: software gates..... 716
17.1.2 Features..... 716
17.2 Memory map/register definition..... 717
17.2.1 SEMA42 register descriptions..... 717
17.2.1.1 SEMA42 memory map..... 717
17.2.1.2 Gate Register (GATE0 - GATE15)..... 718
17.2.1.3 Reset Gate Read (RSTGT_R)..... 719
17.2.1.4 Reset Gate Write (RSTGT_W)..... 721
17.3 Functional description..... 722
17.4 Glossary..... 723

Chapter 18 System Resource Controller (SRC)..... 724
18.1 Introduction..... 724
18.2 SRC register descriptions..... 724
18.2.1 SRC memory map..... 724
18.2.2 Software-Triggered Faults (SW_NCF)..... 724
18.2.3 GMAC Control (GMAC_0_CTRL_STS)..... 726
18.2.4 HSE Cortex-M7 Status (HSE_CM7_STATUS_REG)..... 727
18.2.5 CMU Status 1 (CMU_STATUS_REG1)..... 728

18.2.6 CMUs Status 2 (CMU_STATUS_REG2)....732
18.2.7 FCCU EOUT Override Clear (FCCU_EOUT_OVERRIDE_CLEAR_REG)....733
18.2.8 GPR21 (GPR21)....734
18.2.9 Debug Control (DEBUG_CONTROL)....736
18.2.10 Timestamp Control (TIMESTAMP_CONTROL_REGISTER)....738
18.2.11 FlexRay OS Tick Input Select (FLEXRAY_OS_TICK_INPUT_SELECT_REG)....739

Chapter 19 Main General Purpose Registers (Main GPRs)....741
19.1 Introduction....741
19.2 Memory map and register definition....741
19.2.1 S32G_GPR register descriptions....741
19.2.1.1 S32G_MAIN_GPR memory map....741
19.2.1.2 PFE Port Coherency Enable (PFE_COH_EN)....741
19.2.1.3 PFE EMAC Interface Mode (PFE_EMACX_INTF_SEL)....743
19.2.1.4 PFE EMACX Power Control (PFE_PWR_CTRL)....744
19.2.1.5 LLCE Subsystem Status (LLCE_STAT)....745
19.2.1.6 LLCE Power Control (LLCE_CTRL)....746
19.2.1.7 DDR Urgent Control (DDR_URGENT_CTRL)....747
19.2.1.8 FlexTimer Global Load Control (FLXTIM_CTRL)....749
19.2.1.9 FlexTimer LDOK Status (FLXTIM_STAT)....749
19.2.1.10 Top CMU_FC Status (CMU_STAT)....750
19.2.1.11 Accelerator NoC NoPendingTrans Status (NOC_NOPEND_TRANS)....752
19.2.1.12 SerDes RD/WD Toggle Control (PCIE_TOGGLE)....753
19.2.1.13 SerDes Toggle Done Status (PCIE_TOGGLEDONE_STAT)....754
19.2.1.14 Generic Control 0 (GENCTRL0)....755
19.2.1.15 Generic Control 1 (GENCTRL1)....756
19.2.1.16 Generic Status 0 (GENSTAT0)....757

Chapter 20 Standby General Purpose Registers (Stby GPRs)....759
20.1 Introduction....759
20.2 S32G_STDBY_GPR register descriptions....759
20.2.1 S32G_STDBY_GPR memory map....759
20.2.2 WKUP Pad Pullup/Pulldown Select (WKUP_PUS)....759

Chapter 21 Register Protection (REG_PROT)....761
21.1 Introduction....761
21.2 Features....761
21.3 Modes of operation....761
21.4 External signal description....761
21.5 Memory map and register definition....761
21.5.1 Memory map....763
21.5.2 Module registers (MR)....763
21.5.3 MR and set soft lock bit (LMR)....763
21.6 REG_PROT register descriptions....763
21.6.1 REG_PROT memory map....764
21.6.2 Soft Lock Bit Register (SLBRn)....764
21.6.3 Global Configuration Register (GCR)....766
21.7 Functional description....767
21.7.1 General....767
21.7.2 Change lock settings....767
21.7.2.1 Change lock settings directly via area #3....767
21.7.2.2 Enable locking via mirror module space (area #2)....769

21.7.2.3 Write protection for locking bits....769
21.7.3 Access errors....770
21.7.4 Sequence....770
21.8 Initialization/application information....770
21.8.1 Reset....770

Chapter 22 Wakeup Unit (WKPU)....771
22.1 Chip-specific WKPU information....771
22.1.1 WKPU configuration....771
22.1.2 Chip-specific NMI Configuration Register (NCR)....771
22.1.3 Interrupts....771
22.1.4 NMI on Standby exit....771
22.1.5 Asynchronous wake-up sources for various modes....772
22.1.6 Pull control of wake-up pads....772
22.1.7 Enabling wakeup pads....772
22.1.8 Wakeup/Interrupt Pull Enable Register (WIPUER_WIPDER)....772
22.2 Introduction....773
22.3 Features....773
22.4 WKPU memory map and registers....774
22.4.1 WKPU register descriptions....774
22.4.1.1 WKPU memory map....774
22.4.1.2 NMI Status Flag Register (NSR)....774
22.4.1.3 NMI Configuration Register (NCR)....776
22.4.1.4 Wakeup Boot Mode Select Register (WBMSR)....778
22.4.1.5 Wakeup/Interrupt Status Flag Register (WISR)....778
22.4.1.6 Interrupt Request Enable Register (IRER)....779
22.4.1.7 Wakeup Request Enable Register (WRER)....780
22.4.1.8 Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER)....781
22.4.1.9 Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER)....782
22.4.1.10 Wakeup/Interrupt Filter Enable Register (WIFER)....783
22.4.1.11 Wakeup/Interrupt Pull Enable Register (WIPUER_WIPDER)....784
22.5 Functional description....785
22.5.1 Non-maskable interrupts....785
22.5.1.1 NMI management....786
22.6 External wakeups interrupts....787
22.6.1 External interrupt management....787
22.7 On-chip wakeups....788
22.8 Initialization information....788
22.8.1 Glitch filter and pad configuration....788
22.8.2 Non-maskable interrupts....788
22.9 Glossary....788

Chapter 23 Clocking....789
23.1 Introduction....789
23.1.1 Features....789
23.1.2 Overview....789
23.1.2.1 Core-related clock overview....790
23.1.2.2 Peripheral-related clock overview....790
23.1.2.3 DDR PLL clock overview....791
23.1.2.4 Accelerator PLL clock overview....791
23.1.2.5 Aurora clocking overview....791
23.1.2.6 CLKOUT*n* overview....792
23.1.2.6.1 CLKOUT*n* clock configuration....792

23.1.2.7 Other clocks....793
23.1.2.7.1 PFE_MAC_0 clocking overview....793
23.1.2.7.2 PFE_MAC_1 clocking overview....794
23.1.2.7.3 PFE_MAC_2 clocking overview....794
23.1.2.7.4 PFE clocking....795
23.2 Clock sources....795
23.2.1 Introduction....795
23.2.2 Input clock pins....796
23.2.3 Output clock pins....796
23.2.4 FIRC....796
23.2.5 SIRC....797
23.2.6 FXOSC....797
23.2.6.1 FXOSC register interface....797
23.2.7 PLL....797
23.2.7.1 PLL input clocks....798
23.2.7.2 PLL output clocks....798
23.2.7.3 PLL register interface....798
23.2.7.4 DFS....798
23.3 Clock generation....799
23.3.1 Clock source mapping on MC_CGM clock selectors....799
23.3.2 MC_CGM_*n* registers....801
23.3.2.1 MC_CGM_0 registers relationship to output clocks....801
23.3.2.2 MC_CGM_1 register relationship to output clocks....803
23.3.2.3 MC_CGM_2 registers relationship to output clocks....803
23.3.2.4 MC_CGM_5 registers relationship to output clocks....805
23.3.3 Application clock source options....805
23.3.4 System clock frequency limitations....807
23.3.5 Default clock configuration....807
23.3.6 Standby clock configuration....808
23.4 Software resettable domain....808
23.5 Clock on/off procedures....808
23.5.1 Clock-on....809
23.5.1.1 PLL SSCG Setup....810
23.5.2 Clock-off....810
23.5.3 PLL turn on sequence....810
23.5.4 Turning on the CLKOUT*n* signals....811
23.5.5 Turning off the CLKOUT*n* signals....811
23.6 Clock gating....811
23.7 Module clocking....811
23.7.1 Safety modules....812
23.7.1.1 ERM....812
23.7.1.2 FCCU....813
23.7.1.3 Redundancy control and checker unit (RCCU)....813
23.7.1.4 SBSW....813
23.7.1.5 STCU2....813
23.7.2 Communication modules....814
23.7.2.1 SerDes....814
23.7.2.2 Ethernet (GMAC_0)....815
23.7.2.2.1 Ethernet (GMAC_0) RGMII configuration....816
23.7.2.2.2 Ethernet (GMAC_0) RMII configuration....817
23.7.2.2.3 Ethernet (GMAC_0) MII configuration....818
23.7.2.2.4 Ethernet (GMAC_0) SGMII configuration....819
23.7.2.3 Ethernet router (PFE) clocking....820
23.7.2.3.1 PFE_MAC_0 clocking overview....822
23.7.2.3.2 PFE_MAC_1 clocking overview....826

23.7.2.3.3 PFE_MAC_2 clocking overview....830
23.7.2.4 LLCE subsystem clocking overview....834
23.7.2.5 Serial peripheral interface (SPI) clocking....835
23.7.2.6 FlexCAN clocking....836
23.7.2.7 FlexRay communication controller clocking....837
23.7.2.8 I^2C clocking....837
23.7.2.9 LINFlexD clocking....839
23.7.2.10 Universal serial bus (USB) clocking....839
23.7.3 Timer modules....839
23.7.3.1 FTM clocking....840
23.7.3.2 RTC clocking....841
23.7.3.3 SWT clocking....842
23.7.4 Generic modules....842
23.7.4.1 SIUL2 clocking....843
23.7.5 Analog modules....843
23.7.5.1 CTU clocking....844
23.7.5.2 SAR_ADC clocking....844
23.7.6 Debug modules....844
23.7.6.1 Debug trace unit clocking....844
23.7.7 Memory-controller modules....845
23.7.7.1 DDR controller clocking....845
23.7.7.2 SRAM controller clocking....845
23.7.7.3 uSDHC clocking....846
23.7.7.4 QuadSPI clocking....846
23.7.8 Security modules....846
23.7.8.1 Hardware Security Engine (HSE_H)....847
23.7.9 Clocking modules....847
23.7.10 Reset modules....848
23.7.10.1 RDC clocking....848
23.7.11 Power-modes modules....849
23.7.11.1 PMC clocking....849
23.7.12 Core platform modules....849
23.7.12.1 Cortex-A53 cluster clocking....850
23.7.12.2 Cortex-M7 clocking....851
23.7.12.3 eDMA clocking....851
23.7.12.4 Arm generic interrupt controller (GIC500) clocking....851
23.8 Clock monitoring....851
23.8.1 Introduction....851
23.8.2 Clock input sources....852
23.8.3 Enabling and disabling CMU_FC_0 and CMU_FC_5....854

Chapter 24 Clock Generation Module (MC_CGM)....855
24.1 Chip-specific MC_CGM information....855
24.2 Chip-specific MC_CGM_2 information....855
24.2.1 MC_CGM feature configuration....855
24.3 Introduction....855
24.4 Features....856
24.5 MC_CGM_0 register descriptions....856
24.5.1 MC_CGM_0 memory map....857
24.5.2 PCFS Step Duration (PCFS_SDUR)....859
24.5.3 PCFS Divider Change 12 Register (PCFS_DIVC12)....860
24.5.4 PCFS Divider End 12 Register (PCFS_DIVE12)....861
24.5.5 PCFS Divider Start 12 Register (PCFS_DIVS12)....862
24.5.6 Clock Mux 0 Select Control Register (MUX_0_CSC)....862

24.5.7 Clock Mux 0 Select Status Register (MUX_0_CSS)..... 864
24.5.8 Clock Mux 0 Divider 0 Control Register (MUX_0_DC_0)..... 866
24.5.9 Clock Mux 0 Divider 1 Control Register (MUX_0_DC_1)..... 867
24.5.10 Clock Mux 0 Divider Update Status Register (MUX_0_DIV_UPD_STAT).....868
24.5.11 Clock Mux 1 Select Control Register (MUX_1_CSC).....869
24.5.12 Clock Mux 1 Select Status Register (MUX_1_CSS)..... 871
24.5.13 Clock Mux 1 Divider 0 Control Register (MUX_1_DC_0)..... 872
24.5.14 Clock Mux 1 Divider Update Status Register (MUX_1_DIV_UPD_STAT).....873
24.5.15 Clock Mux 2 Select Control Register (MUX_2_CSC).....874
24.5.16 Clock Mux 2 Select Status Register (MUX_2_CSS)..... 875
24.5.17 Clock Mux 2 Divider 0 Control Register (MUX_2_DC_0)..... 877
24.5.18 Clock Mux 2 Divider Update Status Register (MUX_2_DIV_UPD_STAT).....878
24.5.19 Clock Mux 3 Select Control Register (MUX_3_CSC).....879
24.5.20 Clock Mux 3 Select Status Register (MUX_3_CSS)..... 880
24.5.21 Clock Mux 3 Divider 0 Control Register (MUX_3_DC_0)..... 882
24.5.22 Clock Mux 3 Divider Update Status Register (MUX_3_DIV_UPD_STAT).....883
24.5.23 Clock Mux 4 Select Control Register (MUX_4_CSC).....884
24.5.24 Clock Mux 4 Select Status Register (MUX_4_CSS)..... 885
24.5.25 Clock Mux 4 Divider 0 Control Register (MUX_4_DC_0)..... 887
24.5.26 Clock Mux 4 Divider Update Status Register (MUX_4_DIV_UPD_STAT).....888
24.5.27 Clock Mux 5 Select Control Register (MUX_5_CSC).....889
24.5.28 Clock Mux 5 Select Status Register (MUX_5_CSS)..... 891
24.5.29 Clock Mux 5 Divider 0 Control Register (MUX_5_DC_0)..... 893
24.5.30 Clock Mux 5 Divider Update Status Register (MUX_5_DIV_UPD_STAT).....894
24.5.31 Clock Mux 6 Select Control Register (MUX_6_CSC).....895
24.5.32 Clock Mux 6 Select Status Register (MUX_6_CSS)..... 896
24.5.33 Clock Mux 6 Divider 0 Control Register (MUX_6_DC_0)..... 898
24.5.34 Clock Mux 6 Divider Update Status Register (MUX_6_DIV_UPD_STAT).....899
24.5.35 Clock Mux 7 Select Control Register (MUX_7_CSC).....900
24.5.36 Clock Mux 7 Select Status Register (MUX_7_CSS)..... 901
24.5.37 Clock Mux 8 Select Control Register (MUX_8_CSC).....903
24.5.38 Clock Mux 8 Select Status Register (MUX_8_CSS)..... 905
24.5.39 Clock Mux 9 Select Control Register (MUX_9_CSC).....907
24.5.40 Clock Mux 9 Select Status Register (MUX_9_CSS)..... 908
24.5.41 Clock Mux 9 Divider 0 Control Register (MUX_9_DC_0)..... 910
24.5.42 Clock Mux 9 Divider Update Status Register (MUX_9_DIV_UPD_STAT).....911
24.5.43 Clock Mux 10 Select Control Register (MUX_10_CSC).....912
24.5.44 Clock Mux 10 Select Status Register (MUX_10_CSS)..... 913
24.5.45 Clock Mux 10 Divider 0 Control Register (MUX_10_DC_0)..... 915
24.5.46 Clock Mux 10 Divider Update Status Register (MUX_10_DIV_UPD_STAT).....916
24.5.47 Clock Mux 11 Select Control Register (MUX_11_CSC).....917
24.5.48 Clock Mux 11 Select Status Register (MUX_11_CSS)..... 919
24.5.49 Clock Mux 12 Select Control Register (MUX_12_CSC).....921
24.5.50 Clock Mux 12 Select Status Register (MUX_12_CSS)..... 922
24.5.51 Clock Mux 12 Divider 0 Control Register (MUX_12_DC_0)..... 924
24.5.52 Clock Mux 12 Divider Update Status Register (MUX_12_DIV_UPD_STAT).....925
24.5.53 Clock Mux 14 Select Control Register (MUX_14_CSC).....926
24.5.54 Clock Mux 14 Select Status Register (MUX_14_CSS)..... 927
24.5.55 Clock Mux 14 Divider 0 Control Register (MUX_14_DC_0)..... 929
24.5.56 Clock Mux 14 Divider Update Status Register (MUX_14_DIV_UPD_STAT).....930
24.5.57 Clock Mux 15 Select Control Register (MUX_15_CSC).....931
24.5.58 Clock Mux 15 Select Status Register (MUX_15_CSS)..... 932
24.5.59 Clock Mux 15 Divider 0 Control Register (MUX_15_DC_0)..... 934
24.5.60 Clock Mux 15 Divider Update Status Register (MUX_15_DIV_UPD_STAT).....935
24.5.61 Clock Mux 16 Select Control Register (MUX_16_CSC).....936

24.5.62 Clock Mux 16 Select Status Register (MUX_16_CSS)..... 938
24.6 MC_CGM_1 register descriptions.....940
24.6.1 MC_CGM_1 memory map.....940
24.6.2 PCFS Step Duration (PCFS_SDUR).....940
24.6.3 PCFS Divider Change 4 Register (PCFS_DIVC4).....941
24.6.4 PCFS Divider End 4 Register (PCFS_DIVE4)..... 942
24.6.5 PCFS Divider Start 4 Register (PCFS_DIVS4)..... 943
24.6.6 Clock Mux 0 Select Control Register (MUX_0_CSC).....944
24.6.7 Clock Mux 0 Select Status Register (MUX_0_CSS)..... 945
24.7 MC_CGM_2 register descriptions.....948
24.7.1 MC_CGM_2 memory map.....948
24.7.2 PCFS Step Duration (PCFS_SDUR).....950
24.7.3 PCFS Divider Change 33 Register (PCFS_DIVC33).....951
24.7.4 PCFS Divider End 33 Register (PCFS_DIVE33)..... 952
24.7.5 PCFS Divider Start 33 Register (PCFS_DIVS33)..... 953
24.7.6 Clock Mux 0 Select Control Register (MUX_0_CSC).....953
24.7.7 Clock Mux 0 Select Status Register (MUX_0_CSS)..... 955
24.7.8 Clock Mux 0 Divider 0 Control Register (MUX_0_DC_0)..... 957
24.7.9 Clock Mux 0 Divider Trigger Control Register (MUX_0_DIV_TRIG_CTRL)..... 958
24.7.10 Clock Mux 0 Divider Trigger Register (MUX_0_DIV_TRIG)..... 959
24.7.11 Clock Mux 0 Divider Update Status Register (MUX_0_DIV_UPD_STAT).....960
24.7.12 Clock Mux 1 Select Control Register (MUX_1_CSC).....961
24.7.13 Clock Mux 1 Select Status Register (MUX_1_CSS)..... 962
24.7.14 Clock Mux 1 Divider 0 Control Register (MUX_1_DC_0)..... 964
24.7.15 Clock Mux 1 Divider 1 Control Register (MUX_1_DC_1)..... 965
24.7.16 Clock Mux 1 Divider Trigger Control Register (MUX_1_DIV_TRIG_CTRL)..... 966
24.7.17 Clock Mux 1 Divider Trigger Register (MUX_1_DIV_TRIG)..... 967
24.7.18 Clock Mux 1 Divider Update Status Register (MUX_1_DIV_UPD_STAT).....968
24.7.19 Clock Mux 2 Select Control Register (MUX_2_CSC).....969
24.7.20 Clock Mux 2 Select Status Register (MUX_2_CSS)..... 971
24.7.21 Clock Mux 2 Divider 0 Control Register (MUX_2_DC_0)..... 973
24.7.22 Clock Mux 2 Divider 1 Control Register (MUX_2_DC_1)..... 974
24.7.23 Clock Mux 2 Divider Trigger Control Register (MUX_2_DIV_TRIG_CTRL)..... 975
24.7.24 Clock Mux 2 Divider Trigger Register (MUX_2_DIV_TRIG)..... 976
24.7.25 Clock Mux 2 Divider Update Status Register (MUX_2_DIV_UPD_STAT).....977
24.7.26 Clock Mux 3 Select Control Register (MUX_3_CSC).....978
24.7.27 Clock Mux 3 Select Status Register (MUX_3_CSS)..... 979
24.7.28 Clock Mux 3 Divider 0 Control Register (MUX_3_DC_0)..... 981
24.7.29 Clock Mux 3 Divider 1 Control Register (MUX_3_DC_1)..... 982
24.7.30 Clock Mux 3 Divider Trigger Control Register (MUX_3_DIV_TRIG_CTRL)..... 983
24.7.31 Clock Mux 3 Divider Trigger Register (MUX_3_DIV_TRIG)..... 984
24.7.32 Clock Mux 3 Divider Update Status Register (MUX_3_DIV_UPD_STAT).....985
24.7.33 Clock Mux 4 Select Control Register (MUX_4_CSC).....986
24.7.34 Clock Mux 4 Select Status Register (MUX_4_CSS)..... 988
24.7.35 Clock Mux 5 Select Control Register (MUX_5_CSC).....990
24.7.36 Clock Mux 5 Select Status Register (MUX_5_CSS)..... 991
24.7.37 Clock Mux 6 Select Control Register (MUX_6_CSC).....993
24.7.38 Clock Mux 6 Select Status Register (MUX_6_CSS)..... 995
24.7.39 Clock Mux 7 Select Control Register (MUX_7_CSC).....997
24.7.40 Clock Mux 7 Select Status Register (MUX_7_CSS)..... 998
24.7.41 Clock Mux 7 Divider 0 Control Register (MUX_7_DC_0)..... 1000
24.7.42 Clock Mux 7 Divider Trigger Control Register (MUX_7_DIV_TRIG_CTRL)..... 1001
24.7.43 Clock Mux 7 Divider Trigger Register (MUX_7_DIV_TRIG)..... 1002
24.7.44 Clock Mux 7 Divider Update Status Register (MUX_7_DIV_UPD_STAT).....1003
24.7.45 Clock Mux 8 Select Control Register (MUX_8_CSC).....1004

24.7.46 Clock Mux 8 Select Status Register (MUX_8_CSS)..... 1005
24.7.47 Clock Mux 8 Divider 0 Control Register (MUX_8_DC_0)..... 1007
24.7.48 Clock Mux 8 Divider Trigger Control Register (MUX_8_DIV_TRIG_CTRL)..... 1008
24.7.49 Clock Mux 8 Divider Trigger Register (MUX_8_DIV_TRIG)..... 1009
24.7.50 Clock Mux 8 Divider Update Status Register (MUX_8_DIV_UPD_STAT)..... 1010
24.7.51 Clock Mux 9 Select Control Register (MUX_9_CSC)..... 1011
24.7.52 Clock Mux 9 Select Status Register (MUX_9_CSS)..... 1012
24.7.53 Clock Mux 9 Divider 0 Control Register (MUX_9_DC_0)..... 1014
24.7.54 Clock Mux 9 Divider Trigger Control Register (MUX_9_DIV_TRIG_CTRL)..... 1015
24.7.55 Clock Mux 9 Divider Trigger Register (MUX_9_DIV_TRIG)..... 1016
24.7.56 Clock Mux 9 Divider Update Status Register (MUX_9_DIV_UPD_STAT)..... 1017
24.8 MC_CGM_5 register descriptions..... 1018
24.8.1 MC_CGM_5 memory map..... 1018
24.8.2 Clock Mux 0 Select Control Register (MUX_0_CSC)..... 1018
24.8.3 Clock Mux 0 Select Status Register (MUX_0_CSS)..... 1019
24.9 Functional description..... 1021
24.9.1 Clock selection multiplexer..... 1021
24.9.1.1 Hardware-controlled clock multiplexer..... 1021
24.9.1.2 Software-controlled clock multiplexer..... 1023
24.9.2 PCFS..... 1025
24.9.2.1 PCFS control..... 1027
24.9.2.2 Clock source powerup and selection..... 1027
24.9.2.3 Clock source powerdown and deselection..... 1028
24.9.2.4 Clock switch with load change..... 1029
24.9.3 Clock dividers..... 1030
24.9.3.1 50% clock divider..... 1030
24.9.3.2 Clock dividers update..... 1031
24.10 Glossary..... 1031

Chapter 25 Digital Frequency Synthesizer (DFS)..... 1032
25.1 Introduction..... 1032
25.1.1 Block diagram..... 1032
25.1.2 Features..... 1033
25.1.3 Modes of operation..... 1034
25.2 Initialization information..... 1034
25.3 DFS register descriptions..... 1035
25.3.1 DFS memory map..... 1035
25.3.2 Port Status Register (PORTSR)..... 1036
25.3.3 Port Loss of Lock Status (PORTLOLSR)..... 1036
25.3.4 Port Reset (PORTRESET)..... 1037
25.3.5 Control (CTL)..... 1038
25.3.6 Divider for Port n (DVPORT0 - DVPORT5)..... 1039
25.4 Functional description..... 1040
25.4.1 Port divider configuration..... 1040

Chapter 26 PLL Digital Interface (PLLDIG)..... 1041
26.1 Introduction..... 1041
26.1.1 Features..... 1041
26.1.2 Block diagram..... 1041
26.2 Modes of operation..... 1042
26.3 ACCEL_PLL register descriptions..... 1042
26.3.1 ACCEL_PLL memory map..... 1042
26.3.2 PLL Control Register (PLLCR)..... 1042

26.3.3 PLL Status Register (PLLSR)..... 1043
26.3.4 PLL Divider (PLLDV)..... 1044
26.3.5 PLL Frequency Modulation (PLLFM)..... 1046
26.3.6 PLL Fractional Divider (PLLFD)..... 1047
26.3.7 PLL Clock Multiplexer (PLLCLKMUX)..... 1049
26.3.8 PLL Output Divider (PLLODIV_0 - PLLODIV_1)..... 1050
26.4 CORE_PLL register descriptions..... 1051
26.4.1 CORE_PLL memory map..... 1051
26.4.2 PLL Control Register (PLLCR)..... 1051
26.4.3 PLL Status Register (PLLSR)..... 1052
26.4.4 PLL Divider (PLLDV)..... 1053
26.4.5 PLL Frequency Modulation (PLLFM)..... 1055
26.4.6 PLL Fractional Divider (PLLFD)..... 1056
26.4.7 PLL Clock Multiplexer (PLLCLKMUX)..... 1058
26.4.8 PLL Output Divider (PLLODIV_0 - PLLODIV_1)..... 1059
26.5 DDR_PLL register descriptions..... 1060
26.5.1 DDR_PLL memory map..... 1060
26.5.2 PLL Control Register (PLLCR)..... 1060
26.5.3 PLL Status Register (PLLSR)..... 1061
26.5.4 PLL Divider (PLLDV)..... 1062
26.5.5 PLL Frequency Modulation (PLLFM)..... 1064
26.5.6 PLL Fractional Divider (PLLFD)..... 1065
26.5.7 PLL Clock Multiplexer (PLLCLKMUX)..... 1067
26.5.8 PLL Output Divider (PLLODIV_0)..... 1068
26.6 PERIPH_PLL register descriptions..... 1069
26.6.1 PERIPH_PLL memory map..... 1069
26.6.2 PLL Control Register (PLLCR)..... 1069
26.6.3 PLL Status Register (PLLSR)..... 1070
26.6.4 PLL Divider (PLLDV)..... 1071
26.6.5 PLL Fractional Divider (PLLFD)..... 1073
26.6.6 PLL Clock Multiplexer (PLLCLKMUX)..... 1074
26.6.7 PLL Output Divider (PLLODIV_0 - PLLODIV_7)..... 1075
26.7 Functional description..... 1076
26.7.1 Input clock frequency..... 1076
26.7.2 Clock configuration..... 1076
26.7.3 LOL..... 1077
26.7.4 Frequency modulation..... 1078
26.7.4.1 Frequency modulation programming..... 1078
26.8 Initialization information..... 1079

Chapter 27 Fast Crystal Oscillator Digital Controller (FXOSC)..... 1080
27.1 Introduction..... 1080
27.1.1 Overview..... 1080
27.1.2 Features..... 1080
27.2 FXOSC register descriptions..... 1080
27.2.1 FXOSC memory map..... 1080
27.2.2 FXOSC Control Register (CTRL)..... 1080
27.2.3 Oscillator Status Register (STAT)..... 1083
27.3 Functional description..... 1084
27.3.1 Clock generation in Crystal mode..... 1084
27.3.2 Clock generation in Single-Input Bypass mode..... 1084
27.3.3 Clock generation in Differential Input Bypass mode..... 1084
27.4 Initialization information..... 1084

Chapter 28 Reset....1086
28.1 Introduction....1086
28.2 Reset features....1087
28.3 High-level reset sequence....1087
28.4 Reset sources....1088
28.5 Reset sources descriptions....1090
28.5.1 POR sources....1090
28.5.1.1 On-chip POR....1090
28.5.1.2 Critical LVDs....1090
28.5.1.3 External POR_B pin....1090
28.5.1.4 POR watchdog timer....1091
28.5.2 Destructive reset sources....1091
28.5.2.1 SPD fail....1091
28.5.2.2 FCCU failure to react....1092
28.5.2.3 STCU2 unrecoverable fault....1092
28.5.2.4 Functional reset escalation to destructive reset....1092
28.5.2.5 FXOSC failure....1092
28.5.2.6 CORE_PLL loss of lock....1092
28.5.2.7 PERIPH_PLL loss of lock....1092
28.5.2.8 DDR_PLL loss of lock....1092
28.5.2.9 ACCEL_PLL loss of lock....1093
28.5.2.10 XBAR_DIV3 clock failure....1093
28.5.2.11 Life-cycle error....1093
28.5.2.12 Software destructive reset....1093
28.5.2.13 Debug destructive reset....1093
28.5.2.14 HSE_H SWT timeout....1093
28.5.2.15 HSE SNVS tamper detected....1093
28.5.3 Functional reset sources....1094
28.5.3.1 FCCU reset reaction....1094
28.5.3.2 Self-test done....1094
28.5.3.3 SWT0 timeout....1094
28.5.3.4 HSE memory ECC error....1094
28.5.3.5 HSE boot error....1094
28.5.3.6 HSE core lock....1094
28.5.3.7 Software functional reset....1094
28.5.3.8 Debug functional reset....1094
28.5.4 Non-MC_RGM and indirect reset sources....1095
28.5.4.1 JCOMP pin....1095
28.5.5 Destructive reset escalation to stay in reset....1095
28.5.6 RESET_B....1095
28.6 Reset process....1096
28.6.1 Overview....1096
28.6.2 Reset process sequence....1096
28.6.2.1 POR sequence....1096
28.6.2.2 Destructive reset sequence....1096
28.6.2.3 Functional reset sequence....1097
28.6.2.4 Standby reset sequence....1099
28.7 Chip status on reset exit....1100
28.8 Module status during reset process....1103
28.9 Determining reset cause on reset exit....1107
28.10 Reset-related I/Os....1107
28.11 Pad states during reset sequence and immediately after reset exit....1108
28.12 Software resettable domains....1108
28.12.1 Introduction....1108

28.12.2 List of software reset domains/partitions on the chip..... 1109
28.12.2.1 Cortex-A53 software-resettable domain/partition.....1109
28.12.3 State of the software reset domains/partitions after power-up/destructive/functional reset sequence.....1110
28.12.4 Software reset partition turn-on flowchart..... 1111
28.12.5 Software reset partition turn-off flowchart..... 1111
28.12.6 PFE software reset partition turn-off flowchart..... 1112
28.12.7 Core turn-on sequence..... 1113
28.12.8 Core turn-off sequence..... 1114
28.12.9 Self-triggered reset (warm reset) sequence for Cortex-M7 application core.....1115
28.12.10 Cortex-A53 core warm reset sequence.....1116
28.12.11 Software peripheral resets..... 1117
28.13 Reset Domain Controller (RDC) register descriptions.....1117
28.13.1 RDC memory map..... 1117
28.13.2 Software Reset Domain 1 Control (RD1_CTRL_REG)..... 1118
28.13.3 Software Reset Domain 2 Control (RD2_CTRL_REG)..... 1119
28.13.4 Software Reset Domain 3 Control (RD3_CTRL_REG)..... 1120
28.13.5 Software Reset Domain 1 Status (RD1_STAT_REG).....1121
28.13.6 Software Reset Domain 2 Status (RD2_STAT_REG).....1122
28.13.7 Software Reset Domain 3 Status (RD3_STAT_REG).....1123

Chapter 29 Reset Generation Module (MC_RGM)..... 1124
29.1 Chip-specific MC_RGM information..... 1124
29.1.1 Reset sources..... 1124
29.1.1.1 Destructive reset sources..... 1124
29.1.1.2 Functional reset sources.....1124
29.1.2 Peripheral numbers.....1124
29.1.3 Clear functional reset counter during initial application sequence..... 1124
29.1.4 Limitations on individual peripheral resets..... 1124
29.2 Introduction.....1124
29.3 Features..... 1125
29.4 Reset sources.....1125
29.5 External signal description.....1126
29.6 RESET_B pin assertion and pin safe state control.....1126
29.7 MC_RGM register descriptions.....1126
29.7.1 MC RGM Register Map memory map.....1126
29.7.2 Destructive Event Status Register (DES).....1127
29.7.3 Functional /External Reset Status Register (FES)..... 1131
29.7.4 Functional Event Reset Disable Register (FERD)..... 1134
29.7.5 Functional Reset Escalation Counter Register (FREC)..... 1137
29.7.6 Functional Reset Escalation Threshold Register (FRET)..... 1138
29.7.7 Destructive Reset Escalation Threshold Register (DRET).....1139
29.7.8 External Reset Control Register (ERCTRL).....1140
29.7.9 Reset During Standby Status Register (RDSS)..... 1141
29.7.10 Peripheral Reset (PRST0_0).....1142
29.7.11 Peripheral Reset (PRST1_0).....1145
29.7.12 Peripheral Reset (PRST2_0).....1148
29.7.13 Peripheral Reset (PRST3_0).....1151
29.7.14 Peripheral Reset (PRST4_0).....1154
29.7.15 Peripheral Reset (PRST5_0).....1157
29.7.16 Peripheral Reset (PRST6_0).....1160
29.7.17 Peripheral Reset (PRST7_0).....1163
29.7.18 Peripheral Reset Status Register (PSTAT0_0)..... 1166
29.7.19 Peripheral Reset Status Register (PSTAT1_0)..... 1170

29.7.20 Peripheral Reset Status Register (PSTAT2_0)....1173
29.7.21 Peripheral Reset Status Register (PSTAT3_0)....1176
29.7.22 Peripheral Reset Status Register (PSTAT4_0)....1179
29.7.23 Peripheral Reset Status Register (PSTAT5_0)....1182
29.7.24 Peripheral Reset Status Register (PSTAT6_0)....1185
29.7.25 Peripheral Reset Status Register (PSTAT7_0)....1188
29.8 Functional description....1191
29.8.1 Reset state machine....1191
29.8.1.1 Power-on reset sequence....1192
29.8.1.2 Destructive reset sequence....1192
29.8.1.3 Functional reset sequence....1193
29.8.1.3.1 Functional reset entry sequence....1193
29.8.1.3.2 Functional reset exit sequence....1193
29.8.1.4 Idle phase....1193
29.8.2 Destructive resets....1193
29.8.3 External reset....1193
29.8.4 Functional resets....1194
29.8.5 External reset assertion control....1194
29.8.6 Functional reset escalation....1194
29.8.7 Destructive reset escalation....1195
29.8.8 Individual peripheral resets....1195

Chapter 30 Boot....1197
30.1 Introduction....1197
30.2 Features....1197
30.3 Boot modes....1197
30.3.1 Serial Boot mode....1198
30.3.1.1 End-of-line programming....1198
30.3.1.2 Non-responsive modules....1198
30.3.2 Boot from fuses and RCON....1199
30.3.2.1 Boot from fuses....1199
30.3.2.2 Boot from RCON....1199
30.3.2.2.1 Boot from parallel RCON....1199
30.3.2.2.2 Boot from serial RCON....1199
30.3.2.3 RCON mode selection....1200
30.3.2.4 Selection of boot from fuses or boot from RCON....1200
30.4 Program image....1201
30.4.1 Image Vector Table (IVT)....1201
30.4.1.1 IVT boot configuration word....1202
30.4.1.2 Life cycle configuration word....1203
30.4.2 Device Configuration Data (DCD)....1204
30.4.2.1 DCD commands....1204
30.4.2.1.1 Write Data command....1204
30.4.2.1.2 Check Data command....1206
30.4.2.1.3 NOP command....1207
30.4.3 Self-Test....1208
30.4.3.1 Self-Test boot operation....1208
30.4.3.2 Self-Test DCD image structure....1208
30.4.4 Application boot....1208
30.4.5 Serial boot....1209
30.5 Boot register descriptions....1211
30.5.1 Boot memory map....1211
30.5.2 Boot Configuration 1 (BOOT_GPR_BMR1)....1212
30.5.3 Boot Configuration 2 (BOOT_GPR_BMR2)....1212

30.5.4 SRC POR Control (SRC_POR_CTRL_REG)....1213
30.6 Boot flow....1214
30.6.1 Boot flow phases....1215
30.6.1.1 Initialize 1 boot flow phase....1216
30.6.1.2 Self-Test....1217
30.6.1.3 Initialize 2 boot flow phase....1217
30.6.2 Boot flow diagram....1219
30.7 Boot settings and fuse map....1219
30.8 BootROM impact on module registers' reset values....1219
30.9 BootROM clock configuration....1220
30.10 Image authentication and decryption....1220
30.11 Serial boot....1220
30.11.1 XOSC configuration....1221
30.11.2 Serial download protocol....1222
30.11.2.1 Serial download protocol – UART and CAN....1222
30.11.2.2 Serial download protocol – Ethernet....1223
30.11.3 FlexCAN....1224
30.11.3.1 FlexCAN I/O multiplexer configuration....1224
30.11.3.2 Clock configuration....1224
30.11.3.3 Baud rates....1224
30.11.3.4 FlexCAN boot operation....1225
30.11.4 UART....1225
30.11.4.1 UART IOMUX configuration....1225
30.11.4.2 Clock configuration....1225
30.11.4.3 UART baud rates....1226
30.11.5 Ethernet boot....1226
30.11.5.1 IOMUX configuration....1226
30.11.5.2 Functional description....1226
30.11.5.2.1 MII interface detection....1226
30.11.5.2.2 PHY identification and configuration....1228
30.11.5.2.3 GMAC_0 speed and clock configuration....1228
30.11.5.2.4 GMAC_0 controller configuration....1228
30.11.5.2.5 MAC address configuration....1228
30.11.5.2.6 DHCP handshake....1229
30.11.5.2.7 TFTP data transfer flow....1229
30.11.5.3 Flow diagram....1230
30.12 Boot from external flash memory....1231
30.12.1 QuadSPI boot....1232
30.12.1.1 Functional description....1232
30.12.1.2 QuadSPI IOMUX configuration....1235
30.12.1.3 QuadSPI clock configuration....1236
30.12.1.4 QuadSPI configuration parameters....1237
30.12.1.5 QuadSPI boot flow diagram....1239
30.12.2 µSDHC boot....1240
30.12.2.1 µSDHC IOMUX configuration....1240
30.12.2.2 µSDHC clock configuration....1241
30.12.2.3 µSDHC supported data rates....1242
30.12.2.4 µSDHC boot flow diagrams....1242
30.12.2.4.1 µSDHC boot flow – startup....1242
30.12.2.4.2 µSDHC boot flow – voltage validation....1243
30.12.2.4.3 µSDHC boot flow – chip initialization....1244
30.12.2.4.4 µSDHC boot flow – data read....1245
30.12.2.4.5 µSDHC MMC boot device initialization....1246
30.12.2.4.6 µSDHC MMC boot voltage validation....1247
30.13 Fail-Safe....1248

30.14 Boot target.....1248
30.15 Boot target watchdog.....1248
30.16 Standby boot.....1249

Chapter 31 Power Management.....1251
31.1 Introduction.....1251
31.1.1 Power management functional blocks.....1251
31.2 Power management features.....1251
31.3 Power-related I/Os.....1252
31.4 Operating modes.....1252
31.4.1 Reset mode.....1253
31.4.2 Run mode.....1253
31.4.3 Standby mode.....1254
31.4.3.1 Standby mode modules.....1254
31.4.3.2 High-level Standby mode power-down/power-up flow diagram.....1255
31.5 Operating mode transitions.....1255
31.5.1 Reset mode to Run mode.....1255
31.5.2 Configuring clocks.....1255
31.5.3 Turning on cores and partitions.....1255
31.5.4 Run mode to Reset mode.....1255
31.5.5 Run mode to Standby mode.....1255
31.5.5.1 Standby mode entry flow.....1255
31.5.5.1.1 Standby mode entry flow diagram.....1256
31.5.6 Standby mode to Run mode.....1256
31.5.6.1 Standby mode exit flow.....1256
31.5.6.1.1 Standby mode exit flow diagram.....1257
31.5.7 Standby to Reset mode.....1257
31.5.8 Wake-up pin pullup/pulldown control during Run and Standby modes.....1257
31.6 Operating mode control blocks.....1259
31.6.1 MC_ME.....1259
31.6.2 MC_PCU.....1259
31.6.3 MC_RGM.....1260
31.6.4 RTC.....1260
31.6.5 WKPU.....1260
31.6.5.1 NMI pins.....1261
31.6.5.2 Wake-up pins.....1262
31.6.5.3 Wake from RTC.....1262
31.6.6 Wake-up pin glitch filter.....1262
31.7 Power management and power domains.....1262
31.7.1 Precision voltage monitoring.....1262
31.7.2 Supply Presence Detectors (SPD).....1263
31.7.2.1 NCSPD configuration.....1264
31.7.2.2 CSPD configuration.....1266
31.7.3 Voltage overshoot and undershoot protection.....1267
31.7.4 External PMIC interface.....1267
31.7.4.1 Use case: Interfacing to external PMIC.....1267
31.7.4.2 Debug use case: Interfacing to external PMIC.....1267
31.7.4.3 Standby mode use case: Interfacing to external PMIC.....1268
31.7.4.4 Safety context for PMIC WDOG.....1269
31.8 Power mode control blocks.....1269
31.8.1 PMIC control.....1269
31.8.1.1 Static Voltage Scaling (SVS).....1269
31.8.2 PMC.....1272
31.9 Powerup/powerdown ramp rates and sequences.....1273

31.9.1 Pin behavior during powerup..... 1273
31.9.2 Chip startup and shutdown..... 1273
31.9.3 Standby mode entry..... 1274
31.9.4 Standby mode exit..... 1274
31.10 Low power modes..... 1274
31.10.1 Wake-up sources..... 1274
31.11 Power management and power domains..... 1274
31.11.1 I/O power domains..... 1274
31.11.2 Standby pads..... 1275
31.12 Glossary..... 1276

Chapter 32 Mode Entry Module (MC_ME)..... 1277
32.1 Chip-specific MC_ME information..... 1277
32.1.1 MC_ME modes..... 1277
32.1.2 MC_ME partition mapping..... 1277
32.1.2.1 MC_ME partition 0 mapping..... 1277
32.1.2.2 MC_ME partition 1 mapping..... 1278
32.1.2.3 MC_ME partition 2 mapping..... 1280
32.1.2.4 MC_ME partition 3 mapping..... 1280
32.1.3 Core controls..... 1281
32.1.4 Turning off cores and partitions..... 1281
32.1.4.1 Enable output isolation..... 1281
32.1.4.2 Disable core clocks..... 1282
32.1.4.3 Disable partition clocks..... 1282
32.1.4.4 Disable COFB clocks..... 1282
32.1.4.5 Assert partition reset signals..... 1282
32.2 Introduction..... 1282
32.3 Features..... 1283
32.4 MC_ME register descriptions..... 1283
32.4.1 MC_ME memory map..... 1284
32.4.2 Control Key Register (CTL_KEY)..... 1286
32.4.3 Mode Configuration Register (MODE_CONF)..... 1287
32.4.4 Mode Update Register (MODE_UPD)..... 1288
32.4.5 Mode Status Register (MODE_STAT)..... 1289
32.4.6 Main Core ID Register (MAIN_COREID)..... 1290
32.4.7 Partition 0 Process Configuration Register (PRTN0_PCONF)..... 1291
32.4.8 Partition 0 Process Update Register (PRTN0_PUPD)..... 1292
32.4.9 Partition 0 Status Register (PRTN0_STAT)..... 1294
32.4.10 Partition 0 COFB Set 0 Clock Status Register (PRTN0_COFB0_STAT)..... 1295
32.4.11 Partition 0 COFB Set 0 Clock Enable Register (PRTN0_COFB0_CLKEN)..... 1300
32.4.12 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)..... 1305
32.4.13 Partition 0 Core 0 Process Update Register (PRTN0_CORE0_PUPD)..... 1306
32.4.14 Partition 0 Core 0 Status Register (PRTN0_CORE0_STAT)..... 1307
32.4.15 Partition 0 Core 0 Address Register (PRTN0_CORE0_ADDR)..... 1308
32.4.16 Partition 0 Core 1 Process Configuration Register (PRTN0_CORE1_PCONF)..... 1308
32.4.17 Partition 0 Core 1 Process Update Register (PRTN0_CORE1_PUPD)..... 1309
32.4.18 Partition 0 Core 1 Status Register (PRTN0_CORE1_STAT)..... 1310
32.4.19 Partition 0 Core 1 Address Register (PRTN0_CORE1_ADDR)..... 1311
32.4.20 Partition 0 Core 2 Process Configuration Register (PRTN0_CORE2_PCONF)..... 1312
32.4.21 Partition 0 Core 2 Process Update Register (PRTN0_CORE2_PUPD)..... 1313
32.4.22 Partition 0 Core 2 Status Register (PRTN0_CORE2_STAT)..... 1314
32.4.23 Partition 0 Core 2 Address Register (PRTN0_CORE2_ADDR)..... 1315
32.4.24 Partition 0 Core 3 Process Configuration Register (PRTN0_CORE3_PCONF)..... 1316
32.4.25 Partition 0 Core 3 Process Update Register (PRTN0_CORE3_PUPD)..... 1317

32.4.26 Partition 0 Core 3 Status Register (PRTN0_CORE3_STAT)..... 1318
32.4.27 Partition 0 Core 3 Address Register (PRTN0_CORE3_ADDR)..... 1319
32.4.28 Partition 1 Process Configuration Register (PRTN1_PCONF).....1320
32.4.29 Partition 1 Process Update Register (PRTN1_PUPD)..... 1322
32.4.30 Partition 1 Status Register (PRTN1_STAT)..... 1323
32.4.31 Partition 1 Core 0 Process Configuration Register (PRTN1_CORE0_PCONF).....1324
32.4.32 Partition 1 Core 0 Process Update Register (PRTN1_CORE0_PUPD)..... 1325
32.4.33 Partition 1 Core 0 Status Register (PRTN1_CORE0_STAT)..... 1326
32.4.34 Partition 1 Core 0 Address Register (PRTN1_CORE0_ADDR)..... 1327
32.4.35 Partition 1 Core 1 Process Configuration Register (PRTN1_CORE1_PCONF).....1328
32.4.36 Partition 1 Core 1 Process Update Register (PRTN1_CORE1_PUPD)..... 1329
32.4.37 Partition 1 Core 1 Status Register (PRTN1_CORE1_STAT)..... 1330
32.4.38 Partition 1 Core 1 Address Register (PRTN1_CORE1_ADDR)..... 1331
32.4.39 Partition 1 Core 2 Process Configuration Register (PRTN1_CORE2_PCONF).....1332
32.4.40 Partition 1 Core 2 Process Update Register (PRTN1_CORE2_PUPD)..... 1333
32.4.41 Partition 1 Core 2 Status Register (PRTN1_CORE2_STAT)..... 1334
32.4.42 Partition 1 Core 2 Address Register (PRTN1_CORE2_ADDR)..... 1335
32.4.43 Partition 1 Core 3 Process Configuration Register (PRTN1_CORE3_PCONF).....1336
32.4.44 Partition 1 Core 3 Process Update Register (PRTN1_CORE3_PUPD)..... 1337
32.4.45 Partition 1 Core 3 Status Register (PRTN1_CORE3_STAT)..... 1338
32.4.46 Partition 1 Core 3 Address Register (PRTN1_CORE3_ADDR)..... 1339
32.4.47 Partition 2 Process Configuration Register (PRTN2_PCONF).....1340
32.4.48 Partition 2 Process Update Register (PRTN2_PUPD)..... 1342
32.4.49 Partition 2 Status Register (PRTN2_STAT)..... 1343
32.4.50 Partition 2 COFB Set 0 Clock Status Register (PRTN2_COFB0_STAT)..... 1344
32.4.51 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)..... 1349
32.4.52 Partition 3 Process Configuration Register (PRTN3_PCONF).....1354
32.4.53 Partition 3 Process Update Register (PRTN3_PUPD)..... 1356
32.4.54 Partition 3 Status Register (PRTN3_STAT)..... 1357
32.4.55 Partition 3 COFB Set 0 Clock Status Register (PRTN3_COFB0_STAT)..... 1358
32.4.56 Partition 3 COFB Set 0 Clock Enable Register (PRTN3_COFB0_CLKEN)..... 1363
32.5 Partition processes..... 1368
32.6 Mode transition..... 1369
32.7 Standby entry..... 1370
32.7.1 Application core shutdown..... 1370
32.7.2 Application cluster shutdown.....1371
32.7.3 Main core shutdown and standby entry..... 1372
32.8 Glossary..... 1373

Chapter 33 Power Control Unit (MC_PCU).....1374
33.1 Introduction.....1374
33.2 Power sequence FSM..... 1374
33.3 Glossary..... 1376

Chapter 34 Power Management Controller (PMC)..... 1377
34.1 Chip-specific PMC information..... 1377
34.1.1 Device Status Flag (DSF*n*) status signal mapping.....1377
34.1.1.1 Device Status Flag (DSF0) register status signals..... 1377
34.1.1.2 Device Status Flag (DSF1) register status signals..... 1378
34.1.1.3 Device Status Flag (DSF2) register status signals..... 1382
34.1.2 Supply naming reference..... 1382
34.2 Introduction.....1382
34.2.1 Features..... 1383

34.2.2 Block diagram ... 1383
34.2.2.1 SPD monitoring ... 1384
34.2.2.2 POR and NCSPD event generation ... 1384
34.2.3 Modes of operation ... 1384
34.3 Memory map and register definition ... 1385
34.3.1 Transfer error description ... 1385
34.3.2 PMC register descriptions ... 1385
34.3.2.1 PMC memory map ... 1385
34.3.2.2 Source of System Reset (SSR) ... 1385
34.3.2.3 Non-Critical Supply Presence Detector Control (NCSPD_CTL) ... 1387
34.3.2.4 NCSPD Status Register (NCSPD_STAT) ... 1390
34.3.2.5 CSPD Event Capture (CSPDEF) (CSPD_EVENT_CAPTURE) ... 1394
34.3.2.6 NCSPD Event Flag (NCSPDEF) (NCSPD_EVENT_CAPTURE) ... 1397
34.3.2.7 Device Status Flag (DSF0) (POR_WDOG_EVENT_CAPTURE0) ... 1400
34.3.2.8 Device Status Flag (DSF1) (POR_WDOG_EVENT_CAPTURE1) ... 1401
34.3.2.9 Device Status Flag (DSF2) (POR_WDOG_EVENT_CAPTURE2) ... 1401
34.4 Functional description ... 1402
34.4.1 Reset ... 1402
34.4.2 Event flag registers ... 1403
34.4.3 POR watchdog ... 1403

Chapter 35 SRAM Controller (SRAMC) ... 1404
35.1 Standby SRAM ... 1404
35.2 SRAMC registers ... 1404
35.3 Introduction ... 1404
35.3.1 Overview ... 1404
35.3.2 Features ... 1405
35.3.3 Modes of operation ... 1406
35.4 SRAMC register descriptions ... 1406
35.4.1 SRAMC memory map ... 1406
35.4.2 Platform RAM Control Register (PRAMCR) ... 1406
35.4.3 Platform RAM Initialization Address Register Start (PRAMIAS) ... 1407
35.4.4 Platform RAM Initialization Address Register End (PRAMIAE) ... 1408
35.4.5 Platform RAM Status Register (PRAMSR) ... 1409
35.4.6 Platform RAM ECC Address (PRAMECCA) ... 1411
35.5 Functional description ... 1412
35.5.1 Latency of read and write accesses ... 1412
35.5.2 Error report ... 1414
35.6 Safety considerations ... 1414
35.6.1 ECC algorithm ... 1414
35.6.2 Safety logic ... 1416
35.7 Initialization ... 1416
35.7.1 Initialization sequence examples ... 1417
35.7.1.1 Example 1: Configuration of a single pipeline, non-interleaving system, 64-bit data (1 memory bank) ... 1417
35.7.1.2 Example 2: Configuration of a single pipeline, non-interleaving system, 128-bit data (2 memory bank) ... 1417

Chapter 36 DDR Subsystem ... 1418
36.1 Chip-specific DDR information ... 1418
36.1.1 Feature configuration ... 1418
36.1.2 Mapping of masters and AXI ports of DDR controller ... 1418
36.1.3 Exclusive access monitors ... 1418

36.1.4 AXI-urgent signals of DDR memory..... 1418
36.1.5 ECC and parity errors..... 1418
36.1.6 Speculative access of DDR memory..... 1418
36.2 Overview..... 1418
36.2.1 Supported DRAM types..... 1419
36.2.2 Memory controller (MC)..... 1419
36.2.3 Physical interface (PHY)..... 1419
36.3 Architecture..... 1419
36.3.1 Block diagram..... 1419
36.3.2 Parity block..... 1420
36.3.3 Performance monitor..... 1420
36.3.3.1 Performance signals/counters..... 1420
36.3.3.1.1 Generic monitored signals..... 1421
36.3.3.1.2 Perf specific signals monitored..... 1421
36.3.3.1.3 Counter control register..... 1422
36.3.3.1.4 MRR read data register..... 1423
36.3.4 APB common interface..... 1423
36.4 Features..... 1423
36.4.1 DDR MC feature list..... 1423
36.4.2 PHY features..... 1425
36.5 Functional description..... 1427
36.5.1 Exclusive access..... 1427
36.5.2 Software coherency for AXI ports..... 1427
36.5.3 Host interface (HIF)..... 1427
36.5.4 Partial writes..... 1428
36.5.5 XPI queues information..... 1428
36.5.6 Overview of DFI interface..... 1428
36.5.7 Low power software interface..... 1429
36.5.8 Transaction service control..... 1430
36.5.9 Page policy..... 1430
36.5.9.1 Explicit auto-precharge (Per Command)..... 1430
36.5.9.2 Intelligent precharges..... 1430
36.5.9.3 Address collision handling..... 1431
36.5.9.4 Write combine..... 1431
36.5.9.4.1 Registers related to transaction service control..... 1431
36.5.10 Overview of quality of service..... 1432
36.5.10.1 Read classes..... 1432
36.5.10.2 Write classes..... 1432
36.5.11 Significance of urgent signal on QoS..... 1433
36.6 ECC scrubber..... 1433
36.6.1 Scrub period..... 1433
36.6.2 Normal operation..... 1433
36.6.3 Low power operation -software controlled..... 1434
36.6.4 Initialization writes..... 1434
36.7 Overview of inline ECC support..... 1435
36.7.1 Address map..... 1435
36.7.2 Selectable protected regions..... 1436
36.7.3 Locking of ECC region..... 1436
36.7.4 Error injection through software (ECC data poisoning)..... 1437
36.7.5 Performance..... 1437
36.7.6 Interrupts related to inline ECC..... 1437
36.8 Refresh controls..... 1438
36.8.1 Overview of refresh controls..... 1438
36.8.2 Refresh using direct software request of refresh command..... 1438
36.8.3 Refresh using auto refresh feature inside the MC..... 1438

36.8.3.1 Single refresh....1439
36.8.3.2 Burst refresh....1439
36.8.3.3 Speculative refresh....1439
36.8.4 Per-bank Refresh (LPDDR4 only)....1439
36.8.5 Fine granularity refresh (DDR4 only)....1439
36.8.6 Constraints on refresh_timerX_start_value_x32....1440
36.9 ZQ calibration....1440
36.9.1 Overview of ZQ calibration....1441
36.9.2 DDR3/DDR4 devices....1441
36.9.3 LPDDR4 devices....1441
36.9.4 Automatic and software Initiated ZQCS....1442
36.9.5 LPDDR4 ZQ reset command....1442
36.10 MRR/MPR specific sequences....1442
36.10.1 Mode register read and write operations....1442
36.10.2 Multi-purpose register (MPR for DDR4 only)....1443
36.11 ODT control....1443
36.11.1 Overview of ODT control....1443
36.12 Programming considerations....1444
36.12.1 Programming fields based on multiples of DFI clock cycles....1445
36.12.2 Converting times into clock cycles....1445
36.12.3 Programming mode....1445
36.12.4 Standby power state (LP3/IO Retention)....1446
36.13 UMCTL2_MP register descriptions....1448
36.13.1 UMCTL2_MP memory map....1448
36.13.2 Port Status (PSTAT)....1449
36.13.3 Port Common Configuration (PCCFG)....1451
36.13.4 Port n Configuration Read (PCFGR_0)....1452
36.13.5 Port n Configuration Write (PCFGW_0)....1455
36.13.6 Port n Control (PCTRL_0)....1456
36.13.7 Port n Read QoS Configuration Register 0 (PCFGQOS0_0)....1457
36.13.8 Port n Read QoS Configuration Register 1 (PCFGQOS1_0)....1459
36.13.9 Port n Write QoS Configuration Register 0 (PCFGWQOS0_0)....1460
36.13.10 Port n Write QoS Configuration Register 1 (PCFGWQOS1_0)....1463
36.13.11 Port n Configuration Read (PCFGR_1)....1463
36.13.12 Port n Configuration Write (PCFGW_1)....1465
36.13.13 Port n Control (PCTRL_1)....1466
36.13.14 Port n Read QoS Configuration Register 0 (PCFGQOS0_1)....1467
36.13.15 Port n Read QoS Configuration Register 1 (PCFGQOS1_1)....1468
36.13.16 Port n Write QoS Configuration Register 0 (PCFGWQOS0_1)....1469
36.13.17 Port n Write QoS Configuration Register 1 (PCFGWQOS1_1)....1471
36.13.18 Port n Configuration Read (PCFGR_2)....1472
36.13.19 Port n Configuration Write (PCFGW_2)....1473
36.13.20 Port n Control (PCTRL_2)....1474
36.13.21 Port n Read QoS Configuration Register 0 (PCFGQOS0_2)....1475
36.13.22 Port n Read QoS Configuration Register 1 (PCFGQOS1_2)....1477
36.13.23 Port n Write QoS Configuration Register 0 (PCFGWQOS0_2)....1477
36.13.24 Port n Write QoS Configuration Register 1 (PCFGWQOS1_2)....1479
36.13.25 Scrubber Control (SBRCTL)....1480
36.13.26 Scrubber Status (SBRSTAT)....1481
36.13.27 Scrubber Write Data Pattern0 (SBRWDATA0)....1482
36.14 UMCTL2_REGS register descriptions....1482
36.14.1 UMCTL2_REGS memory map....1482
36.14.2 Master (MSTR)....1487
36.14.3 Operating mode status (STAT)....1491
36.14.4 Mode Register read/write control 0 (MRCTRL0)....1493

36.14.5 Mode Register Read/Write Control 1 (MRCTRL1)....1496
36.14.6 Mode Register Read/Write Status (MRSTAT)....1497
36.14.7 Mode Register Read/Write Control 2 (MRCTRL2)....1498
36.14.8 Temperature derate enable (DERATEEN)....1499
36.14.9 Temperature derate interval (DERATEINT)....1501
36.14.10 Temperature derate control (DERATECTL)....1502
36.14.11 Low power control (PWRCTL)....1503
36.14.12 Low Power Timing (PWRTMG)....1506
36.14.13 Hardware low power control (HWLPCTL)....1507
36.14.14 Refresh Control 0 (RFSHCTL0)....1509
36.14.15 Refresh control 1 (RFSHCTL1)....1512
36.14.16 Refresh Control 3 (RFSHCTL3)....1513
36.14.17 Refresh Timing (RFSHTMG)....1514
36.14.18 Refresh timing 1 (RFSHTMG1)....1516
36.14.19 ECC Configuration 0 (ECCCFG0)....1517
36.14.20 ECC Configuration 1 (ECCCFG1)....1520
36.14.21 SECDED ECC Status (ECCSTAT)....1522
36.14.22 ECC Control (ECCCTL)....1524
36.14.23 ECC Error Counter (ECCERRCNT)....1527
36.14.24 ECC Corrected Error Address 0 (ECCCADDR0)....1528
36.14.25 ECC Corrected Error Address 1 (ECCCADDR1)....1529
36.14.26 ECC Corrected Syndrome 0 (ECCCSYN0)....1530
36.14.27 ECC Corrected Syndrome 1 (ECCCSYN1)....1531
36.14.28 ECC Corrected Syndrome 2 (ECCCSYN2)....1531
36.14.29 ECC Corrected Data Bit Mask 0 (ECCBITMASK0)....1532
36.14.30 ECC Corrected Data Bit Mask 1 (ECCBITMASK1)....1533
36.14.31 ECC Corrected Data Bit Mask 2 (ECCBITMASK2)....1534
36.14.32 ECC Uncorrected Error Address 0 (ECCUADDR0)....1535
36.14.33 ECC Uncorrected Error Address 1 (ECCUADDR1)....1536
36.14.34 ECC Uncorrected Syndrome 0 (ECCUSYN0)....1537
36.14.35 ECC Uncorrected Syndrome 1 (ECCUSYN1)....1538
36.14.36 ECC Uncorrected Syndrome 2 (ECCUSYN2)....1538
36.14.37 ECC Data Poisoning Address 0 (ECCPOISONADDR0)....1539
36.14.38 ECC Data Poisoning Address 1 (ECCPOISONADDR1)....1540
36.14.39 CRC Parity Control 0 (CRCPARCTL0)....1541
36.14.40 CRC Parity Control 1 (CRCPARCTL1)....1542
36.14.41 CRC Parity Status (CRCPARSTAT)....1544
36.14.42 DRAM Initialization 0 (INIT0)....1544
36.14.43 DRAM Initialization 1 (INIT1)....1546
36.14.44 DRAM Initialization 2 (INIT2)....1547
36.14.45 DRAM Initialization 3 (INIT3)....1548
36.14.46 DRAM Initialization 4 (INIT4)....1549
36.14.47 DRAM Initialization 5 (INIT5)....1550
36.14.48 DRAM Initialization 6 (INIT6)....1551
36.14.49 DRAM Initialization 7 (INIT7)....1552
36.14.50 DIMM Control (DIMMCTL)....1553
36.14.51 Rank Control (RANKCTL)....1555
36.14.52 DRAM Timing 0 (DRAMTMG0)....1557
36.14.53 DRAM Timing 1 (DRAMTMG1)....1559
36.14.54 DRAM Timing 2 (DRAMTMG2)....1561
36.14.55 DRAM Timing 3 (DRAMTMG3)....1564
36.14.56 DRAM Timing 4 (DRAMTMG4)....1566
36.14.57 DRAM Timing 5 (DRAMTMG5)....1568
36.14.58 DRAM Timing 6 (DRAMTMG6)....1570
36.14.59 DRAM Timing 7 (DRAMTMG7)....1572

36.14.60 DRAM Timing 8 (DRAMTMG8)....1573
36.14.61 DRAM Timing 9 (DRAMTMG9)....1574
36.14.62 DRAM Timing 10 (DRAMTMG10)....1575
36.14.63 DRAM Timing 11 (DRAMTMG11)....1577
36.14.64 DRAM Timing 12 (DRAMTMG12)....1578
36.14.65 DRAM Timing 13 (DRAMTMG13)....1579
36.14.66 DRAM Timing 14 (DRAMTMG14)....1580
36.14.67 DRAM Timing 15 (DRAMTMG15)....1581
36.14.68 ZQ Control 0 (ZQCTL0)....1582
36.14.69 ZQ Control 1 (ZQCTL1)....1584
36.14.70 ZQ Control 2 (ZQCTL2)....1585
36.14.71 ZQ Status (ZQSTAT)....1586
36.14.72 DFI Timing 0 (DFITMG0)....1586
36.14.73 DFI Timing 1 (DFITMG1)....1589
36.14.74 DFI Low Power Configuration 0 (DFILPCFG0)....1591
36.14.75 DFI Low Power Configuration 1 (DFILPCFG1)....1592
36.14.76 DFI Update 0 (DFIUPD0)....1593
36.14.77 DFI Update 1 (DFIUPD1)....1595
36.14.78 DFI Update 2 (DFIUPD2)....1596
36.14.79 DFI Miscellaneous Control (DFIMISC)....1597
36.14.80 DFI Timing 2 (DFITMG2)....1599
36.14.81 DFI Timing 3 (DFITMG3)....1600
36.14.82 DFI Status (DFISTAT)....1601
36.14.83 DM/DBI Control (DBICTL)....1602
36.14.84 DFI PHY Master (DFIPHYMSTR)....1603
36.14.85 Address Map 0 (ADDRMAP0)....1604
36.14.86 Address Map 1 (ADDRMAP1)....1605
36.14.87 Address Map 2 (ADDRMAP2)....1606
36.14.88 Address Map 3 (ADDRMAP3)....1608
36.14.89 Address Map 4 (ADDRMAP4)....1611
36.14.90 Address Map 5 (ADDRMAP5)....1613
36.14.91 Address Map 6 (ADDRMAP6)....1615
36.14.92 Address Map 7 (ADDRMAP7)....1617
36.14.93 Address Map 8 (ADDRMAP8)....1618
36.14.94 Address Map 9 (ADDRMAP9)....1619
36.14.95 Address Map 10 (ADDRMAP10)....1620
36.14.96 Address Map 11 (ADDRMAP11)....1621
36.14.97 ODT Configuration (ODTCFG)....1622
36.14.98 ODT/Rank Map (ODTMAP)....1624
36.14.99 Scheduler Control (SCHED)....1625
36.14.100 Scheduler Control 1 (SCHED1)....1628
36.14.101 High Priority Read CAM 1 (PERFHPR1)....1628
36.14.102 Low Priority Read CAM 1 (PERFLPR1)....1630
36.14.103 Write CAM 1 (PERFWR1)....1631
36.14.104 Debug 0 (DBG0)....1632
36.14.105 Debug 1 (DBG1)....1633
36.14.106 CAM Debug (DBGCAM)....1634
36.14.107 Command Debug (DBGCMD)....1636
36.14.108 Status Debug (DBGSTAT)....1637
36.14.109 CAM Debug 1 (DBGCAM1)....1638
36.14.110 Software Register Programming Control Enable (SWCTL)....1639
36.14.111 Software Register Programming Control Status (SWSTAT)....1640
36.14.112 On-Chip Parity Configuration 0 (OCPARCFG0)....1640
36.14.113 On-Chip Parity Configuration 1 (OCPARCFG1)....1643
36.14.114 On-Chip Parity Status 0 (OCPARSTAT0)....1644

36.14.115 On-Chip Parity Status 1 (OCPARSTAT1)..... 1645
36.14.116 On-Chip Parity Status 2 (OCPARSTAT2)..... 1647
36.14.117 AXI Poison Configuration (POISONCFG)..... 1647
36.14.118 AXI Poison Status (POISONSTAT)..... 1649
36.14.119 Advanced ECC Index (ADVECCINDEX)..... 1651
36.14.120 ECC Poison Pattern 0 (ECCPOISONPAT0)..... 1652
36.14.121 ECC Poison Pattern 2 (ECCPOISONPAT2)..... 1652
36.14.122 Address protection within ECC Status (ECCAPSTAT)..... 1653
36.14.123 Register parity configuration (REGPARCFG)..... 1654
36.14.124 Register parity status (REGPARSTAT)..... 1655
36.14.125 On-Chip command/Address Protection Configuration (OCCAPCFG)..... 1656
36.14.126 On-Chip command/Address Protection Status (OCCAPSTAT)..... 1657
36.14.127 On-Chip command/Address Protection Configuration 1 (OCCAPCFG1)..... 1659
36.14.128 On-Chip command/Address Protection Status 1 (OCCAPSTAT1)..... 1661
36.14.129 Temperature Derate Status (DERATESTAT)..... 1662
36.15 Performance monitor register descriptions..... 1663
36.15.1 PERF memory map..... 1663
36.15.2 Counter control 0 (COUNTER_0_CTRL_REG_ADDR)..... 1664
36.15.3 Counter control 1 (COUNTER_1_CTRL_REG_ADDR)..... 1665
36.15.4 Counter control 2 (COUNTER_2_CTRL_REG_ADDR)..... 1668
36.15.5 Counter control 3 (COUNTER_3_CTRL_REG_ADDR)..... 1670
36.15.6 Counter Data (COUNTER_0_DATA_REG_ADDR - COUNTER_3_DATA_REG_ADDR). 1673
36.15.7 Mode Register Read 0 address (MRR_0_DATA_REG_ADDR)..... 1674
36.15.8 Mode Register Read 1 address (MRR_1_DATA_REG_ADDR)..... 1675

Chapter 37 DDR General Purpose Registers (DDR_GPR)..... 1678
37.1 Introduction..... 1678
37.2 DDR_GPR register descriptions..... 1678
37.2.1 DDR_GPR memory map..... 1678
37.2.2 Configuration 0 (DDR_Config_0)..... 1678
37.2.3 Configuration 1 (DDR_Config_1)..... 1680
37.2.4 Configuration 2 (DDR_Config_2)..... 1681
37.2.5 Configuration 3 (DDR_Config_3)..... 1682
37.2.6 Configuration 4 (DDR_Config_4)..... 1683
37.2.7 Configuration 5 (DDR_Config_5)..... 1685
37.2.8 LP3 IO Retention Control (DDR_RET_CONTROL)..... 1687

Chapter 38 Quad Serial Peripheral Interface (QuadSPI)..... 1689
38.1 Chip-specific QuadSPI configuration..... 1689
38.1.1 Overview..... 1689
38.1.2 Supported modes..... 1689
38.1.3 QuadSPI clocking..... 1690
38.1.4 QuadSPI limitations..... 1690
38.1.5 Chip-specific feature configuration..... 1690
38.2 Introduction..... 1690
38.2.1 Features..... 1691
38.2.2 RX buffer push event..... 1691
38.2.3 RX buffer POP event..... 1691
38.2.4 Block diagram..... 1691
38.2.5 QuadSPI modes of operation..... 1692
38.3 External signal description..... 1693
38.3.1 Driving external signals..... 1694
38.4 Memory map and register definition..... 1696

38.4.1 Register write access..... 1696
38.4.2 QuadSPI register descriptions..... 1696
38.4.2.1 QuadSPI memory map..... 1696
38.4.2.2 Module Configuration Register (MCR)..... 1698
38.4.2.3 IP Configuration Register (IPCR)..... 1703
38.4.2.4 Flash Memory Configuration Register (FLSHCR)..... 1704
38.4.2.5 Buffer 0 Configuration Register (BUF0CR)..... 1705
38.4.2.6 Buffer 1 Configuration Register (BUF1CR)..... 1706
38.4.2.7 Buffer 2 Configuration Register (BUF2CR)..... 1708
38.4.2.8 Buffer 3 Configuration Register (BUF3CR)..... 1709
38.4.2.9 Buffer Generic Configuration Register (BFGENCR)..... 1710
38.4.2.10 Buffer 0 Top Index Register (BUF0IND)..... 1711
38.4.2.11 Buffer 1 Top Index Register (BUF1IND)..... 1712
38.4.2.12 Buffer 2 Top Index Register (BUF2IND)..... 1713
38.4.2.13 AHB Write Configuration Register (AWRCR)..... 1714
38.4.2.14 DLL Flash Memory A Configuration Register (DLLCRA)..... 1716
38.4.2.15 DLL Flash Memory B Configuration Register (DLLCRB)..... 1718
38.4.2.16 Parity Configuration Register (PARITYCR)..... 1720
38.4.2.17 Serial Flash Memory Address Register (SFAR)..... 1722
38.4.2.18 Serial Flash Memory Address Configuration Register (SFACR)..... 1723
38.4.2.19 Sampling Register (SMPR)..... 1725
38.4.2.20 RX Buffer Status Register (RBSR)..... 1726
38.4.2.21 RX Buffer Control Register (RBCT)..... 1727
38.4.2.22 AHB Write Status Register (AWRSR)..... 1728
38.4.2.23 DLL Status Register (DLLSR)..... 1729
38.4.2.24 Data Learning Configuration Register (DLCR)..... 1731
38.4.2.25 Data Learning Status Flash Memory A Register (DLSR_FA)..... 1733
38.4.2.26 Data Learning Status Flash Memory B Register (DLSR_FB)..... 1734
38.4.2.27 TX Buffer Status Register (TBSR)..... 1735
38.4.2.28 TX Buffer Data Register (TBDR)..... 1736
38.4.2.29 TX Buffer Control Register (TBCT)..... 1737
38.4.2.30 Status Register (SR)..... 1737
38.4.2.31 Flag Register (FR)..... 1740
38.4.2.32 Interrupt and DMA Request Select and Enable Register (RSER)..... 1744
38.4.2.33 Sequence Pointer Clear Register (SPTRCLR)..... 1748
38.4.2.34 Serial Flash Memory A1 Top Address Register (SFA1AD)..... 1749
38.4.2.35 Serial Flash Memory A2 Top Address Register (SFA2AD)..... 1750
38.4.2.36 Serial Flash Memory B1 Top Address Register (SFB1AD)..... 1751
38.4.2.37 Serial Flash Memory B2 Top Address Register (SFB2AD)..... 1752
38.4.2.38 Data Learn Pattern Register (DLPR)..... 1753
38.4.2.39 Flash Memory A Failing Address Status Register (FAILA_ADDR)..... 1754
38.4.2.40 flash Memory B Failing Address Status Register (FAILB_ADDR)..... 1755
38.4.2.41 RX Buffer Data Register (RBDR0 - RBDR63)..... 1755
38.4.2.42 LUT Key Register (LUTKEY)..... 1756
38.4.2.43 LUT Lock Configuration Register (LCKCR)..... 1757
38.4.2.44 LUT Register (LUT0)..... 1758
38.4.2.45 LUT Register (LUT1)..... 1760
38.4.2.46 LUT Register (LUT2 - LUT79)..... 1761
38.4.3 Serial flash memory address assignment..... 1762
38.5 Flash memory mapped AMBA bus..... 1763
38.5.1 AHB bus access read considerations..... 1764
38.5.2 Memory-mapped serial flash memory data—individual flash memory mode on flash memory A..... 1765
38.5.3 Memory-mapped serial flash memory data—individual flash memory mode on flash memory B..... 1766

38.5.4 Parallel flash memory mode....1766
38.5.5 ARDB register descriptions....1767
38.5.5.1 ARDB memory map....1767
38.5.5.2 AHB RX Data Buffer Register (ARDB0 - ARDB127)....1768
38.6 Functional description....1769
38.6.1 Serial flash memory access schemes....1769
38.6.2 Normal mode....1769
38.6.2.1 Programmable sequence engine....1770
38.6.2.2 Flexible read xAHB buffers....1773
38.6.2.3 Abort mechanism during AHB read....1774
38.6.2.4 HBURST support with AHB read....1774
38.6.2.5 LUT....1775
38.6.2.6 Issuing SFM commands....1776
38.6.2.7 Flash memory programming....1777
38.6.2.8 Flash memory read....1778
38.6.2.9 AHB write....1780
38.6.2.10 Byte ordering of serial flash memory read data....1781
38.6.2.11 Normal mode interrupt and DMA requests....1783
38.6.2.12 TX buffer operation....1785
38.6.2.13 Address scheme....1785
38.6.2.14 OTFAD support....1786
38.6.3 Module Disable mode....1786
38.6.4 Leaving Module Disable mode....1787
38.7 Initialization/application information....1787
38.7.1 Power up and reset....1787
38.7.2 Available status/flag information....1787
38.7.2.1 IP commands....1787
38.7.2.2 AHB commands....1787
38.7.2.3 SFM commands....1788
38.7.2.4 Overview of error flags....1788
38.7.2.5 IP bus and AHB access command collisions....1789
38.7.3 Flash memory device selection....1789
38.7.4 DMA usage....1789
38.7.4.1 DMA usage in normal mode....1789
38.7.4.1.1 Bandwidth considerations....1789
38.7.5 Flash memory devices address mapping....1792
38.7.5.1 Single mode....1793
38.7.5.2 Serial mode....1793
38.7.5.3 Parallel mode....1794
38.8 Byte ordering – endianness....1795
38.8.1 Programming flash memory data....1795
38.8.2 Reading flash memory data into the RX buffer....1796
38.8.2.1 Readout of the RX buffer through RBDRn....1796
38.8.2.2 Readout of the RX buffer through ARDBn....1796
38.8.3 Reading flash memory data into the AHB buffer....1796
38.8.3.1 Readout of the AHB buffer through memory-mapped read....1796
38.9 Driving flash memory control signals in single and dual modes....1796
38.10 Serial flash memory devices....1797
38.10.1 Example sequences....1797
38.10.1.1 Read command (Spansion hyperflash memory)....1797
38.10.1.2 Read status register (Spansion hyperflash memory)....1798
38.10.1.3 Word program (Spansion hyperflash memory)....1798
38.10.1.4 Fast read sequence (Macronix/Numonyx/Spansion/Winbond)....1800
38.10.1.5 Fast dual I/O DT read sequence (Macronix)....1800
38.10.1.6 Fast read quad output (Winbond)....1801

38.10.1.7 4 x I/O read enhance performance mode (XIP) (Macronix)....1801
38.10.1.8 Dual command page program (Numonyx)....1801
38.10.1.9 Sector erase (Macronix/Numonyx/Spansion)....1802
38.10.1.10 Read status register (Macronix/Numonyx/Spansion/Winbond)....1802
38.10.1.11 Data learn instruction sequence....1802
38.10.2 Dual-die flash memories....1804
38.10.3 Boot initialization sequence....1804
38.11 Sampling of serial flash memory input data....1805
38.11.1 Basic description....1805
38.11.2 DQS sampling method....1805
38.11.2.1 Basic description....1805
38.11.2.2 External DQS....1806
38.11.2.3 Pad loopback....1807
38.11.2.4 External center-aligned read strobe....1807
38.12 Data learning....1808
38.12.1 Basic description....1808
38.12.2 DQS sampling method....1808
38.12.3 Programming the data learning pattern in flash memory....1810
38.13 DLL and delay chain usage....1810
38.14 Data input hold requirement of flash memory....1811
38.15 Glossary....1812

Chapter 39 Ultra Secured Digital Host Controller (uSDHC)....1813
39.1 Chip-specific uSDHC information....1813
39.1.1 Chip-specific uSDHC information....1813
39.2 Introduction....1813
39.2.1 Features....1814
39.2.2 Modes and operations....1815
39.2.2.1 Data transfer modes....1815
39.3 External Signals....1815
39.3.1 Signals overview....1816
39.4 uSDHC memory map/register definition....1817
39.4.1 uSDHC register descriptions....1817
39.4.1.1 uSDHC memory map....1817
39.4.1.2 DMA System Address (DS_ADDR)....1819
39.4.1.3 Block Attributes (BLK_ATT)....1820
39.4.1.4 Command Argument (CMD_ARG)....1822
39.4.1.5 Command Transfer Type (CMD_XFR_TYP)....1823
39.4.1.6 Command Response0 (CMD_RSP0)....1826
39.4.1.7 Command Response1 (CMD_RSP1)....1827
39.4.1.8 Command Response2 (CMD_RSP2)....1828
39.4.1.9 Command Response3 (CMD_RSP3)....1828
39.4.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)....1830
39.4.1.11 Present State (PRES_STATE)....1831
39.4.1.12 Protocol Control (PROT_CTRL)....1837
39.4.1.13 System Control (SYS_CTRL)....1841
39.4.1.14 Interrupt Status (INT_STATUS)....1846
39.4.1.15 Interrupt Status Enable (INT_STATUS_EN)....1852
39.4.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)....1856
39.4.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)....1859
39.4.1.18 Host Controller Capabilities (HOST_CTRL_CAP)....1862
39.4.1.19 Watermark Level (WTMK_LVL)....1865
39.4.1.20 Mixer Control (MIX_CTRL)....1866
39.4.1.21 Force Event (FORCE_EVENT)....1869

39.4.1.22 ADMA Error Status (ADMA_ERR_STATUS)..... 1872
39.4.1.23 ADMA System Address (ADMA_SYS_ADDR)..... 1873
39.4.1.24 DLL (Delay Line) Control (DLL_CTRL)..... 1874
39.4.1.25 DLL Status (DLL_STATUS)..... 1876
39.4.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)..... 1877
39.4.1.27 Strobe DLL control (STROBE_DLL_CTRL)..... 1879
39.4.1.28 Strobe DLL status (STROBE_DLL_STATUS)..... 1881
39.4.1.29 Vendor Specific Register (VEND_SPEC)..... 1882
39.4.1.30 MMC Boot (MMC_BOOT)..... 1885
39.4.1.31 Vendor Specific 2 Register (VEND_SPEC2)..... 1887
39.4.1.32 Tuning Control (TUNING_CTRL)..... 1889
39.4.1.33 Command Queuing Version (CQVER)..... 1890
39.4.1.34 Command Queuing Capabilities (CQCAP)..... 1891
39.4.1.35 Command Queuing Configuration (CQCFG)..... 1892
39.4.1.36 Command Queuing Control (CQCTL)..... 1894
39.4.1.37 Command Queuing Interrupt Status (CQIS)..... 1895
39.4.1.38 Command Queuing Interrupt Status Enable (CQISTE)..... 1896
39.4.1.39 Command Queuing Interrupt Signal Enable (CQISGE)..... 1898
39.4.1.40 Command Queuing Interrupt Coalescing (CQIC)..... 1899
39.4.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)..... 1901
39.4.1.42 Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU)..... 1902
39.4.1.43 Command Queuing Task Doorbell (CQTDBR)..... 1902
39.4.1.44 Command Queuing Task Completion Notification (CQTCN)..... 1904
39.4.1.45 Command Queuing Device Queue Status (CQDQS)..... 1904
39.4.1.46 Command Queuing Device Pending Tasks (CQDPT)..... 1905
39.4.1.47 Command Queuing Task Clear (CQTCLR)..... 1906
39.4.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)..... 1907
39.4.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)..... 1908
39.4.1.50 Command Queuing Command Response for Direct-Command Task (CQCRDCT)..... 1909
39.4.1.51 Command Queuing Response Mode Error Mask (CQRMEM)..... 1910
39.4.1.52 Command Queuing Task Error Information (CQTERRI)..... 1911
39.4.1.53 Command Queuing Command Response Index (CQCRI)..... 1913
39.4.1.54 Command Queuing Command Response Argument (CQCRA)..... 1914
39.5 Functional Description..... 1914
39.5.1 Data buffer..... 1914
39.5.1.1 Write operation sequence..... 1915
39.5.1.2 Read operation sequence..... 1916
39.5.1.3 Data buffer and block size..... 1916
39.5.1.4 Dividing large data transfer..... 1916
39.5.2 DMA AXI interface..... 1917
39.5.2.1 Internal DMA request..... 1917
39.5.2.2 AXI master interface..... 1918
39.5.2.3 ADMA engine..... 1918
39.5.2.3.1 ADMA concept and descriptor format..... 1918
39.5.2.3.2 ADMA interrupt..... 1921
39.5.2.3.3 ADMA error..... 1921
39.5.3 Register bank with IP bus interface..... 1922
39.5.3.1 SD protocol unit..... 1922
39.5.3.2 SD control misc..... 1923
39.5.3.3 SD clock control..... 1923
39.5.3.4 Command control..... 1923
39.5.3.5 Data control..... 1923
39.5.4 Clock and reset manager..... 1924
39.5.5 Clock generator..... 1924
39.5.6 SDIO card interrupt..... 1924

39.5.6.1 Interrupts in 1-bit mode....1924
39.5.6.2 Interrupt in 4-bit mode....1924
39.5.6.3 Card interrupt handling....1925
39.5.7 Card insertion and removal detection....1926
39.5.8 Power management and wakeup events....1926
39.5.8.1 Setting wakeup events....1927
39.5.9 MMC fast boot....1927
39.5.9.1 Boot operation....1927
39.5.9.2 Alternative boot operation....1928
39.6 Initialization/Application of uSDHC....1928
39.6.1 Command send & response receive basic operation....1929
39.6.2 Card identification mode....1929
39.6.2.1 Card detect....1929
39.6.2.2 Reset....1930
39.6.2.3 Voltage validation....1931
39.6.2.4 Card registry....1932
39.6.3 Card access....1933
39.6.3.1 Block write....1933
39.6.3.1.1 Normal Write....1933
39.6.3.1.2 DDR write....1934
39.6.3.1.3 Write with Pause....1934
39.6.3.2 Block read....1935
39.6.3.2.1 Normal read....1935
39.6.3.2.2 DDR read....1936
39.6.3.2.3 Read with Pause....1936
39.6.3.2.4 Delay Line (DLL) in read path....1937
39.6.3.3 Suspend Resume....1938
39.6.3.3.1 Suspend....1938
39.6.3.3.2 Resume....1939
39.6.3.4 ADMA usage....1939
39.6.3.5 Transfer error....1939
39.6.3.5.1 CRC error....1939
39.6.3.5.2 Internal DMA error....1939
39.6.3.5.3 Transfer ADMA error....1940
39.6.3.5.4 Auto CMD12 error....1940
39.6.3.6 Card interrupt....1940
39.6.4 Switch function....1940
39.6.4.1 Query, enable, and disable SDIO high-speed mode....1941
39.6.4.2 Query, enable, and disable SD high-speed mode/DDR50/SDR50/SDR104....1941
39.6.4.3 Query, enable, and disable MMC high-speed mode....1942
39.6.4.4 Set MMC bus width....1942
39.6.5 ADMA operation....1942
39.6.5.1 ADMA1 operation....1943
39.6.5.2 ADMA2 operation....1943
39.6.6 Fast boot operation....1944
39.6.6.1 Normal fast boot flow....1944
39.6.6.2 Alternative fast boot flow....1944
39.6.6.3 Fast boot application case (in DMA mode)....1945
39.7 Commands for MMC/SD/SDIO....1946
39.8 Software Restrictions....1952
39.8.1 Initialization active....1952
39.8.2 Software polling procedure....1952
39.8.3 Suspend operation....1953
39.8.4 Data length setting....1953
39.8.5 (A)DMA address setting....1953

39.8.6 Data port access ... 1953
39.8.7 Change clock frequency ... 1953
39.8.8 Multi-block read ... 1953

Chapter 40 System Timer Module (STM) ... 1954
40.1 Chip-specific STM information ... 1954
40.1.1 STM instances ... 1954
40.2 Introduction ... 1954
40.3 Features ... 1954
40.4 STM block diagram ... 1955
40.5 STM_TS register descriptions ... 1955
40.5.1 STM_TS memory map ... 1955
40.5.2 Control (CR) ... 1956
40.5.3 Count (CNT) ... 1957
40.5.4 Channel Control (CCR0 - CCR3) ... 1958
40.5.5 Channel Interrupt (CIR0 - CIR3) ... 1959
40.5.6 Channel Compare (CMP0 - CMP3) ... 1960
40.6 STM register descriptions ... 1961
40.6.1 STM memory map ... 1961
40.6.2 Control (CR) ... 1961
40.6.3 Count (CNT) ... 1963
40.6.4 Channel Control (CCR0 - CCR3) ... 1963
40.6.5 Channel Interrupt (CIR0 - CIR3) ... 1964
40.6.6 Channel Compare (CMP0 - CMP3) ... 1965
40.7 Configure the timer ... 1966
40.8 Configure the compare channels ... 1966
40.9 Respond to compare channel events ... 1966
40.10 Functional description ... 1966
40.10.1 Count-up timer ... 1966
40.10.2 Compare channels ... 1967
40.10.3 Behavior in different chip modes ... 1967
40.11 Glossary ... 1967

Chapter 41 Software Watchdog Timer (SWT) ... 1968
41.1 Chip-specific SWT information ... 1968
41.1.1 SWT instances ... 1968
41.1.2 SWT time-out events: configuring reset and interrupt requests ... 1968
41.1.3 Reset SWT only when a timeout triggers a reset request ... 1968
41.2 Introduction ... 1968
41.2.1 Features ... 1969
41.3 Initialize the SWT ... 1969
41.3.1 Select the clock source ... 1969
41.3.2 Set the timeout period ... 1969
41.3.3 Control timeout behavior ... 1969
41.3.3.1 Select reset request on timeout ... 1969
41.3.3.2 Select interrupt on initial timeout ... 1970
41.3.4 Configure locking and unlocking ... 1970
41.3.4.1 Enable the hard lock ... 1970
41.3.4.2 Enable the soft lock ... 1970
41.3.4.3 Unlock the soft lock ... 1970
41.3.4.4 Avoid accidental soft unlock ... 1970
41.3.5 Select behavior on an invalid access ... 1971
41.4 Enable the SWT ... 1971

41.5 Initiate service operations....1971
41.5.1 Initiate a fixed service sequence....1971
41.5.2 Initiate a keyed service sequence....1971
41.5.3 Select window service mode....1972
41.6 Reset only the SWT....1972
41.7 Test SWT operation....1972
41.8 Functional description....1972
41.8.1 Behavior in different chip modes....1972
41.8.2 Register access latency....1973
41.8.3 Service key generation....1973
41.9 SWT register descriptions....1973
41.9.1 SWT memory map....1973
41.9.2 Control (CR)....1974
41.9.3 Interrupt (IR)....1977
41.9.4 Timeout (TO)....1978
41.9.5 Window (WN)....1979
41.9.6 Service (SR)....1980
41.9.7 Counter Output (CO)....1981
41.9.8 Service Key (SK)....1982
41.9.9 Reset Request (RRR)....1982

Chapter 42 Periodic Interrupt Timer (PIT)....1984
42.1 Chip-specific PIT information....1984
42.1.1 PIT module instance details....1984
42.1.2 PIT triggers....1984
42.2 Introduction....1984
42.2.1 Block diagram....1984
42.2.2 Features....1985
42.3 Modes of operation....1985
42.4 PIT register descriptions....1985
42.4.1 PIT memory map....1986
42.4.2 PIT Module Control Register (MCR)....1987
42.4.3 PIT Upper Lifetime Timer Register (LTMR64H)....1988
42.4.4 PIT Lower Lifetime Timer Register (LTMR64L)....1989
42.4.5 Timer Load Value Register (LDVAL0 - LDVAL6)....1989
42.4.6 Current Timer Value Register (CVAL0 - CVAL6)....1991
42.4.7 Timer Control Register (TCTRL0 - TCTRL6)....1992
42.4.8 Timer Flag Register (TFLG0 - TFLG6)....1994
42.5 Functional description....1995
42.5.1 General operation....1995
42.5.1.1 Timers....1995
42.5.1.2 Debug mode....1996
42.5.2 Interrupts....1996
42.5.3 Chained timers....1996
42.6 Initialization and application information....1996
42.7 Example configuration for chained timers....1997
42.8 Example configuration for the Lifetime Timer....1998

Chapter 43 FlexTimer (FTM)....1999
43.1 Chip-specific FTM information....1999
43.1.1 FTM instances....1999
43.1.2 FTM global time base....1999
43.1.3 Initialization triggers and external triggers....2000

43.2 Introduction....2000
43.2.1 Features....2000
43.2.2 Modes of operation....2001
43.2.3 Block Diagram....2001
43.3 Signal Description....2002
43.4 Memory Map and Register Definition....2003
43.4.1 Memory map....2003
43.4.2 Register descriptions....2003
43.4.3 FTM register descriptions....2003
43.4.3.1 FTM memory map....2003
43.4.3.2 Status And Control (SC)....2005
43.4.3.3 Counter (CNT)....2008
43.4.3.4 Modulo (MOD)....2009
43.4.3.5 Channel (n) Status And Control (C0SC - C5SC)....2010
43.4.3.6 Channel (n) Value (C0V - C5V)....2012
43.4.3.7 Counter Initial Value (CNTIN)....2013
43.4.3.8 Capture And Compare Status (STATUS)....2014
43.4.3.9 Features Mode Selection (MODE)....2015
43.4.3.10 Synchronization (SYNC)....2017
43.4.3.11 Initial State For Channels Output (OUTINIT)....2019
43.4.3.12 Output Mask (OUTMASK)....2020
43.4.3.13 Function For Linked Channels (COMBINE)....2021
43.4.3.14 Deadtime Configuration (DEADTIME)....2025
43.4.3.15 FTM External Trigger (EXTTRIG)....2027
43.4.3.16 Channels Polarity (POL)....2029
43.4.3.17 Fault Mode Status (FMS)....2030
43.4.3.18 Input Capture Filter Control (FILTER)....2031
43.4.3.19 Quadrature Decoder Control And Status (QDCTRL)....2032
43.4.3.20 Configuration (CONF)....2034
43.4.3.21 Synchronization Configuration (SYNCONF)....2036
43.4.3.22 FTM Inverting Control (INVCTRL)....2038
43.4.3.23 FTM Software Output Control (SWOCTRL)....2039
43.4.3.24 FTM PWM Load (PWMLOAD)....2040
43.4.3.25 Half Cycle Register (HCR)....2042
43.4.3.26 Mirror of Modulo Value (MOD_MIRROR)....2043
43.4.3.27 Mirror of Channel (n) Match Value (C0V_MIRROR - C5V_MIRROR)....2044
43.5 Functional Description....2045
43.5.1 Clock source....2045
43.5.1.1 Counter clock source....2045
43.5.2 Prescaler....2045
43.5.3 Counter....2046
43.5.3.1 Up counting....2046
43.5.3.2 Up-down counting....2047
43.5.3.3 Free running counter....2049
43.5.3.4 Counter reset....2049
43.5.3.5 Counter events....2049
43.5.4 Channel Modes....2050
43.5.5 Input Capture Mode....2052
43.5.5.1 Filter for Input Capture Mode....2053
43.5.5.2 FTM Counter Reset in Input Capture Mode....2055
43.5.6 Output Compare mode....2055
43.5.7 Edge-Aligned PWM (EPWM) mode....2056
43.5.8 Center-Aligned PWM (CPWM) mode....2057
43.5.9 Combine mode....2059
43.5.9.1 Asymmetrical PWM....2065

43.5.10 Modified Combine PWM Mode ... 2065
43.5.10.1 Synchronization ... 2067
43.5.11 Complementary Mode ... 2067
43.5.12 Registers updated from write buffers ... 2068
43.5.12.1 CNTIN register update ... 2068
43.5.12.2 MOD and HCR registers update ... 2069
43.5.12.3 CnV register update ... 2069
43.5.13 PWM synchronization ... 2070
43.5.13.1 Hardware trigger ... 2070
43.5.13.2 Software trigger ... 2071
43.5.13.3 Synchronization Points ... 2071
43.5.13.4 MOD register synchronization ... 2072
43.5.13.5 CNTIN register synchronization ... 2075
43.5.13.6 C(n)V and C(n+1)V register synchronization ... 2075
43.5.13.7 OUTMASK register synchronization ... 2075
43.5.13.8 INVCTRL register synchronization ... 2077
43.5.13.9 SWOCTRL register synchronization ... 2078
43.5.13.10 FTM counter synchronization ... 2079
43.5.14 Inverting ... 2081
43.5.15 Software Output Control Mode ... 2083
43.5.16 Deadtime insertion ... 2084
43.5.16.1 Deadtime insertion corner cases ... 2085
43.5.17 Output mask ... 2086
43.5.18 Polarity Control ... 2087
43.5.19 Initialization ... 2087
43.5.20 Features Priority ... 2088
43.5.21 External Trigger ... 2088
43.5.22 Initialization Trigger ... 2089
43.5.23 Capture Test Mode ... 2091
43.5.24 DMA ... 2092
43.5.25 Dual Edge Capture Mode ... 2092
43.5.25.1 One-Shot Capture mode ... 2093
43.5.25.2 Continuous Capture mode ... 2093
43.5.25.3 Pulse width measurement ... 2094
43.5.25.4 Period measurement ... 2095
43.5.25.5 Read coherency mechanism ... 2097
43.5.26 Quadrature Decoder Mode ... 2098
43.5.26.1 Quadrature Decoder boundary conditions ... 2101
43.5.27 Debug mode ... 2102
43.5.28 Reload Points ... 2102
43.5.28.1 Reload Opportunities ... 2103
43.5.28.2 Frequency of Reload Opportunities ... 2104
43.5.28.3 Update of the Registers ... 2104
43.5.29 Global Load ... 2105
43.5.30 Global time base (GTB) ... 2105
43.5.30.1 Enabling the global time base (GTB) ... 2106
43.5.31 Channel trigger output ... 2106
43.5.32 External Control of Channels Output ... 2107
43.5.33 Dithering ... 2107
43.5.33.1 PWM Period Dithering ... 2107
43.5.33.1.1 Up Counting ... 2108
43.5.33.1.2 Up-Down Counting ... 2109
43.5.33.2 PWM Edge Dithering ... 2110
43.5.33.2.1 EPWM Mode ... 2110
43.5.33.2.2 CPWM Mode ... 2111

43.5.33.2.3 Combine Mode....2112
43.5.33.2.4 Modified Combine PWM Mode....2114
43.6 Reset Overview....2115
43.7 FTM Interrupts....2116
43.7.1 Timer Overflow Interrupt....2116
43.7.2 Reload Point Interrupt....2116
43.7.3 Channel (n) Interrupt....2117
43.8 Initialization Procedure....2117

Chapter 44 Real Time Clock (RTC)....2119
44.1 Chip-specific RTC information....2119
44.1.1 RTC clocking....2119
44.2 Introduction....2119
44.2.1 Features....2119
44.2.2 Block diagram....2119
44.2.3 Modes of operation....2120
44.2.3.1 Functional mode....2120
44.2.3.2 Debug mode....2121
44.3 RTC register descriptions....2121
44.3.1 RTC memory map....2121
44.3.2 RTC Supervisor control register (RTCSUPV)....2121
44.3.3 RTC Control register (RTCC)....2122
44.3.4 RTC Status register (RTCS)....2124
44.3.5 RTC Counter register (RTCCNT)....2126
44.3.6 API Compare value register (APIVAL)....2127
44.3.7 RTC Compare value register (RTCVAL)....2128
44.4 Functional description....2128
44.4.1 RTC....2128
44.4.2 API functional description....2129
44.5 Recommended programming flow....2129
44.6 Glossary....2130

Chapter 45 Inter-Integrated Circuit (I2C)....2131
45.1 Overview....2131
45.2 Introduction to I^2C....2131
45.2.1 Definition: I^2C module....2131
45.2.2 Module block diagram....2131
45.2.3 Features....2132
45.2.4 Modes of operation....2132
45.2.5 Definition: I^2C conditions....2133
45.3 External signal descriptions....2133
45.3.1 Signal overview....2133
45.3.2 Detailed external signal descriptions....2134
45.4 I2C register descriptions....2134
45.4.1 I2C memory map....2134
45.4.2 I2C Bus Address Register (IBAD)....2135
45.4.3 I2C Bus Frequency Divider Register (IBFD)....2135
45.4.4 I2C Bus Control Register (IBCR)....2136
45.4.5 I2C Bus Status Register (IBSR)....2138
45.4.6 I2C Bus Data I/O Register (IBDR)....2141
45.4.7 I2C Bus Interrupt Config Register (IBIC)....2142
45.4.8 I2C Bus Debug Register (IBDBG)....2142
45.5 Functional description....2144

45.5.1 Notes about module operation....2144
45.5.2 Transactions....2144
45.5.2.1 Protocol overview....2144
45.5.2.2 Transaction protocol definitions....2145
45.5.2.3 I2C calling address requirements....2145
45.5.2.4 High-level protocol steps....2145
45.5.2.5 START condition....2146
45.5.2.6 Slave address transmission....2146
45.5.2.7 Data transmission....2146
45.5.2.8 STOP condition....2147
45.5.2.9 Repeated START condition....2147
45.5.3 Arbitration procedure....2147
45.5.4 Clock behavior....2147
45.5.4.1 Clock synchronization....2147
45.5.4.2 Clock stretching....2148
45.5.4.3 Handshaking....2148
45.5.4.4 Clock rate and IBFD settings....2148
45.5.4.4.1 Timing definitions....2148
45.5.4.4.2 Divider and hold values....2149
45.5.5 Interrupts....2163
45.5.5.1 Interrupt vector....2163
45.5.5.2 Interrupt description....2164
45.5.6 DEBUG mode....2164
45.5.7 DMA interface....2166
45.6 Initialization/application information....2166
45.6.1 Recommended interrupt service flow....2166
45.6.2 General programming guidelines (for both master and slave mode)....2167
45.6.2.1 Initializing the I2C module....2167
45.6.2.2 Software response after a transfer....2168
45.6.3 Programming guidelines specific to Master mode....2168
45.6.3.1 Generating START....2168
45.6.3.2 Transmit/receive sequence....2169
45.6.3.3 Generating STOP....2171
45.6.3.4 Generating repeated START....2172
45.6.3.5 Loss of arbitration....2172
45.6.4 Programming guidelines specific to Slave mode....2172
45.6.5 DMA application information....2172
45.6.5.1 DMA mode, master transmit....2173
45.6.5.2 DMA mode, master reception....2173
45.6.5.3 Exiting DMA mode and system requirement considerations....2174

Chapter 46 Gigabit Ethernet Media Access Controller (GMAC)....2177
46.1 Introduction....2177
46.2 Features....2178
46.3 Architecture....2179
46.3.1 Interfaces....2181
46.3.2 DMA controller....2181
46.3.3 MAC Transaction Layer (MTL)....2181
46.3.4 Media Access Controller (MAC)....2181
46.3.5 Interrupts....2181
46.4 Transmit and receive FIFOs....2182
46.5 Flow control....2182
46.6 Double VLAN tagging....2182
46.7 Descriptors....2182

46.7.1 Descriptor structure....2182
46.7.2 Transmit descriptor.... 2183
46.7.3 Receive descriptor.... 2183
46.8 Functional description....2183

Chapter 47 Packet Forwarding Engine (PFE)....2185
47.1 Introduction....2185
47.2 Features.... 2185
47.3 Initialization....2186
47.4 Functional description....2186
47.5 Packet parsing....2186
47.6 Layer 2 parsing....2186
47.7 Bridge classifier.... 2186
47.8 Layer 3 parsing....2187
47.9 Route classifier....2187
47.10 Queuing block....2187
47.11 Traffic manager unit (TMU).... 2187
47.12 Buffer management....2188
47.13 Host Interface (HIF)....2188
47.14 PHY interface options....2188
47.15 PFE configuration....2188
47.16 Software components....2188

Chapter 48 LINFlexD.... 2190
48.1 Chip-specific LINFlexD information.... 2190
48.1.1 Number of LINFlexD filters and channels.... 2190
48.1.2 LIN_CLK and bus clock relationship.... 2190
48.2 Introduction....2190
48.2.1 Block diagram.... 2190
48.3 Main features....2191
48.3.1 LIN mode features....2192
48.3.2 UART mode features.... 2192
48.4 Functional description....2193
48.4.1 LIN protocol....2193
48.4.1.1 Frames....2193
48.4.1.2 Data field....2193
48.4.1.3 Break....2193
48.4.1.4 Sync byte.... 2194
48.4.1.5 Identifier.... 2194
48.4.1.6 Checksum....2194
48.4.2 LINFlexD features.... 2194
48.4.2.1 Operating modes.... 2194
48.4.2.2 Test mode s.... 2195
48.4.2.3 Master mode....2196
48.4.2.3.1 Header transmission....2196
48.4.2.3.2 Data transmission.... 2196
48.4.2.3.3 Data reception....2197
48.4.2.3.4 Data discard....2197
48.4.2.4 Slave mode....2197
48.4.2.4.1 Data transmission.... 2197
48.4.2.4.2 Data reception....2197
48.4.2.5 Errors.... 2198
48.4.2.5.1 Header error....2198

48.4.2.5.2 SDEF ... 2198
48.4.2.5.3 IDPEF ... 2198
48.4.2.6 Bit error ... 2198
48.4.2.7 Framing error ... 2198
48.4.2.8 Checksum error ... 2199
48.4.2.9 Overrun error ... 2199
48.4.2.10 Timeout error ... 2199
48.4.2.10.1 Response timeout mechanism ... 2199
48.4.2.10.2 Header timeout mechanism ... 2200
48.4.2.11 Noise ... 2200
48.4.2.12 Start Detection and Delimiter Detection in receiver ... 2200
48.4.2.12.1 Start detection mechanism ... 2202
48.4.2.12.2 Break delimiter detection mechanism ... 2202
48.4.2.13 Baud rate generation ... 2204
48.4.2.14 Wakeup management ... 2205
48.4.3 Timer ... 2206
48.4.4 UART mode ... 2206
48.4.4.1 8-bit data frames ... 2206
48.4.4.2 9-bit frames ... 2206
48.4.4.3 Buffer in UART mode ... 2207
48.4.4.4 UART transmitter ... 2207
48.4.4.5 UART receiver ... 2208
48.4.5 DMA interface ... 2210
48.4.5.1 Main features ... 2210
48.4.5.2 Definitions ... 2210
48.4.5.3 Master node – TX mode ... 2211
48.4.5.4 Master node - RX mode ... 2214
48.4.5.5 UART – TX mode ... 2216
48.4.5.6 UART – RX mode ... 2218
48.4.5.7 Use cases and limitations ... 2220
48.5 LINFlexD register descriptions ... 2220
48.5.1 LINFlexD memory map ... 2221
48.5.2 LIN Control Register 1 (LINCR1) ... 2222
48.5.3 LIN Interrupt Enable Register (LINIER) ... 2225
48.5.4 LIN Status Register (LINSR) ... 2228
48.5.5 LIN Error Status Register (LINESR) ... 2231
48.5.6 UART Mode Control Register (UARTCR) ... 2233
48.5.7 UART Mode Status Register (UARTSR) ... 2239
48.5.8 LIN Time-Out Control Status Register (LINTCSR) ... 2241
48.5.9 LIN Output Compare Register (LINOCR) ... 2243
48.5.10 LIN Time-Out Control Register (LINTOCR) ... 2243
48.5.11 LIN Fractional Baud Rate Register (LINFBRR) ... 2244
48.5.12 LIN Integer Baud Rate Register (LINIBRR) ... 2246
48.5.13 LIN Checksum Field Register (LINCFR) ... 2247
48.5.14 LIN Control Register 2 (LINCR2) ... 2248
48.5.15 Buffer Identifier Register (BIDR) ... 2250
48.5.16 Buffer Data Register Least Significant (BDRL) ... 2252
48.5.17 Buffer Data Register Most Significant (BDRM) ... 2252
48.5.18 Global Control Register (GCR) ... 2253
48.5.19 UART Preset Timeout Register (UARTPTO) ... 2255
48.5.20 UART Current Timeout Register (UARTCTO) ... 2256
48.5.21 DMA Tx Enable Register (DMATXE) ... 2257
48.5.22 DMA Rx Enable Register (DMARXE) ... 2258
48.6 Programming considerations ... 2259
48.6.1 Master node ... 2259

48.6.1.1 Transmitter....2260
48.6.1.2 Receiver....2260
48.6.1.3 Transmitter, bit error....2260
48.6.1.4 Receiver, checksum error....2261
48.6.2 Slave node....2261
48.6.2.1 Transmitter (no identifier filters)....2261
48.6.2.2 Receiver (no identifier filters)....2261
48.6.2.3 No filters, transmitter, bit error....2261
48.6.2.4 No filters, receiver, checksum error....2262
48.6.3 Timeout....2262
48.6.4 UART mode....2263
48.6.5 Interrupts....2263
48.6.6 LINFlexD clock tolerance....2264
48.6.6.1 Faster receiver tolerance....2264
48.6.6.2 Slower receiver tolerance....2265

Chapter 49 Serial Peripheral Interface (SPI)....2266
49.1 Chip-specific SPI information....2266
49.1.1 Module instance information....2266
49.2 Introduction....2266
49.2.1 Block diagram....2266
49.2.2 Features....2267
49.2.3 Interface configurations....2268
49.2.3.1 SPI configuration....2268
49.2.4 Modes of operation....2269
49.2.4.1 Master mode....2269
49.2.4.2 Slave mode....2269
49.2.4.3 Module Disable mode....2269
49.2.4.4 Debug mode....2269
49.3 Module signal descriptions....2269
49.3.1 PCS0/SS_b....2270
49.3.2 PCS1....2270
49.3.3 PCS2....2270
49.3.4 PCS3....2270
49.3.5 PCS4....2270
49.3.6 PCS5/PCSS_b....2270
49.3.7 PCS6–PCS7....2271
49.3.8 SCK....2271
49.3.9 SIN....2271
49.3.10 SOUT....2271
49.4 SPI register descriptions....2271
49.4.1 SPI memory map....2271
49.4.2 Module Configuration Register (MCR)....2272
49.4.3 Transfer Count Register (TCR)....2277
49.4.4 Clock and Transfer Attributes Register (in Master mode) (CTAR0 - CTAR5)....2278
49.4.5 Clock and Transfer Attributes Register (in Slave mode) (CTAR0_SLAVE)....2283
49.4.6 Status Register (SR)....2285
49.4.7 DMA/Interrupt Request Select and Enable Register (RSER)....2288
49.4.8 PUSH TX FIFO Register In Master Mode (PUSHR)....2291
49.4.9 PUSH TX FIFO Register In Slave Mode (PUSHR_SLAVE)....2294
49.4.10 POP RX FIFO Register (POPR)....2295
49.4.11 Transmit FIFO Registers (TXFR0 - TXFR4)....2296
49.4.12 Receive FIFO Registers (RXFR0 - RXFR4)....2297
49.4.13 Clock and Transfer Attributes Register Extended (CTARE0 - CTARE5)....2298

49.4.14 Status Register Extended (SREX)..... 2299
49.5 Functional description.....2300
49.5.1 Starting and stopping module transfers..... 2301
49.5.2 SPI configuration.....2301
49.5.2.1 Master mode.....2302
49.5.2.2 Slave mode.....2302
49.5.2.3 FIFO disable operation..... 2302
49.5.2.4 TX FIFO buffering mechanism.....2302
49.5.2.4.1 Filling the TX FIFO.....2302
49.5.2.4.2 Draining the TX FIFO.....2303
49.5.2.5 CMD FIFO buffering mechanism..... 2303
49.5.2.6 RX FIFO buffering mechanism..... 2303
49.5.2.6.1 Filling the RX FIFO..... 2304
49.5.2.6.2 Draining the RX FIFO..... 2304
49.5.3 Module baud rate and clock delay generation..... 2304
49.5.3.1 Baud rate generator.....2304
49.5.3.2 PCS to SCK delay (t_{CSC}).....2304
49.5.3.3 After SCK delay (t_{ASC})..... 2305
49.5.3.4 Delay after transfer (t_{DT})..... 2305
49.5.3.5 PCSS enable (PCSS_b)..... 2305
49.5.4 Transfer formats.....2306
49.5.4.1 Classic SPI transfer format (CPHA = 0).....2307
49.5.4.2 Classic SPI transfer format (CPHA = 1).....2307
49.5.4.3 Modified SPI transfer format (MTFE = 1, CPHA = 0).....2308
49.5.4.4 Modified SPI transfer format (MTFE = 1, CPHA = 1).....2310
49.5.4.5 Continuous selection format..... 2311
49.5.4.6 Fast continuous selection format.....2313
49.5.5 Continuous SCK.....2313
49.5.6 Slave mode operation constraints.....2315
49.5.7 Parity generation and check.....2315
49.5.7.1 Parity for SPI frames.....2315
49.5.8 Interrupts/DMA requests..... 2316
49.5.8.1 EOQ interrupt request.....2316
49.5.8.2 Transmit FIFO fill interrupt or DMA request.....2316
49.5.8.3 CMD FIFO fill interrupt or DMA request.....2317
49.5.8.4 Transmit FIFO invalid write interrupt request.....2317
49.5.8.5 Transfer complete interrupt request.....2317
49.5.8.6 Command transfer complete interrupt request..... 2317
49.5.8.7 Transmit FIFO underflow interrupt request.....2317
49.5.8.8 Receive FIFO drain interrupt or DMA request..... 2317
49.5.8.9 Receive FIFO overflow interrupt request..... 2318
49.5.8.10 SPI frame parity error interrupt request..... 2318
49.5.9 Power saving features.....2318
49.5.9.1 Module Disable mode.....2318
49.6 Initialization/application information.....2318
49.6.1 How to manage queues..... 2318
49.6.2 Switching Master and Slave modes..... 2319
49.6.3 Initializing module in Master/Slave modes..... 2319
49.6.4 Baud rate settings..... 2319
49.6.5 Delay settings.....2320
49.6.6 Calculation of FIFO pointer addresses.....2321
49.6.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO.....2322
49.6.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO.....2322
49.6.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO..... 2322

Chapter 50 CAN (FlexCAN).....2323
50.1 Chip-specific FlexCAN information.....2323
50.1.1 Overview.....2323
50.1.2 Message buffers and data rate.....2323
50.1.3 Rx FIFO.....2323
50.1.4 Mode configuration.....2323
50.1.5 Booting with FlexCAN.....2323
50.1.6 High-resolution timestamp.....2323
50.2 Introduction.....2324
50.2.1 Overview.....2324
50.2.2 FlexCAN module features.....2325
50.2.3 Modes of operation.....2326
50.3 FlexCAN signal descriptions.....2327
50.3.1 CAN Rx.....2327
50.3.2 CAN Tx.....2327
50.4 Memory map/register definition.....2327
50.4.1 FlexCAN memory mapping.....2327
50.4.2 CAN register descriptions.....2329
50.4.2.1 CAN memory map.....2330
50.4.2.2 Module Configuration register (MCR).....2331
50.4.2.3 Control 1 register (CTRL1).....2337
50.4.2.4 Free Running Timer (TIMER).....2341
50.4.2.5 Rx Mailboxes Global Mask register (RXMGMASK).....2342
50.4.2.6 Rx 14 Mask register (RX14MASK).....2344
50.4.2.7 Rx 15 Mask register (RX15MASK).....2345
50.4.2.8 Error Counter (ECR).....2345
50.4.2.9 Error and Status 1 register (ESR1).....2347
50.4.2.10 Interrupt Masks 2 register (IMASK2).....2354
50.4.2.11 Interrupt Masks 1 register (IMASK1).....2355
50.4.2.12 Interrupt Flags 2 register (IFLAG2).....2356
50.4.2.13 Interrupt Flags 1 register (IFLAG1).....2357
50.4.2.14 Control 2 register (CTRL2).....2360
50.4.2.15 Error and Status 2 register (ESR2).....2366
50.4.2.16 CRC register (CRCR).....2367
50.4.2.17 Legacy Rx FIFO Global Mask register (RXFGMASK).....2368
50.4.2.18 Legacy Rx FIFO Information register (RXFIR).....2370
50.4.2.19 CAN Bit Timing register (CBT).....2371
50.4.2.20 Interrupt Masks 4 register (IMASK4).....2373
50.4.2.21 Interrupt Masks 3 register (IMASK3).....2373
50.4.2.22 Interrupt Flags 4 register (IFLAG4).....2374
50.4.2.23 Interrupt Flags 3 register (IFLAG3).....2375
50.4.2.24 Rx Individual Mask registers (RXIMR0 - RXIMR127).....2376
50.4.2.25 Memory Error Control register (MECR).....2377
50.4.2.26 Error Injection Address register (ERRIAR).....2380
50.4.2.27 Error Injection Data Pattern register (ERRIDPR).....2381
50.4.2.28 Error Injection Parity Pattern register (ERRIPPR).....2382
50.4.2.29 Error Report Address register (RERRAR).....2383
50.4.2.30 Error Report Data register (RERRDR).....2385
50.4.2.31 Error Report Syndrome register (RERRSYNR).....2386
50.4.2.32 Error Status register (ERRSR).....2388
50.4.2.33 Enhanced CAN Bit Timing Prescalers (EPRS).....2390
50.4.2.34 Enhanced Nominal CAN Bit Timing (ENCBT).....2391
50.4.2.35 Enhanced Data Phase CAN bit Timing (EDCBT).....2393
50.4.2.36 Enhanced Transceiver Delay Compensation (ETDC).....2394

50.4.2.37 CAN FD Control register (FDCTRL)..... 2396
50.4.2.38 CAN FD Bit Timing register (FDCBT)..... 2400
50.4.2.39 CAN FD CRC register (FDCRC)..... 2402
50.4.2.40 Enhanced Rx FIFO Control register (ERFCR)..... 2404
50.4.2.41 Enhanced Rx FIFO Interrupt Enable register (ERFIER)..... 2411
50.4.2.42 Enhanced Rx FIFO Status register (ERFSR)..... 2413
50.4.2.43 High Resolution Time Stamp (HR_TIME_STAMP0 - HR_TIME_STAMP127)..... 2415
50.4.2.44 Enhanced Rx FIFO Filter Element (ERFFEL0 - ERFFEL127)..... 2416
50.4.3 Message buffer structure..... 2417
50.4.4 FlexCAN memory partition for CAN FD..... 2424
50.4.5 FlexCAN message buffer memory map..... 2426
50.4.6 Legacy Rx FIFO structure..... 2436
50.4.7 Enhanced Rx FIFO structure..... 2438
50.5 Functional description..... 2441
50.5.1 Transmit process..... 2441
50.5.2 Arbitration process..... 2442
50.5.2.1 Lowest-number mailbox first..... 2443
50.5.2.2 Highest-priority mailbox first..... 2443
50.5.2.2.1 Local priority disabled..... 2443
50.5.2.2.2 Local priority enabled..... 2443
50.5.2.3 Arbitration process (continued)..... 2444
50.5.3 Receive process..... 2445
50.5.4 Matching process..... 2446
50.5.5 Move process..... 2448
50.5.5.1 Move-in..... 2448
50.5.5.2 Move-out..... 2449
50.5.6 Data coherence..... 2449
50.5.6.1 Transmission abort mechanism..... 2449
50.5.6.2 Mailbox inactivation..... 2450
50.5.6.3 Mailbox lock mechanism..... 2450
50.5.7 Enhanced Rx FIFO..... 2451
50.5.7.1 Enhanced Rx FIFO matching process..... 2452
50.5.7.2 Enhanced Rx FIFO under DMA operation..... 2454
50.5.7.3 Enhanced Rx FIFO clear operation..... 2455
50.5.8 Legacy Rx FIFO..... 2455
50.5.8.1 Legacy Rx FIFO under DMA operation..... 2456
50.5.8.2 Clear Legacy FIFO operation..... 2456
50.5.9 CAN protocol related features..... 2457
50.5.9.1 CAN FD ISO compliance..... 2457
50.5.9.2 CAN FD frames..... 2457
50.5.9.3 Transceiver delay compensation..... 2460
50.5.9.4 Remote frames..... 2462
50.5.9.5 Overload frames..... 2463
50.5.9.6 Message buffer time stamp..... 2463
50.5.9.7 High resolution time stamp..... 2463
50.5.9.8 Protocol timing..... 2463
50.5.9.9 Arbitration and matching timing..... 2468
50.5.9.10 Tx arbitration start delay..... 2468
50.5.10 Clock domains and restrictions..... 2472
50.5.11 Modes of operation details..... 2476
50.5.11.1 Freeze mode..... 2476
50.5.11.2 Module Disable mode..... 2477
50.5.12 Interrupts..... 2477
50.5.13 Bus interface..... 2478
50.5.14 Detection and correction of memory errors..... 2478

50.5.14.1 Sources of the memory access....2479
50.5.14.2 Error indication....2479
50.5.14.3 Error reporting....2480
50.5.14.4 Response to errors....2480
50.5.14.5 Error injection....2481
50.6 Initialization/application information....2481
50.6.1 FlexCAN initialization sequence....2481
50.7 Glossary....2482

Chapter 51 Timestamp....2484
51.1 Timestamping and distribution....2484
51.2 Block diagram....2484
51.3 Timestamp synchronization controls....2484
51.4 Application information....2485
51.4.1 Enable timestamping....2485
51.4.2 Disable timestamping or changing the timestamp source....2485

Chapter 52 SerDes Subsystem....2486
52.1 Chip-specific SerDes information....2486
52.1.1 Mapping of SerDes signals to general purpose registers....2486
52.1.2 SerDes subsystem working modes....2486
52.1.3 Resets required for operation....2487
52.1.4 Register configuration for SerDes base spec....2487
52.1.5 Linking up mode0 and SerDes....2487
52.1.6 Unexpected behavior when enabling error injection in DMA Channel context memories of SerDes....2487
52.1.7 Converting nonsecure accesses to secure accesses....2487

Chapter 53 SerDes General Purpose Registers (SERDES_GPR)....2488
53.1 PCIe GPRs....2488
53.1.1 Introduction....2488
53.1.2 SERDES_GPR register descriptions....2488
53.1.2.1 SERDES_GPR memory map....2488
53.1.2.2 PCIE Configuration 0 (PCIE_Config_0)....2488
53.2 PCIe GPRs....2489
53.2.1 Introduction....2489
53.2.2 SERDES_GPR register descriptions....2489
53.2.2.1 SERDES_GPR memory map....2489
53.2.2.2 PCIE Configuration 0 (PCIE_Config_0)....2490

Chapter 54 Low Latency Communication Engine (LLCE)....2492
54.1 Introduction....2492
54.2 High-level features....2493
54.3 Reset and boot....2494
54.4 Modes of operation....2494
54.5 Subsystem control....2494
54.5.1 Reset control....2494
54.6 Host interface....2494
54.7 Clocking options....2495
54.8 Global timestamping....2496
54.9 Host interface events or interrupts....2496

54.10 FIFO interrupts..... 2496
54.11 LLCE generic FIFO.....2496
54.11.1 Features.....2497
54.11.2 Modes of operation..... 2497
54.11.3 LLCE FIFO register descriptions.....2498
54.11.3.1 LLCE FIFO registers memory map.....2498
54.11.3.2 FIFO Configuration Register (FCR)..... 2498
54.11.3.3 FIFO Status Register 0 (SR0).....2500
54.11.3.4 FIFO Status Register 1 (SR1).....2503
54.11.3.5 FIFO interrupt enable register (IER)..... 2506
54.11.3.6 FIFO Interrupt Line Register (ILR)..... 2508
54.11.3.7 FIFO push register 0 (PUSHR0).....2510
54.11.3.8 FIFO POP Register 0 (POPR0)..... 2510
54.11.3.9 FIFO Fixed MSB Register (FMR0).....2511
54.11.4 Functional description..... 2512
54.11.4.1 Basic push operation..... 2512
54.11.4.2 Mulit-word push operation.....2512
54.11.4.3 Basic pop operation..... 2512
54.11.4.4 Multi-word pop operation..... 2512
54.11.4.5 Pop operation when FIFO_FCR[POPEN] is 0..... 2512
54.11.4.6 FIFO flush..... 2512
54.11.4.7 FIFO watermark operation.....2513
54.11.4.8 Last FIFO entry overwrite operation..... 2513
54.11.4.9 Error scenarios.....2513
54.11.4.10 FIFO performance.....2513
54.11.5 Interrupts..... 2514
54.11.6 Programming.....2514
54.12 Core-to-Core module.....2515
54.12.1 Block diagram..... 2516
54.12.2 Features..... 2516
54.12.3 Core-to-core register descriptions.....2517
54.12.3.1 Core_to_core memory map.....2517
54.12.3.2 HOST interrupt from Core 0 Register (HINTC0R)..... 2518
54.12.3.3 HOST Interrupt from Core 1 Register (HINTC1R)..... 2520
54.12.3.4 HOST Interrupt from Core 2 Register (HINTC2R)..... 2523
54.12.3.5 HOST Interrupt from Core 3 Register (HINTC3R)..... 2526
54.12.3.6 Core 0 Interrupt from HOST (C0INTHR).....2528
54.12.3.7 Core 1 Interrupt From HOST Register (C1INTHR).....2531
54.12.3.8 Core 2 Interrupt from HOST Register (C2INTHR)..... 2534
54.12.3.9 Core 3 Interrupt from HOST Register (C3INTHR)..... 2536
54.12.3.10 HOST Interrupt from Core 0 Enable Register (HINTC0ER).....2539
54.12.3.11 HOST Interrupt from Core 1 Enable Register (HINTC1ER).....2541
54.12.3.12 HOST Interrupt from Core 2 Enable Register (HINTC2ER).....2544
54.12.3.13 HOST Interrupt from Core 3 Enable Register (HINTC3ER).....2546
54.12.3.14 Core 0 Interrupt from Host Enable Register (C0INTHER)..... 2548
54.12.3.15 Core 1 Interrupt from HOST Enable Register (C1INTHER).....2551
54.12.3.16 Core 2 Interrupt from HOST Enable Register (C2INTHER).....2553
54.12.3.17 Core 3 Interrupt from HOST Enable Register (C3INTHER).....2555
54.12.4 Functional description..... 2557
54.13 Interrupts and status.....2560
54.13.1 Interrupt concentrator (IC).....2560
54.13.2 Interrupt Routing Configuration Module (IRCM).....2560
54.14 External signal description.....2564
54.15 LLCE register descriptions..... 2565
54.15.1 System control memory map..... 2565

54.15.2 System Reset Control (LLCE_SYSRSTR)..... 2565

Chapter 55 Universal Serial Bus On-The-Go Controller (USBOTG)..... 2567
55.1 Chip-specific USB information..... 2567
55.1.1 Chip-specific USBOTG information..... 2567
55.1.2 SBUSCFG[AHBBRST] field reset value..... 2567
55.2 Introduction..... 2567
55.2.1 Overview..... 2568
55.2.2 Features..... 2568
55.2.3 Modes of operation..... 2569
55.3 External signal description..... 2569
55.4 USBOTG register descriptions..... 2570
55.4.1 Core register descriptions..... 2570
55.4.1.1 UOTG memory map..... 2570
55.4.1.2 Identification (ID)..... 2572
55.4.1.3 General Hardware Parameters (HWGENERAL)..... 2573
55.4.1.4 Host Hardware Parameters (HWHOST)..... 2574
55.4.1.5 Device Hardware Parameters (HWDEVICE)..... 2575
55.4.1.6 TX Buffer Hardware Parameters (HWTXBUF)..... 2576
55.4.1.7 RX Buffer Hardware Parameters (HWRXBUF)..... 2577
55.4.1.8 General Purpose Timer Load (GPTIMER0LD - GPTIMER1LD)..... 2578
55.4.1.9 General Purpose Timer Controller (GPTIMER0CTRL - GPTIMER1CTRL)..... 2579
55.4.1.10 System Bus Configuration (SBUSCFG)..... 2580
55.4.1.11 Capability Register Length (CAPLENGTH)..... 2582
55.4.1.12 Host Controller Interface Version (HCIVERSION)..... 2582
55.4.1.13 Host Controller Structural Parameters (HCSPARAMS)..... 2583
55.4.1.14 Host Controller Capability Parameters (HCCPARAMS)..... 2585
55.4.1.15 Device Controller Interface Version (DCIVERSION)..... 2586
55.4.1.16 Device Controller Capability Parameters (DCCPARAMS)..... 2587
55.4.1.17 USB Command (USBCMD)..... 2588
55.4.1.18 USB Status (USBSTS)..... 2592
55.4.1.19 Interrupt Enable (USBINTR)..... 2596
55.4.1.20 USB Frame Index (FRINDEX)..... 2598
55.4.1.21 Frame List Base Address or Device Address (PERIODICLISTBASE_or_DEVICEADDR)..... 2599
55.4.1.22 Next Asynchronous Address or Endpoint List Address (ASYNCLISTADDR_or_ENDPOINTLISTADDR)..... 2601
55.4.1.23 Programmable Burst Size (BURSTSIZE)..... 2602
55.4.1.24 TX FIFO Fill Tuning (TXFILLTUNING)..... 2603
55.4.1.25 IC_USB Enable and Voltage Negotiation (IC_USB)..... 2605
55.4.1.26 ULPI Register Access (ULPI_VIEWPORT)..... 2606
55.4.1.27 Endpoint NAK (ENDPTNAK)..... 2608
55.4.1.28 Endpoint NAK Enable (ENDPTNAKEN)..... 2609
55.4.1.29 Configure Flag (CONFIGFLAG)..... 2610
55.4.1.30 Port Status and Control (PORTSC1)..... 2611
55.4.1.31 OTG Status Control (OTGSC)..... 2619
55.4.1.32 USB Device Mode (USBMODE)..... 2622
55.4.1.33 Endpoint Setup Status (ENDPTSETUPSTAT)..... 2624
55.4.1.34 Endpoint Initialization (ENDPTPRIME)..... 2625
55.4.1.35 Endpoint De-Initialize (ENDPTFLUSH)..... 2626
55.4.1.36 Endpoint Status (ENDPTSTAT)..... 2627
55.4.1.37 Endpoint Complete (ENDPTCOMPLETE)..... 2629
55.4.1.38 Endpoint Control 0 (ENDPTCTRL0)..... 2630
55.4.1.39 Endpoint Control (ENDPTCTRL1 - ENDPTCTRL5)..... 2632
55.4.2 Non-core register descriptions..... 2635

55.4.2.1 UOTGNC memory map ... 2635
55.4.2.2 Control register (CR) ... 2635
55.5 Functional description ... 2637
55.5.1 USB dual role device/host controller ... 2637
55.5.1.1 Host mode ... 2638
55.5.1.2 Peripheral (Device) mode ... 2638
55.5.2 System interface ... 2638
55.5.3 DMA engine ... 2638
55.5.4 FIFO RAM controller ... 2638
55.5.5 USB power control block ... 2638
55.5.5.1 Entering low-power Suspend mode ... 2638
55.6 Wake-up events ... 2638
55.6.1 Host mode events ... 2639
55.6.2 Device mode events ... 2639
55.7 Interrupts ... 2639
55.7.1 USB core interrupts ... 2639
55.7.2 USB wake-up interrupts ... 2639
55.8 Data structures ... 2639
55.8.1 Device data structures ... 2639
55.8.1.1 Endpoint dQH ... 2640
55.8.1.1.1 Endpoint capabilities and characteristics (offset = 0h) ... 2641
55.8.1.1.2 Transfer overlay (offset = 8h-20h) ... 2642
55.8.1.1.3 Current dTD Pointer (offset = 0h) ... 2642
55.8.1.1.4 Setup buffer (offset = 28h-2Ch) ... 2643
55.8.1.2 Endpoint dTD ... 2643
55.8.1.2.1 Next dTD pointer (offset = 0h) ... 2644
55.8.1.2.2 dTD token (offset = 4h) ... 2644
55.8.1.2.3 dTD buffer page pointer list (offset = 8h-18h) ... 2646
55.8.2 Host data structures ... 2646
55.8.2.1 Periodic frame list ... 2647
55.8.2.2 Asynchronous list QH pointer ... 2648
55.8.2.3 iTD ... 2649
55.8.2.3.1 Next link pointer ... 2650
55.8.2.3.2 iTD transaction status and control list ... 2651
55.8.2.3.3 iTD buffer page pointer list (plus) ... 2652
55.8.2.4 siTD ... 2654
55.8.2.4.1 Next link pointer ... 2654
55.8.2.4.2 siTD endpoint capabilities/characteristics ... 2655
55.8.2.4.3 siTD transfer state ... 2656
55.8.2.4.4 siTD buffer pointer list (plus) ... 2657
55.8.2.4.5 siTD back link pointer ... 2658
55.8.2.5 Queue element transfer descriptor (qTD) ... 2659
55.8.2.5.1 Next qTD pointer ... 2660
55.8.2.5.2 Alternate next qTD pointer ... 2660
55.8.2.5.3 qTD token ... 2661
55.8.2.5.4 qTD buffer page pointer list ... 2664
55.8.2.6 QH ... 2665
55.8.2.6.1 QHLP ... 2666
55.8.2.6.2 QH endpoint capabilities/characteristics ... 2666
55.8.2.6.3 Transfer overlay-QH ... 2668
55.8.2.7 Periodic FSTN ... 2669
55.8.2.7.1 FSTN normal path pointer ... 2670
55.8.2.7.2 FSTN back path link pointer ... 2671
55.9 Device mode operation ... 2671
55.9.1 Port state and control ... 2671

55.9.2 Bus reset....2672
55.9.3 Suspend/resume....2673
55.9.3.1 Suspend operational model....2673
55.9.3.2 Resume....2673
55.9.4 Managing endpoints....2674
55.9.4.1 Endpoint initialization....2674
55.9.4.2 Stalling....2675
55.9.4.3 Data toggle....2675
55.9.4.3.1 Data toggle reset....2675
55.9.4.3.2 Data toggle inhibit....2675
55.9.5 Packet transfers....2676
55.9.5.1 Priming transmit endpoints....2676
55.9.5.2 Priming receive endpoints....2676
55.9.5.3 Interrupt/bulk endpoint operation....2676
55.9.6 Control endpoint operation....2678
55.9.6.1 Setup phase....2678
55.9.6.2 Data phase....2678
55.9.6.3 Status phase....2679
55.9.6.4 Control endpoint bus response matrix....2679
55.9.7 Isochronous endpoint operation....2679
55.9.7.1 Isochronous pipe synchronization....2680
55.9.7.2 Isochronous endpoint bus response matrix....2681
55.9.8 Managing QHs....2681
55.9.8.1 QH initialization....2682
55.9.8.2 Setup transfers operation....2682
55.9.9 Managing transfers with transfer descriptors....2682
55.9.9.1 Software link pointers....2682
55.9.9.2 Building a TD....2683
55.9.9.3 Executing a TD....2683
55.9.9.4 Transfer completion....2684
55.9.9.5 Flushing/de-priming an endpoint....2684
55.9.9.6 Device error matrix....2684
55.9.10 Servicing interrupts....2685
55.9.10.1 High frequency interrupts....2685
55.9.10.2 Error interrupts....2686
55.10 Host mode operation....2686
55.10.1 Servicing interrupts....2686
55.10.1.1 High frequency interrupts....2686
55.10.1.2 Low frequency interrupts....2686
55.10.1.3 Error interrupts....2687
55.10.2 Managing isochronous transfers using iTDs....2687
55.10.2.1 Host controller operational model for iTDs....2687
55.10.2.2 Software operational model for iTDs....2689
55.10.2.2.1 Periodic scheduling threshold....2690
55.10.3 Managing control/bulk/interrupt transfers through QHs....2690
55.10.3.1 Fetch QH....2692
55.10.3.2 Advance queue....2692
55.10.3.3 Execute transaction....2693
55.10.3.3.1 Interrupt transfer pre-condition criteria....2693
55.10.3.3.2 Asynchronous transfer pre-operations and pre-condition criteria....2693
55.10.3.3.3 Transfer type independent pre-operations....2693
55.10.3.3.4 Halting a QH....2695
55.10.3.3.5 Asynchronous Schedule Park mode....2695
55.10.3.4 Write back qTD....2696
55.10.3.5 Follow QH horizontal pointer....2697

55.10.3.6 Buffer pointer list use for data streaming with qTDs..... 2697
55.10.3.7 Adding interrupt QHs to the periodic schedule..... 2698
55.10.3.8 Managing transfer complete interrupts from queue heads..... 2699
55.10.4 Split transactions..... 2699
55.10.4.1 Split transactions for asynchronous transfers..... 2699
55.10.4.1.1 Asynchronous—do start split..... 2700
55.10.4.1.2 Asynchronous—do complete split..... 2700
55.10.4.2 Split transaction interrupt..... 2701
55.10.4.2.1 Split transaction scheduling mechanisms for interrupt..... 2701
55.10.4.2.2 Host controller operational model for FSTNs..... 2703
55.10.4.2.3 Software operational model for FSTNs..... 2705
55.10.4.2.4 Tracking split transaction progress for interrupt transfers..... 2705
55.10.4.2.5 Split transaction execution state machine for interrupt..... 2706
55.10.4.2.6 Rebalancing the periodic schedule..... 2710
55.10.4.3 Split transaction isochronous..... 2711
55.10.4.3.1 Split transaction scheduling mechanisms for isochronous..... 2711
55.10.4.3.2 Tracking split transaction progress for isochronous transfers..... 2714
55.10.4.3.3 Split transaction execution state machine for isochronous..... 2715
55.10.4.3.4 Periodic isochronous - do start split..... 2716
55.10.4.3.5 Periodic isochronous - do complete split..... 2718
55.10.4.3.6 Complete-split for scheduling boundary cases 2a, 2b..... 2719
55.11 Deviations from the EHCI specifications..... 2720
55.11.1 Embedded transaction translator function..... 2720
55.11.1.1 Capability registers..... 2720
55.11.1.2 Operational registers..... 2721
55.11.1.3 Discovery..... 2721
55.11.1.4 Data structures..... 2721
55.11.1.5 Operational model..... 2722
55.11.1.5.1 Microframe pipeline..... 2722
55.11.1.5.2 Split-state machines..... 2722
55.11.1.5.3 Asynchronous transaction scheduling and buffer management..... 2723
55.11.1.5.4 Periodic transaction scheduling and buffer management..... 2723
55.11.1.5.5 Multiple transaction translators..... 2724
55.11.2 Non-zero fields in the register file..... 2724
55.11.3 SOF interrupt..... 2724
55.11.4 Embedded design..... 2724
55.11.4.1 Frame adjust register..... 2724
55.11.5 Miscellaneous variations from EHCI..... 2724
55.11.5.1 Programmable physical interface behavior..... 2724
55.11.5.2 Discovery..... 2724
55.11.5.2.1 Port reset..... 2724
55.11.5.2.2 Port speed detection..... 2725
55.11.5.3 Port Test mode..... 2725

Chapter 56 FlexRay Communication Controller (FlexRay)..... 2726
56.1 Introduction..... 2726
56.1.1 References..... 2726
56.1.2 Overview..... 2726
56.1.3 Features..... 2727
56.1.4 Modes of operation..... 2728
56.1.4.1 Disabled mode..... 2728
56.1.4.1.1 Leave Disabled mode..... 2728
56.1.4.2 Normal mode..... 2728
56.1.4.2.1 Enter Normal mode..... 2728

56.2 External signal description....2728
56.3 PE clocking....2729
56.4 Register descriptions....2729
56.4.1 Register reset....2730
56.4.2 Register write access....2730
56.4.2.1 Register write access restriction....2730
56.4.2.2 Register write access requirements....2731
56.4.2.3 Internal register access....2731
56.4.3 PCR*n* fields....2731
56.5 FlexRay register descriptions....2734
56.5.1 FlexRay memory map....2735
56.5.2 Module Version (MVR)....2772
56.5.3 Module Configuration (MCR)....2772
56.5.4 System Memory Base Address High (SYMBADHR)....2775
56.5.5 System Memory Base Address Low (SYMBADLR)....2776
56.5.6 Strobe Signal Control (STBSCR)....2777
56.5.7 MB Data Size (MBDSR)....2779
56.5.8 MB Segment Size and Utilization (MBSSUTR)....2780
56.5.9 PE DRAM Access (PEDRAR)....2782
56.5.10 PE DRAM Data (PEDRDR)....2783
56.5.11 Protocol Operation Control Register (POCR)....2783
56.5.12 Global Interrupt Flag And Enable (GIFER)....2786
56.5.13 Protocol Interrupt Flag 0 (PIFR0)....2789
56.5.14 Protocol Interrupt Flag 1 (PIFR1)....2792
56.5.15 Protocol Interrupt Enable 0 (PIER0)....2794
56.5.16 Protocol Interrupt Enable 1 (PIER1)....2797
56.5.17 CHI Error Flag (CHIERFR)....2798
56.5.18 MB Interrupt Vector (MBIVEC)....2801
56.5.19 Channel A Status Error Counter Register (CASERCR)....2802
56.5.20 Channel B Status Error Counter (CBSERCR)....2803
56.5.21 Protocol Status 0 (PSR0)....2804
56.5.22 Protocol Status 1 (PSR1)....2806
56.5.23 Protocol Status Register 2 (PSR2)....2808
56.5.24 Protocol Status 3 (PSR3)....2811
56.5.25 MT Counter (MTCTR)....2814
56.5.26 Cycle Counter (CYCTR)....2814
56.5.27 Slot Counter Channel A (SLTCTAR)....2815
56.5.28 Slot Counter Channel B (SLTCTBR)....2816
56.5.29 Rate Correction Value (RTCORVR)....2817
56.5.30 Offset Correction Value (OFCORVR)....2818
56.5.31 Combined Interrupt Flag (CIFR)....2818
56.5.32 System Memory Access Timeout (SYMATOR)....2820
56.5.33 Sync Frame Counter (SFCNTR)....2821
56.5.34 Sync Frame Table Offset (SFTOR)....2822
56.5.35 Sync Frame Table Configuration Control Status (SFTCCSR)....2823
56.5.36 Sync Frame ID Rejection Filter (SFIDRFR)....2825
56.5.37 Sync Frame ID Acceptance Filter Value (SFIDAFVR)....2825
56.5.38 Sync Frame ID Acceptance Filter Mask (SFIDAFMR)....2826
56.5.39 NMV n (NMVR0 - NMVR5)....2827
56.5.40 Network Management Vector Length Register (NMVLR)....2828
56.5.41 Timer Configuration And Control (TICCR)....2829
56.5.42 Timer 1 Cycle Set Register (TI1CYSR)....2831
56.5.43 Timer 1 MT Offset (TI1MTOR)....2832
56.5.44 Timer 2 Configuration 0 (Absolute Timer Configuration) (TI2CR0_ABS)....2832
56.5.45 Timer 2 Configuration 0 (Relative Timer Configuration) (TI2CR0_REL)....2833

56.5.46 Timer 2 Configuration 1 (Absolute Timer Configuration) (TI2CR1_ABS)....2834
56.5.47 Timer 2 Configuration 1 (Relative Timer Configuration) (TI2CR1_REL)....2835
56.5.48 Slot Status Selection (SSSR)....2835
56.5.49 Slot Status Counter Condition (SSCCR)....2837
56.5.50 Slot Status (SSR0 - SSR7)....2839
56.5.51 Slot Status Counter (SSCR0 - SSCR3)....2842
56.5.52 MTS A Configuration (MTSACFR)....2843
56.5.53 MTS B Configuration (MTSBCFR)....2844
56.5.54 Receive Shadow Buffer Index (RSBIR)....2845
56.5.55 Receive FIFO Watermark And Selection (RFWMSR)....2846
56.5.56 Receive FIFO Start Index (RFSIR)....2847
56.5.57 Receive FIFO Depth And Size (RFDSR)....2848
56.5.58 Receive FIFO A Read Index (RFARIR)....2849
56.5.59 Receive FIFO B Read Index (RFBRIR)....2850
56.5.60 Receive FIFO Message ID Acceptance Filter Value (RFMIDAFVR)....2850
56.5.61 Receive FIFO Message ID Acceptance Filter Mask (RFMIDAFMR)....2851
56.5.62 Receive FIFO Frame ID Rejection Filter Value (RFFIDRFVR)....2852
56.5.63 Receive FIFO Frame ID Rejection Filter Mask (RFFIDRFMR)....2852
56.5.64 Receive FIFO Range Filter Configuration (RFRFCFR)....2853
56.5.65 Receive FIFO Range Filter Control (RFRFCTR)....2854
56.5.66 Last Dynamic Transmit Slot Channel A (LDTXSLAR)....2856
56.5.67 Last Dynamic Transmit Slot Channel B (LDTXSLBR)....2857
56.5.68 Protocol Configuration 0 (PCR0)....2858
56.5.69 Protocol Configuration 1 (PCR1)....2858
56.5.70 Protocol Configuration 2 (PCR2)....2859
56.5.71 Protocol Configuration 3 (PCR3)....2860
56.5.72 Protocol Configuration 4 (PCR4)....2861
56.5.73 Protocol Configuration 5 (PCR5)....2861
56.5.74 Protocol Configuration 6 (PCR6)....2862
56.5.75 Protocol Configuration 7 (PCR7)....2863
56.5.76 Protocol Configuration 8 (PCR8)....2864
56.5.77 Protocol Configuration 9 (PCR9)....2864
56.5.78 Protocol Configuration 10 (PCR10)....2865
56.5.79 Protocol Configuration 11 (PCR11)....2866
56.5.80 Protocol Configuration 12 (PCR12)....2867
56.5.81 Protocol Configuration 13 (PCR13)....2867
56.5.82 Protocol Configuration 14 (PCR14)....2868
56.5.83 Protocol Configuration 15 (PCR15)....2869
56.5.84 Protocol Configuration 16 (PCR16)....2869
56.5.85 Protocol Configuration 17 (PCR17)....2870
56.5.86 Protocol Configuration 18 (PCR18)....2871
56.5.87 Protocol Configuration 19 (PCR19)....2871
56.5.88 Protocol Configuration 20 (PCR20)....2872
56.5.89 Protocol Configuration 21 (PCR21)....2873
56.5.90 Protocol Configuration 22 (PCR22)....2873
56.5.91 Protocol Configuration 23 (PCR23)....2874
56.5.92 Protocol Configuration 24 (PCR24)....2875
56.5.93 Protocol Configuration 25 (PCR25)....2875
56.5.94 Protocol Configuration 26 (PCR26)....2876
56.5.95 Protocol Configuration 27 (PCR27)....2877
56.5.96 Protocol Configuration 28 (PCR28)....2877
56.5.97 Protocol Configuration 29 (PCR29)....2878
56.5.98 Protocol Configuration 30 (PCR30)....2879
56.5.99 Stopwatch Count High (STPWHR)....2879
56.5.100 Stopwatch Count Low (STPWLR)....2880

56.5.101 Protocol Event Output Enable And Stopwatch Control (PEOER)....2881
56.5.102 Receive FIFO Start Data Offset (RFSDOR)....2882
56.5.103 Receive FIFO System Memory Base Address High (RFSYMBADHR)....2882
56.5.104 Receive FIFO System Memory Base Address Low (RFSYMBADLR)....2883
56.5.105 Receive FIFO Periodic Timer (RFPTR)....2884
56.5.106 Receive FIFO Fill Level and Pop Count (RFFLPCR)....2884
56.5.107 ECC Error Interrupt Flag And Enable (EEIFER)....2885
56.5.108 ECC Error Report And Injection Control (EERICR)....2888
56.5.109 ECC Error Report Address (EERAR)....2889
56.5.110 ECC Error Report Data (EERDR)....2891
56.5.111 ECC Error Report Code (EERCR)....2892
56.5.112 ECC Error Injection Address Register (EEIAR)....2893
56.5.113 ECC Error Injection Data (EEIDR)....2894
56.5.114 ECC Error Injection Code (EEICR)....2895
56.5.115 MB Configuration Control Status (MBCCSR0 - MBCCSR255)....2896
56.5.116 MB Cycle Counter Filter (MBCCFR0 - MBCCFR255)....2898
56.5.117 MB Frame ID (MBFIDR0 - MBFIDR255)....2900
56.5.118 MB Index (MBIDXR0 - MBIDXR255)....2901
56.5.119 MB Data Field Offset (MBDOR0 - MBDOR259)....2901
56.5.120 LRAM ECC Error Test Register (LEETR0 - LEETR5)....2902
56.6 Functional description....2903
56.6.1 MB concept....2903
56.6.2 Physical MB....2903
56.6.2.1 MB header field....2903
56.6.2.1.1 Frame header....2904
56.6.2.1.2 Slot status....2904
56.6.2.2 MB data field....2904
56.6.3 MB types....2904
56.6.3.1 Individual MBs....2904
56.6.3.1.1 Individual MB segments....2905
56.6.3.2 Receive shadow buffers....2906
56.6.3.3 Receive FIFO....2906
56.6.3.4 MB configuration and control data....2908
56.6.3.4.1 Individual MB configuration data....2908
56.6.3.5 Individual MB control data....2909
56.6.3.6 Receive shadow buffer configuration data....2909
56.6.3.7 Receive FIFO control and configuration data....2909
56.6.3.7.1 Receive FIFO configuration data....2909
56.6.3.7.2 Receive FIFO control data....2909
56.6.3.7.3 Receive FIFO status data....2909
56.6.4 FlexRay memory area layout....2909
56.6.4.1 FlexRay memory area layout when MCR[FAM] = 0....2910
56.6.4.2 FlexRay memory area layout when MCR[FAM] = 1....2910
56.6.4.3 MB header area when MCR[FAM] = 0....2911
56.6.4.4 MB header area with MCR[FAM] = 1....2911
56.6.4.5 FIFO MB header area with MCR[FAM] = 1....2912
56.6.4.6 MB data area....2912
56.6.4.7 Sync frame table area....2912
56.6.5 Physical MB description....2912
56.6.5.1 MB protection and data consistency....2912
56.6.5.2 MB header field description....2912
56.6.5.2.1 Frame header description....2912
56.6.5.2.2 Slot status description....2915
56.6.5.3 MB data field description....2921
56.6.5.3.1 MB data field read access....2922

56.6.5.3.2 MB data field write access....2922
56.6.6 Individual MB functional description....2922
56.6.6.1 Individual MB configuration....2923
56.6.6.1.1 Common configuration data....2923
56.6.6.1.2 Specific configuration data....2923
56.6.6.2 Transmit MBs....2924
56.6.6.2.1 Access regions....2924
56.6.6.2.2 MB states....2925
56.6.6.2.3 MB transitions....2926
56.6.6.2.4 Transmit message setup....2928
56.6.6.2.5 Message transmission....2929
56.6.6.2.6 Null frame transmission....2930
56.6.6.2.7 MB status update....2931
56.6.6.3 Receive MBs....2932
56.6.6.3.1 MB transitions....2934
56.6.6.3.2 Message reception....2935
56.6.6.3.3 MB update....2936
56.6.6.3.4 Received message access....2937
56.6.6.3.5 Receive shadow buffer concept....2938
56.6.7 Individual MB search....2938
56.6.7.1 MB cycle counter filtering....2939
56.6.7.2 MB channel assignment consistency....2939
56.6.7.3 Node-related slot multiplexing....2940
56.6.7.4 MB search error....2940
56.6.7.4.1 MB search start while running....2940
56.6.7.4.2 Illegal MB index found....2940
56.6.8 Individual Message Buffer Reconfiguration....2940
56.6.8.1 Reconfiguration Schemes....2940
56.6.8.1.1 Basic Type Not Changed (RC1)....2941
56.6.8.1.2 Buffer Type Not Changed (RC2)....2941
56.6.9 Receive FIFOs....2941
56.6.9.1 Overview....2941
56.6.9.2 FIFO Configuration....2941
56.6.9.2.1 Single System Memory Base Address Mode....2941
56.6.9.2.2 Dual System Memory Base Address Mode....2941
56.6.9.3 FIFO Periodic Timer....2942
56.6.9.4 FIFO Reception....2942
56.6.9.5 FIFO Almost-Full Interrupt Generation....2942
56.6.9.6 FIFO Overflow Error Generation....2942
56.6.9.7 FIFO Message Access....2942
56.6.9.8 FIFO Update....2943
56.6.9.8.1 FIFO Interrupt Flag Update....2943
56.6.9.9 FIFO Filtering....2943
56.6.9.9.1 RX FIFO Frame ID Value-Mask Rejection Filter....2944
56.6.9.9.2 RX FIFO Frame ID Range Rejection Filter....2945
56.6.9.9.3 RX FIFO Frame ID Range Acceptance filter....2945
56.6.9.9.4 RX FIFO Message ID Acceptance Filter....2945
56.6.10 Channel Device Modes....2946
56.6.10.1 Dual Channel Device Mode....2946
56.6.10.2 Single Channel Device Mode....2946
56.6.11 External Clock Synchronization....2947
56.6.12 Sync Frame ID and Sync Frame Deviation Tables....2948
56.6.12.1 Sync Frame ID Table Content....2948
56.6.12.2 Sync Frame Deviation Table Content....2948
56.6.12.3 Sync Frame ID and Sync Frame Deviation Table Setup....2949

56.6.12.4 Sync Frame ID and Sync Frame Deviation Table Generation....2949
56.6.12.5 Sync Frame Table Access....2950
56.6.12.5.1 Sync Frame Table Locking and Unlocking....2950
56.6.13 MTS Generation....2951
56.6.14 Key Slot Transmission....2951
56.6.14.1 Key Slot Assignment....2951
56.6.14.2 Key Slot Transmission in POC:startup....2951
56.6.14.3 Key Slot Transmission in POC:normal active....2951
56.6.15 Sync Frame Filtering....2952
56.6.15.1 Sync Frame Acceptance Filtering....2952
56.6.15.2 Sync Frame Rejection Filtering....2952
56.6.16 Strobe Signal Support....2952
56.6.16.1 Strobe Signal Assignment....2953
56.6.16.2 Strobe Signal Timing....2953
56.6.17 Timer Support....2953
56.6.17.1 Absolute Timer T1....2953
56.6.17.2 Absolute / Relative Timer T2....2954
56.6.17.2.1 Absolute Timer T2....2954
56.6.17.2.2 Relative Timer T2....2954
56.6.18 Slot Status Monitoring....2954
56.6.18.1 Channel Status Error Counter Registers....2956
56.6.18.2 Protocol Status Registers....2956
56.6.18.3 Slot Status Registers....2956
56.6.18.4 Slot Status Counter Registers....2956
56.6.18.5 Message Buffer Slot Status Field....2957
56.6.19 System Bus Access....2958
56.6.19.1 System Bus Access Failure Types....2958
56.6.19.1.1 System Bus Illegal Address Access....2958
56.6.19.1.2 System Bus Access Timeout....2958
56.6.19.2 System Bus Access Failure Response....2958
56.6.19.2.1 Continue after System Bus Access Failure....2958
56.6.19.2.2 Freeze after System Bus Access Failure....2958
56.6.20 Interrupt Support....2959
56.6.20.1 Individual Interrupt Sources....2959
56.6.20.1.1 Message Buffer Interrupts....2959
56.6.20.1.2 FIFO Interrupts....2959
56.6.20.1.3 Wakeup Interrupt....2959
56.6.20.1.4 Protocol Interrupts....2959
56.6.20.1.5 CHI Interrupts....2959
56.6.20.2 Combined Interrupt Sources....2959
56.6.20.2.1 Receive Message Buffer Interrupt....2959
56.6.20.2.2 Transmit Message Buffer Interrupt....2959
56.6.20.2.3 Protocol Interrupt....2959
56.6.20.2.4 CHI Interrupt....2960
56.6.20.2.5 Module Interrupt....2960
56.6.21 Lower Bit Rate Support....2961
56.6.22 PE Data Memory PE DRAM....2962
56.6.22.1 PE DRAM Read Access....2962
56.6.22.2 PE DRAM Write Access....2963
56.6.22.3 PE DRAM Write Access Limitations....2963
56.6.23 CHI Lookup-Table Memory CHI LRAM....2963
56.6.23.1 CHI LRAM Read and Write Access....2964
56.6.24 Memory Content Error Detection....2964
56.6.24.1 Memory Error Types....2964
56.6.24.2 Memory Error Reporting....2965

56.6.24.2.1 PE DRAM Checkbits....2965
56.6.24.2.2 PE DRAM Syndrome....2966
56.6.24.2.3 CHI LRAM checkbits....2967
56.6.24.2.4 CHI LRAM Syndrome....2967
56.6.24.3 Memory Error Response....2967
56.6.24.3.1 CHI LRAM Error Response after CC Read....2968
56.6.24.3.2 CHI LRAM Error Response after Application Read....2968
56.6.24.3.3 PE DRAM Error Response after CC Read....2968
56.6.24.3.4 PE DRAM Error Response after Application Read in *POC:default config* state....2968
56.6.24.3.5 PE DRAM Error Response after Application Read out of *POC:default config*....2968
56.6.25 Memory Error Injection....2968
56.6.25.1 CHI LRAM Error Injection....2968
56.6.25.2 PE DRAM Error Injection....2969
56.6.26 Stopwatch Function....2970
56.7 Application Information....2971
56.7.1 Module Configuration....2971
56.7.1.1 Configure System Memory Access Time-Out Register (SYMATOR)....2971
56.7.1.1.1 System Bus Wait State Constraints....2972
56.7.1.2 Configure Data Field Offsets....2972
56.7.2 Initialization Sequence....2972
56.7.2.1 Module Initialization....2972
56.7.2.2 Protocol Initialization....2972
56.7.2.3 CHI LRAM Initialization....2973
56.7.2.4 PE DRAM Initialization....2973
56.7.3 Memory Fault Injection out of POC:default config....2973
56.7.3.1 CHI LRAM Error Injection out of POC:default config....2973
56.7.3.2 PE DRAM Error Injection out of POC:default config....2973
56.7.4 Shut Down Sequence....2973
56.7.5 Number of Usable Message Buffers....2974
56.7.6 Protocol Control Command Execution....2975
56.7.7 Message Buffer Search On Simple Message Buffer Configuration....2975
56.7.7.1 Simple Message Buffer Configuration....2976
56.7.7.2 Behavior in static segment....2977
56.7.7.3 Behavior in dynamic segment....2977
56.7.7.3.1 Transmit Data Not Available....2977
56.7.7.3.2 Transmit Data Available....2977
56.8 Glossary....2978

Chapter 57 Cross-Triggering Unit (CTU)....2980
57.1 Chip-specific CTU information....2980
57.1.1 CTU connections....2980
57.2 Introduction....2980
57.3 Block diagram....2981
57.4 CTU overview....2981
57.4.1 Modes of operation....2982
57.5 Signal description....2982
57.6 CTU register descriptions....2982
57.6.1 CTU memory map....2982
57.6.2 Trigger Generator Subunit Input Selection Register (TGSISR)....2984
57.6.3 Trigger Generator Subunit Control Register (TGSCR)....2987
57.6.4 Trigger Compare Register (T0CR - T7CR)....2988
57.6.5 TGS Counter Compare Register (TGSCCR)....2988
57.6.6 TGS Counter Reload Register (TGSCRR)....2989
57.6.7 Commands List Control Register 1 (CLCR1)....2989

57.6.8 Commands List Control Register 2 (CLCR2)....2991
57.6.9 Trigger Handler Control Register 1 (THCR1)....2992
57.6.10 Trigger Handler Control Register 2 (THCR2)....2995
57.6.11 Commands List Register A for ADC single-conversion mode commands (CLR_A_1 - CLR_A_24)....2998
57.6.12 Command List Register B for ADC dual-conversion mode commands (CLR_B_1 - CLR_B_24)....3000
57.6.13 Command List Register C for self-test commands (CLR_C_1 - CLR_C_24)....3001
57.6.14 FIFO DMA Control Register (FDCR)....3003
57.6.15 FIFO Control Register (FCR)....3005
57.6.16 FIFO Threshold Register (FTH)....3007
57.6.17 FIFO Status Register (FST)....3008
57.6.18 FIFO Right Aligned Data Register (FR0 - FR3)....3011
57.6.19 FIFO Signed Left Aligned Data Register (FL0 - FL3)....3012
57.6.20 Error Flag Register (EFR)....3013
57.6.21 Interrupt Flag Register (IFR)....3015
57.6.22 Interrupt/DMA Register (IR)....3017
57.6.23 Control ON Time Register (COTR)....3019
57.6.24 Control Register (CR)....3019
57.6.25 Digital Filter Register (DFR)....3021
57.6.26 Expected Value A Register (EXPAR)....3022
57.6.27 Expected Value B Register (EXPBR)....3023
57.6.28 Counter Range Register (CNTRNGR)....3024
57.6.29 List Control/Status Register (LISTCSR)....3025
57.7 Functional description....3026
57.7.1 Trigger Generator Subunit (TGS)....3026
57.7.2 TGS in triggered mode....3026
57.7.3 TGS in sequential mode....3028
57.7.4 TGS counter....3029
57.7.5 Scheduler subunit (SU)....3031
57.7.6 ADC commands list....3032
57.7.7 ADC command list format....3032
57.7.8 ADC command list operation modes....3034
57.7.9 ADC results FIFOs....3034
57.7.10 Reload mechanism....3035
57.8 Interrupts and DMA requests....3036
57.8.1 DMA support....3037
57.8.2 CTU faults and errors....3037
57.8.2.1 CTU parallel list errors....3037
57.8.3 CTU interrupt/DMA requests....3038
57.9 Self-test mode....3038
57.9.1 Self-test execution errors....3040

Chapter 58 Analog-to-Digital Converter (SAR_ADC)....3041
58.1 Chip-specific SAR_ADC information....3041
58.1.1 SAR_ADC instances....3041
58.1.2 SAR_ADC resolution....3041
58.1.3 Analog watchdogs....3041
58.1.4 Normal and injection trigger....3041
58.1.5 SAR_ADC channel assignments....3041
58.2 Introduction....3042
58.3 Overview....3042
58.3.1 Interfaces....3043
58.3.2 Submodules....3043

58.3.3 Clock and reset.... 3043
58.3.4 Special channels.... 3044
58.4 Features.... 3044
58.5 Functional description.... 3045
58.5.1 Conversion.... 3045
58.5.2 Normal Conversion mode.... 3045
58.5.2.1 Starting conversions in Normal Conversion mode.... 3046
58.5.2.2 Operation modes in Normal Conversion mode.... 3046
58.5.3 Injected Conversion mode.... 3047
58.5.3.1 Starting conversions in Injected Conversion mode.... 3048
58.5.4 Abort of conversion.... 3048
58.5.5 CTU.... 3049
58.5.6 ADC clock prescaler and sample time settings.... 3049
58.5.7 Presampling.... 3049
58.5.7.1 Presampling channel enable.... 3050
58.5.8 Programmable analog watchdog.... 3050
58.5.9 DMA functionality.... 3052
58.5.10 Interrupts.... 3052
58.5.11 Power-Down mode.... 3055
58.5.12 Low-power mode support.... 3056
58.5.13 External start feature.... 3056
58.5.14 Auto-Clock-Off mode.... 3056
58.5.15 Calibration.... 3057
58.5.16 Self-test.... 3058
58.5.16.1 CPU mode.... 3059
58.5.16.2 CTU mode.... 3061
58.5.16.3 Abort and abort chain for self-testing channel.... 3061
58.5.16.4 Self-test analog watchdog.... 3061
58.5.16.5 S1 algorithm: calculated voltage comparison method.... 3063
58.5.16.6 Watchdog timer.... 3063
58.5.16.6.1 Watchdog sequence checking.... 3064
58.5.16.7 Baud rate control for test channel.... 3065
58.5.16.7.1 Abort chain when baud rate is non-zero.... 3065
58.5.17 Conversion time.... 3065
58.5.18 Conversion data processing.... 3068
58.5.19 User defined offset and gain values.... 3068
58.5.19.1 Writing for 12-bit ADC.... 3068
58.5.19.1.1 User gain compensation (GAIN_USER).... 3068
58.5.19.1.2 User offset compensation (OFFSET_USER).... 3069
58.5.19.1.3 Using OFFSET_USER and GAIN_USER together.... 3069
58.6 Programming sequences.... 3069
58.6.1 Running calibration.... 3069
58.6.2 Running normal conversion.... 3070
58.6.3 Running injected conversion.... 3070
58.6.4 Running CTU triggered conversion.... 3071
58.6.5 Running self-test.... 3071
58.7 SAR_ADC register descriptions.... 3071
58.7.1 SAR_ADC memory map.... 3071
58.7.2 Main Configuration Register (MCR).... 3073
58.7.3 Main Status Register (MSR).... 3077
58.7.4 Interrupt Status Register (ISR).... 3080
58.7.5 Channel Pending Register (CEOCFR0).... 3081
58.7.6 Channel Pending Register 1 (CEOCFR1).... 3083
58.7.7 Interrupt Mask Register (IMR).... 3084
58.7.8 Channel Interrupt Mask Register 0 (CIMR0).... 3086

58.7.9 Channel Interrupt Mask Register 1 (CIMR1)....3087
58.7.10 Watchdog Threshold Interrupt Status Register (WTISR)....3089
58.7.11 Watchdog Threshold Interrupt Mask Register (WTIMR)....3092
58.7.12 DMAE Register (DMAE)....3095
58.7.13 DMA Register 0 (DMAR0)....3096
58.7.14 DMA Register 1 (DMAR1)....3098
58.7.15 Analog Watchdog Threshold Register 0 (THRHLR0)....3100
58.7.16 Analog Watchdog Threshold Register 1 (THRHLR1)....3101
58.7.17 Analog Watchdog Threshold Register 2 (THRHLR2)....3101
58.7.18 Analog Watchdog Threshold Register 2 (THRHLR3)....3102
58.7.19 Presampling Control Register (PSCR)....3103
58.7.20 Presampling Register 0 (PSR0)....3104
58.7.21 Presampling Register 1 (PSR1)....3106
58.7.22 Conversion Timing Register 0 (CTR0)....3107
58.7.23 Conversion Timing Register 1 (CTR1)....3108
58.7.24 Normal Conversion Mask Register (NCMR0)....3109
58.7.25 Normal Conversion Mask Register (NCMR1)....3110
58.7.26 Injected Conversion Mask Register (JCMR0)....3111
58.7.27 Injected Conversion Mask Register (JCMR1)....3113
58.7.28 User OFFSET and Gain Register (USROFSGN)....3114
58.7.29 Power Down Exit Delay Register (PDEDR)....3115
58.7.30 Precision Channel n Data Register (PCDR0 - PCDR7)....3116
58.7.31 Internal Channel n Data Register (ICDR32 - ICDR39)....3117
58.7.32 Analog Watchdog Threshold Register 4 (THRHLR4)....3118
58.7.33 Analog Watchdog Threshold Register 5 (THRHLR5)....3119
58.7.34 Analog Watchdog Threshold Register 6 (THRHLR6)....3120
58.7.35 Analog Watchdog Threshold Register 7 (THRHLR7)....3121
58.7.36 Channel Watchdog Select Register 0 (CWSELR0)....3121
58.7.37 Channel Watchdog Select Register 4 (CWSELR4)....3124
58.7.38 Channel Watchdog Enable Register (CWENR0)....3126
58.7.39 Channel Watchdog Enable Register (CWENR1)....3127
58.7.40 Analog Watchdog Out of Range Register (AWORR0)....3129
58.7.41 Analog Watchdog Out of Range Register (AWORR1)....3130
58.7.42 Self-Test Configuration Register 1 (STCR1)....3131
58.7.43 Self-Test Configuration Register 2 (STCR2)....3132
58.7.44 Self-Test Configuration Register 3 (STCR3)....3135
58.7.45 Self-Test Baud Rate Register (STBRR)....3137
58.7.46 Self-Test Status Register 1 (STSR1)....3138
58.7.47 Self-Test Status Register 2 (STSR2)....3141
58.7.48 Self-Test Status Register 3 (STSR3)....3142
58.7.49 Self-Test Status Register 4 (STSR4)....3143
58.7.50 Self-Test Data Register 1 (STDR1)....3144
58.7.51 Self-Test Data Register 2 (STDR2)....3145
58.7.52 Self-Test Analog Watchdog Register (STAW0R)....3146
58.7.53 Self-Test Analog Watchdog Register (STAW1AR)....3148
58.7.54 Self-Test Analog Watchdog Register 1B (STAW1BR)....3148
58.7.55 Self-Test Analog Watchdog Register 2 (STAW2R)....3149
58.7.56 Self-Test Analog Watchdog Register 3 (STAW3R)....3150
58.7.57 Self-Test Analog Watchdog Register 4 (STAW4R)....3151
58.7.58 Self-Test Analog Watchdog Register 5 (STAW5R)....3152
58.7.59 Calibration Status register (CALSTAT)....3154

Chapter 59 Thermal Monitoring Unit (TMU)....3158
59.1 Chip-specific TMU information....3158

59.1.1 Local temperature sensor placements....3158
59.1.2 Recommended TCMCFG register settings....3158
59.1.3 Calibration table....3158
59.2 Introduction....3159
59.2.1 Features....3160
59.2.2 Modes of operation....3160
59.3 TMU register descriptions....3160
59.3.1 TMU memory map....3160
59.3.2 Mode (TMR)....3161
59.3.3 Status (TSR)....3163
59.3.4 Monitor Site (TMSR)....3164
59.3.5 Monitor Temperature Measurement Interval (TMTMIR)....3165
59.3.6 Interrupt Enable (TIER)....3166
59.3.7 Interrupt Detect (TIDR)....3168
59.3.8 Interrupt Immediate Site Capture (TIISCR)....3170
59.3.9 Interrupt Average Site Capture (TIASCR)....3171
59.3.10 Interrupt Critical Site Capture (TICSCR)....3172
59.3.11 Monitor High Temperature Capture (TMHTCR)....3173
59.3.12 Monitor Low Temperature Capture (TMLTCR)....3174
59.3.13 Monitor Rising Temperature Rate Capture (TMRTRCR)....3175
59.3.14 Monitor Falling Temperature Rate Capture (TMFTRCR)....3176
59.3.15 Monitor High Temperature Immediate Threshold (TMHTITR)....3177
59.3.16 Monitor High Temperature Average Threshold (TMHTATR)....3178
59.3.17 Monitor High Temperature Average Critical Threshold (TMHTACTR)....3179
59.3.18 Monitor Low Temperature Immediate Threshold (TMLTITR)....3180
59.3.19 Monitor Low Temperature Average Threshold (TMLTATR)....3181
59.3.20 Monitor Low Temperature Average Critical Threshold (TMLTACTR)....3182
59.3.21 Monitor Rising Temperature Rate Critical Threshold (TMRTRCTR)....3183
59.3.22 Monitor Falling Temperature Rate Critical Threshold (TMFTRCTR)....3184
59.3.23 Temperature Configuration (TTCFGR)....3185
59.3.24 Sensor Configuration (TSCFGR)....3187
59.3.25 Report Immediate Temperature at Site (TRITSR0 - TRITSR2)....3187
59.3.26 Report Average Temperature at Site (TRATSR0 - TRATSR2)....3188
59.3.27 Central Module Configuration (TCMCFG)....3189
59.3.28 Temperature Range Control a (TTRCR0 - TTRCR15)....3192
59.4 Functional description....3193
59.4.1 Monitoring....3194
59.4.2 Reporting....3194
59.4.3 Using temperature thresholds....3195
59.5 Initialization information....3195

Chapter 60 Security....3197
60.1 Introduction....3197
60.1.1 Detection and response to parametric intrusion attempts....3198
60.1.2 Secure software updates....3198
60.1.3 Secure vehicle network and messaging....3198
60.1.4 Secure boot....3198
60.2 Security subsystem registers....3198
60.2.1 Security subsystem register descriptions....3198
60.2.1.1 SEC memory map....3198
60.2.1.2 External Debugger Status (EXT_DBGSTAT)....3199
60.2.1.3 HSE GPR 0 (HSE_GPR0)....3200
60.2.1.4 HSE GPR n (HSE_GPR1)....3201
60.2.1.5 HSE GPR n (HSE_GPR2)....3201

60.2.1.6 HSE GPR n (HSE_GPR3 - HSE_GPR11)....3202

Chapter 61 Messaging Unit (MU)....3204
61.1 Chip-specific MU information....3204
61.2 Overview....3204
61.2.1 Features....3205
61.3 Register Definition....3205
61.3.1 MUA register descriptions....3206
61.3.1.1 MUA memory map....3206
61.3.1.2 Version ID Register (VER)....3207
61.3.1.3 Parameter Register (PAR)....3208
61.3.1.4 Control Register (CR)....3209
61.3.1.5 Status Register (SR)....3210
61.3.1.6 Core Control Register 0 (CCR0)....3212
61.3.1.7 Core Sticky Status Register 0 (CSSR0)....3214
61.3.1.8 Flag Control Register (FCR)....3215
61.3.1.9 Flag Status Register (FSR)....3216
61.3.1.10 General Interrupt Enable Register (GIER)....3217
61.3.1.11 General Control Register (GCR)....3218
61.3.1.12 General Status Register (GSR)....3219
61.3.1.13 Transmit Control Register (TCR)....3220
61.3.1.14 Transmit Status Register (TSR)....3221
61.3.1.15 Receive Control Register (RCR)....3222
61.3.1.16 Receive Status Register (RSR)....3223
61.3.1.17 Transmit Register (TR0 - TR15)....3224
61.3.1.18 Receive Register (RR0 - RR15)....3224
61.3.2 MUB register descriptions....3225
61.3.2.1 MUB memory map....3225
61.3.2.2 Version ID Register (VER)....3226
61.3.2.3 Parameter Register (PAR)....3227
61.3.2.4 Control Register (CR)....3228
61.3.2.5 Status Register (SR)....3230
61.3.2.6 Core Control Register 0 (CCR0)....3232
61.3.2.7 Core Sticky Status Register 0 (CSSR0)....3233
61.3.2.8 Flag Control Register (FCR)....3235
61.3.2.9 Flag Status Register (FSR)....3236
61.3.2.10 General Interrupt Enable Register (GIER)....3237
61.3.2.11 General Control Register (GCR)....3238
61.3.2.12 General Status Register (GSR)....3239
61.3.2.13 Transmit Control Register (TCR)....3239
61.3.2.14 Transmit Status Register (TSR)....3240
61.3.2.15 Receive Control Register (RCR)....3241
61.3.2.16 Receive Status Register (RSR)....3242
61.3.2.17 Transmit Register (TR0 - TR15)....3243
61.3.2.18 Receive Register (RR0 - RR15)....3244
61.4 Functional Description....3245
61.4.1 Messaging Examples....3246
61.4.1.1 Messaging Protocols using Interrupts....3246
61.4.1.2 Messaging Protocols using Event Interrupts....3248
61.4.1.3 Exclusive Access to Shared Memory....3249
61.4.1.4 Packet Data Transfers....3250
61.4.1.5 Free the Processor from Deadlock....3251
61.4.2 Event Update Timing....3251
61.4.3 Interrupts....3252

61.4.4 Resets....3252

Chapter 62 On-Chip One Time Programmable (OCOTP) Controller....3254
62.1 Introduction....3254
62.2 Features....3254
62.3 Block diagram....3254
62.4 Operation....3255
62.4.1 Shadow register reload....3255
62.4.2 Fuse values....3255
62.4.3 Fuse protection and overrides....3256
62.4.4 eFuse and shadow register read....3256
62.4.5 eFuse and shadow register writes....3257
62.4.6 eFuse powerdown....3258
62.4.7 Write postamble....3258
62.5 Behavior during reset....3258
62.6 Power control of OTP memory....3258
62.7 CRC (Polynomial CRC-32/MPEG-2) test....3259
62.8 Fuse ECC....3259
62.9 Memory maps/register definitions....3260
62.9.1 OCOTP register descriptions....3260
62.9.1.1 OCOTP memory map....3260
62.9.1.2 System master's control (CTRL_SYS)....3261
62.9.1.3 System master's eFuse address for read or write operation (ADDR_SYS)....3263
62.9.1.4 System master's eFuse write data (WRDATA_SYS)....3264
62.9.1.5 System master's eFuse read data (RDATA_SYS)....3264
62.9.1.6 FBXC control (CTRL_FBX)....3265
62.9.1.7 eFuse region for CRC validation (CRC_RGN_SYS)....3266
62.9.1.8 Pre-calculated CRC eFuse address for comparision (CRC_ADDR_SYS)....3267
62.9.1.9 CRC calculated from the eFuses (CRC_VALUE_SYS)....3268
62.9.1.10 General purpose (GPR0 - GPR1)....3269
62.9.1.11 System master's access status (STATUS_SYS)....3269
62.9.1.12 OCOTP design version (VERSION)....3271
62.9.1.13 ECC status for single-bit ECC error (SEC0)....3272
62.9.1.14 ECC status for single-bit ECC error (SEC1)....3273
62.9.1.15 ECC status for single-bit ECC error (SEC2)....3273
62.9.1.16 ECC status for single-bit ECC error (SEC3)....3274
62.9.1.17 ECC status for double-bit ECC error (DED0)....3275
62.9.1.18 ECC status for double-bit ECC error (DED1)....3276
62.9.1.19 ECC status for double-bit ECC error (DED2)....3276
62.9.1.20 ECC status for double-bit ECC error (DED3)....3277
62.9.1.21 ECC error injector (ERR_INJCTR)....3278
62.9.1.22 Shadow (SHADOWS0 - SHADOWS127)....3279

Chapter 63 Fusebox Controller (FBXC)....3280
63.1 Introduction....3280
63.1.1 Overview....3280
63.1.2 Features....3280

Chapter 64 Safety....3281
64.1 Introduction....3281

Chapter 65 Error Reporting Module (ERM)..... 3282
65.1 Chip-specific ERM information..... 3282
65.1.1 Instances and numbers of channels..... 3282
65.1.2 Memory error event sources and captured information..... 3282
65.1.3 Over-reported single-bit ECC errors for QuadSPI accesses..... 3300
65.2 ERM_PFE, ERM_LLCE, and ERM_Standby_RAM instances..... 3300
65.2.1 Instances and numbers of channels..... 3300
65.2.2 Memory error event sources and captured information..... 3301
65.3 Introduction..... 3314
65.3.1 Overview..... 3314
65.3.2 Features..... 3314
65.4 ERM_CPU0 register descriptions..... 3314
65.4.1 ERM_CPU0 memory map..... 3315
65.4.2 ERM Configuration Register 0 (CR0)..... 3315
65.4.3 ERM Status Register 0 (SR0)..... 3319
65.4.4 ERM Memory a Error Address Register (EAR0 - EAR1)..... 3322
65.4.5 ERM Memory a Syndrome Register (SYN0 - SYN1)..... 3323
65.4.6 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 5)..... 3324
65.5 ERM_CPU1 register descriptions..... 3325
65.5.1 ERM_CPU1 memory map..... 3325
65.5.2 ERM Configuration Register 0 (CR0)..... 3326
65.5.3 ERM Status Register 0 (SR0)..... 3330
65.5.4 ERM Memory a Error Address Register (EAR0 - EAR1)..... 3333
65.5.5 ERM Memory a Syndrome Register (SYN0 - SYN1)..... 3334
65.5.6 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 5)..... 3335
65.6 ERM_CPU2 register descriptions..... 3336
65.6.1 ERM_CPU2 memory map..... 3336
65.6.2 ERM Configuration Register 0 (CR0)..... 3337
65.6.3 ERM Status Register 0 (SR0)..... 3341
65.6.4 ERM Memory a Error Address Register (EAR0 - EAR1)..... 3344
65.6.5 ERM Memory a Syndrome Register (SYN0 - SYN1)..... 3345
65.6.6 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 5)..... 3346
65.7 ERM_PER register descriptions..... 3347
65.7.1 ERM_PER memory map..... 3347
65.7.2 ERM Configuration Register 0 (CR0)..... 3349
65.7.3 ERM Configuration Register 1 (CR1)..... 3353
65.7.4 ERM Status Register 0 (SR0)..... 3355
65.7.5 ERM Status Register 1 (SR1)..... 3360
65.7.6 ERM Memory a Error Address Register (EAR0 - EAR9)..... 3362
65.7.7 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 9)..... 3363
65.7.8 ERM Memory a Syndrome Register (SYN8 - SYN9)..... 3364
65.8 ERM_PFE0 register descriptions..... 3365
65.8.1 ERM_PFE0 memory map..... 3365
65.8.2 ERM Configuration Register 0 (CR0)..... 3367
65.8.3 ERM Configuration Register 1 (CR1)..... 3371
65.8.4 ERM Status Register 0 (SR0)..... 3373
65.8.5 ERM Status Register 1 (SR1)..... 3378
65.8.6 ERM Memory a Error Address Register (EAR0 - EAR10)..... 3380
65.8.7 ERM Memory a Syndrome Register (SYN0 - SYN10)..... 3381

65.8.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 10)....3382
65.9 ERM_PFE1 register descriptions....3383
65.9.1 ERM_PFE1 memory map....3383
65.9.2 ERM Configuration Register 0 (CR0)....3385
65.9.3 ERM Configuration Register 1 (CR1)....3389
65.9.4 ERM Status Register 0 (SR0)....3392
65.9.5 ERM Status Register 1 (SR1)....3397
65.9.6 ERM Memory a Error Address Register (EAR0 - EAR12)....3401
65.9.7 ERM Memory a Syndrome Register (SYN0 - SYN12)....3401
65.9.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 12)....3402
65.10 ERM_PFE10 register descriptions....3403
65.10.1 ERM_PFE10 memory map....3404
65.10.2 ERM Configuration Register 0 (CR0)....3406
65.10.3 ERM Configuration Register 1 (CR1)....3410
65.10.4 ERM Status Register 0 (SR0)....3413
65.10.5 ERM Status Register 1 (SR1)....3418
65.10.6 ERM Memory a Error Address Register (EAR0 - EAR12)....3421
65.10.7 ERM Memory a Syndrome Register (SYN0 - SYN12)....3422
65.10.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)....3423
65.11 ERM_PFE11 register descriptions....3424
65.11.1 ERM_PFE11 memory map....3424
65.11.2 ERM Configuration Register 0 (CR0)....3427
65.11.3 ERM Configuration Register 1 (CR1)....3431
65.11.4 ERM Configuration Register 2 (CR2)....3435
65.11.5 ERM Status Register 0 (SR0)....3439
65.11.6 ERM Status Register 1 (SR1)....3444
65.11.7 ERM Status Register 2 (SR2)....3449
65.11.8 ERM Memory a Error Address Register (EAR0 - EAR23)....3453
65.11.9 ERM Memory a Syndrome Register (SYN0 - SYN23)....3454
65.11.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT23)....3455
65.12 ERM_PFE12 register descriptions....3457
65.12.1 ERM_PFE12 memory map....3457
65.12.2 ERM Configuration Register 0 (CR0)....3460
65.12.3 ERM Configuration Register 1 (CR1)....3464
65.12.4 ERM Configuration Register 2 (CR2)....3468
65.12.5 ERM Status Register 0 (SR0)....3470
65.12.6 ERM Status Register 1 (SR1)....3474
65.12.7 ERM Status Register 2 (SR2)....3479
65.12.8 ERM Memory a Error Address Register (EAR0 - EAR16)....3481
65.12.9 ERM Memory a Syndrome Register (SYN0 - SYN16)....3481
65.12.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)....3482
65.13 ERM_PFE13 register descriptions....3484
65.13.1 ERM_PFE13 memory map....3484
65.13.2 ERM Configuration Register 0 (CR0)....3486
65.13.3 ERM Configuration Register 1 (CR1)....3490
65.13.4 ERM Configuration Register 2 (CR2)....3494
65.13.5 ERM Status Register 0 (SR0)....3497
65.13.6 ERM Status Register 1 (SR1)....3501
65.13.7 ERM Status Register 2 (SR2)....3506
65.13.8 ERM Memory a Error Address Register (EAR0 - EAR17)....3508

65.13.9 ERM Memory a Syndrome Register (SYN0 - SYN17)....3509
65.13.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT17)....3510
65.14 ERM_PFE14 register descriptions....3511
65.14.1 ERM_PFE14 memory map....3511
65.14.2 ERM Configuration Register 0 (CR0)....3513
65.14.3 ERM Configuration Register 1 (CR1)....3517
65.14.4 ERM Status Register 0 (SR0)....3520
65.14.5 ERM Status Register 1 (SR1)....3525
65.14.6 ERM Memory a Error Address Register (EAR0 - EAR12)....3529
65.14.7 ERM Memory a Syndrome Register (SYN0 - SYN12)....3529
65.14.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)....3530
65.15 ERM_PFE15 register descriptions....3531
65.15.1 ERM_PFE15 memory map....3532
65.15.2 ERM Configuration Register 0 (CR0)....3534
65.15.3 ERM Configuration Register 1 (CR1)....3538
65.15.4 ERM Status Register 0 (SR0)....3541
65.15.5 ERM Status Register 1 (SR1)....3546
65.15.6 ERM Memory a Error Address Register (EAR0 - EAR12)....3549
65.15.7 ERM Memory a Syndrome Register (SYN0 - SYN12)....3550
65.15.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)....3551
65.16 ERM_PFE2 register descriptions....3552
65.16.1 ERM_PFE2 memory map....3552
65.16.2 ERM Configuration Register 0 (CR0)....3555
65.16.3 ERM Configuration Register 1 (CR1)....3559
65.16.4 ERM Configuration Register 2 (CR2)....3563
65.16.5 ERM Status Register 0 (SR0)....3565
65.16.6 ERM Status Register 1 (SR1)....3569
65.16.7 ERM Status Register 2 (SR2)....3574
65.16.8 ERM Memory a Error Address Register (EAR0 - EAR16)....3576
65.16.9 ERM Memory a Syndrome Register (SYN0 - SYN16)....3576
65.16.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)....3577
65.17 ERM_PFE3 register descriptions....3579
65.17.1 ERM_PFE3 memory map....3579
65.17.2 ERM Configuration Register 0 (CR0)....3581
65.17.3 ERM Configuration Register 1 (CR1)....3585
65.17.4 ERM Configuration Register 2 (CR2)....3589
65.17.5 ERM Status Register 0 (SR0)....3591
65.17.6 ERM Status Register 1 (SR1)....3596
65.17.7 ERM Status Register 2 (SR2)....3601
65.17.8 ERM Memory a Error Address Register (EAR0 - EAR16)....3602
65.17.9 ERM Memory a Syndrome Register (SYN0 - SYN16)....3603
65.17.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)....3604
65.18 ERM_PFE4 register descriptions....3605
65.18.1 ERM_PFE4 memory map....3606
65.18.2 ERM Configuration Register 0 (CR0)....3608
65.18.3 ERM Configuration Register 1 (CR1)....3612
65.18.4 ERM Configuration Register 2 (CR2)....3616
65.18.5 ERM Status Register 0 (SR0)....3618
65.18.6 ERM Status Register 1 (SR1)....3623
65.18.7 ERM Status Register 2 (SR2)....3628

65.18.8 ERM Memory a Error Address Register (EAR0 - EAR16)..... 3629
65.18.9 ERM Memory a Syndrome Register (SYN0 - SYN16)..... 3630
65.18.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)..... 3631
65.19 ERM_PFE5 register descriptions..... 3632
65.19.1 ERM_PFE5 memory map..... 3633
65.19.2 ERM Configuration Register 0 (CR0)..... 3635
65.19.3 ERM Configuration Register 1 (CR1)..... 3639
65.19.4 ERM Configuration Register 2 (CR2)..... 3643
65.19.5 ERM Status Register 0 (SR0)..... 3645
65.19.6 ERM Status Register 1 (SR1)..... 3650
65.19.7 ERM Status Register 2 (SR2)..... 3655
65.19.8 ERM Memory a Error Address Register (EAR0 - EAR16)..... 3656
65.19.9 ERM Memory a Syndrome Register (SYN0 - SYN16)..... 3657
65.19.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)..... 3658
65.20 ERM_PFE6 register descriptions..... 3659
65.20.1 ERM_PFE6 memory map..... 3660
65.20.2 ERM Configuration Register 0 (CR0)..... 3662
65.20.3 ERM Configuration Register 1 (CR1)..... 3666
65.20.4 ERM Configuration Register 2 (CR2)..... 3670
65.20.5 ERM Status Register 0 (SR0)..... 3672
65.20.6 ERM Status Register 1 (SR1)..... 3677
65.20.7 ERM Status Register 2 (SR2)..... 3682
65.20.8 ERM Memory a Error Address Register (EAR0 - EAR16)..... 3683
65.20.9 ERM Memory a Syndrome Register (SYN0 - SYN16)..... 3684
65.20.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)..... 3685
65.21 ERM_PFE7 register descriptions..... 3686
65.21.1 ERM_PFE7 memory map..... 3687
65.21.2 ERM Configuration Register 0 (CR0)..... 3689
65.21.3 ERM Configuration Register 1 (CR1)..... 3693
65.21.4 ERM Configuration Register 2 (CR2)..... 3697
65.21.5 ERM Status Register 0 (SR0)..... 3699
65.21.6 ERM Status Register 1 (SR1)..... 3704
65.21.7 ERM Status Register 2 (SR2)..... 3709
65.21.8 ERM Memory a Error Address Register (EAR0 - EAR16)..... 3710
65.21.9 ERM Memory a Syndrome Register (SYN0 - SYN16)..... 3711
65.21.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)..... 3712
65.22 ERM_PFE8 register descriptions..... 3713
65.22.1 ERM_PFE8 memory map..... 3714
65.22.2 ERM Configuration Register 0 (CR0)..... 3716
65.22.3 ERM Configuration Register 1 (CR1)..... 3720
65.22.4 ERM Configuration Register 2 (CR2)..... 3724
65.22.5 ERM Status Register 0 (SR0)..... 3726
65.22.6 ERM Status Register 1 (SR1)..... 3731
65.22.7 ERM Status Register 2 (SR2)..... 3736
65.22.8 ERM Memory a Error Address Register (EAR0 - EAR16)..... 3737
65.22.9 ERM Memory a Syndrome Register (SYN0 - SYN16)..... 3738
65.22.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)..... 3739
65.23 ERM_PFE9 register descriptions..... 3740
65.23.1 ERM_PFE9 memory map..... 3741
65.23.2 ERM Configuration Register 0 (CR0)..... 3743

65.23.3 ERM Configuration Register 1 (CR1)....3747
65.23.4 ERM Configuration Register 2 (CR2)....3751
65.23.5 ERM Status Register 0 (SR0)....3753
65.23.6 ERM Status Register 1 (SR1)....3758
65.23.7 ERM Status Register 2 (SR2)....3763
65.23.8 ERM Memory a Error Address Register (EAR0 - EAR16)....3764
65.23.9 ERM Memory a Syndrome Register (SYN0 - SYN16)....3765
65.23.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT16)....3766
65.24 ERM_STDBY_SRAM register descriptions....3767
65.24.1 ERM_STDBY_SRAM memory map....3768
65.24.2 ERM Configuration Register 0 (CR0)....3768
65.24.3 ERM Status Register 0 (SR0)....3770
65.24.4 ERM Memory 0 Error Address Register (EAR0)....3772
65.24.5 ERM Memory 0 Syndrome Register (SYN0)....3773
65.24.6 ERM Memory 0 Correctable Error Count Register (CORR_ERR_CNT0)....3774
65.25 ERM_eDMA0 register descriptions....3774
65.25.1 ERM_eDMA0 memory map....3775
65.25.2 ERM Configuration Register 0 (CR0)....3775
65.25.3 ERM Status Register 0 (SR0)....3777
65.25.4 ERM Memory 0 Error Address Register (EAR0)....3779
65.25.5 ERM Memory 0 Syndrome Register (SYN0)....3779
65.25.6 ERM Memory 0 Correctable Error Count Register (CORR_ERR_CNT0)....3780
65.26 ERM_eDMA1 register descriptions....3781
65.26.1 ERM_eDMA1 memory map....3781
65.26.2 ERM Configuration Register 0 (CR0)....3782
65.26.3 ERM Status Register 0 (SR0)....3784
65.26.4 ERM Memory 0 Error Address Register (EAR0)....3786
65.26.5 ERM Memory 0 Syndrome Register (SYN0)....3786
65.26.6 ERM Memory 0 Correctable Error Count Register (CORR_ERR_CNT0)....3787
65.27 ERM register descriptions....3788
65.27.1 ERM memory map....3788
65.27.2 ERM Configuration Register 0 (CR0)....3790
65.27.3 ERM Configuration Register 1 (CR1)....3794
65.27.4 ERM Status Register 0 (SR0)....3796
65.27.5 ERM Status Register 1 (SR1)....3800
65.27.6 ERM Memory a Error Address Register (EAR0 - EAR6)....3802
65.27.7 ERM Memory a Syndrome Register (SYN0 - SYN6)....3803
65.27.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT8)....3804
65.28 Functional description....3805
65.28.1 Single-bit correction events....3805
65.28.2 Non-correctable error events....3805
65.29 Initialization....3806
65.30 Glossary....3806

Chapter 66 Fault Collection and Control Unit (FCCU)....3807
66.1 Chip-specific FCCU information....3807
66.1.1 Chip-boundary FCCU signals....3807
66.1.2 Fault mapping....3807
66.1.3 Clock frequency....3807
66.1.4 FOSU timer interval....3807
66.1.5 CFG register event bit values by source (C)....3807
66.1.6 Supported internal chip reactions....3809

66.1.7 Supported FCCU EOUT fault output modes (protocols)....3809
66.1.8 Recommended reaction for the fault NCF[21] NoC Mission_Fault_0....3809
66.1.9 NCFs reaction restriction....3809
66.1.10 Clearing FCCU faults....3809
66.2 Introduction....3809
66.3 Features....3809
66.4 Block diagram....3810
66.5 Signal description....3811
66.5.1 Signals....3811
66.6 Functional description....3813
66.6.1 Definitions....3813
66.6.2 FSM description....3813
66.6.3 Fault priority scheme and nesting....3815
66.6.4 Fault recovery....3815
66.6.5 EOUT interface....3817
66.6.5.1 Bi-Stable protocol....3819
66.7 Prepare FCCU for configuration....3819
66.7.1 Introduction....3819
66.7.2 About preparing FCCU for configuration....3820
66.7.3 Configure the CONFIG state....3820
66.7.4 Put FCCU in the CONFIG state....3820
66.8 Configure FCCU....3820
66.8.1 Introduction....3820
66.8.2 About configuring FCCU....3820
66.8.3 Configure the non-critical fault channels....3821
66.9 Put FCCU in the NORMAL state....3821
66.9.1 Introduction....3821
66.9.2 About putting FCCU in NORMAL state....3821
66.9.3 Put FCCU in the NORMAL state....3821
66.10 Manage faults....3822
66.10.1 Introduction....3822
66.10.2 Determine if there are any unrecovered non-critical faults....3822
66.10.3 Recover a software-recoverable non-critical fault....3822
66.10.4 Clear the freeze-status indicators....3822
66.11 Run operations....3823
66.11.1 Introduction....3823
66.11.2 About running operations....3823
66.11.3 Run an operation....3823
66.12 Register descriptions....3823
66.12.1 FCCU register descriptions....3823
66.12.1.1 FCCU memory map....3823
66.12.1.2 Control (CTRL)....3825
66.12.1.3 Control Key (CTRLK)....3827
66.12.1.4 Configuration (CFG)....3828
66.12.1.5 Non-critical Fault Configuration (NCF_CFG0 - NCF_CFG3)....3830
66.12.1.6 Non-critical Fault-State Configuration (NCFS_CFG0 - NCFS_CFG7)....3832
66.12.1.7 Non-critical Fault Status (NCF_S0 - NCF_S3)....3834
66.12.1.8 Non-critical Fault Key (NCFK)....3835
66.12.1.9 Non-critical Fault Enable (NCF_E0 - NCF_E3)....3836
66.12.1.10 Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0 - NCF_TOE3)....3837
66.12.1.11 Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)....3839
66.12.1.12 Configuration-State Timeout Interval (CFG_TO)....3840
66.12.1.13 IO Control (EINOUT)....3841
66.12.1.14 Status (STAT)....3843
66.12.1.15 Normal-to-Alarm Freeze Status (N2AF_STATUS)....3844

66.12.1.16 Alarm-to-Fault Freeze Status (A2FF_STATUS)....3845
66.12.1.17 Normal-to-Fault Freeze Status (N2FF_STATUS)....3847
66.12.1.18 Fault-to-Alarm Freeze Status (F2AF_STATUS)....3848
66.12.1.19 Non-critical Fault Fake (NCFF)....3849
66.12.1.20 IRQ Status (IRQ_STAT)....3850
66.12.1.21 IRQ Enable (IRQ_EN)....3852
66.12.1.22 Transient Configuration Lock (TRANS_LOCK)....3853
66.12.1.23 Permanent Configuration Lock (PERMNT_LOCK)....3854
66.12.1.24 Delta T (DELTA_T)....3855
66.12.1.25 Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0 - IRQ_ALARM_EN3)....3856
66.12.1.26 Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0 - NMI_EN3)3858
66.12.1.27 Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0 - EOUT_SIG_EN3)....3859
66.12.1.28 Alarm-State Timer (TMR_ALARM)....3860
66.12.1.29 Configuration-State Timer (TMR_CFG)....3861
66.12.1.30 Fault-Output Timer (TMR_ETMR)....3862
66.12.2 Configuration registers....3863
66.12.2.1 Definition....3863
66.12.2.2 Configuration registers....3863
66.12.3 CFG register bit value at different events....3864
66.13 FOSU....3864
66.14 Use cases and limitations....3865
66.15 Glossary....3866

Chapter 67 Clock Monitoring Unit-Frequency Check (CMU_FC)....3867
67.1 Chip-specific CMU_FC information....3867
67.1.1 Overview....3867
67.2 Introduction....3867
67.2.1 Basic operation....3867
67.2.2 Features....3868
67.3 CMU_FC register descriptions....3869
67.3.1 CMU_FC memory map....3869
67.3.2 Global Configuration Register (GCR)....3870
67.3.3 Reference Count Configuration Register (RCCR)....3871
67.3.4 High Threshold Configuration Register (HTCR)....3872
67.3.5 Low Threshold Configuration Register (LTCR)....3872
67.3.6 Status Register (SR)....3873
67.3.7 Interrupt Enable Register (IER)....3875
67.4 Functional description....3882
67.4.1 Frequency checking....3882
67.4.1.1 Monitored clock lost....3883
67.5 Programming guidelines....3883
67.5.1 Programming RCCR[REF_CNT]....3883
67.5.2 Programming HFREF and LFREF....3884
67.5.3 Module programming sequence....3886
67.6 Glossary....3887

Chapter 68 Clock Monitoring Unit - Frequency Meter (CMU_FM)....3888
68.1 Chip-specific CMU_FM information....3888
68.1.1 Overview....3888
68.2 Introduction....3888
68.2.1 Basic operation....3888
68.2.2 Features....3888

68.3 CMU_FM register descriptions....3889
68.3.1 CMU_FM memory map....3889
68.3.2 Global Configuration Register (GCR)....3889
68.3.3 Reference Count Configuration Register (RCCR)....3890
68.3.4 Status Register (SR)....3891
68.4 Functional description....3892
68.5 Programming guidelines....3892
68.5.1 Programming RCCR[REF_CNT]....3892
68.5.2 Module programming sequence....3893

Chapter 69 Selftest Top General Purpose Registers (SELFTEST_GPR_TOP)....3895
69.1 Introduction....3895
69.2 SELFTEST_GPR_TOP register descriptions....3895
69.2.1 SELFTEST_GPR_TOP memory map....3895
69.2.2 Reset Domain Self-test Enable (Reset_Domain_Selftest_Enable_Register)....3895
69.2.3 Reset Domain Self-test Enable Status (Reset_Domain_Selftest_Enable_Status_Register)....3896

Chapter 70 Selftest General Purpose Registers (SELFTEST_GPR)....3898
70.1 Introduction....3898
70.2 Memory map for self-test GPRs....3898
70.3 SELFTEST_GPR register descriptions....3898
70.3.1 SELFTEST_GPR memory map....3898
70.3.2 Generic 0 (Generic_Reg0)....3899
70.3.3 Generic 1 (Generic_Reg1)....3900
70.3.4 LBIST Program (LBIST_Prog_Reg)....3900

Chapter 71 Self-Test Control Unit (STCU2)....3902
71.1 Chip-specific STCU2 information....3902
71.1.1 Supported BIST sequences....3902
71.1.2 Self-test overview....3902
71.1.3 STCU2 LBIST mapping....3903
71.1.4 STCU2 MBIST mapping....3905
71.1.5 Running MBIST sequences on CM7 memories....3907
71.1.6 Indicating fault state during the main reset domain self-test....3907
71.1.7 Error events management in main reset domain self-test....3907
71.1.8 Online self-test reset or interrupt generation....3908
71.1.9 AUTOLOCK_VALUE for register write access through STCU2_SKC....3908
71.1.10 PLL loss of lock during self test....3908
71.1.11 STCU2 BIST start (BSTART) register description....3908
71.1.12 STCU2 algorithm select (ALGOSEL) register description....3909
71.1.13 Self-test programming sequence....3910
71.1.14 Handling unrecoverable faults....3911
71.2 Introduction....3911
71.3 Main features....3911
71.4 Block diagram....3912
71.5 Peripheral bus interface....3913
71.6 BISTs and BIST partitions....3914
71.6.1 Definition: BIST....3914
71.6.2 Definition: BIST partition....3914
71.6.3 Example: BIST partitions on a chip....3914
71.6.4 Types of BIST partitions....3914
71.7 BIST sequences....3915

71.7.1 Definition: BIST sequence....3915
71.7.2 STCU2 executes MBISTs before LBISTs....3915
71.7.3 Example: Single-phase BIST sequence....3915
71.7.4 Example: Multi-phase BIST sequence....3915
71.7.5 Types of BIST sequences....3915
71.7.6 Supported BIST sequences....3916
71.8 STCU2 register descriptions....3916
71.8.1 STCU2 memory map....3916
71.8.2 STCU2 Run Software (RUNSW)....3929
71.8.3 STCU2 SK Code (SKC)....3930
71.8.4 STCU2 Configuration (CFG)....3931
71.8.5 STCU2 Watchdog Granularity (WDG)....3934
71.8.6 STCU2 Interrupt Flag (INT_FLG)....3935
71.8.7 STCU2 Error (ERR_STAT)....3936
71.8.8 STCU2 Error FM (ERR_FM)....3938
71.8.9 STCU2 Online LBIST Status (LBSSW0)....3939
71.8.10 STCU2 Online LBIST Status (LBSSW1)....3940
71.8.11 STCU2 Online LBIST End Flag (LBESW0)....3941
71.8.12 STCU2 Online LBIST End Flag (LBESW1)....3942
71.8.13 STCU2 Online LBIST Unrecoverable FM (LBUFM0)....3943
71.8.14 STCU2 Online LBIST Unrecoverable FM (LBUFM1)....3944
71.8.15 STCU2 Online MBIST Status (MBSSW0)....3945
71.8.16 STCU2 Online MBIST Status (MBSSW1)....3950
71.8.17 STCU2 Online MBIST Status (MBSSW2)....3955
71.8.18 STCU2 Online MBIST Status (MBSSW3)....3960
71.8.19 STCU2 Online MBIST End Flag (MBESW0)....3960
71.8.20 STCU2 Online MBIST End Flag (MBESW1)....3964
71.8.21 STCU2 Online MBIST End Flag (MBESW2)....3968
71.8.22 STCU2 Online MBIST End Flag (MBESW3)....3972
71.8.23 STCU2 MBIST Unrecoverable FM (MBUFM0)....3973
71.8.24 STCU2 MBIST Unrecoverable FM (MBUFM1)....3978
71.8.25 STCU2 MBIST Unrecoverable FM (MBUFM2)....3983
71.8.26 STCU2 MBIST Unrecoverable FM (MBUFM3)....3988
71.8.27 STCU2 LBIST Control (LB_CTRL0 - LB_CTRL59)....3989
71.8.28 STCU2 LBIST PC Stop (LB_PCS0 - LB_PCS59)....3993
71.8.29 STCU2 Online LBIST MISR Expected Low (LB_MISRELSW0 - LB_MISRELSW59)....3994
71.8.30 STCU2 Online LBIST MISR Expected High (LB_MISREHSW0 - LB_MISREHSW59)....3994
71.8.31 STCU2 Online LBIST MISR Read Low (LB_MISRRLSW0 - LB_MISRRLSW59)....3995
71.8.32 STCU2 Online LBIST MISR Read High (LB_MISRRHSW0 - LB_MISRRHSW59)....3996
71.8.33 STCU2 Algorithm Select (ALGOSEL)....3997
71.8.34 STCU2 MBIST Stagger (STGGR)....3997
71.8.35 STCU2 BIST Start (BSTART)....3998
71.8.36 STCU2 MBIST Control (MB_CTRL0 - MB_CTRL109)....3999
71.9 Functional description....4000
71.9.1 FSM description....4000
71.9.2 BIST scheduling....4000
71.9.3 ABORT management....4001
71.9.3.1 Hardware ABORT management....4001
71.9.4 FCCU interface....4001
71.9.5 Watchdogs....4001
71.9.5.1 BIST watchdog timer....4001
71.9.5.2 Register write-access watchdog timer....4001
71.10 Use cases and limitations....4001
71.11 Glossary....4002

Chapter 72 Safety by Software (SBSW)..... 4003
72.1 Introduction..... 4003
72.1.1 Acronyms and abbreviations..... 4003
72.2 Block diagram..... 4003
72.3 Signal descriptions..... 4006
72.4 Functional description..... 4006
72.4.1 SBSW controller..... 4007
72.4.1.1 Unlocking/locking the TMC configuration..... 4007
72.4.1.2 Unlocking/locking the TMWDP configuration..... 4008
72.4.2 TMC..... 4008
72.4.2.1 Digital comparator..... 4009
72.4.2.2 Timer..... 4009
72.4.2.3 Block diagram..... 4011
72.4.2.4 TMC states..... 4011
72.4.2.5 TMC events..... 4012
72.4.3 TMWDPI..... 4012
72.4.3.1 TMWDP description..... 4013
72.4.3.2 Block diagram..... 4014
72.4.3.3 TMWDPI registers..... 4015
72.4.3.4 TMWDP/TMWDPI events..... 4016
72.4.4 SBSW interface summary..... 4016
72.5 Memory map and register definition..... 4017
72.5.1 SBSW register descriptions..... 4017
72.5.1.1 SBSW memory map..... 4017
72.5.1.2 TMC Configuration Unlock (TMC_CONFIG_UNLOCK)..... 4028
72.5.1.3 TMWDP Configuration Unlock (TMWDP_CONFIG_UNLOCK)..... 4029
72.5.1.4 TMC Configuration Status (TMC_CONFIG_STATUS)..... 4030
72.5.1.5 TMWDP Configuration Status (TMWDP_CONFIG_STATUS)..... 4031
72.5.1.6 Debug Mode (DEBUG_MODE)..... 4032
72.5.1.7 TMC Fault Status (TMC_FAULT_STATUS)..... 4033
72.5.1.8 TMWDP Fault Status (TMWDP_FAULT_STATUS)..... 4033
72.5.1.9 TMC Configuration (TMC_0_CONFIG - TMC_31_CONFIG)..... 4034
72.5.1.10 TMC Distance (TMC_0_DISTANCE - TMC_31_DISTANCE)..... 4035
72.5.1.11 TMC Timeout (TMC_0_TIMEOUT - TMC_31_TIMEOUT)..... 4036
72.5.1.12 TMC Control (TMC_0_CONTROL - TMC_31_CONTROL)..... 4037
72.5.1.13 TMC R0 Data (TMC_0_R0 - TMC_31_R0)..... 4038
72.5.1.14 TMC R1 Data (TMC_0_R1 - TMC_31_R1)..... 4039
72.5.1.15 TMC Status (TMC_0_STATUS - TMC_31_STATUS)..... 4040
72.5.1.16 TMC Timer (TMC_0_TIMER - TMC_31_TIMER)..... 4041
72.5.1.17 TMWDP Configuration Address (TMWDP_CONFIG_ADDR)..... 4042
72.5.1.18 TMWDP Control (TMWDP_CONTROL)..... 4043
72.5.1.19 TMWDP Status (TMWDP_STATUS)..... 4044
72.5.1.20 TMWDP Automata Status (TMWDP_AUTOMATA_STATUS)..... 4045
72.5.1.21 TMWDP Automata Illegal Transition (TMWDP_AUTOMATA_ILLGL_TRANS)..... 4046
72.5.1.22 TMWDP Automata Time Violation (TMWDP_AUTOMATA_TIME_VIOLATION)..... 4047
72.5.1.23 TMWDP Automaton Status (AUT_0_STATUS - AUT_31_STATUS)..... 4048
72.5.1.24 TMWDP Automaton Progress Request (AUT_0_PRGS_REQ - AUT_31_PRGS_REQ)..... 4049
72.5.1.25 TMWDP Core Domain ID (TC_ID)..... 4051

Chapter 73 Error Injection Module (EIM)..... 4053
73.1 Chip-specific EIM information..... 4053
73.1.1 EIM instances..... 4053
73.1.2 ACP_EIM channel assignments..... 4053

73.1.3 EIM_0 channel assignments.... 4062
73.1.4 EIM_1 channel assignments.... 4064
73.1.5 EIM_2 channel assignments.... 4068
73.1.6 EIM_3 channel assignments.... 4070
73.1.7 Constraints to use EIM on A53 cache memories.... 4071
73.2 Chip-specific EIM information.... 4072
73.2.1 EIM instances.... 4072
73.2.2 EIM_MISC channel assignments.... 4076
73.2.3 EIM_PFE channel assignments.... 4078
73.2.4 EIM_LLCE channel assignments.... 4087
73.3 Introduction.... 4088
73.3.1 Overview.... 4088
73.3.2 Features.... 4089
73.4 EIM register descriptions.... 4089
73.4.1 EIM memory map.... 4092
73.4.2 Error Injection Module Configuration Register (EIMCR).... 4098
73.4.3 Error Injection Channel Enable register (EICHEN).... 4099
73.4.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD7_WORD0).... 4108
73.4.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD10_WORD1).... 4109
73.4.6 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD28_WORD2).... 4111
73.4.7 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD28_WORD3).... 4112
73.4.8 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD27_WORD4).... 4114
73.4.9 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD7_WORD5).... 4115
73.4.10 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD7_WORD6).... 4117
73.4.11 Error Injection Channel Descriptor n, Word7 (EICHD0_WORD7 - EICHD7_WORD7).... 4118
73.4.12 Error Injection Channel Descriptor n, Word8 (EICHD0_WORD8 - EICHD7_WORD8).... 4119
73.4.13 Error Injection Channel Descriptor n, Word0 (EICHD8_WORD0 - EICHD9_WORD0).... 4120
73.4.14 Error Injection Channel Descriptor 10, Word0 (EICHD10_WORD0).... 4121
73.4.15 Error Injection Channel Descriptor 11, Word0 (EICHD11_WORD0).... 4122
73.4.16 Error Injection Channel Descriptor 11, Word1 (EICHD11_WORD1).... 4123
73.4.17 Error Injection Channel Descriptor 12, Word0 (EICHD12_WORD0).... 4124
73.4.18 Error Injection Channel Descriptor 12, Word1 (EICHD12_WORD1).... 4125
73.4.19 Error Injection Channel Descriptor n, Word0 (EICHD13_WORD0 - EICHD15_WORD0).... 4126
73.4.20 Error Injection Channel Descriptor 13, Word1 (EICHD13_WORD1).... 4127
73.4.21 Error Injection Channel Descriptor n, Word1 (EICHD14_WORD1 - EICHD16_WORD1).... 4128
73.4.22 Error Injection Channel Descriptor 16, Word0 (EICHD16_WORD0).... 4129
73.4.23 Error Injection Channel Descriptor 17, Word0 (EICHD17_WORD0).... 4130
73.4.24 Error Injection Channel Descriptor 17, Word1 (EICHD17_WORD1).... 4131
73.4.25 Error Injection Channel Descriptor 18, Word0 (EICHD18_WORD0).... 4132
73.4.26 Error Injection Channel Descriptor 18, Word1 (EICHD18_WORD1).... 4133
73.4.27 Error Injection Channel Descriptor n, Word0 (EICHD19_WORD0 - EICHD21_WORD0).... 4134
73.4.28 Error Injection Channel Descriptor 19, Word1 (EICHD19_WORD1).... 4135
73.4.29 Error Injection Channel Descriptor n, Word1 (EICHD20_WORD1 - EICHD22_WORD1).... 4136
73.4.30 Error Injection Channel Descriptor 22, Word0 (EICHD22_WORD0).... 4137
73.4.31 Error Injection Channel Descriptor 23, Word0 (EICHD23_WORD0).... 4138
73.4.32 Error Injection Channel Descriptor 23, Word1 (EICHD23_WORD1).... 4139
73.4.33 Error Injection Channel Descriptor 24, Word0 (EICHD24_WORD0).... 4140
73.4.34 Error Injection Channel Descriptor 24, Word1 (EICHD24_WORD1).... 4141
73.4.35 Error Injection Channel Descriptor n, Word0 (EICHD25_WORD0 - EICHD27_WORD0).... 4142
73.4.36 Error Injection Channel Descriptor 25, Word1 (EICHD25_WORD1).... 4143
73.4.37 Error Injection Channel Descriptor n, Word1 (EICHD26_WORD1 - EICHD27_WORD1).... 4144
73.4.38 Error Injection Channel Descriptor 28, Word1 (EICHD28_WORD1).... 4145
73.4.39 Error Injection Channel Descriptor 29, Word1 (EICHD29_WORD1).... 4146
73.4.40 Error Injection Channel Descriptor 30, Word1 (EICHD30_WORD1).... 4147
73.5 EIM_0 register descriptions.... 4148

73.5.1 EIM_0 memory map....4149
73.5.2 Error Injection Module Configuration Register (EIMCR)....4150
73.5.3 Error Injection Channel Enable register (EICHEN)....4150
73.5.4 Error Injection Channel Descriptor 0, Word1 (EICHD0_WORD1)....4154
73.5.5 Error Injection Channel Descriptor 0, Word2 (EICHD0_WORD2)....4154
73.5.6 Error Injection Channel Descriptor 0, Word3 (EICHD0_WORD3)....4155
73.5.7 Error Injection Channel Descriptor 0, Word4 (EICHD0_WORD4)....4156
73.5.8 Error Injection Channel Descriptor 0, Word5 (EICHD0_WORD5)....4157
73.5.9 Error Injection Channel Descriptor 0, Word6 (EICHD0_WORD6)....4158
73.5.10 Error Injection Channel Descriptor 0, Word7 (EICHD0_WORD7)....4159
73.5.11 Error Injection Channel Descriptor 0, Word8 (EICHD0_WORD8)....4160
73.6 EIM_1 register descriptions....4161
73.6.1 EIM_1 memory map....4163
73.6.2 Error Injection Module Configuration Register (EIMCR)....4167
73.6.3 Error Injection Channel Enable register (EICHEN)....4168
73.6.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD14_WORD1)....4174
73.6.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD14_WORD2)....4176
73.6.6 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD14_WORD3)....4177
73.6.7 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD14_WORD4)....4178
73.6.8 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD14_WORD5)....4180
73.6.9 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD14_WORD6)....4181
73.6.10 Error Injection Channel Descriptor n, Word7 (EICHD0_WORD7 - EICHD14_WORD7)....4182
73.6.11 Error Injection Channel Descriptor n, Word8 (EICHD0_WORD8 - EICHD14_WORD8)....4184
73.7 EIM_2 register descriptions....4185
73.7.1 EIM_2 memory map....4186
73.7.2 Error Injection Module Configuration Register (EIMCR)....4188
73.7.3 Error Injection Channel Enable register (EICHEN)....4189
73.7.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD5_WORD1)....4193
73.7.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD5_WORD2)....4194
73.7.6 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD5_WORD3)....4195
73.7.7 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD5_WORD4)....4196
73.7.8 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD5_WORD5)....4197
73.7.9 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD5_WORD6)....4198
73.7.10 Error Injection Channel Descriptor n, Word7 (EICHD0_WORD7 - EICHD5_WORD7)....4199
73.7.11 Error Injection Channel Descriptor n, Word8 (EICHD0_WORD8 - EICHD5_WORD8)....4200
73.8 EIM_3 register descriptions....4201
73.8.1 EIM_3 memory map....4202
73.8.2 Error Injection Module Configuration Register (EIMCR)....4204
73.8.3 Error Injection Channel Enable register (EICHEN)....4204
73.8.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD3_WORD1)....4208
73.8.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD3_WORD2)....4209
73.8.6 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD3_WORD3)....4210
73.8.7 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD3_WORD4)....4211
73.8.8 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD3_WORD5)....4212
73.8.9 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD3_WORD6)....4213
73.8.10 Error Injection Channel Descriptor n, Word7 (EICHD0_WORD7 - EICHD3_WORD7)....4214
73.8.11 Error Injection Channel Descriptor n, Word8 (EICHD0_WORD8 - EICHD3_WORD8)....4215
73.9 EIM_LLCE register descriptions....4216
73.9.1 EIM_LLCE memory map....4217
73.9.2 Error Injection Module Configuration Register (EIMCR)....4218
73.9.3 Error Injection Channel Enable register (EICHEN)....4219
73.9.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD6_WORD0)....4223
73.9.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD6_WORD1)....4224
73.10 EIM_MISC register descriptions....4225
73.10.1 EIM_MISC memory map....4227

73.10.2 Error Injection Module Configuration Register (EIMCR)..... 4229
73.10.3 Error Injection Channel Enable register (EICHEN)..... 4229
73.10.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD4_WORD1)..... 4236
73.10.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD15_WORD2)... 4237
73.10.6 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD14_WORD3)... 4238
73.10.7 Error Injection Channel Descriptor n, Word4 (EICHD2_WORD4 - EICHD4_WORD4)..... 4240
73.10.8 Error Injection Channel Descriptor 5, Word1 (EICHD5_WORD1).....4241
73.10.9 Error Injection Channel Descriptor 6, Word1 (EICHD6_WORD1).....4242
73.10.10 Error Injection Channel Descriptor n, Word1 (EICHD7_WORD1 - EICHD8_WORD1)... 4243
73.10.11 Error Injection Channel Descriptor 9, Word1 (EICHD9_WORD1).....4244
73.10.12 Error Injection Channel Descriptor n, Word1 (EICHD10_WORD1 - EICHD11_WORD1)4245
73.10.13 Error Injection Channel Descriptor 12, Word1 (EICHD12_WORD1).....4246
73.10.14 Error Injection Channel Descriptor n, Word1 (EICHD13_WORD1 - EICHD14_WORD1)4247
73.10.15 Error Injection Channel Descriptor 15, Word1 (EICHD15_WORD1).....4248
73.10.16 Error Injection Channel Descriptor 16, Word1 (EICHD16_WORD1).....4249
73.11 EIM_PFE0 register descriptions..... 4249
73.11.1 EIM_PFE0 memory map..... 4252
73.11.2 Error Injection Module Configuration Register (EIMCR)..... 4254
73.11.3 Error Injection Channel Enable register (EICHEN)..... 4255
73.11.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0).....4265
73.11.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD1_WORD1)..... 4266
73.11.6 Error Injection Channel Descriptor 1, Word0 (EICHD1_WORD0).....4267
73.11.7 Error Injection Channel Descriptor n, Word2 (EICHD1_WORD2 - EICHD28_WORD2)... 4268
73.11.8 Error Injection Channel Descriptor 2, Word0 (EICHD2_WORD0).....4269
73.11.9 Error Injection Channel Descriptor 2, Word1 (EICHD2_WORD1).....4270
73.11.10 Error Injection Channel Descriptor 2, Word3 (EICHD2_WORD3).....4271
73.11.11 Error Injection Channel Descriptor 2, Word4 (EICHD2_WORD4).....4272
73.11.12 Error Injection Channel Descriptor 3, Word0 (EICHD3_WORD0).....4273
73.11.13 Error Injection Channel Descriptor n, Word1 (EICHD3_WORD1 - EICHD4_WORD1)... 4274
73.11.14 Error Injection Channel Descriptor 4, Word0 (EICHD4_WORD0).....4275
73.11.15 Error Injection Channel Descriptor n, Word0 (EICHD5_WORD0 - EICHD6_WORD0)... 4276
73.11.16 Error Injection Channel Descriptor n, Word1 (EICHD5_WORD1 - EICHD7_WORD1)... 4277
73.11.17 Error Injection Channel Descriptor 7, Word0 (EICHD7_WORD0).....4278
73.11.18 Error Injection Channel Descriptor 8, Word0 (EICHD8_WORD0).....4279
73.11.19 Error Injection Channel Descriptor n, Word1 (EICHD8_WORD1 - EICHD9_WORD1)... 4280
73.11.20 Error Injection Channel Descriptor 9, Word0 (EICHD9_WORD0).....4281
73.11.21 Error Injection Channel Descriptor n, Word0 (EICHD10_WORD0 - EICHD11_WORD0)4282
73.11.22 Error Injection Channel Descriptor n, Word1 (EICHD10_WORD1 - EICHD12_WORD1)4283
73.11.23 Error Injection Channel Descriptor 12, Word0 (EICHD12_WORD0).....4284
73.11.24 Error Injection Channel Descriptor 13, Word0 (EICHD13_WORD0).....4285
73.11.25 Error Injection Channel Descriptor n, Word1 (EICHD13_WORD1 - EICHD14_WORD1)4286
73.11.26 Error Injection Channel Descriptor 14, Word0 (EICHD14_WORD0).....4287
73.11.27 Error Injection Channel Descriptor n, Word0 (EICHD15_WORD0 - EICHD16_WORD0)4288
73.11.28 Error Injection Channel Descriptor n, Word1 (EICHD15_WORD1 - EICHD17_WORD1)4289
73.11.29 Error Injection Channel Descriptor 17, Word0 (EICHD17_WORD0).....4290
73.11.30 Error Injection Channel Descriptor 18, Word0 (EICHD18_WORD0).....4291
73.11.31 Error Injection Channel Descriptor n, Word1 (EICHD18_WORD1 - EICHD19_WORD1)4292
73.11.32 Error Injection Channel Descriptor 19, Word0 (EICHD19_WORD0).....4293
73.11.33 Error Injection Channel Descriptor n, Word0 (EICHD20_WORD0 - EICHD21_WORD0)4294
73.11.34 Error Injection Channel Descriptor n, Word1 (EICHD20_WORD1 - EICHD22_WORD1)4295
73.11.35 Error Injection Channel Descriptor 22, Word0 (EICHD22_WORD0).....4296
73.11.36 Error Injection Channel Descriptor 23, Word0 (EICHD23_WORD0).....4297
73.11.37 Error Injection Channel Descriptor n, Word1 (EICHD23_WORD1 - EICHD24_WORD1)4298
73.11.38 Error Injection Channel Descriptor 24, Word0 (EICHD24_WORD0).....4299
73.11.39 Error Injection Channel Descriptor n, Word0 (EICHD25_WORD0 - EICHD26_WORD0)4300

73.11.40 Error Injection Channel Descriptor n, Word1 (EICHD25_WORD1 - EICHD27_WORD1)4301
73.11.41 Error Injection Channel Descriptor 27, Word0 (EICHD27_WORD0).....4302
73.11.42 Error Injection Channel Descriptor 28, Word0 (EICHD28_WORD0).....4303
73.11.43 Error Injection Channel Descriptor n, Word1 (EICHD28_WORD1 - EICHD29_WORD1)4304
73.11.44 Error Injection Channel Descriptor 29, Word0 (EICHD29_WORD0).....4305
73.11.45 Error Injection Channel Descriptor n, Word0 (EICHD30_WORD0 - EICHD31_WORD0)4306
73.11.46 Error Injection Channel Descriptor n, Word1 (EICHD30_WORD1 - EICHD31_WORD1)4307
73.12 EIM_PFE1 register descriptions..... 4308
73.12.1 EIM_PFE1 memory map..... 4310
73.12.2 Error Injection Module Configuration Register (EIMCR)..... 4311
73.12.3 Error Injection Channel Enable register (EICHEN)..... 4312
73.12.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0).....4318
73.12.5 Error Injection Channel Descriptor 0, Word1 (EICHD0_WORD1).....4319
73.12.6 Error Injection Channel Descriptor 1, Word0 (EICHD1_WORD0).....4320
73.12.7 Error Injection Channel Descriptor n, Word1 (EICHD1_WORD1 - EICHD2_WORD1)..... 4321
73.12.8 Error Injection Channel Descriptor n, Word2 (EICHD1_WORD2 - EICHD14_WORD2)... 4322
73.12.9 Error Injection Channel Descriptor 2, Word0 (EICHD2_WORD0).....4323
73.12.10 Error Injection Channel Descriptor n, Word0 (EICHD3_WORD0 - EICHD4_WORD0)... 4324
73.12.11 Error Injection Channel Descriptor n, Word1 (EICHD3_WORD1 - EICHD5_WORD1)... 4325
73.12.12 Error Injection Channel Descriptor 5, Word0 (EICHD5_WORD0).....4326
73.12.13 Error Injection Channel Descriptor 6, Word0 (EICHD6_WORD0).....4327
73.12.14 Error Injection Channel Descriptor n, Word1 (EICHD6_WORD1 - EICHD7_WORD1)... 4328
73.12.15 Error Injection Channel Descriptor 7, Word0 (EICHD7_WORD0).....4329
73.12.16 Error Injection Channel Descriptor n, Word0 (EICHD8_WORD0 - EICHD9_WORD0)... 4330
73.12.17 Error Injection Channel Descriptor n, Word1 (EICHD8_WORD1 - EICHD13_WORD1). 4331
73.12.18 Error Injection Channel Descriptor 10, Word0 (EICHD10_WORD0).....4332
73.12.19 Error Injection Channel Descriptor 11, Word0 (EICHD11_WORD0).....4333
73.12.20 Error Injection Channel Descriptor 12, Word0 (EICHD12_WORD0).....4334
73.12.21 Error Injection Channel Descriptor n, Word0 (EICHD13_WORD0 - EICHD14_WORD0)4335
73.12.22 Error Injection Channel Descriptor n, Word3 (EICHD13_WORD3 - EICHD14_WORD3)4336
73.12.23 Error Injection Channel Descriptor n, Word4 (EICHD13_WORD4 - EICHD14_WORD4)4337
73.12.24 Error Injection Channel Descriptor 14, Word1 (EICHD14_WORD1).....4338
73.13 EIM_PFE2 register descriptions..... 4339
73.13.1 EIM_PFE2 memory map..... 4341
73.13.2 Error Injection Module Configuration Register (EIMCR)..... 4344
73.13.3 Error Injection Channel Enable register (EICHEN)..... 4345
73.13.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD3_WORD1)..... 4354
73.13.5 Error Injection Channel Descriptor n, Word1 (EICHD4_WORD1 - EICHD5_WORD1)..... 4355
73.13.6 Error Injection Channel Descriptor 6, Word1 (EICHD6_WORD1).....4356
73.13.7 Error Injection Channel Descriptor n, Word1 (EICHD7_WORD1 - EICHD8_WORD1)..... 4357
73.13.8 Error Injection Channel Descriptor 9, Word1 (EICHD9_WORD1).....4358
73.13.9 Error Injection Channel Descriptor n, Word1 (EICHD10_WORD1 - EICHD11_WORD1). 4359
73.13.10 Error Injection Channel Descriptor 12, Word1 (EICHD12_WORD1).....4360
73.13.11 Error Injection Channel Descriptor n, Word1 (EICHD13_WORD1 - EICHD14_WORD1)4361
73.13.12 Error Injection Channel Descriptor 15, Word1 (EICHD15_WORD1).....4362
73.13.13 Error Injection Channel Descriptor n, Word0 (EICHD16_WORD0 - EICHD21_WORD0)4363
73.13.14 Error Injection Channel Descriptor n, Word1 (EICHD16_WORD1 - EICHD30_WORD1)4364
73.13.15 Error Injection Channel Descriptor n, Word2 (EICHD16_WORD2 - EICHD30_WORD2)4366
73.13.16 Error Injection Channel Descriptor 22, Word0 (EICHD22_WORD0).....4367
73.13.17 Error Injection Channel Descriptor 22, Word3 (EICHD22_WORD3).....4368
73.13.18 Error Injection Channel Descriptor 22, Word4 (EICHD22_WORD4).....4369
73.13.19 Error Injection Channel Descriptor 22, Word5 (EICHD22_WORD5).....4370
73.13.20 Error Injection Channel Descriptor 22, Word6 (EICHD22_WORD6).....4371
73.13.21 Error Injection Channel Descriptor 22, Word7 (EICHD22_WORD7).....4372
73.13.22 Error Injection Channel Descriptor 22, Word8 (EICHD22_WORD8).....4373

73.13.23 Error Injection Channel Descriptor n, Word0 (EICHD23_WORD0 - EICHD30_WORD0)4374
73.13.24 Error Injection Channel Descriptor 31, Word0 (EICHD31_WORD0).....4375
73.13.25 Error Injection Channel Descriptor 31, Word1 (EICHD31_WORD1).....4376
73.14 EIM_PFE3 register descriptions..... 4377
73.14.1 EIM_PFE3 memory map..... 4379
73.14.2 Error Injection Module Configuration Register (EIMCR)..... 4383
73.14.3 Error Injection Channel Enable register (EICHEN)..... 4384
73.14.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0).....4393
73.14.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD8_WORD1)..... 4394
73.14.6 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD31_WORD2)... 4396
73.14.7 Error Injection Channel Descriptor n, Word3 (EICHD0_WORD3 - EICHD10_WORD3)... 4397
73.14.8 Error Injection Channel Descriptor n, Word4 (EICHD0_WORD4 - EICHD10_WORD4)... 4398
73.14.9 Error Injection Channel Descriptor n, Word5 (EICHD0_WORD5 - EICHD10_WORD5)... 4399
73.14.10 Error Injection Channel Descriptor n, Word6 (EICHD0_WORD6 - EICHD10_WORD6). 4400
73.14.11 Error Injection Channel Descriptor n, Word7 (EICHD0_WORD7 - EICHD10_WORD7). 4401
73.14.12 Error Injection Channel Descriptor n, Word8 (EICHD0_WORD8 - EICHD10_WORD8). 4402
73.14.13 Error Injection Channel Descriptor n, Word0 (EICHD1_WORD0 - EICHD8_WORD0)... 4403
73.14.14 Error Injection Channel Descriptor 9, Word0 (EICHD9_WORD0).....4404
73.14.15 Error Injection Channel Descriptor 9, Word1 (EICHD9_WORD1).....4405
73.14.16 Error Injection Channel Descriptor 10, Word0 (EICHD10_WORD0).....4406
73.14.17 Error Injection Channel Descriptor n, Word1 (EICHD10_WORD1 - EICHD18_WORD1)4407
73.14.18 Error Injection Channel Descriptor n, Word0 (EICHD11_WORD0 - EICHD18_WORD0)4408
73.14.19 Error Injection Channel Descriptor 19, Word0 (EICHD19_WORD0).....4410
73.14.20 Error Injection Channel Descriptor 19, Word1 (EICHD19_WORD1).....4411
73.14.21 Error Injection Channel Descriptor n, Word0 (EICHD20_WORD0 - EICHD31_WORD0)4412
73.14.22 Error Injection Channel Descriptor n, Word1 (EICHD20_WORD1 - EICHD31_WORD1)4413
73.15 EIM_PFE4 register descriptions..... 4414
73.15.1 EIM_PFE4 memory map..... 4415
73.15.2 Error Injection Module Configuration Register (EIMCR)..... 4416
73.15.3 Error Injection Channel Enable register (EICHEN)..... 4417
73.15.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0).....4422
73.15.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD9_WORD1)..... 4423
73.15.6 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD9_WORD2)..... 4425
73.15.7 Error Injection Channel Descriptor 1, Word0 (EICHD1_WORD0).....4426
73.15.8 Error Injection Channel Descriptor n, Word0 (EICHD2_WORD0 - EICHD9_WORD0)..... 4427
73.16 EIM_PFE5 register descriptions..... 4428
73.16.1 EIM_PFE5 memory map..... 4430
73.16.2 Error Injection Module Configuration Register (EIMCR)..... 4433
73.16.3 Error Injection Channel Enable register (EICHEN)..... 4434
73.16.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD1_WORD1)..... 4443
73.16.5 Error Injection Channel Descriptor n, Word1 (EICHD2_WORD1 - EICHD3_WORD1)..... 4444
73.16.6 Error Injection Channel Descriptor 4, Word1 (EICHD4_WORD1).....4445
73.16.7 Error Injection Channel Descriptor n, Word1 (EICHD5_WORD1 - EICHD6_WORD1)..... 4446
73.16.8 Error Injection Channel Descriptor 7, Word1 (EICHD7_WORD1).....4447
73.16.9 Error Injection Channel Descriptor n, Word0 (EICHD8_WORD0 - EICHD13_WORD0)... 4448
73.16.10 Error Injection Channel Descriptor n, Word1 (EICHD8_WORD1 - EICHD27_WORD1). 4449
73.16.11 Error Injection Channel Descriptor n, Word2 (EICHD8_WORD2 - EICHD28_WORD2). 4451
73.16.12 Error Injection Channel Descriptor 14, Word0 (EICHD14_WORD0).....4452
73.16.13 Error Injection Channel Descriptor 15, Word0 (EICHD15_WORD0).....4453
73.16.14 Error Injection Channel Descriptor 16, Word0 (EICHD16_WORD0).....4454
73.16.15 Error Injection Channel Descriptor 17, Word0 (EICHD17_WORD0).....4455
73.16.16 Error Injection Channel Descriptor 18, Word0 (EICHD18_WORD0).....4456
73.16.17 Error Injection Channel Descriptor 19, Word0 (EICHD19_WORD0).....4457
73.16.18 Error Injection Channel Descriptor 20, Word0 (EICHD20_WORD0).....4458
73.16.19 Error Injection Channel Descriptor 21, Word0 (EICHD21_WORD0).....4459

73.16.20 Error Injection Channel Descriptor 22, Word0 (EICHD22_WORD0)....4460
73.16.21 Error Injection Channel Descriptor 23, Word0 (EICHD23_WORD0)....4461
73.16.22 Error Injection Channel Descriptor 24, Word0 (EICHD24_WORD0)....4462
73.16.23 Error Injection Channel Descriptor 25, Word0 (EICHD25_WORD0)....4463
73.16.24 Error Injection Channel Descriptor 25, Word3 (EICHD25_WORD3)....4464
73.16.25 Error Injection Channel Descriptor 25, Word4 (EICHD25_WORD4)....4465
73.16.26 Error Injection Channel Descriptor 26, Word0 (EICHD26_WORD0)....4466
73.16.27 Error Injection Channel Descriptor 27, Word0 (EICHD27_WORD0)....4467
73.16.28 Error Injection Channel Descriptor 28, Word0 (EICHD28_WORD0)....4468
73.16.29 Error Injection Channel Descriptor n, Word1 (EICHD28_WORD1 - EICHD29_WORD1)4469
73.16.30 Error Injection Channel Descriptor 29, Word0 (EICHD29_WORD0)....4470
73.16.31 Error Injection Channel Descriptor n, Word0 (EICHD30_WORD0 - EICHD31_WORD0)4471
73.16.32 Error Injection Channel Descriptor n, Word1 (EICHD30_WORD1 - EICHD31_WORD1)4472
73.17 EIM_PFE6 register descriptions.... 4473
73.17.1 EIM_PFE6 memory map.... 4474
73.17.2 Error Injection Module Configuration Register (EIMCR).... 4474
73.17.3 Error Injection Channel Enable register (EICHEN).... 4475
73.17.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD1_WORD0)..... 4479
73.17.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD1_WORD1)..... 4480
73.18 Functional description....4480
73.19 Glossary.... 4481

Chapter 74 Cyclic Redundancy Check (CRC) Unit....4482
74.1 Introduction....4482
74.2 Main features....4482
74.3 Block diagram....4482
74.4 Signal description.... 4482
74.4.1 Peripheral bus interface.... 4482
74.5 CRC register descriptions....4483
74.5.1 CRC memory map.... 4483
74.5.2 Configuration Register (CFG1 - CFG3)....4484
74.5.3 Input Register (INP1 - INP3).... 4485
74.5.4 Current Status Register (CSTAT1 - CSTAT3).... 4486
74.5.5 Output Register (OUTP1 - OUTP3).... 4487
74.6 Functional description....4488
74.7 Use cases....4490
74.7.1 Programming example....4490
74.7.2 Register programming....4491
74.7.2.1 Configuration Register values....4492
74.7.2.2 Current Status Register initial values....4492
74.7.2.3 Examples of input data and expected output data....4492

Chapter 75 Debug....4494
75.1 Introduction....4494
75.2 Block diagram....4494
75.2.1 S32G accelerator subsystem debug block diagram....4495
75.3 Glossary.... 4496
75.4 Features.... 4497
75.5 Debug....4499
75.5.1 Test and Debug Access Port (TAP) connectivity.... 4499
75.5.2 Debug Access Port (DAP) TAP....4499
75.5.3 System JTAG Controller (JTAGC).... 4500
75.5.3.1 Chip JTAG ID....4502

75.5.3.2 JTAG Data Communication (JDC) module....4502
75.6 APB memory map....4502
75.6.1 S32G accelerator debug APB memory map....4510
75.7 Trace....4512
75.7.1 Trace modules and connectivity....4512
75.7.1.1 S32G accelerator trace modules and connectivity....4513
75.7.2 Trace assignments....4514
75.7.2.1 S32G accelerator trace assignments....4515
75.8 Embedded Cross Trigger (ECT)....4516
75.8.1 CTI assignments....4516
75.8.1.1 S32G accelerator subsystem CTI assignments....4520
75.9 NoC trace....4523
75.9.1 S32G accelerator subsystem NoC trace....4529
75.9.2 Observability....4531
75.9.2.1 Concepts....4531
75.9.2.1.1 Packet and transaction probes....4531
75.9.2.1.2 Observers....4532
75.9.2.2 Operation....4532
75.9.2.2.1 Logging errors....4532
75.9.2.2.2 Tracing packets....4533
75.9.2.2.3 Collecting statistics....4536
75.9.2.2.4 Transaction profiling operation....4537
75.9.2.2.5 Activating observer debug output....4538
75.9.2.3 Technical reference....4538
75.9.2.3.1 Observation probes....4538
75.9.2.3.2 Observers....4539
75.10 Debug and trace under functional reset....4547
75.11 MDM_AP register descriptions....4548
75.11.1 MDM_AP memory map....4549
75.11.2 MDM_AP status (STATUS)....4549
75.11.3 MDM_AP control (CONTROL)....4552
75.11.4 WIR enable (WIR_EN)....4557
75.11.5 WIR release (WIR_REL)....4557
75.11.6 MDM_AP status 2 (STATUS2)....4558
75.11.7 Cortex-A53 A0 debug (CORTEX_A53_A0_IP_DBG)....4560
75.11.8 MDM_AP control 2 (CONTROL2)....4561
75.11.9 Cortex-A53 A1 debug (CA53_A1_IP_DBG)....4562
75.11.10 Cortex-A53 B0 debug (CORTEX_A53_B0_IP_DBG)....4563
75.11.11 Cortex-A53 B1 debug (CORTEX_A53_B1_IP_DBG)....4564
75.11.12 Cortex M7_0 debug (CORTEX_M7_0_IP_DBG)....4564
75.11.13 Cortex M7_1 debug (CORTEX_M7_1_IP_DBG)....4565
75.11.14 Cortex M7_2 debug (CORTEX_M7_2_IP_DBG)....4566
75.11.15 DAP enable control (DAP_EN_CTRL)....4567
75.12 Debug resets....4568
75.13 Security....4568
75.13.1 Arm authentication signals....4569
75.13.2 Security fuses....4569
75.14 Programming checklists....4569
75.14.1 JTAG switching sequence....4569
75.14.2 FCCU considerations....4569
75.14.3 Lockstep considerations....4569
75.15 Pin interface....4569
75.15.1 Debug port pin descriptions....4570
75.15.2 Trace port pin descriptions....4570
75.16 Timestamp distribution network....4571

75.16.1 S32G accelerator timestamp distribution network....4572
75.17 Low power debug....4572
75.18 References....4573

Chapter 76 JTAG Controller (JTAGC)....4574
76.1 Chip-specific JTAGC information....4574
76.1.1 JTAGC device identification register....4574
76.2 Introduction....4574
76.2.1 Block diagram....4574
76.2.2 Features....4574
76.2.3 Modes of operation....4575
76.2.3.1 Reset....4575
76.2.3.2 IEEE 1149.1–2001 defined test modes....4575
76.2.3.3 Bypass mode....4575
76.3 External signal description....4575
76.3.1 Test clock input (TCK)....4576
76.3.2 Test data input (TDI)....4576
76.3.3 Test data output (TDO)....4576
76.3.4 Test mode select (TMS)....4576
76.3.5 JCOMP JTAG compliancy....4576
76.4 Register description....4576
76.4.1 Instruction register....4576
76.4.2 Bypass register....4577
76.4.3 Device identification register....4577
76.4.4 Boundary scan register....4578
76.5 Functional description....4578
76.5.1 JTAGC reset configuration....4578
76.5.2 IEEE 1149.1-2001 (JTAG) TAP....4578
76.5.3 TAP controller state machine....4579
76.5.3.1 Enabling the TAP controller....4579
76.5.3.2 Selecting an IEEE 1149.1-2001 register....4580
76.5.4 JTAGC block instructions....4580
76.5.4.1 IDCODE instruction....4580
76.5.4.2 SAMPLE/PRELOAD instruction....4580
76.5.4.3 SAMPLE instruction....4580
76.5.4.4 EXTEST external test instruction....4580
76.5.4.5 HIGHZ instruction....4581
76.5.4.6 CLAMP instruction....4581
76.5.4.7 ACCESS_AUX_x instructions....4581
76.5.4.8 BYPASS instruction....4581
76.5.5 Boundary scan....4581
76.6 Initialization/application information....4581

Chapter 77 JTAG Data Communication (JDC)....4582
77.1 Introduction....4582
77.2 Overview....4582
77.3 Signal description....4582
77.4 JDC register descriptions....4583
77.4.1 JDC memory map....4583
77.4.2 Module Configuration Register (MCR)....4583
77.4.3 Module Status Register (MSR)....4584
77.4.4 JTAG Output Data Register (JOUT_IPS)....4586
77.4.5 JTAG Input Data Register (JIN_IPS)....4586

77.5 Non-memory-mapped register definition.... 4587
77.5.1 JTAG output data register (JOUT).... 4587
77.5.2 JTAG input data register (JIN).... 4588
77.6 Functional description.... 4588
77.6.1 JTAG register access.... 4589
77.6.1.1 JDC block instructions.... 4589
77.7 Secure challenge/response connection procedure.... 4589
77.8 Glossary.... 4590

Chapter 78 Aurora Trace Port (ATP) Subsystem.... 4591
78.1 Introduction.... 4591
78.1.1 Features.... 4591
78.2 External signal description.... 4592
78.3 Overview.... 4592
78.4 ATP register descriptions.... 4593
78.4.1 ATP memory map.... 4593
78.4.2 PLL Control (PLLC).... 4594
78.4.3 PLL Status (PLLS).... 4595
78.4.4 PLL Divider (PLLDIV).... 4597
78.4.5 PLL Calibration 2 (PLLCAL_2).... 4598
78.4.6 PLL Clock MUX (PLLCKMUX).... 4599
78.4.7 AL Status (ALS).... 4600
78.4.8 AL General Control (ALGC).... 4602
78.4.9 AL Training Control (ALTC).... 4604
78.4.10 LVDS TX IO Configuration (LVDSTX).... 4607
78.4.11 LVDS RX IO Configuration (LVDSRX).... 4609
78.4.12 LVDS TX OBE Configuration (LVDSTXOBE).... 4610
78.4.13 CIA Control (CIAC).... 4611
78.4.14 Aurora Trace Port Enable (ATPE).... 4613
78.4.15 Integration Mode Control (ITCTRL).... 4614
78.4.16 Claim Tag Set (CLAIMSET).... 4614
78.4.17 Claim Tag Clear (CLAIMCLR).... 4615
78.4.18 Device Affinity 0 (DEVAFF0).... 4616
78.4.19 Device Affinity 1 (DEVAFF1).... 4616
78.4.20 Lock Access Register (LAR).... 4617
78.4.21 Lock Status Register (LSR).... 4618
78.4.22 Authentication Status (AUTHSTATUS).... 4619
78.4.23 Device Architecture (DEVARCH).... 4620
78.4.24 Device Configuration 2 (DEVID2).... 4621
78.4.25 Device Configuration 1 (DEVID1).... 4621
78.4.26 Device Configuration (DEVID).... 4622
78.4.27 Device Type Identifier (DEVTYPE).... 4623
78.4.28 Peripheral Identification Register 4 (PIDR4).... 4624
78.4.29 Peripheral Identification Register 0 (PIDR0).... 4624
78.4.30 Peripheral Identification Register 1 (PIDR1).... 4625
78.4.31 Peripheral Identification Register 2 (PIDR2).... 4626
78.4.32 Peripheral Identification Register 3 (PIDR3).... 4627
78.4.33 Component Identification Register 0 (CIDR0).... 4628
78.4.34 Component Identification Register 1 (CIDR1).... 4628
78.4.35 Component Identification Register 2 (CIDR2).... 4629
78.4.36 Component Identification Register 3 (CIDR3).... 4630
78.5 Functional description.... 4631
78.5.1 CoreSight interface adaptor.... 4631
78.5.1.1 CIA functional blocks.... 4631

78.5.1.2 TPIU interface module....4632
78.5.1.3 Buffer management module....4632
78.5.1.4 AL interface module....4632
78.5.1.5 Register configuration module....4632
78.5.1.6 Clock gating module....4632
78.5.2 Aurora link....4633
78.5.2.1 AL functional blocks....4633
78.5.2.2 AL link training....4634
78.5.2.3 AL static training....4634
78.5.2.4 AL transmission procedure....4635
78.5.2.5 AL clock compensation considerations....4635
78.5.3 Aurora PHY....4636
78.5.3.1 AP modes of operation....4636
78.5.3.2 AP functional blocks....4636
78.5.4 Aurora PLL....4637
78.5.4.1 PLL clock configuration....4637
78.6 Initialization sequence....4638

Appendix A Revision History....4641
A.1 About_This_Manual module changes....4641
A.2 Introduction changes....4641
A.3 Arm modules changes....4641
A.4 FlexNoC module changes....4641
A.5 Chip-specific Ncore information changes....4641
A.6 Ncore module changes....4641
A.7 MCM module changes....4642
A.8 A53_CLUSTER_GPR module changes....4642
A.9 CM7_CLUSTER_GPR module changes....4642
A.10 Chip-specific eDMA information changes....4642
A.11 eDMA3 module changes....4642
A.12 DMA_CRC module changes....4642
A.13 Chip-specific DMAMUX information changes....4642
A.14 DMAMUX module changes....4642
A.15 Chip-specific XRDC information changes....4643
A.16 XRDC module changes....4643
A.17 Application Extension-Specific SIUL2 Changes....4643
A.18 SIUL2 module changes....4643
A.19 SEMA42 module changes....4643
A.20 SRC module changes....4643
A.21 S32G_MAIN_GPR module changes....4644
A.22 S32G_STDBY_GPR module changes....4644
A.23 REG_PROT module changes....4644
A.24 Chip-specific [S32G] information changes....4645
A.25 WKPU module changes....4645
A.26 Clocking changes....4645
A.27 MC_CGM module changes....4646
A.28 DFS module changes....4646
A.29 PLLDIG module changes....4646
A.30 FXOSC module changes....4646
A.31 Reset changes....4647
A.32 Chip-specific MC_RGM information changes....4647
A.33 MC_RGM module changes....4647

A.34 Boot changes..... 4647
A.35 Power management changes..... 4648
A.36 Chip-specific MC_ME information changes..... 4648
A.37 MC_ME module changes..... 4649
A.38 MC_PCU changes..... 4649
A.39 Chip-specific PMC information changes..... 4649
A.40 PMC module changes..... 4649
A.41 Chip-specific [S32G] information changes..... 4649
A.42 SRAMC module changes..... 4649
A.43 DDR module changes..... 4649
A.44 DDR_GPR module changes..... 4650
A.45 Chip-specific QuadSPI changes..... 4650
A.46 QuadSPI module changes..... 4650
A.47 uSDHC module changes..... 4650
A.48 Chip-specific STM information changes..... 4651
A.49 STM module changes..... 4651
A.50 Chip-specific SWT information changes..... 4651
A.51 SWT module changes..... 4651
A.52 Chip-specific PIT information changes..... 4651
A.53 PIT_RTI module changes..... 4651
A.54 Chip-specific FTM information changes..... 4651
A.55 FTM module changes..... 4651
A.56 RTC module changes..... 4652
A.57 I^2C module changes..... 4652
A.58 Chip-specific GMAC changes..... 4652
A.59 PFE module changes..... 4652
A.60 Chip-specific FlexRay information changes..... 4652
A.61 FlexRay module changes..... 4652
A.62 LINFlexD module changes..... 4652
A.63 Chip-specific SPI information changes..... 4652
A.64 Chip-specific FlexCAN information changes..... 4652
A.65 FlexCAN module changes..... 4652
A.66 S32G CAN Timestamp changes..... 4653
A.67 Chip-specific SerDes information changes..... 4653
A.68 SERDES_GPR module changes..... 4653
A.69 LLCE module..... 4653
A.70 Chip-specific USBOTG changes..... 4653
A.71 USBOTG module changes..... 4653
A.72 Chip-specific CTU changes..... 4654
A.73 CTU module changes..... 4654
A.74 Chip-specific ADC information changes..... 4654
A.75 SAR_ADC module changes..... 4654
A.76 Chip-specific TMU information changes..... 4655
A.77 TMU changes..... 4655
A.78 Security changes..... 4655
A.79 Chip-specific MU information changes..... 4655
A.80 MU changes..... 4655
A.81 OCOTP Controller module changes..... 4655
A.82 FBXC module changes..... 4656
A.83 Safety changes..... 4656
A.84 Chip-specific ERM information changes..... 4656
A.85 ERM module changes..... 4656
A.86 FCCU chip-specific changes..... 4656
A.87 FCCU module changes..... 4656
A.88 Chip-specific CMU_FC information changes..... 4657

A.89 Chip-specific CMU_FM information changes....4657
A.90 SELFTEST_GPR module changes....4657
A.91 SELFTEST_GPR_TOP module changes....4657
A.92 Chip-specific STCU2 information changes....4657
A.93 STCU2 module changes....4658
A.94 SBSW module changes....4658
A.95 Chip-specific EIM information changes....4659
A.96 EIM changes....4659
A.97 CRC module changes....4659
A.98 Chip-specific JTAGC information changes....4659

Chapter 1
About This Manual

1.1 Audience

This reference manual (RM) is intended for system software, hardware developers, and applications programmers who need to develop products using this chip. It assumes that its users understand operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

This manual has two main sets of chapters.

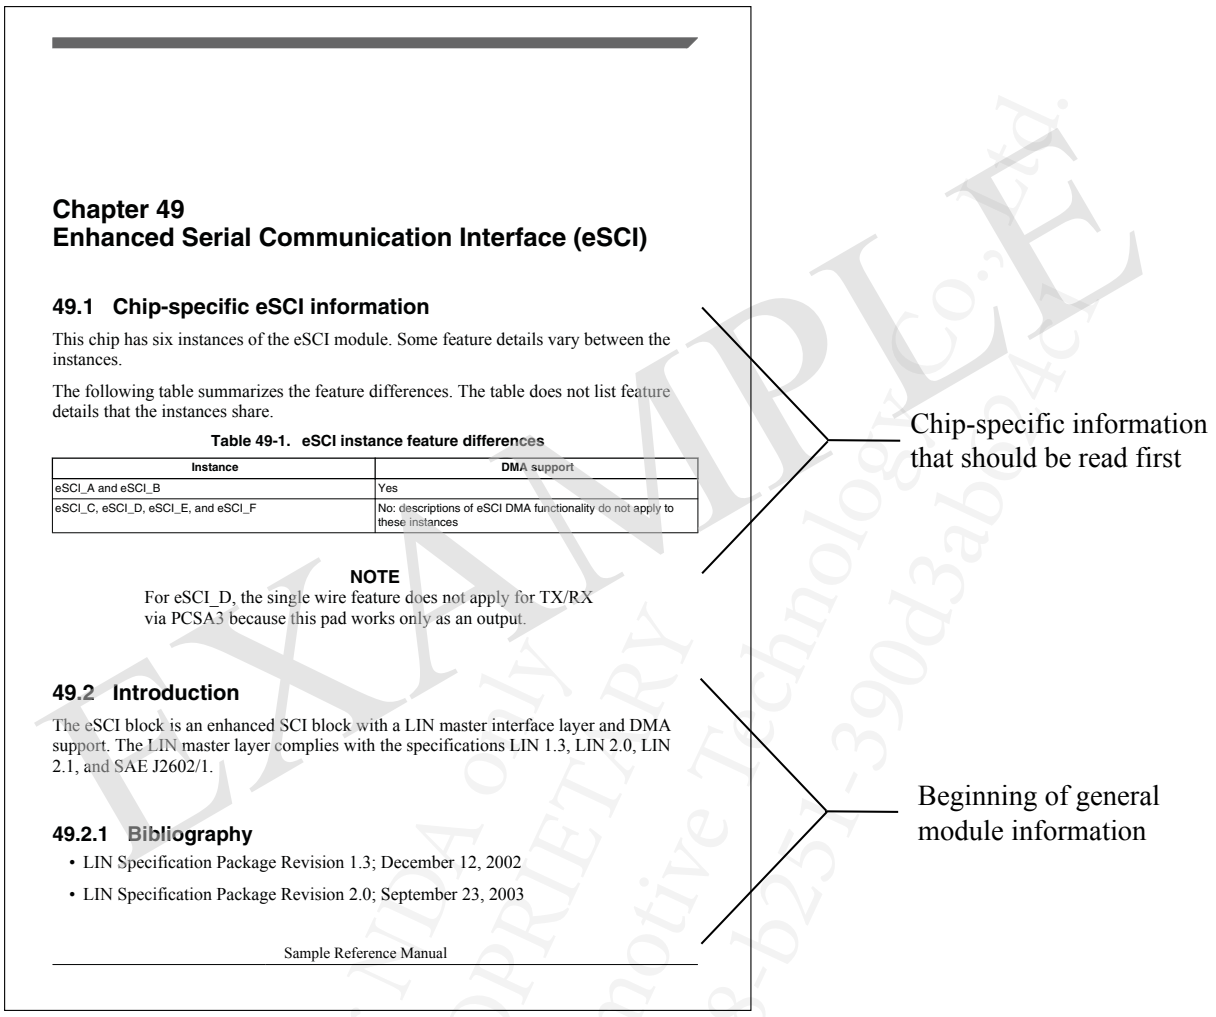
- Chapters in the first set contain information that applies to all components on the chip.
- Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

1.2.1 Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

Select the paperclip icon on the left side of the PDF window to see the list of attachments.



1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.

Provided under NDA only

Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Introduction

System Integration Unit Lite2 (SIUL2)

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 Chip-specific SIUL2 information

9.1.1 Feature configurations

In this device, the SIUL2_0 module instance does not support the following features described in the generic description:

- Interrupts
- DMA channels

9.1.2 Notes for IMCR

Out of reset, PA_00, PA_04, and PA_05 pads have JTAG input functionality selected by default. It should be disabled in the corresponding IMCR registers (IMCR61, IMCR60, and IMCR50 respectively) in order to use other functionality such as GPIO.

9.2 Introduction

9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is to enable the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

Figure 23. System Integration Unit Lite2 block diagram

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ESR), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR master and slave assignments

The following table lists the XBAR physical port numbers and logical IDs for all master ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical master port. This default priority equals the reset value of the priority field for each master port in the PRS*n* registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

Module	Physical master port	Logical master ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

Figure 3. Example of chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in the following:

- Memory maps, which contain:
  - An offset from the module's base address
  - The mnemonic and name of each register
  - The width of each register (in bits)
  - The reset value of each register
- Register figures
- Field-description tables
- Associated text

The following figure shows register figure conventions used throughout the manual.

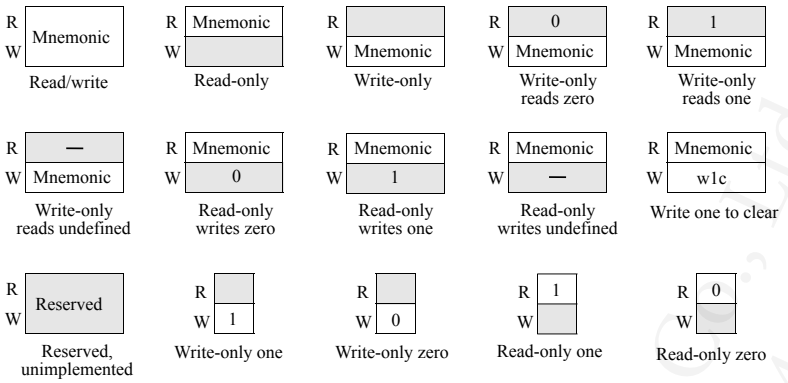

Figure 4. Register figure conventions

NOTE

Reset values of reserved locations documented in this manual are subject to change and must not be used for diagnostic purposes.

1.5 Conventions

1.5.1 Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

Table 1. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

1.5.3 Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

Example	Description
x and other italicized text	The italized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period between a module abbreviation and a register mnemonic indicates that the register is located in that module. For example, SIUL2.MSCRn means that the MSCRn register is located in the SIUL2 module.

1.5.4 Special terms

The following terms have special meanings.

Table 3. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must: • Not modify the default value of a reserved programming setting, such as the reset value of a reserved register field.

Table continues on the next page...

Table 3. Special terms (continued)

Term	Meaning
	• Consider undefined locations in memory to be reserved. • Not use the reset values of reserved locations documented in this manual for diagnostic purposes. They subject to change.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

1.6 Editorial changes

Each new release of this document includes editorial improvements such as:

- Spelling
- Grammar
- Punctuation
- Voice
- Tense
- Capitalization
- Formatting

Chapter 2
Introduction

2.1 Overview

S32G2 is a family of high-performance vehicle network processors that combine controller area network (CAN), local interconnect network (LIN), and FlexRay networking with high-data-rate Ethernet networking. It also combines a functional safe-core infrastructure with MPU cores and includes high-level security features.

S32G2 family includes the following variants:

- S32G234M
- S32G233A
- S32G254A
- S32G274A

This document primarily represents the features offered by the superset S32G274A. To compare the features of the S32G2 family variants, please see the #unique_15 .

2.2 Applications

S32G2 targets the applications that support the following functions:

- Central gateways and domain controllers connecting various networks and translating their protocols
- Firmware over-the-air (FOTA) masters controlling secure software image downloads and their distribution to the engine control units (ECUs) in the network
- Secure key management
- Smart antennas
- High-performance central compute nodes

2.3 Block diagram

2.4 Module functional categories

The modules related to S32G2 on this device are grouped into functional categories.

NOTE

The module names in the following table may change in future releases.

Table 4. Module functional categories

Module categories	Module names
System	• Arm® Cortex-A53 • Arm Cortex-M7 • System NoC • Accelerator NoC • NCore • Enhanced Direct Memory Access (eDMA) • DMA CRC • Direct Memory Access Multiplexer (DMAMUX) • Extended Resource Domain Controller (XRDC) • System Integration Unit Lite2 (SIUL) • Semaphores2 (SEMA42) • Miscellaneous System Control Module (MSCM) • Wakeup Unit (WKPU)

Table continues on the next page...

Table 4. Module functional categories (continued)

Module categories	Module names
Clocking	• Clock Generation Module (MC_CGM) • Fast Internal RC Oscillator Digital Interface (FIRC) • Slow Internal RC Oscillator (SIRC) • Digital Frequency Synthesizer (DFS) • Phase-Locked Loop (PLL) for Aurora • Dual PLL Digital Interface (PLLDIG) • Fast Crystal Oscillator Digital Controller (FXOSC)
Reset and boot	• Reset Generation Module (MC_RGM)
Power management	• Mode Entry Module (MC_ME) • Power Control Unit (MC_PCU) • Power Management Controller (PMC) digital • Supply Presence Detector (SPD)
Memories and memory interfaces	• System RAM (SRAM) • DDR DRAM CTRL • DDR DRAM PHY • External flash memory interface • Quad Serial Peripheral Interface (QuadSPI) • On-the-Fly AES Decryption module (OTFAD) • Ultra Secured Digital Host Controller (uSDHC)
Timer	• Software Watchdog Timer (SWT) • System Timer Module (STM) • Periodic Interrupt Timer (PIT) • FlexTimer module (FlexTimer) • Real Time Clock (RTC)
Communication interface	• Inter-Integrated Circuit (I^2C) • Ethernet • FlexRay communication controller (FlexRay) • LINFlexD • CAN (FlexCAN) • De-serial Serial Peripheral Interface (DSPI) • Peripheral Component Interconnect Express (PCIe) controller • PCIe Gen3 PHY

Table continues on the next page...

Table 4. Module functional categories (continued)

Module categories	Module names
	• Low Latency Communications Engine (LLCE) • Ethernet Packet Forwarding Engine (PFE) • Universal Serial Bus (USB) • Universal Serial Bus OTG Controller (USBOTG)
Analog	• Analog-to-Digital Converter (SAR_ADC) • Cross Trigger Unit (CTU) • Temperature Monitor Unit (TMU) digital • TMU analog • TMU sense • Thermal diode • Thermal RESCAL circuit • Secure Digital (SD)
Security	• On-Chip One-Time Programmable (OCOTP) Controller • External Interface Module (EIM) • Register Protection (REG_PROT) • SRAM Controller (OCPSRAMC) • Hardware Security Engine (HSE_H)
Safety	• Error Reporting Module (ERM) • Fault Collection and Control Unit (FCCU) • Redundancy Control and Checker Unit (RCCU) • Clock Monitor Unit (CMU) • Self-Test Control Unit (STCU2) • Safety by Software (SBSW) • Error Injection Module (EIM) • Cyclic Redundancy Check (CRC)
Debug and trace	• JTAG Controller (JTAGC) • IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) • JTAG Data Controller (JDC) • Aurora Trace Port (ATP)

2.5 Feature comparison

The following table compares the features of these devices in the S32G2 family: S32G234M, S32G233A, S32G254A, and S32G274A.

Arm Modules

5.1 Core complex platform components

The following table lists the platform components which comprise the core complex.

Table 6. Core complex platform components

Component	Description	Reference
Arm Cortex-A53 MPCore clusters complex	• Two Arm Cortex-A53 clusters, two cores per cluster, up to 1 GHz • NoC Interconnect fabric • Ncore Cache Coherent Interconnect	• Overview: Cortex-A53 cluster complex • Cortex-A53 implementation details: Arm Cortex-A53 MPCore • Cortex-A53 documentation: *Arm Cortex-A53 MPCore Processor Technical Reference Manual, Revision r0p4* at www.arm.com
Arm® Cortex®-M7 processor clusters	• Three Arm Cortex-M7 delayed lockstep clusters, two cores per cluster, up to 400 Mhz • An in-order issue, super-scalar pipeline with dynamic branch prediction	• Overview: Cortex-M7 Core Introduction • Cortex-M7 documentation: *Arm Cortex-M7 Processor Technical Reference Manual, DDI 0489D Revision r1p1* at www.arm.com
Arm CoreLink Generic Interrupt Controller (GIC-500)	• The Arm GIC architecture divides interrupt management and processing among a distributor block and one or more CPU interface blocks. • The GIC-500 includes a register set for managing interrupt sources, interrupt behavior, and interrupt routing.	• Overview: Arm CoreLink Generic Interrupt Controller (GIC-500) • *Arm CoreLink GIC-500 Generic Interrupt Controller Technical Reference Manual* at infocenter.arm.com
Device debug and trace interfaces	Based on Arm CoreSight™ architecture supplemented with the Secured JTAG controller (SJC) to support security features	• Arm debug documentation: *Arm Debug Interface Architecture Specification ADIv5.0 to ADIv5.2* and *Arm CoreSight Architecture Specification* at www.arm.com

5.2 Cortex-A53 cluster complex

The Arm Cortex-A53 complex provides a high-performance host processing environment. It also supports lower power run modes on the chip through frequency scaling and power gating on unused non-primary cores.

The GIC-500 module provides interrupt management and routing outside of the processors.

5.2.1 Arm Cortex-A53 MPCore

The Arm® Cortex®-A53 cluster is a mid-range, low-power Arm processor that implements the Armv8-A architecture. Each chip includes two identical Arm Cortex-A53 clusters. The implementation options for each chip are shown below.

Preliminary Information COMPANY CONFIDENTIAL Beijing HJ Automotive Technology Co., Ltd. c8c62e8-1821-48a8-b251-5903e624c1

Table 7. Arm Cortex-A53 cluster configuration by chip

Implementation option	Quad	
	Cluster 0	Cluster 1
Number of cores	2	
L1 data cache size	• 32 KB 2-way set associative instruction cache • 32 KB 4-way set associative data cache	
L2 cache	Included	
L2 cache size	512 KB	
SCU-L2 cache protection	Included	
Advanced SIMD and floating-point extension[1]	Included	
Cryptography extension	Included	
CPU cache protection	Included	
AMBA 5 CHI or AMBA 4 ACE interface	AMBA 4 ACE	
v7 or v8 debug memory map	v8	

1. Also, referred to as FPU and Neon extension

Additionally, the standard features include:

- A Snoop Control Unit (SCU) to maintain L1 cache coherency among the cores
- A generic timer to schedule events and trigger interrupts based on an incrementing counter value. It provides generation of timer events as interrupt outputs and generation of event streams.
- Instruction tracing capability through Embedded Trace Macrocell
- A cross-trigger module

Each core includes:

- Arm v8-A instruction set architecture and both AArch32 and AArch64 execution states
- Asymmetric/symmetric multi-processing capability
- A Floating Point Unit (FPU) implemented with the Arm Vector Floating Point v3 architecture with 16 double-precision registers (VFPv3-D16), compliant with the ANSI/IEEE Std 754-1985 and IEEE Standard for Binary Floating-Point Arithmetic (IEEE 754)
- A Cortex-A53 Neon Media Processing Engine (MPE), which extends the capabilities of the FPU with an implementation of the Arm Neon Advanced SIMD instruction set for further acceleration of media and signal processing functions. It includes an additional register set supporting a rich set of SIMD operations over 8, 16, and 32-bit integer and 32-bit floating-point data types.
- In-order 8-stage dual issue pipeline implementation
- 512-KB L2 cache with ECC protection including software control for L2 cache flush.
- MMU that provides fine-grained memory system control through a set of virtual-to-physical address mappings and memory attributes. For example, cacheability and shareability, held in page tables.
- Debug resources for supporting trace and cross-trigger functions[1]
- A set of timer registers

[1] The device debug and trace is based on the Arm CoreSight™ architecture. For more information on the CoreSight Debug components, see the Arm® CoreSight™ Technical Reference Manual.

- A Generic Interrupt Controller (GIC) CPU interface, in conjunction with the external (to the clusters) GIC-500 Generic Interrupt Controller, acts as a centralized resource for supporting and managing interrupts.
  - Includes registers for managing interrupt sources, interrupt behavior, and interrupt routing to the Cortex-A53
  - Supports the Arm architecture security extensions
  - Supports enabling, disabling, and generating cluster interrupts from hardware (peripheral) interrupt sources
  - Supports generation of software interrupts
  - Supports interrupt masking and prioritization
  - Supports virtualization of interrupts for each Cortex-A53 CPU
  - Supports Interrupt Translation Service (ITS) that provides ID translation and core migration for message-based interrupts

The Cortex-A53 supports cache protection in the form of ECC or parity on all the RAM instances:

- L2 Cache Tag Array is protected with the Single-Bit Error Correction, Double-bit Error Detection (SECDED) capability through ECC protection. On a single-bit upset, the tag is rewritten with the corrected data and the access is retried. On a multi-bit upset, the tag is invalidated. The event is reported in the L2MERRSR register. Uncorrectable errors in the L2 Cache Tag Array cause the nINTERRIRQ interrupt line to be asserted.
- L2 Cache Data Array is protected with the SECDED capability through ECC protection on L2 Cache Tag and Data arrays. On a single-bit upset, the data is rewritten in-line. On a multi-bit upset, the tag is invalidated. The event is reported in the L2MERRSR register. Uncorrectable errors in the L2 Data Array because of an instruction fetch, TLB pagewalk, or load instruction result in either a precise data abort or a prefetch abort, and the event is reported to the L2MERRSR register. Uncorrectable errors in the L2 Data Array because of cache eviction cause the nINTERRIRQ interrupt line to be asserted. The event is reported in the L2MERRSR register.
- L1 Instruction Cache Tag arrays are protected with the SED capability through the parity coverage. In the event of a parity mismatch, both lines in the cache set are invalidated, then the line requested is refetched. The event is reported to the CPUMERRSR register.
- L1 Data Cache Tag arrays are protected with the Single-Error Detection (SED) capability through the parity coverage. In the event of a parity mismatch, the line is cleaned then evicted from the L1. The correct address for eviction is retrieved from the SCU duplicate tags. The event is reported to the CPUMERRSR register.
- L1 Instruction Cache Data arrays are protected with SED capability through the parity coverage. In the event of a parity mismatch, both lines in the cache set are invalidated, then the line requested is refetched. The event is reported to the CPUMERRSR register.
- L1 Data Cache Data arrays are protected with SECDED capability through ECC protection. On a single-bit upset, the data is rewritten in-line and the line is invalidated from the L1 cache. The event is reported to the CPUMERRSR register. On a multi-bit upset, the line is invalidated from the L1 cache and either causes an abort or the nINTERRIRQ interrupt line to be asserted. The event is reported to the CPUMERRSR register.

NOTE

nINTERRIRQ is mapped as an SPI in interrupt controllers and also reported as an NCF in FCCU.

5.2.2 Arm CoreLink Generic Interrupt Controller (GIC-500)

The Arm GIC architecture divides interrupt management and processing among a distributor block and one or more CPU interface blocks. The GIC-500 module is the distributor block. It provides central interrupt management and interrupt routing for both the clusters. Each processor core has a GIC CPU interface, which enables GIC-500 to route interrupts to either individual or multiple cores, depending on the interrupt type.

Freescale Semiconductor, Inc.
COMPANY PROPRIETARY
Beijing CH Electronics Technology Co., Ltd.
c8c2e5-5-821485-2-1-3-3-624-1

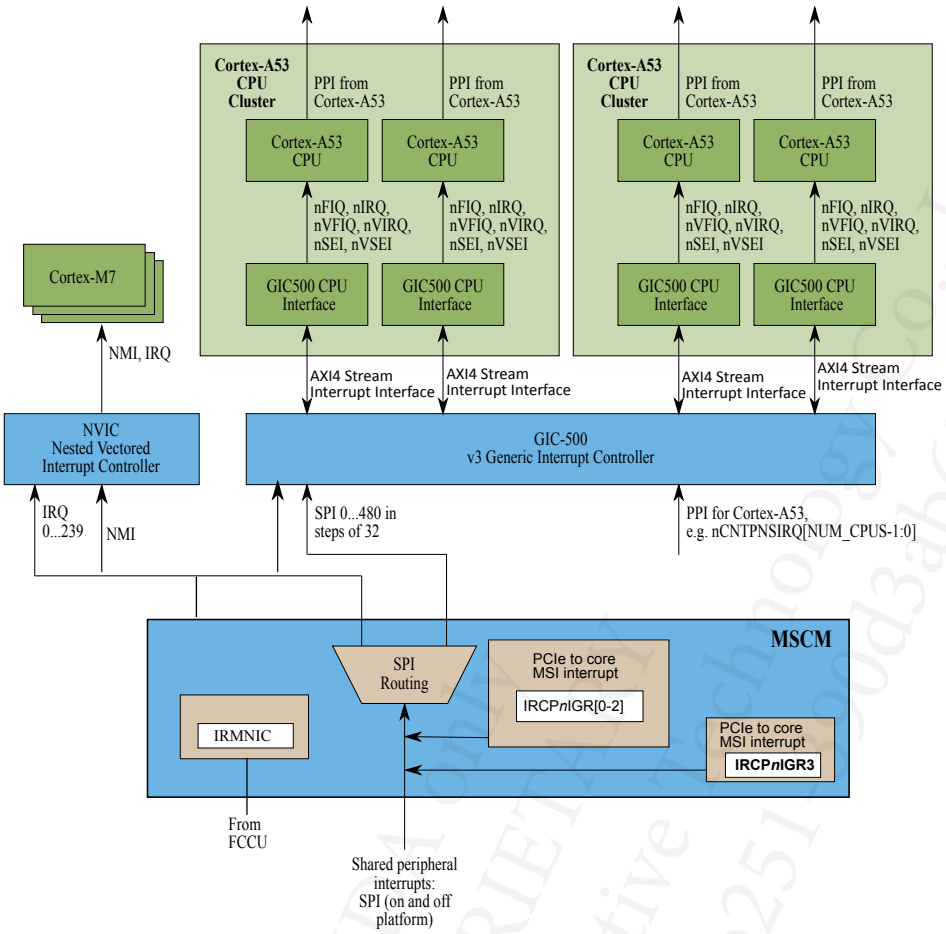

Figure 6. Interrupt architecture

The GIC-500 module includes a register set for managing interrupt sources, interrupt behavior, and interrupt routing. Support is included for:

- Enabling, disabling, and generating processor interrupts from the hardware (peripheral) interrupt sources
- 16 software-generated interrupts (SGIs)
- Interrupt masking and prioritization
- Uniprocessor and multiprocessor environments
- Wakeup events in power-management environments
- Locality-specific peripheral interrupts (LPIs)
- Shared peripheral interrupts (SPIs)
- 16 private peripheral interrupts (PPIs)

Provided under NXP ONLY

5.3 Operation details

5.3.1 Operation mode

The chip supports two modes of operation for Cortex-A53 clusters.

- **Decoupled mode**: The decoupled or performance mode allows the two Cortex-A53 clusters to operate in an independent manner. All the four cores are available for the software application.
- **Lock step mode**: In this mode, the two Cortex-A53 clusters operate in delayed lockstep configuration, that is, core0 of cluster0 is in lock step with core0 of cluster1 and core1 of cluster0 is in lock step with core1 of cluster1. Only cluster0 is available in the system for software application while cluster1 works as a checker or redundant module. The clock, reset, or other configurations of cluster1 and its cores, as available in MC_RGM, MC_ME, and A53 GPR registers, are not used in this mode.

The default mode of operation for the Cortex-A53 clusters is the decoupled mode. The selection between lockstep and decoupled mode is controlled by the A53 GPR06[CA53_LOCKSTEP_EN] register bit.

NOTE

The operating mode should be changed only when A53 reset domain is in the reset state.

5.3.2 Booting Cortex-A53 cores in 32-bit mode

The default boot mode of Cortex-A53 core is AArch64. Booting in AArch32 mode shall be done through the exception level in software, that is, by moving from the higher exception level to lower exception level.

5.3.3 Cluster clock gating

For information about turning on the Cortex-M7 application cores or the Cortex-A53 cluster cores, see the section "Core turn-on sequence" in the Reset chapter of this document. The Technical Reference Manual (TRM) provides more detail about core shutdown procedures.

- Cortex-A53 Technical Reference Manual

  http://infocenter.arm.com/help/topic/com.arm.doc.ddi0500f/DDI0500F_cortex_a53_r0p4_trm.pdf

- Cortex-M7 Technical Reference Manual

  http://infocenter.arm.com/help/topic/com.arm.doc.ddi0489b/DDI0489B_cortex_m7_trm.pdf

5.3.4 Cortex-A53 system counter

The A53 system counter value is driven from a 64-bit counter generated of a divided clock of FXOSC_CLK. The divide factor is controlled by GPR00[CA53_COUNTER_CLK_DIV_VAL]. The divide value equals to GPR00[CA53_COUNTER_CLK_DIV_VAL]+1.

The system counters get reset along with Cortex-A53 clusters whenever A53 reset domain is reset following the sequence described in section "Software reset partition turn-off flowchart" of Reset chapter.

5.3.5 Cortex-A53 system error interrupt

NMIs from FCCU and WKPU are routed as system error interrupts to the Cortex-A53 cores. The reporting of the NMIs to each of the four cores can be enabled through the IRNMIC register inside MSCM.

5.3.6 Cortex-A53 wake-up from WFE

Executing the SEV instruction from any of the Cortex-A53 core generates a wake-up event for all the Cortex-A53 cores available in the chip. Cortex-M7 cores can also generate a wake-up event for Cortex-A53 cores in a cluster using GPR01 in A53_GPR (bit 0 – cluster0 and bit 1 – cluster1). The GPR mechanism is not used by the Cortex-A53 cores and executing SEV instruction suffices. GPR01[bit 1] is not used when Cortex-A53 clusters are operating in the lockstep mode as only cluster0 is operational effectively.

5.3.7 Cortex-A53 PMUEVENT bus signals observation

The chip contains observers to capture and count the number of times events are signaled on PMUEVENT bus of Cortex-A53 cores. This information can be particularly useful to Cortex-M7 cores for debug or safety application. There is one PMUEVENT bus observer per Cortex-A53 core available in the chip. There are 30 counters present inside a PMUEVENT bus observer, one counter per bus signal. Each counter has a control register and a status register.

Base address of PMUEVENT observer

- A53 cluster0 core0 PMUEVENT bus observer - 0x4004_8100
- A53 cluster0 core1 PMUEVENT bus observer - 0x4004_8200
- A53 cluster1 core0 PMUEVENT bus observer - 0x4004_8300
- A53 cluster1 core1 PMUEVENT bus observer - 0x4004_8400

Procedure to read event count on PMUEVENT bus signals

The software should follow the following procedure to enable the counter and read the count of a number of times an event is signaled on a PMUEVENT bus signal "a" of a Cortex-A53 core. Here, "a" ranges from 0 to 29.

1. Program fields of PMUEVENT Observer Control Register (CTLa) to values mentioned below.
   - REVTINPSEL = 2'b01
   - CTRSTRTSEL = 2'b01
   - CTRSTPSEL = 2'b10
   - CPYCOUNT = 1'b1
   - CLRCNTR = 1'b0

2. On a PMU interrupt or FCCU interrupt (due to memory errors related PMUEVENTs, see FCCU NCF list list attached to this document), read the count value in the status register - PMUEVENT Observer Status Register (STATa).
3. Program CTLa[CLRCNTR] to 1'b1 in order to clear the counter and the status register.

5.3.7.1 PMUEVENT observer register descriptions

NOTE

For more information on the base address of PMUEVENT observer, see the section base address of PMUEVENT observer.

5.3.7.1.1 PMUEVENTOBSERVER memory map

PMUEVENTOBSERVER base address: 0h

Offset	Register	Width (In bits)	Access	Reset value
0h - 74h	PMUEVENT Observer Control Register (CTL0 - CTL29)	32	RW	0000_000Ch
80h - F4h	PMUEVENT Observer Status Register (STAT0 - STAT29)	32	RW	0000_0000h

The Cortex-A53 clusters are configurable to run either independently or in a delayed lockstep configuration. In the lockstep mode, one cluster is considered the main cluster and the second cluster is considered the checker cluster. From a software perspective, the two clusters operate as a single cluster in the lockstep mode. Cortex-A53 Cluster0 is the main execution cluster, where Cortex-A53 Cluster1 follows execution of Cortex-A53 Cluster0. The replicated processing elements within each cluster contain:

- Cores
- L1 Cache Controller
- L2 Cache Controller
- Snoop Control Unit (SCU)

Equivalent operation of replicated resources is supervised by comparators (RCCU) on all functional signals leaving the cluster for the rest of the MCU. Any operational deviations between the supervised signals causes the FCCU to be notified of the discrepancy.

The Checker Cluster does not have a direct connection to the system. All of the outputs of Checker Cluster that target the system (as well as any other non-duplicated resource, like cache memories) terminates in an RCCU for analysis, and all the inputs to Checker Cluster from the system are siphoned from the main cluster system inputs. An abstract view of the implementation including delays and RCCUs is shown in the following figure, but does not show the local memory.

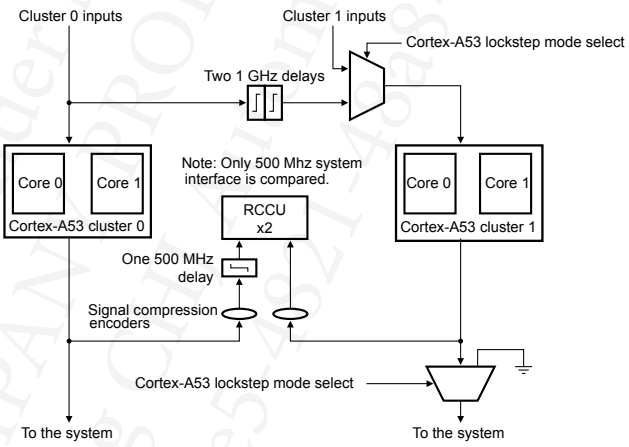

Figure 7. Cortex-A53 Integration

Similarly, the GIC500 interrupt controller for the Cortex-A53 can be optionally run in a delayed lockstep configuration. In the lockstep mode, one GIC500 instance is considered the main component and the second GIC500 instance is considered the checker component. From a software perspective, two components operate as a single interrupt controller in the lockstep mode. GIC500_0 is the main interrupt controller component, where GIC500_1 follows execution of GIC500_0.

Equivalent operation of replicated resources is supervised by comparators (RCCU) on all functional signals leaving the cluster for the rest of the MCU. Any operational deviations between the supervised signals causes the FCCU to be notified of the discrepancy.

The checker GIC500_1 does not have a direct connection to the system. All of the outputs of checker GIC500_1 that target terminates in an RCCU for analysis, and all the inputs to Checker GIC500_1 from the system are siphoned from the Main Cluster system inputs. An abstract view of the implementation including delays and RCCUs is shown in figure, but does not show the local memory.

NOTE

There are controls for selecting to run the Cortex-A53 clusters in either lockstep mode or performance mode. However, in either mode the GIC500 continues to run in lockstep mode with GIC500_0 as the main interrupt controller component.

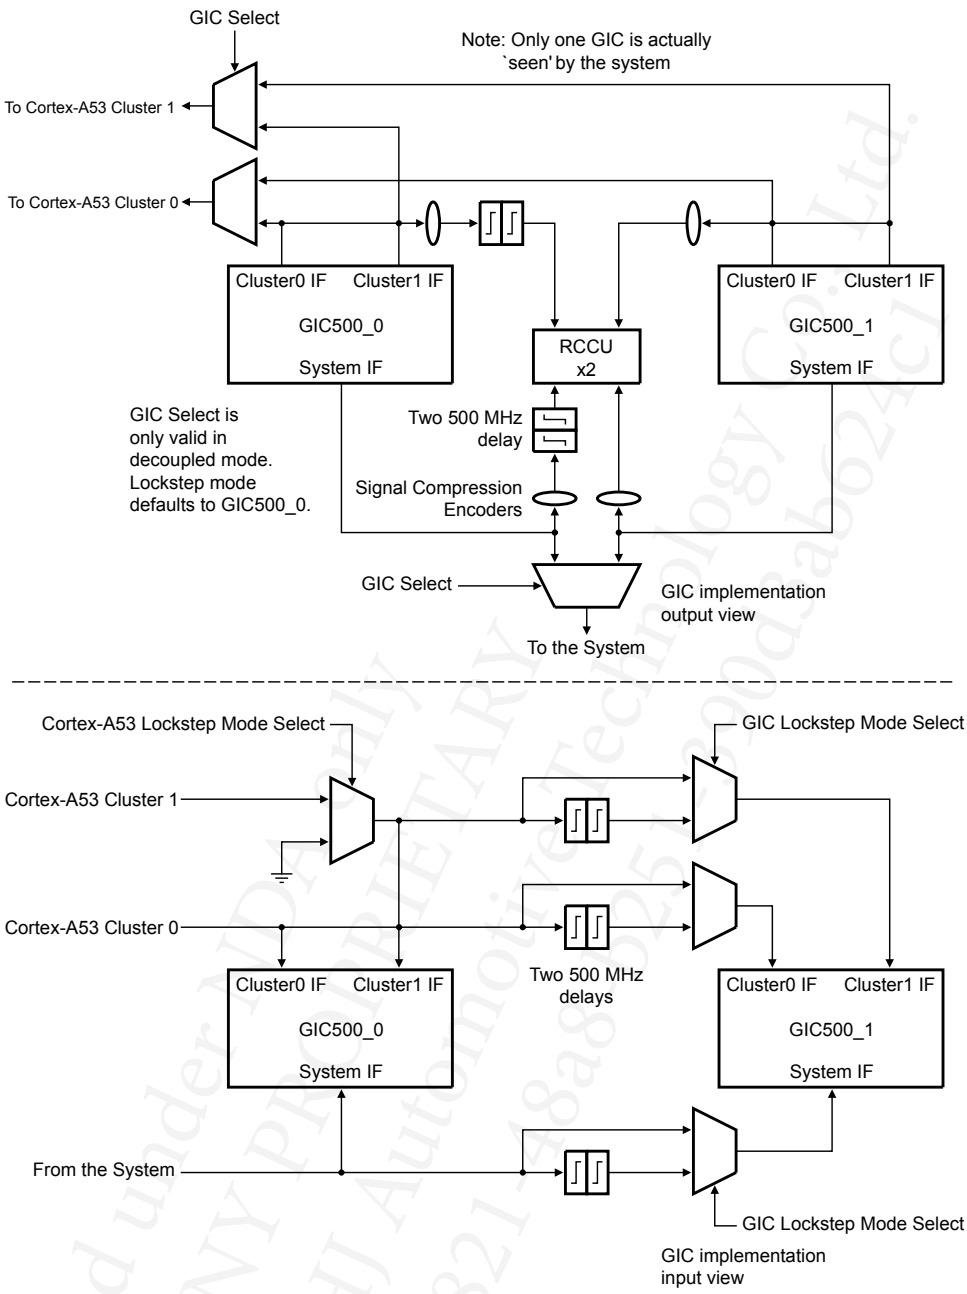

Figure 8. GIC500 Integration

5.3.9 Cortex-M7 lockstep operation

The checker Cortex-M7 does not have a direct connection to the system. All of the outputs of checker CM7 that target the system (as well as any other non-duplicated resource, like cache memories) will terminate in an RCCU for analysis, and all the inputs to Checker CM7 from the system will be siphoned from the Main Core system inputs. An abstract view of the implementation including delays and RCCUs is shown in the following figure.

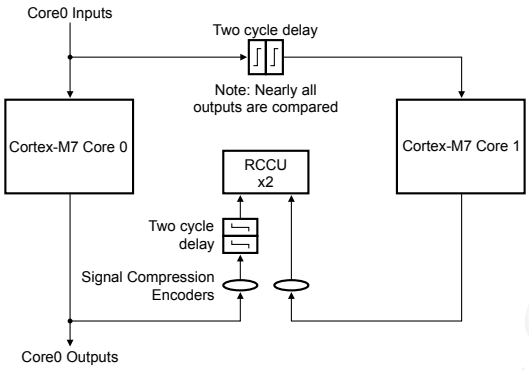

Figure 9. Cortex-M7 Integration

5.4 Cortex-M7 overview

5.4.1 Cortex-M7 core introduction

The Cortex-M7 processor is a highly efficient, high-performance embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline and supports dual-issue of load/load and load/store instruction pairs to multiple memory interfaces.

Memory interfaces that the processor supports include:

- Tightly Coupled Memory (TCM) interface
- Harvard instruction and data caches and AXI master (AXIM) interface
- Dedicated low-latency AHB-Lite peripheral (AHBP) interface

The processor includes a Memory Protection Unit (MPU) that you can configure to protect regions of memory. The MPU contains support for up to 16 regions.

The Cortex-M7 processor includes floating-point arithmetic functionality, with support for single-precision arithmetic.

The Cortex-M7 core includes several memory interfaces:

- 64-bit Data Tightly Coupled Memory (DTCM), which is split into two interleaved 32-bit interfaces named D0TCM and D1TCM. RAM is expected to be connected to these interfaces and provides zero wait state data fetches.
- 64-bit AXI AMBA4 memory interface with a 32K instruction cache and a 32K data cache for efficient access to external resources
- 32-bit AHBP Peripheral port for interfacing with low latency on chip peripherals
- 32-bit AHBS Slave port for interfacing with slaves such as DMA

The Cortex-M7 core also includes:

- Nested Vectored Interrupt Controller (NVIC)
- Debug and Trace Unit (Coresight components)

The Cortex-M7 processor is intended for deeply embedded applications that require fast interrupt response features.

With D-Cache enabled, Cortex-M7 can randomly perform speculative load from any Normal type memory space through its AXIM bus.

5.4.1.1 Buses, interconnects, and interfaces

The Arm Cortex-M7 core includes four buses, as described in the following table.

Bus name	Description
AXI Master (AXIM) bus	This bus connects to NoC and provides the Cortex-M7 high-bandwith access to memory and peripherals.
AHB Slave (AHBS) bus	The AHBS interface provides system access to Cortex-M7 TCM.
AHB Peripheral (AHBP) bus	This bus connects to NoC and provides the Cortex-M7 low-latency D-side access to peripherals.
Private Peripheral bus (PPB)	The PPB bus provides access to these modules: • Arm modules such as the NVIC, ETCM, ITM, DWT, and ROM tables • Miscellaneous Control Module (MCM)

5.4.2 Debug facilities

This device has extensive debug capabilities including run control and tracing capabilities. The standard Arm debug port that supports JTAG.

Chapter 6
NoC Subsystem

6.1 Introduction

The NoC is an interconnect matrix which supports communication between various initiators and targets. A NoC instance on the Common Chassis supports communication to and from system resources including core clusters, cores, peripherals, and system RAM. A NoC instance in the Accelerator subsystem supports communication to and from modules in that subsystem.

6.2 Functional description

6.2.1 Observability

6.2.1.1 Concepts

The technology, which allows activity within NoC interconnects to be observed and reported, provides the following services:

- Error detection, logging, and reporting.
- Packet tracing.
- Traffic or link statistics computation.
- Transaction latency profiling.
- Events or statistics reporting to the system via industry standard third-party interface, MIPI® STPv2 over the ARM® ATB Coresight™ trace interface.

To provide these services, NoC technology uses task-specific probes placed on probe points located in the datapath topology. Traced packets and observed events are gathered by observers, which can issue interrupts and forward detailed data to supported third-party interfaces.

6.2.1.1.1 Packet and transaction probes

NoC packet probes provide the following features:

- Run-time programmable selection of packet probe points for probes connected to multiple points.
- Run-time programmable filtering for packet tracing.
- Recording of traffic and link statistics.
- Event counting of signals external to the NoC.
- Generation of trace or statistic packets, or both, for the observation network.
- Optional time stamping of packets.

NoC transaction probes provide the following features:

- Run-time programmable selection of transaction probe points.
- Transaction profiling in terms of latency or number of pending transactions.
- Event counting of signals external to the NoC.
- Generation of statistic packets for the observation network.
- Optional time stamping of packets.

NoC error probes detect packets in error and forward them to the associated observer via the observation network. The error packets are recorded by error loggers in the observer. An error logger can be programmed to assert an output signal when an error packet is received. The signal can be used as a system interrupt. Observers can contain one or more loggers and associated interrupt signals, each dedicated to specific error codes or error security levels.

By default, a new error can only be logged when the previous one is cleared by proper register access. If an error probe reports new errors and the associated logger is already full, then subsequent errors are dropped. Alternatively, the error logger can be programmed to queue up error packets and only accept them once the currently logged error has been cleared.

6.2.1.1.2 Observers

Data collected by certain NoC probes can be transferred to NoC observer units via the observation network.

Observers can be connected to NoCs via an ATB™ interface, with MIPI STPv2 encapsulation and time stamping. Collected data can be forwarded either to an off-chip interface, or on-chip storage buffer for analysis by an on-chip debugger.

6.2.1.1.2.1 Time stamping the observation subsystem

Data collected by certain NoC probes can be transferred to NoC observer units via the observation network.

Observers can be connected to NoCs via an ATB® interface, with MIPI STPv2 encapsulation and time stamping. Collected data can be forwarded either to an off-chip interface, or on-chip storage buffer for analysis by an on-chip debugger.

6.2.1.1.2.2 Time stamping probed events

The timestamp is added to the observation packet, regardless of whether the probe is configured for tracing or statistic collection.

The timestamp remains attached to the observation packet until the packet reaches the observer. This timestamp value is extracted and the difference between the current timestamp and the previous timestamp value, which was sent in the STPv2 stream, is calculated. This delta value is appended to the first STPv2 packet embedding the ATB packet.

6.2.1.2 Operation

6.2.1.2.1 Logging errors

6.2.1.2.1.1 Reconstructing transaction addresses

6.2.1.2.1.1.1 Calculating initiator – target transaction addresses

Once the initiator–target mapping associated with the logged packet has been identified, the complete transaction address, either from the perspective of the initiator or the target, can be calculated.

6.2.1.2.1.1.1.1 Initiator transaction address

From the perspective of the initiator, calculate InitAddr by:

```
InitAddr = Init localAddress | Addr
```

where:

- Addr – Logged packet transport address Addr given in register ErrLog3 and, additionally, ErrLog4, in the case where the address exceeds 32 bits.
- Init localAddress – Value from the identified initiator-target mapping in subsection "Aperture values” of the structure information file.

6.2.1.2.1.1.1.2 Target transaction address

The transaction address from the perspective of the target, calculate TargAddr by:

```
TargAddr = Targ localAddress | Addr
```

Where the definitions of the terms are the same as used for calculating the initiator transaction address (see Initiator transaction address).

6.2.1.2.2 Tracing packets

6.2.1.2.2.1 Basic packet tracing

To trace packets, the packet probe must be programmed as follows:

1. Set field TraceEn of register MainCtl to 1 to enable forwarding of traced packets to the connected observer. Optionally set field PayloadEn of register MainCtl to 1 if the packet payload should be included in the trace.
2. Set register TracePortSel to the value corresponding to the probe point of interest.
3. Set field GlobalEn of register CfgCtl to 1.
4. Set register FilterLut to -1 (all bits set).

NOTE

A lookup table acts as a simple gate when there are no filters.

After competing the programming sequence above, filters must be configured (see Filtering packets).

6.2.1.2.2.2 Filtering packets

Each packet probe supports up to four packet filters.

The following list comprises the complete set of filter registers, where the value for filter *n* ranges from 0 to 3.

- Filters_N_RouteIdBase
- Filters_N_Status
- Filters_N_RouteIdMask
- Filters_N_Length
- Filters_N_AddrBase_Low
- Filters_N_Urgency
- Filters_N_AddrBase_High
- Filters_N_UserBase
- Filters_N_WindowSize
- Filters_N_UserMask
- Filters_N_UserBaseHigh
- Filters_N_UserMaskHigh
- Filters_N_Opcode

6.2.1.2.2.2.1 Filtering on an address range

Packets which target a given address range of a specific mapping may be filtered by programming the set of filter registers.

Table 9. Packet filtering registers

Register	Value
Filters_N_RouteIdBase	RouteId subfields Initflow, TargFlow, and TargSubRange.
Filters_N_RouteIdMask	Set bits to 1 if RouteId fields are to be used by filter.
Filters_N_AddrBase_Low/ High	Address offset from initiator or target local address.
Filters_N_WindowSize	Log_2 of address range.

6.2.1.2.2.2.2 Selecting packets based on packet opcode

Packets can be selected based on the opcode field (Opc) in the packet header using register Filters_N_Opcode. In the following example, the filter is required to select all packets with Opc equal to RD and all packets belonging to a locked sequence.

Program the register fields of Filters_N_Opcode as shown in Table 10.

Table 10. Packet filtering registers

Field name	Setting
RdEn	1
LockEn	1

The other register fields are set to 0. Figure 10 shows a sequence of packets with the resulting filter hits.

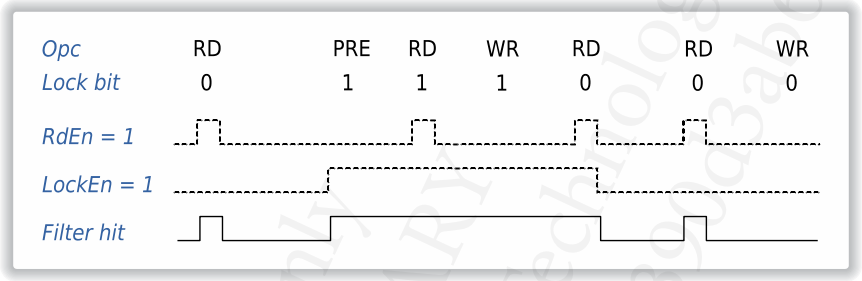

Figure 10. Sequence of packets

6.2.1.2.2.2.3 Excluding packet header fields from filter criteria

To ignore a specific packet header field in the filter, set its associated register with the value in shown Table 11.

Table 11. Excluding packet header field register settings

Register name	Setting
Filters_N_RouteIdMask	0
Filters_N_WindowSize	-1[1]
Filters_N_Opcode	Fh
Filters_N_Status	3h
Filters_N_Length	Fh
Filters_N_Urgency	0
Filters_N_UserMask (if present)	0
Filters_N_UserMaskHigh (if present)	0

1. Setting register Filters_N_WindowSize to –1 programs the filter to accept packets which target anywhere in the full address range supported by the transport network. Hence the address is effectively excluded from the filter criteria.

6.2.1.2.2.2.4 Tracing all packets

If it is required to trace all packets, then the probe's filtering function must be programmed as follows:

1. Program one of the filters to accept all packet header field values. Set the filter registers to the values given in the table in the preceding section "Excluding packet header fields from filter criteria".

2. Program register FilterLut to select the output of filter programmed in the previous step.

6.2.1.2.2.3 Tracing error packets

Error packets, that is packets with header field Status set to ERR, are not traced by default. To include error packets in the trace output, write MainCtl[ErrEn] = 1 and MainCtl[ErrEn] = 1.

6.2.1.2.2.4 Combining filters

A look-up table (LUT) is instantiated in the probe, which allows a hit to be generated on any logical combination of packet filters. The logic function is programmed via register FilterLut. The value programmed in the register corresponds to the truth table applied on the filter outputs.

For example, with two filters F0 and F1, sixteen possible functions can be defined, a subset of which is shown in the following table.

Table 12. Example subset of sixteen possible functions

Filter hit			Required filter combination					
F1	F0		F0	F1	F1 & F0	F1 | F0	F1 ^ F0	~F0
0	0		0	0	0	0	0	1
0	1		1	0	0	1	1	0
1	0		0	1	0	1	1	1
1	1		1	1	1	1	0	0
			Value to program in FilterLut					
			Ah	Ch	8h	Eh	6h	5h

NOTE

In this example, setting register FilterLut to Fh will generate a LUT hit for any combination of filter hits, effectively bypassing the filters.

6.2.1.2.2.5 Configuring and managing trace alarm events

Trace alarm events can be separately enabled, recorded, and cleared using registers TraceAlarmEn, TraceAlarmStatus, and TraceAlarmClr respectively. In each register, a dedicated bit is associated with each filter hit; the MSB is associated with the LUT hit.

The trace alarm logic can be configured to drive output signal TraceAlarm if one or more trace alarm events are recorded in register TraceAlarmStatus. Signal TraceAlarm can be used directly as an interrupt source, or can be routed through a sideband manager.

To use the trace alarm feature

1. Enable hits from selected filters 0 to (nFilter – 1) to generate a trace alarm by setting register TraceAlarmEn bits 0 to (nFilter – 1) to 1.
   - Optionally, enable LUT hits to generate a trace alarm by setting the MSB of TraceAlarmEn.
2. Set field AlarmEn to 1 in register MainCtl in order to activate signal TraceAlarm when a trace alarm occurs.

If TraceAlarm is asserted, the interrupt service routine should:

1. Identify the source or sources of the trace alarm by reading register TraceAlarmStatus.
2. Clear the source or sources of the trace alarm by setting the corresponding bits to 1 in register TraceAlarmClr. Signal TraceAlarm deasserts when all bits in TraceAlarmStatus have been cleared.

6.2.1.2.3 Collecting statistics

6.2.1.2.3.1 Counting packets over fixed period

The following programming sequence counts packets at a given probe point using statistic counter 0.

1. Set field StatEn to 1 in register MainCtl.
2. Set register Counters_0_PortSel to the value corresponding to the probe point of interest.
3. Set register Counters_0_Src to 6h (PKT) to count packets.
4. Specify the period during which the packets should be counted by setting register StatPeriod to: log2 (interval expressed in number of probe clock cycles)
5. Set field GlobalEn of register CfgCtl to 1 to enable packet counting.

Once time $2^{StatPeriod}$ has elapsed, the number of packets counted is dumped to the observer.

6.2.1.2.3.2 Counting filtered packets over fixed period

The following programming sequence counts hits from packet filter 2 using statistic counter 0.

NOTE

The important distinction between this sequence and the one in a related programming example (see Counting packets over fixed period) is that the probe port is selected using register TracePortSel rather than Counters_0_PortSel

1. Set field StatEn to 1 in register MainCtl.
2. Set register TracePortSel to the value corresponding to the probe port of interest.
3. Set register Counters_0_Src to 0xE (FILT2) to count packets from filter 2.
4. Specify the period during which the packets should be counted by setting register StatPeriod to: log2(interval expressed in number of probe clock cycles)
5. Set field GlobalEn of register CfgCtl to 1 to enable packet counting.

Once time $2^{StatPeriod}$ has elapsed, the number of filtered packets counted is dumped to the observer.

6.2.1.2.3.3 Measuring bandwidth

The following programming sequence example shows how a packet probe can be used to measure the average bandwidth, over a given interval, at a probe point.

Some important points to note about this example are:

- Statistics counters are chained together to support the maximum theoretical bandwidth. Counter 0 is configured to count bytes; counter 1 increments when counter 0 rolls over.
- The counter values are dumped to an observer after time $2^{StatPeriod}$.
- A maximum bandwidth threshold is defined. A statistics alarm signal is asserted if this threshold is exceeded when statistics data is dumped. The comparison is made against the concatenated value of the two counters.

The programming sequence is as follows:

1. Set field StatEn to 1 in register MainCtl.
2. Set register Counters_0_PortSel to the value corresponding to the probe point of interest.
3. To count bytes, set register Counters_0_Src to 8h (BYTES).
4. To increment when counter 0 wraps, set register Counters_1_Src to 10h (CHAIN).

5. Specify the period during which the bytes should be counted by setting register StatPeriod to: log2 (interval expressed in number of probe clock cycles)
6. Set register Counters_0_AlarmMode to 2h (MAX) and Counters_1_AlarmMode to 0h (OFF). A statistics alarm is raised if the combined count of counter 0 and counter 1 is greater than the value specified in register StatAlarmMax.
7. Set register StatAlarmMax to a value corresponding to the upper bandwidth limit required to trigger the statistics alarm.
8. Set field AlarmEn to 1 in register MainCtl. Ensure bit 0 of register StatAlarmEn is set to 1 (default value) if the alarm output signal StatAlarm is required.
9. Set field GlobalEn of register CfgCtl to 1 to enable the counting of bytes.

In the event StatAlarm is asserted, the interrupt service routine should:

1. Optionally read the number of packets contained in registers Counters_0_Val and Counters_1_Val.
2. Clear the statistics alarm by setting bit 0 to 1 in StatAlarmClr. The signal StatAlarm deasserts.

NOTE

Statistics counters are frozen and the dump timer is suspended until bit 0 is set to 1 in register StatAlarmClr.

6.2.1.2.4 Transaction profiling operation

The programming sequence examples in this section constitute, for a given category of use cases, the obligatory base from which to develop sequences to handle specific needs within the category.

6.2.1.2.4.1 Measuring latency

The following example of a run-time programming sequence shows how a transaction probe can be used to measure transaction latency.

The measurement specification is:

- For init0, monitor delays for read transactions only.
- For init1, monitor delays for read and write transactions.

6.2.1.2.4.2 Programming the packet probe statistics subsystem

The statistics counters in the packet probe unit of the transaction probe must be programmed to count the delay events recorded by the transaction profiler unit.

1. Map the five delay event bins, associated with transactions issued by init0, from the transaction profiler unit to statistics counters in the packet probe unit by programming the following registers:
   - Counters_0_Src = 20h => Counts the number of transactions from init0 with a delay between 0 and 1.
   - Counters_1_Src = 21h => Counts the number of transactions from init0 with a delay between 2 and 4.
   - Counters_2_Src = 22h => Counts the number of transactions from init0 with a delay between 5 and 9.
   - Counters_3_Src = 23h => Counts the number of transactions from init0 with a delay between 10 and 99.
   - Counters_4_Src = 24h => Counts the number of transactions from init0 with a delay greater than 100.
2. Map the five delay event bins, associated with transactions issued by init1, from the transaction profiler unit to statistics counters in the packet probe unit by programming the following registers:
   - Counters_5_Src = 25h => Counts the number of transactions from init1 with a delay between 0 and 1.
   - Counters_6_Src = 26h => Counts the number of transactions from init1 with a delay between 2 and 4.
   - Counters_7_Src = 27h => Counts the number of transactions from init1 with a delay between 5 and 9.
   - Counters_8_Src = 28h => Counts the number of transactions from init1 with a delay between 10 and 99.

- Counters_9_Src = 29h => Counts the number of transactions from init1 with a delay greater than 100.

3. Set register StatPeriod to $\log_2$(period), that is, the period during which delay events should be counted before being sent to the observer.
4. Set field StatEn of register MainCtl to 1 to enable the statistics counters to count delay events.

6.2.1.2.4.3 Enabling the transaction probe

1. Set field GlobalEn of register CfgCtl to 1 to enable the statistics counters.
2. Set register En to 1 to enable the transaction profiling counters.

6.2.1.2.4.4 Programming the init0 NIU transaction filter

1. Set register Mode to 1 to set the delay mode to LATENCY.
2. Set field RdEn of register Opcode to 1 to monitor read transactions only.

6.2.1.2.4.5 Programming the init1 NIU transaction filter

1. Set register Mode to 1 to set the delay mode to LATENCY.
2. Set fields RdEn and WrEn of register Opcode both to 1 to monitor read and write transactions.

6.2.1.2.5 Activating observer debug output

6.2.1.2.5.1 STPv2 interface

The observers generate STPv2 formatted trace packets. To enable trace output, the following registers must be programmed.

1. Specify the required period between STP synchronization sequences in register AsyncPeriod. Ensure that the value of AsyncPeriod is large enough to allow STPv2 cells, encapsulating Trace / Statistic Packets, to be inserted in between STPv2 synchronization sequences.
2. Ensure that register STPv2En is set to 1 to enable the STPv2 interface.
3. Set register AtbId to a value that is unique not only within the NoC but also within the debug system.
4. Set register AtbEn to 1 to enable the ATB function.

6.2.1.3 Technical reference

NoC observability technology comprises two principle components: observation probes and observer units.

The section provides detailed technical reference information for these components, along with the NoC packet format description needed to analyze error logs and packet trace information.

6.2.1.3.1 Observation probes

This section provides detailed technical reference information for the NoC Observability technology collectively called observation probe units.

6.2.1.3.1.1 Packet probe

The NoC packet probe unit collects trace and statistics data. The unit can be used in conjunction with the NoC transaction profiler unit to create a transaction probe.

6.2.1.3.1.1.1 Packet probe features

The unit has the following main features:

- Support for any transport packet format and serialization.
- Trace mode with programmable packet filters.
- Optional packet payload tracing.
- Programmable flow-control modes: Overflow Management and Intrusive
- Statistics can be collected and sent to an observer either periodically or after manual triggering.
- Alarms on both trace filters and statistics counters.
- Optional time stamping of probed events.

6.2.1.3.1.2 Overflow flow-control for tracing

When not using Intrusive Mode (see register field IntrusiveMode of register MainCtl), an overflow packet is added after the stalled packet(s), which reports how many observation packets have been lost.

This Overflow packet has the following format:

- Opc = WR, Status = ERR.
- Debug = (probeId, Urgency= 0, Mod=1).
- RouteId = RouteID of the packet that triggered the overflow.
- Addr[8:0] = number of lost or uncompleted observation packets, minus one.
- Len: 0 if no payload lost; 1 otherwise.
- Lock = Addr[8:0] = Security = User = 0.

In case of payload overflow, the current packet is completed according to its type; then an overflow packet is also sent:

- Write request packets are fully completed with the correct number of words, all having null Data and BE.
- A single data word with null data that terminates the tracing of the read payload for that transaction completes Read response and Read continuous packets.

6.2.1.3.1.3 Transaction filter

The NoC transaction filter unit uses programmable criteria to select request and response events.

The unit is integrated into the NIU and is connected to the NIU generic-to-transport unit. More than one transaction filter can be connected to a NoC transaction profiler unit.

6.2.1.3.1.4 Transaction profiler

The NoC transaction profiler unit receives events from one or more transaction filters and organizes them into histogram bins, defined by programmable thresholds.

The unit is connected to a standard Packet Probe via the unit external event input ports.

6.2.1.3.2 Observers

This section provides detailed technical reference information for the NoC Observability technology Observer unit.

6.2.1.3.2.1 Error logging

Errors that occur in packets observed by probes can be logged.

6.2.1.3.2.1.1 Features

- Error filtering can be based on selected error codes, user and security flags and sideband signals.
- An optional fault interrupt can be asserted on an error.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c46235-4821-4a38-b251-390d3ab624c1

- Can be used in conjunction with trace probe filtering to monitor a specific port.

6.2.1.3.2.1.2 NoC error codes

The following table lists all error codes that are relevant to NoC interconnect operation.

Table 13. NoC error codes

Code	Value	Source	Type
SLV	0	Target	Target error detected by slave.
DEC	1	Initiator NIU	Address decode error.
UNS	2	Target NIU	Unsupported request.
DISC	3	Power disconnect	Disconnected target or domain.
SEC	4	Initiator NIU or firewall	Security violation.
HIDE	5	Firewall	Hidden security violation, reported as ok to initiator.
TMO	6	Target NIU	Timeout.
RSV	7	None	Reserved.

6.2.1.3.2.2 STPv2 stream generation

The NoC STPv2 adapter in the observer encapsulates ATB packets and generates synchronization sequences to provide a MIPI-STPv2 compliant STP stream. Time stamps can optionally be included in the stream.

6.2.1.3.2.2.1 Features

- Compliant with AMBA®-3 ATB and MIPI® STPv2 specifications.
- Supports ATB data widths from 8 to 64 bits.
- Supports STPv2 opcodes ASYNC, VERSION, NULL, NULL_TS, D64, D64MTS, and MERR.
- Synchronization sequence generation with optional time stamp.
- Encapsulation of probe time stamps.
- Supports all time stamp length encodings.

NOTE

For details, see MIPI® Alliance Specification for System Trace Protocol (STP), version 2.00.01, 24 February 2010.-STPv2 specification.

6.2.1.3.2.2.2 Synchronization sequence generation

The synchronization sequence permits the SoC debug system to identify the STPv2 packet boundary. A time stamp can be optionally inserted in the sequence to which the SoC debug system may resynchronize itself.

The synchronization sequence is sent when one of the following events occurs:

- After a reset.
- On the rising edge of input signal SyncReq.
- When the number of clock cycles since the last synchronization sequence is between 2AsyncPeriod and 223 inclusive, and register AsyncPeriod is greater than 0.

NOTE

The synchronization sequences are inserted instead of ATB synchronization cells.

The STPv2 adapter can issue synchronization sequences either with or without time stamps. The examples in figures that follow are represented according to the following key.

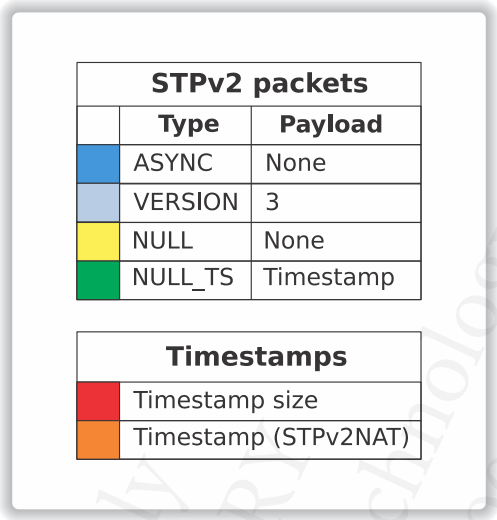

Figure 11. STPv2 synchronization sequence key

6.2.1.3.2.2.2.1 STPv2 synchronization sequence without timestamp

Synchronization sequences are sent without a timestamp when the observer STPv2 parameter wTimeStamp is set to 0. In this case, the sequence comprises the STPv2 packets ASYNC and VERSION, as well as NULL packets for padding. Such a sequence is shown in the following figure.

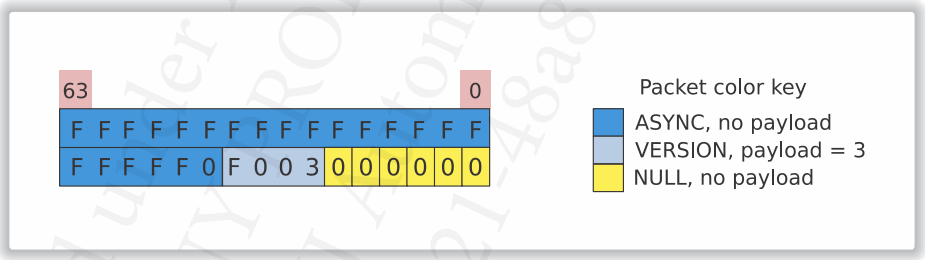

Figure 12. STPv2 synchronization sequence without timestamp

NOTE

The sequence in the figure assumes a data width of 64 for the ATB debug port, as set by parameter wData (Specification: Interface: Observation: debugOutput).

6.2.1.3.2.2.2.2 STPv2 synchronization sequence with timestamp

If wTimeStamp is greater than zero, synchronization sequences are sent with time stamps. The sequence comprises the STPv2 packets ASYNC, VERSION, NULL, and NULL_TS. The time stamp value, received on observer input signal TimeStamp and extended to 64 bits, is sent in the payload of NULL_TS.

The synchronization sequence with time stamp is shown in the following figure.

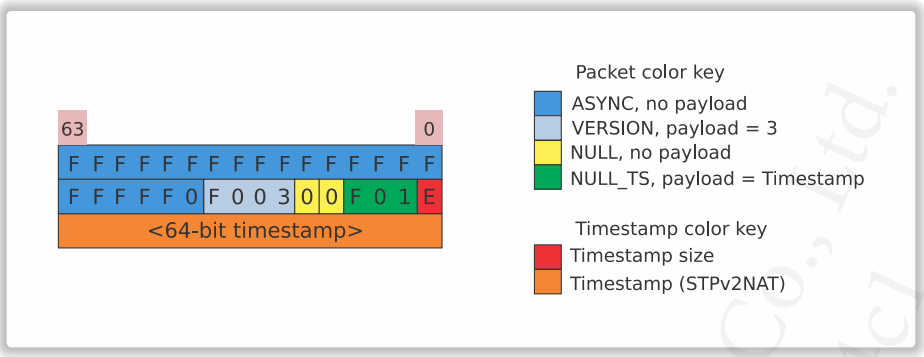

Figure 13. STPv2 synchronization sequence with timestamp

In the figure:

- Regardless of the width of the time stamp, specified by wTimeStamp, the time stamp is extended to 64 bits.
- All 16 nibbles of the time stamp are significant, indicated by the time stamp size nibble being set to Eh.
- The protocol version is set to 3 in the payload of packet VERSION. This indicates that the time stamp is encoded using the uncompressed STPv2NAT format.

6.2.1.3.2.2.3 Encapsulation of ATB packets

The STPv2 adapter encapsulates 64–bit ATB cells into the payload of 64–bit STPv2 data packets. The first ATB cell of an observation packet is encapsulated into a D64MTS STPv2 packet; D64 STPv2 packets are used for subsequent cells of the same observation packet. If observer parameter wTimeStamp is set to a value greater than 0, a Timestamp Size nibble and the time stamp are appended to the D64MTS packet. If wTimeStamp is 0, only the Timestamp Size nibble, set to a value of 0, is appended.

If an overflow packet is received by the observer, an MERR STPv2 packet is sent, indicating an STPv2 master error, prior to the encapsulation of the probed data into D64MTS and D64 packets.

6.2.1.3.2.2.3.1 Timestamp compression

When wTimeStamp is greater than 0, the number of bits sent in the Timestamp field of D64MTS packets depends on the difference between the time stamp from the current observation packet and the previous time stamp value sent in the STPv2 stream. The previous time stamp may be either itself the time stamp of the previous observation packet or the absolute time stamp sent in an STPv2 synchronization sequence.

Only nibbles which are different between the current and previous time stamps are sent, left-aligned, in the Timestamp field of the D64MTS packet. The field is preceded by a Timestamp Size nibble, which indicates the field size, in nibbles. The encoding of TimeStamp Size is defined in Section 7.2 of MIPI STP specification version 2.00.01.

The following table shows several examples of time stamp compression values.

Table 14. Timestamp compression values

Timestamp value		STP timestampe	
Previous	Current	Timpstamp Size	Compressed timestamp
0000_0000_1111_2222h	0000_0000_1111_2222h	0	—
0000_0000_1111_2222h	0000_0000_1111_2234h	2	34h
0000_0000_1234_5678h	0000_0000_1254_5601h	6	545601h
0123_0000_0000_0000h	0226_0000_0002_0030h	16[1]	0226_0000_0002_0030h
0000_0000_0012_3459h	0000_0000_0012_3457h	1	7h[2]

1. The Timestamp Size nibble is encoded for 16 nibbles even though only 15 nibbles are different because there is no encoding for 15 (see MIPI STP specification).
2. It is possible for the time stamp value of the packet being processed to be less than the time stamp of the previous packet. This can occur if an observation packet, which has an earlier time stamp than a packet from another probe, is delayed due to buffering in the observation network.

6.2.1.3.2.3 Observer registers

Observer functions, such as error logging, ATB formatting, and STPv2 encapsulation, are run-time programmable via registers. For a given function, in addition to the specific registers for that function, the register set includes standard identification registers .

See "APB memory map" in the Debug Subsystem chapter in the compute complex RM.

See "Memory maps/register definitions" in this document for reset values of registers.

6.2.1.3.2.3.1 Error logging registers

Registers related to error logging are summarized in the following table.

Address offset	Name	Type	Retention
0008h	FaultEn	Control	Yes
000Ch	ErrVld	Status	No
0010h	ErrClr	Pulse	No
0014h	ErrLog0	Status	No
0018h	ErrLog1	Status	No
001Ch	ErrLog2	Status	No
0020h	ErrLog3	Status	No
0024h	ErrLog4	Status	No
0028h	ErrLog5	Status	No
002Ch	ErrLog6	Status	No
0030h	ErrLog7	Status	No
0034h	ErrLog8	Status	No
0038h	StallEn	Control	Yes

6.2.1.3.2.3.1.1 FaultEn

When 1-bit register FaultEn is set to 1, error reporting signal Fault is enabled and asserted when register ErrVld is 1. When FaultEn is cleared to 0, signal Fault is driven to 0.

- Bit – (0)

Related signals:

- Fault

6.2.1.3.2.3.1.2 ErrVld

Register ErrVld indicates that the ErrLog registers contain valid error information.

- Bit – (0)

6.2.1.3.2.3.1.3 ErrLog0

Register ErrLog0 logs fields from the NoC packet transport protocol header of the logged packet.

The MSB field indicates the transport protocol version number.

The following table shows the field assignments. All other bits are reserved and read as 0.

Table 15. ErrLog0 field assignments

Bit range	Field name	Type	Access
0	Lock	Status	Read only
4:1	Opc	Status	Read only
10:8	ErrCode	Status	Read only
27:16	Len	Status	Read only
31	Format	Status	Read only

6.2.1.3.2.3.1.3.1 Lock

Register field Lock contains the packet header bit Lock.

6.2.1.3.2.3.1.3.2 Opc

Register field Opc contains the packet header field Opc.

6.2.1.3.2.3.1.3.3 Len1

Register field Len1 contains the packet header field Len1.

6.2.1.3.2.3.1.3.4 ErrCode

Register field ErrCode contains the packet header field ErrCode.

If the packet field does not exist, the register field contains 0.

6.2.1.3.2.3.1.3.5 Format

Register field Format specifies the version of the NoC packet transport protocol .

6.2.1.3.2.3.1.4 ErrLog1

Register Errlog1 contains the least significant part of the NoC packet transport protocol packet header field RouteId of the logged error. Up to 32 bits will be stored, depending on the width of RouteId. The field is right-aligned in the register, and unused bits are read as 0.

The RouteId value can be used to identify the initiator–target mapping associated with the logged error, in order to calculate the complete address.

When decoding RouteId sub-field SeqId, bit index 0 corresponds to the value for packet header field Opc when:

- The transaction comes from an interface with a protocol, such as AHB, AXI, or AMBA, that allows response disorder based on transaction opcodes.
- The NoC supports other interface protocols that do not.

A description of the sub-fields comprising RouteId is provided in related reference documentation.

- Type – Status

6.2.1.3.2.3.1.5 ErrLog2

Register Errlog2 contains the most significant part of the NoC packet transport protocol packet header field RouteId of the logged error. Up to 16 MSBs of RouteId are stored, depending on the width of RouteId. The field is right-aligned in the register, and unused bits are read as 0.

The RouteId value can be used to identify the initiator–target mapping associated with the logged error, in order to calculate the complete address.

A description of the sub-fields comprising RouteId is provided in related reference documentation.

This register is only present if the width of RouteId is greater than 32 bits.

- Type – Status

6.2.1.3.2.3.1.6 ErrLog3

Register Errlog3 contains the least significant part of the NoC packet transport protocol packet header field Addr of the logged error. Up to 32 bits will be stored, depending on the width of Addr. The field is right-aligned in the register and unused bits are read as 0.

Because ErrLog3 only contains the transport address offset within the particular mapped region, its value must be used in conjunction with the local addresses of the initiator–target mapping, in order to reconstitute the complete transaction address. The mapping is identified using RouteId, logged in ErrLog1 and optionally ErrLog2.

6.2.1.3.2.3.1.7 ErrLog4

Register Errlog4 contains the most significant part of the NoC packet transport protocol packet header field Addr of the logged error. Up to 16 MSBs of Addr are stored, depending on the width of Addr. The field is right-aligned in the register and unused bits are read as 0.

Because ErrLog4 only contains the transport address offset within the particular mapped region, its value, concatenated with ErrLog3, must be used in conjunction with the local addresses of the initiator–target mapping in order to reconstitute the complete transaction address. The mapping is identified using RouteId, logged in ErrLog1, and optionally, ErrLog2.

This register is only present if the width of Addr is greater than 32 bits.

6.2.1.3.2.3.1.8 ErrLog5

Register Errlog5 contains the least significant part of the NoC packet transport protocol packet header field User of the logged error.

Up to 32 bits will be stored, depending on the width of User. The field is right-aligned in the register, and unused bits are read as 0.

6.2.1.3.2.3.1.9 ErrLog6

Register Errlog6 contains the midrange part of field User contained in the packet header of the packet transport protocol. Bit User (32) up to bit User (63) will be stored, depending on the width of User. The field is right-aligned in the register, and unused bits are read as 0.

The register is present only if the width of User is greater than 32 bits.

6.2.1.3.2.3.1.10 ErrLog7

Register Errlog7 contains the NoC packet transport protocol packet header field Security of the logged error. The field is right-aligned in the register and unused bits are read as 0.

6.2.1.3.2.3.1.11 ErrLog8

Register Errlog8 contains the most significant part of the NoC packet transport protocol packet header field User of the logged error. Bits User(64) up to User(95) are stored, depending on the width of User. The field is right-aligned in the register, and unused bits are read as 0.

The register is present only if the width of User is greater than 64 bits.

6.2.1.3.2.3.1.12 StallEn

Register StallEn controls the stall mode of the NoC error logger.

When set to 1, error packets (status = ERR) are stalled, that is, queued at the input to the error logger. The packets are only passed into the error logger once the currently logged error packet has been cleared by setting register ErrClr to 1.

When set to 0, only the first error packet is stored in the error logger. Subsequent error packets are lost.

NOTE

The number of error packets which may be queued is 4.

6.2.1.3.2.3.2 ATB endpoints registers

Registers which are used to control the ATB endpoint are summarized in the following table.

Address offset	Name	Type	Retention	Width
0008h	AtbId	Control	Yes	7 bits
000Ch	AtbEn	Control	Yes	1 bit
0010h	SyncPeriod	Control	Yes	3 bits (4:0)

6.2.1.3.2.3.2.1 AtbId

Register AtbId sets the ATB identifier of the observer. The identifier is carried on signal ATId.

Each observer within the NoC must have a unique ID value. The value is used along with probe IDs to identify probes.

NOTE

Values 00h and 70h to 7Fh are reserved for ARM® CoreSight™ debug systems.

6.2.1.3.2.3.2.2 AtbEn

When AtbEn = 1, register AtbEn enables ATB output.

NOTE

Writing AtbEn = 0 is equivalent to a power disconnect on the affected socket: the current transmission of an ATB packet is completed before the ATB output is disabled.

6.2.1.3.2.3.2.3 SyncPeriod

Register SyncPeriod sets the period, in terms of the number of ATB cells sent, between insertion of ATB synchronization cells.

The following table summarizes the relationship between SyncPeriod and the delay between synchronization cells.

Table 16. SyncPeriod and delay between synchronization cells

SyncPeriod value	Period of sync cell insertion
0	No sync cell insertion
1...2	8
3...22	$2^{(SyncPeriod + 1)}$
23...31	Not supported

SyncPeriod is not present when setting parameter debugOutput of the observer to STPv2, since ATB synchronization cells are not generated when using the STPv2 adapter.

6.2.1.3.2.3.3 STPv2 encapsulation registers

Registers relative to STPv2 encapsulation are summarized in the following table.

Address offset	Name	Type	Retention	Width
0008h	AsyncPeriod	Control	Yes	5 bits (4:0)
000Ch	STPv2En	Control	Yes	1 bit (bit 0)

SyncPeriod is not present when setting parameter debugOutput of the observer to STPv2, since ATB synchronization cells are not generated when using the STPv2 adapter.

6.2.1.3.2.3.3.1 AsyncPeriod

Register AsyncPeriod defines the period, in observer clock cycles, between transmission of STPv2 synchronization sequences.

The following table summarizes the relationship between AsyncPeriod and the delay between synchronization sequences.

Table 17. AsyncPeriod and delay between synchronization cells

AsyncPeriod value	Period between synchronization sequences
0	No sync sequence inserted due to AsyncPeriod
1...22	$2^{(SyncPeriod + 1)}$
23...31	2^{23}

SyncPeriod is not present when setting parameter debugOutput of the observer to STPv2, since ATB synchronization cells are not generated when using the STPv2 adapter.

6.2.1.3.2.3.3.2 STPV2En

When STPV2En = 1, register STPV2En enables the STPv2 output.

When STPV2En = 0, the observer debug interface is disabled: neither STPv2 packets nor synchronization sequences are sent.

By default, the reset value is 1 so that STPv2 stream generation is enabled. If it should be enabled explicitly by software, the reset value can be changed to 0 by setting its parameter rstVal (Structure: Parameters: Control Setting).

NOTE

Writing STPv2En =0 has an equivalent effect to a power disconnect on this interface: the STPv2 encapsulation and transmission of an ATB packet will be completed before the observer debug output is disabled.

6.2.2 QoS

6.2.2.1 Concepts

In NoC interconnects, quality of service (QoS) is the statistical allocation of throughput and delay, in terms of bandwidth and latency, to the transactions transported between initiators and targets.

This section describes how QoS mechanisms balance the access of the traffic of different initiators to suit the finite available resources of the interconnect.

6.2.2.1.1 QoS generators

NoC QoS generators are used to prevent initiator sockets from degrading the QoS of other sockets. The generators, in order of increasing functionality:

- Fixed – Assigns a fixed urgency levels to packets.
- Limiter – Generates flow control when a pre-defined bandwidth threshold is reached.

- Regulator – Ensures that initiators obtain the required bandwidth from targets.

QoS generators are programmable through registers.

Software can only switch a generator to an operating mode with a lower level of functionality.

For example, regulators can be programmed to operate in either Limiter or Fixed mode.

Bandwidth counters are reset when modes are switched.

6.2.2.1.1.1 Fixed mode

Fixed generators assign a pre-defined urgency level, which can be different for read and write transactions, to each packet transiting the NIU.

The assigned urgency levels can be programmed by software.

6.2.2.1.1.2 Limiter mode

NoC QoS generators in limiter mode ensure that initiators do not send too many requests to targets.

To do this, the generator monitors requests instead of responses because monitoring responses would delay feedback, thus allowing initiators to send many requests until bandwidth is restricted.

6.2.2.1.1.3 Regulator mode

NoC QoS generators in regulator mode ensure that initiators obtain the required bandwidth from targets. When bandwidth is insufficient, requests urgency values must be adjusted before the request-path buffering capacity is saturated. Consequently, regulators monitor response rates, because this is the fastest way of identifying slow processing by targets.

Because regulators measure the NIU response bandwidth, they can restrict initiator bandwidth more evenly than limiters.

When a predefined bandwidth threshold is reached, the urgency, pressure, and hurry levels at the initiator interface decrease. The threshold is determined by field Saturation, according to the following equation:

```
Threshold = (Saturation × 16) × 256 / 2
```

6.2.2.2 Programming

This section provides guidelines for programming NoC QoS hardware features to meet performance requirements in different use cases.

6.2.2.2.1 Programming QoS generators

NoC QoS generators, programmed correctly, ensure that throughput is allocated to initiators according to the needs of the system. These needs can include latency requirements.

6.2.2.2.1.1 Programming fixed generators

An initiator with a fixed type of QoS generator can be programmed to give its data transfers a desired priority. The priority remains constant until reprogrammed.

Read and write data transfers can be given different priorities. For example, system performance can be affected more by reads than by writes, and it is therefore desirable to give higher priority to reads.

The following table lists the registers that control data transfer priority.

Table 18. Registers controlling data transfer priority

Register name	Byte offset	Mode	Field	Bits	Bit offset	Description
Priority	08h	bwdComp = True	P0 / Low	2	0	Priority of writes.

Table continues on the next page...

Table 18. Registers controlling data transfer priority (continued)

Register name	Byte offset	Mode	Field	Bits	Bit offset	Description
			P1 / High	2	8	Priority of reads.
			Mark	1	31	Value of 0 for backwward compatibility.
		bwdComp = False	P0 / Low	log_2(nUrgencyLevel + 1)	0	Priority of writes.
			P1 / High	log_2(nUrgencyLevel + 1)	8	Priority of reads.
			Mark	1	31	Value of 10 for backwward compatibility.
Mode	0Ch		Mode	2	0	0 = Fixed 2 = Bypass
ExtControl	18h		SocketQos En	1	0	Initiator drives QoS
			ExtThrEn	1	1	No function.
			IntClkEn	1	2	No function.

The parameter bwdComp indicate if the old (True) or new (false) layout of the Priority register is used.

A chip operating in different use cases may reprogram all of its initiators accordingly. Because priorities can be changed at any time with no risk to data integrity, reprogramming can be in real-time based on system feedback.

Depending on chip design, priorities might be reset when a part of a chip is powered down. The reset value of all priorities is zero.

6.2.2.2.1.2 Programming limiter generators

Initiators with a limiter type of QoS generator have all of the functionality of a fixed QoS generator, and can be programmed to behave as a throughput limiter.

Limiters monitor initiator socket throughput, and throttles the socket to the programmed Bandwidth register value. This mechanism prevents the initiator from causing congestion for others.

The following table lists the registers that can be used to program limiter generators.

Table 19. Registers to program limiter generators

Register name	Byte offset	Field	Bits	Bit offset	Description
Priority	08h	P0	3	0	Priority of writes.
		P1	3	8	Priority of reads.
Mode	0Ch	Mode	2	0	0 = Fixed 1 = Limiter 2 = Bypass

Table continues on the next page...

Table 19. Registers to program limiter generators (continued)

Register name	Byte offset	Field	Bits	Bit offset	Description
Bandwidth	10h	Bandwidth	if (useExtRef) 13 + $\log_2$(2 × wData / 8) else 9 + $\log_2$(2 × wData / 8)	0	Throughput threshold in 1/256th-byte-per-cycle units.
Saturation	14h	Saturation	10	0	Maximum unregulated burst.
ExtControl	18h	SocketQosEn	1	0	Initiator drives QoS
		ExtThrEn	1	1	Use external threshold.
		IntClkEn	1	2	Use external threshold.

Throughput is programmed by setting register Bandwidth in 1/256th-byte-per-cycle units. Consequently, to program a desired throughput rate BW, in megabytes per second, the register must be set to:

```
Bandwidth = 256 × BW / F   // F is the initiator clock frequency in MHz.
```

where F is the initiator clock frequency in MHz. When using an external reference clock, the register must be set to:

```
Bandwidth = 256 × BW / (2 × Fext)   // Fext is the external clock frequency in MHz.
```

In certain cases, some initiators can generate bursty activity. Register saturation sets the maximum number of bytes that can be requested at full speed before the limiter triggers. The register must be set to the desired number of bytes divided by 16.

6.2.2.2.1.3 Programming regulator generators

An initiator NIU with a regulator type of QoS generator has all the functionality of a limiter QoS generator, and can be programmed to behave as a throughput regulator. A regulator monitors throughput usage of the initiator and adjusts the priority of its data transfers based on how much throughput the initiator has been using. Unlike the limiter's strict throttle, which aggressively blocks a initiator from exceeding a throughput quota, a regulator gently allows the initiator to use excess available throughput, but at a priority level that will ensure that other competing initiators have their necessary share.

Table 20. Registers to program regulator generators

Register name	Byte offset	Field	Bits	Bit offset	Description
Priority	08h	P0	3	0	High throughput priority level (or priority of writes).
		P1	3	8	Low throughput priority level (or priority of reads.
Mode	0Ch	Mode	2	0	0 = Fixed 1 = Limiter 2 = Bypass 3 = Regulator
Bandwidth	10h	Bandwidth	if (useExtRef) 13 + $\log_2$(2 × wData / 8) else	0	Throughput threshold in 1/256th-byte-per-cycle units.

Table continues on the next page...

Table 20. Registers to program regulator generators (continued)

Register name	Byte offset	Field	Bits	Bit offset	Description
			$9 + \log_2(2 \times wData / 8)$		
Saturation	14h	Saturation	10	0	Maximum unregulated burst.
ExtControl	18h	SocketQosEn	1	0	Initiator and regulator drive QoS.
		ExtThrEn	1	1	Use external threshold.
		IntClkEn	1	2	Use special clock reference.

A regulator has the same P0 and P1 fields of the Priority register: P0 stores the priority level to use for all data transfers when throughput is above the threshold, and P1 stores the priority level to use for all data transfers when throughput is below the threshold. Generally, the priority in P0 is a lower number than in P1. Both read and write transfers have the same priority when the QoS generator is configured in regulator mode.

Some initiators assert a priority level for data transfers apart from the regulator. Asserting the SocketQosEn bit of the ExtControl register causes the regulator to use the greater of either the initiator or the QoS generator priority levels. This behavior can be used for initiators that have internal buffering where data transfer priority is a function of the fullness of the buffer.

6.2.3 Resilience features

6.2.3.1 Fault aggregation and reporting

6.2.3.1.1 Unit fault aggregation and reporting

When the various resilience mechanisms detect a hardware fault in a unit, they assert a fault output during one clock cycle. At each NoC unit level, all faults are sent to a single checker/BIST module, which aggregates the faults and reports them to a single controller per NoC power domain, which interacts with system software.

The following figure depicts the functionality of the checker/BIST module (in a case of duplicated unit).

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-4a4b-b251-5

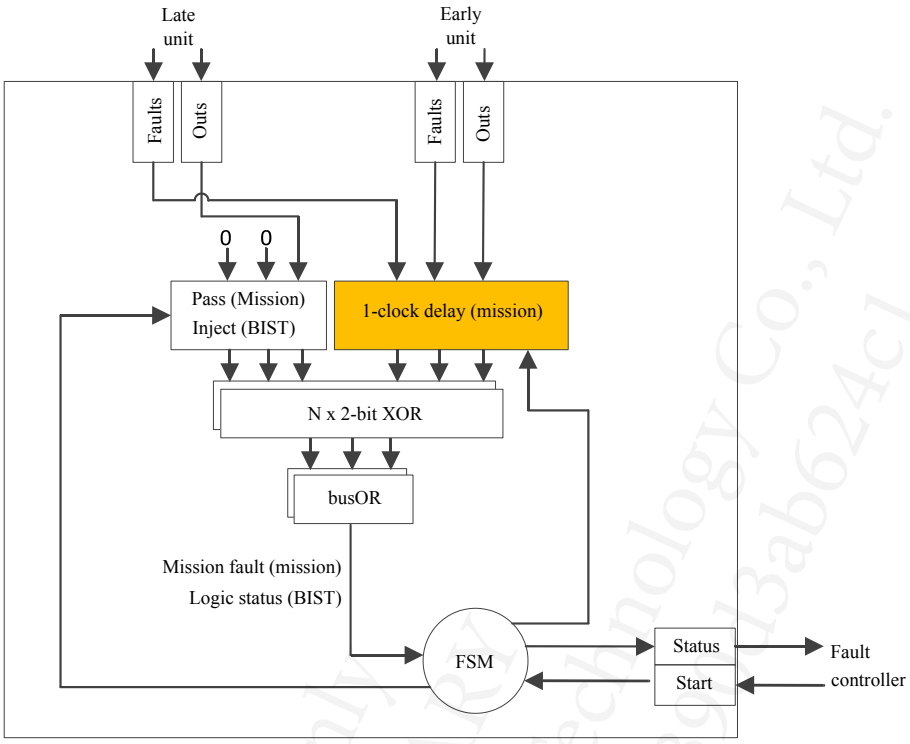

Figure 14. Checker/BIST module functionality

Checker/BIST modules are automatically instantiated by the NoC software synthesis engine in all units that produce faults according to the fault parameter values.

6.2.3.1.1.1 Mission mode

In mission mode, the fault controller reports faults from the checker/BIST modules under its control, typically using the MissionInt output as an interrupt.

The granularity of mission fault reporting is per checker/BIST, i.e. registers indicate which checker/BIT module, and consequently which associated NoC unit has experienced a hardware fault. There is no way to discriminate inside a unit which resilience mechanism triggered the reported fault, neither how many faults were reported.

After reset, the fault controller starts in mission mode.

6.2.3.1.1.2 BIST mode

The checker/BIST module implements a BIST function that detects possible faults in the fault aggregation logic.

The checker/BIST module goes into BIST mode under request by the fault controller on its Start input. In BIST mode, the module does not report unit faults, but performs the following steps:

- Applies patterns in the register that check the fault detection and aggregation logic.
- Reports any failure of the patterns detected by the FSM to the fault controller on the Status output.
- Reports successful completion of the BIST sequence to the fault controller on the Status output and goes back into mission mode, with a Status indicating absence of fault, until a new unit fault is detected by the mission mode function.

6.2.3.1.2 Fault controller

A single fault controller is automatically instantiated per power domain that contains units with fault outputs.

The fault controller performs the following functions:

- In mission mode, reports to the system software the NoC units faults detected by the resilience mechanisms.
- Under system software control, triggers BIST sequences of the fault reporting chain, to detect Latent fault in all checker/BIST modules under its control.

The fault controller has the following single-bit outputs, that can be exported to the NoC boundary:

- MissionInt – Reflects the value of the MissionFault field of the Faults register, when enable is set. When high, indicates that a mission fault has been detected in one of the units, and more information is available in the fault controller registers.
- LatentInt – Reflects the value of the BistDone field of the BistDone status register, when BistDoneEn field of IntEn register is set. When high, indicates that the BIST sequence is done, so the software can read the LatentFault field of the Faults status register to check if BIST sequences have been successful or not. More information is available in the fault controller LatentFault 0-3 status registers.

6.2.3.1.2.1 Mission mode

Mission mode is the normal operating mode of the checker/BIST module, in which it monitors the unit itself and aggregates results into a single Status, stored in a local FSM before being issued to the fault controller.

After reset of the unit, the checker/BIST module is in mission mode, and output Status is 0, indicating absence of a fault.

6.2.3.1.2.2 BIST mode

The fault controller enters BIST mode under software control, using the BistCtl register.

In BIST mode, the controller starts a BIST sequence in parallel on all the checker/BIST modules under its control. Latent fault reporting granularity is per checker/BIST, like mission faults.

NOTE

Until BIST sequence has completed, the system is fully functional but blind to any possible mission fault. The interval during which it is blind to mission fault depends on the timeout register settings of the controller, themselves depending on the largest number of inputs of all checker/BIST modules under its control, see timeout registers below.

After a BIST sequence has completed successfully for all checker/BIST modules, the controller resumes mission mode.

For more information about behavior after BIST failures, see Programming model.

6.2.3.1.2.3 Programming model

The programming model of the fault controller is made complex by the possibility of latent faults in the checker-BIST, or the controller itself, or both. Note that before programming the fault controller, the system should verify the integrity of the service network path by at least reading, for example, its identification registers, and checking their values.

6.2.3.1.2.3.1 Operating in mission mode

To operate in mission mode, the system should either set register IntEn field MissionFaultEn to 1, in order to receive an interrupt on MissionInt controller output, or regularly poll register Faults field MissionFault.

When a mission fault occurs, detected either by the interrupt or the polling method, the system should:

- Verify that Faults field MissionFault is set, when not already done by polling.
- Optionally identify the source of the fault in registers MissionFault 0–3.
- Take appropriate system action, such as running diagnostics.
- Optionally run a BIST sequence to attempt to clear the mission fault. This can permanently succeed if the fault was a transient fault that did not wholly corrupt the state of the system.

NOTE

Unless the sources of faults are reset, or the controller is put in BIST mode, faults continue to be monitored, and other fault sources may become active in registers MissionFault 0–3.

6.2.3.1.2.3.2 Clearing mission faults

If a unit has experienced a transient fault that did not corrupt the whole NoC state, for example, if the fault only affected a data value written into a memory target of the NoC, then by following the appropriate procedure (see To clear mission fault without resetting the faulty unit), it may be possible to clear the fault, although success is not guaranteed.

6.2.3.1.2.3.3 Running successful BIST sequences

A BIST sequence is successful because it correctly detects whether or not there is a latent fault in the fault reporting chain. A BIST sequence will finish successfully even if the FSM of a checker BIST is faulty, in which case a latent fault is reported for the module concerned.

6.2.3.1.2.3.4 Identifying unsuccessful BIST sequences

Identifying unsuccessful BIST sequences When fault controller FSMs are themselves faulty, the BIST sequence may not finish successfully, that is, some unexpected events during the sequence may occur:

- After writing 1 in register BistCtl field BistStart, the polling or interrupt method fails to indicate BIST sequence completion in register BistDone field BistDone before register BistTO1 controller clock cycles.
- After a successful indication that a successful BIST sequence ran correctly in BistDone field BistDone, the controller fails to indicate that it is returned to mission mode in BistDone field MissionMode before BistTO2 controller clock cycles.
- After writing 1 in BistCtl field BistDoneClr, the BistDone field BistDone value is not read back to be 0.

When such events are detected, the fault controller itself must be assumed to have experienced a hardware fault.

Although such a hardware fault does not compromise the operation of the SoC, it may prevent detection of further mission or latent faults, or both.

An attempt can be made to clear mission faults by resetting the power domain containing the controller (see To clear mission fault after resetting the faulty unit). This may be successful if the fault controller experienced a transient fault, because a successful BIST sequence after reset of the power domain indicates that the fault controller is not permanently faulty.

6.2.3.1.2.4 To clear mission fault without resetting the faulty unit

1. Run a BIST sequence. This will clear the state and the Status output of the checker or BIST that reported a fault, assuming that the checker or BIST itself is functional.
2. Write 1 in register IntClr field MissionFaultClr.
3. Either a new mission fault is quickly reported (system dependent), in which case the system is probably permanently faulty, or the system must decide any further action required to resume mission mode.

6.2.3.1.2.5 To clear mission fault after resetting the faulty unit

Since the controlled units are in the same power domain as their controller, resetting the unit usually involves resetting the whole power domain, including the fault controller itself. The action sequence is:

1. Use the domain power controller and bring it to an idle state, then reset the power domain.

   NOTE

   This assumes that the NoC is configured to support such capability, and that the reported hardware fault does not compromise the operation of the power controller.

2. The checker field BIST is reset and the fault controller restarts in mission mode.
3. Either a new mission fault is quickly reported (system dependent), in which case the system is probably permanently faulty, or the system must decide any further action required to resume mission mode.

6.2.3.1.2.6 To run a successful BIST sequence

1. Program registers BistTO1 and BistTO2 to appropriate values. Set register IntEn field BistDoneEn according to the chosen method to detect the end of the BIST sequence: when set to 0, the system must poll register BistDone field BistDone and wait for the field to be set to 1. When set to 1, the system can wait for an interrupt on LatentInt.
2. Write 1 in register BistCtl field BistStart to start the BIST sequence.
3. Once BIST completion is detected by polling or the interrupt method referred to in step 2, check the value of register Faults field LatentFault:
   - If 0, the BIST run was successful and no latent fault was detected.
   - If 1, the BIST run was successful and a latent fault was detected, as indicated by registers LatentFault 0–3.
4. Write 1 into register BistCtl field BistDoneClr.
5. Poll register BistDone fields BistDone and MissionMode until they show values of 0 and 1 respectively. This should happen before BistTO2 clock cycles but after the BIST sequence finishes its run.

Chapter 7
Ncore

7.1 Chip-specific Ncore information

7.1.1 Ncore interface units

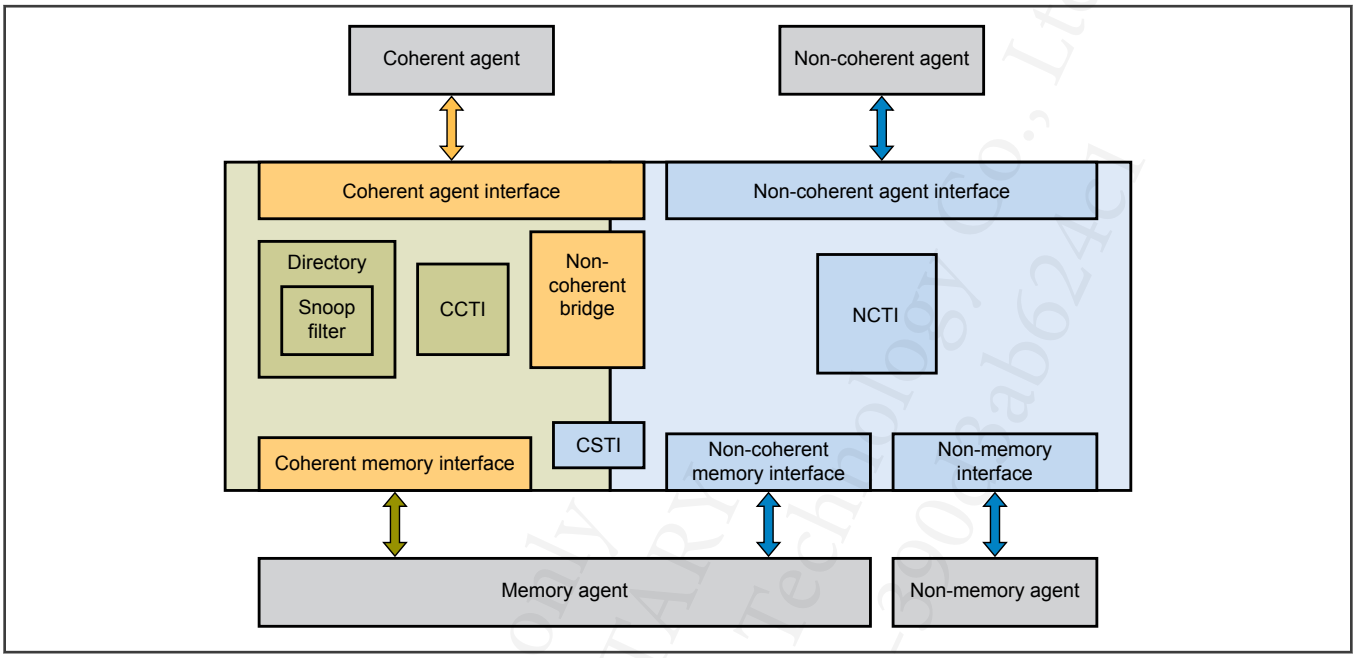
This table provides a mapping between the Ncore interface units and the modules in this chip with which they are connected.

Ncore interface unit	Chip modules	Type of agent	Notes
CAIU0	A53 Cluster0	Fully-coherent agent	Connects to Ncore via AMBA ACE interface.
CAIU1	A53 Cluster1	Fully-coherent agent	Connects to Ncore via AMBA ACE interface.
NCBU0	SerDes_1, PFE	IO-coherent agent	Originating traffic is routed through the NoC_1 to the Ncore via a shared AXI4 interface.
NCBU1	SerDes_0, GMAC_0	IO-coherent agent	Originating traffic is routed through the NoC_0 to the Ncore via a shared AXI4 interface
CMIU	—	Memory agent	Routes the transactions to the NoC_0

7.2 Introduction

Ncore is a cache-coherent interconnect module. It enables the integration of heterogenous coherent agents and non-coherent agents in a chip. It processes transactions with coherent access semantics from various fully-coherent and IO-coherent masters, targeting shared resources.

7.3 Features



- Configurable heterogenous agents that are:
  - Fully-coherent
  - IO-coherent
  - Non-coherent
- Configurable snoop filter
- Heterogenous coherence models including:
  - Cache state models
  - Transaction processing models
  - Transaction types
- Resiliency package that provides additional functional safety features, such as:
  - Configurable link data protection
  - Hardware unit duplication

7.4 Block diagram

7.5 Signal description

Ncore has a single clock domain. All agent interfaces and transport datapath operate synchronously at the same operating frequency.

7.6 Functional description

7.6.1 Caches and cache coherency

Caching is a common performance feature that buffers copies of data (caches) near to the processing units on the chip that manipulates data. Caches consist of relatively small memory arrays and have a short access time. This increases system performance by reducing average memory latency along two dimensions:

- Data which are accessed previously and are likely to be accessed again, and data that are accessed frequently are allocated in the cache. This decreases the waiting time that a processing unit may spend for receiving the data.
- Data are allocated to the caches in quantities (cachelines) larger than the typical size of memory access performed by a processing unit. This prefetch effect reduces the latency for subsequent memory accesses.

The presence of caches creates multiple copies of the same data. All copies must remain consistent. This complete process is termed as cache coherency.

7.6.2 Ncore agents

This chip consists of following set of agents that communicate through the Ncore:

- Master agent: This block initiates read and write transactions to a single physical address. These agents are classified based on the type of transactions they issue:
  - Non-coherent agent: For a given physical address, a non-coherent agent directly accesses the data in the corresponding memory location.

  - Coherent agent: For a given physical address, a coherent agent may access the data either in the corresponding memory location or in one of the caches in the system. Coherent agents are further classified as:
    - Fully-coherent agent: The master agent that performs the coherent transaction obtains a copy of the data that is required to remain coherent with respect to coherent transactions from other master agents.
    - IO-coherent agent: The master agent obtains a copy of the data that is not required to remain coherent.
- Slave agent: This block services read and write transactions for a given set of physical addresses. These agents are classified based on how they access the read and write transaction results:
  - Memory agent: It provides access to memory locations. A read access to the physical address by a memory agent returns the last value written.
  - Non-memory agent: It provides access to other forms of system functionality. A read access to the physical address by a memory agent may not return the last value written, and multiple reads may return different values. A read and write access may cause side effects like raising an interrupt or initiating a hardware state machine.

For mapping between the modules on this chip and their respective Ncore agent classification, see the chip-specific Ncore information.

7.6.3 Ncore interfaces

The Ncore agents connect with Ncore through the following interfaces.

7.6.3.1 Coherent agent interface (CAI)

CAI provides a means for a fully-coherent agent to be connected to the Ncore. The CAI behaves as a fully-coherent slave (ACE slave).

CAI classifies agent transactions as either non-coherent or coherent. Non-coherent agent transactions are delivered directly to the NCTI or an external interconnect. Coherent agent transactions are decoded and translated into individual protocol transactions. Each protocol transaction allocates an entry in an outstanding transaction table (OTT) that tracks the outstanding protocol transactions as they progress through the various phases of the coherence protocol. In addition, coherent read and write transactions also allocate an OTT data buffer for staging read data or write data, respectively.

In CAI, each functional port has an analogous structural unit—Coherent agent interface unit (CAIU).

The CAI in this chip has the following properties:

- ACE protocol
- 32-bit address
- 6-bit transaction ID width
- 128-bit data width
- Supports distributed virtual memory (DVM) on AR and AC channels
- Supports outstanding transactions

The CAI in this chip has the following configuration for supporting outstanding transactions:

- Supports up to 16 outstanding protocol transactions
- Supports 16 data buffers for outstanding protocol transactions, protected by SECDED ECC
- Supports up to four command messages per port and directory pair
- Supports up to four cache-to-cache data messages per port
- Supports heterogeneous mix of coherent and non-coherent transactions sharing the same transaction ID. Only one non-coherent transaction may have the same transaction ID

7.6.3.2 Coherent memory interface (CMI)

CMI provides a mechanism for the Ncore to access a memory agent coherently. The CMI has an analogous structural unit—Coherent memory interface unit (CMIU).

The CMI in this chip has the following properties:

- AXI protocol
- 40-bit address
- 5-bit transaction ID width
- 128-bit data width

7.6.3.3 Non coherent bridge (NCB)

NCB translates a non-coherent transaction into one or more coherent transactions that access a directory cacheline. The NCB behaves as an IO-coherent master.

In an NCB, each functional port has an analogous structural unit—Non-coherent bridge unit (NCBU).

The NCB in this chip has the following properties:

- AXI protocol
- 32-bit address
- 6-bit transaction ID width
- 128-bit data width
- Supports outstanding transactions

The NCB in this chip has the following configuration for supporting outstanding transactions:

- Up to 16 outstanding protocol transactions
- 16 data buffers for outstanding protocol transactions, protected by SECDED ECC

7.6.3.4 Directory

The directory provides a point of serialization for establishing transaction ordering and sequences coherence operations and memory accesses. The directory is configured with a snoop filter. See Snoop filter for more information.

The directory has an analogous structural unit—Directory unit (DIRU).

The directory in this chip has the following properties:

- Supports a 64-byte line size
- Supports up to 48 active protocol transactions
- Four exclusive monitors per port

7.6.3.4.1 Snoop filter

This unit is configured within the DIRU to reduce the system bandwidth needed to enforce coherence. The DIRU accesses the snoop filter in parallel with its regular operations, to determine the state of the caching agent, and thus identifying the required coherence operations.

A snoop filter is configured to store different types of information to make trade-offs between snoop filter area and coherence bandwidth. A snoop filter is of two types, depending upon the type of information stored:

- Null filter
- Tag filter

The null filter stores no information about its associated caching agents. For every coherent transaction, the directory broadcasts snoop messages to the caching agents.

Snoop message - A snoop filter transmits coherency operations to caching agents through snoop messages.

The tag filter is a set-associative structure that stores information about previous cached transactions. This ensures that only the necessary coherence operations are performed on those caching agents. Tag filter achieves this by:

- Tagging entries by physical address
- Storing cacheline validity
- Storing ownership information about its associated caching agents

Snoop filter is further classified into two types based on the information stored in a tag filter entry:

- Presence vector filter:

  Each caching agent is represented by a bit that indicates whether the caching agent possesses a valid copy of the cacheline.
- Owner-sharer filter:

  The tag filter categorizes the caching agents into two types—owner and sharer.

  Owner- Each caching agent that is represented by a pointer field, indicates that the caching agent is an owner. An owner caches a valid copy of data that may be either dirty or unique.

  Sharer- Each caching agent that is represented by a bit, indicates that the caching agent is a sharer. A sharer caches a valid, clean and non-unique copy of data.

The snoop filter in this chip is a tag filter of the owner-sharer type. It has the following features:

- Organized as a 12-way set associative caching agent with 2048 sets per way
- Supports up to eight outstanding snoop messages per directory port and caching agent port pair.

7.6.4 Transport interconnect

The transport interconnect provide a means for the Ncore interfaces to communicate with each other. It also enables communication with and between the non-coherent agents. Ncore uses the following transport interconnects:

- Non-coherent transport interconnect (NCTI): It provides connection between the non-coherent master and the coherent bridges, and between the non-coherent ports of a CAIU. The functionality of NCTI is performed by NoC in this chip.
- Coherent-capable transport interconnect (CCTI): It provides communication between the coherent units to communicate with each other. The functionality of CCTI is performed by NoC in this chip.
- Control and status transport interconnect (CSTI): It transport non-coherent transactions to the control and status registers in the Ncore coherent units.

7.6.5 Storage protection

Storage structures in this chip, such as tag filters and transaction table data buffers, are configured with a protection scheme to enable error detection and correction capability. This protection scheme is called SECDED entry—Single-error correction, double-error detection code per entry

With the SECDED entry storage protection scheme, Ncore can:

- Detect double-bit errors in an entry. These are uncorrectable errors.
- Correct single-bit errors in an entry. These are correctable errors.

Each structural unit connected to the Ncore interfaces logs and signals correctable and uncorrectable errors separately. Ncore aggregates all the error interrupts from the units and outputs two interrupt signals—a combined correctable interrupt signal and a combined uncorrectable interrupt signal.

7.6.5.1 Error types

An error is defined to be a deviation from correct or expected system behavior. Following are the various errors that Ncore interacts with:

- Undetectable error—deviation that Ncore is unable to detect.
- Detectable error—deviation that Ncore is able to detect. These errors are classified as follows:
  - Data corruption error—an uncorrectable error that a transaction encounters in a data storage (for example, data buffers).
  - Address corruption error—an uncorrectable error that a transaction encounters in an address storage (for example, tag filters).
  - Transport error—an uncorrectable error that a transaction encounters in a transport interconnect (for example, CCTI).

7.6.6 Resiliency

Ncore has a highly reliable resiliency feature that enables functional safety and fault tolerance for the chip. It has the following units to support its resiliency feature:

- Fault controller to monitor and log faults detected in the interconnect
- Built-in self-test (BIST) finite state machine (FSM) that enables checking of the Ncore fault detection logic

Ncore has the following properties to support its resiliency feature:

- Duplication of CAI, CMI, DIR and NCB
- Protects datapath packet including packet validity checker, header parity and payload parity
- Protects control register parity
- Transport timeout detection with 32K clocks timeout period

The following figure illustrates a high-level overview of the different elements of Ncore enabled with the resiliency feature:

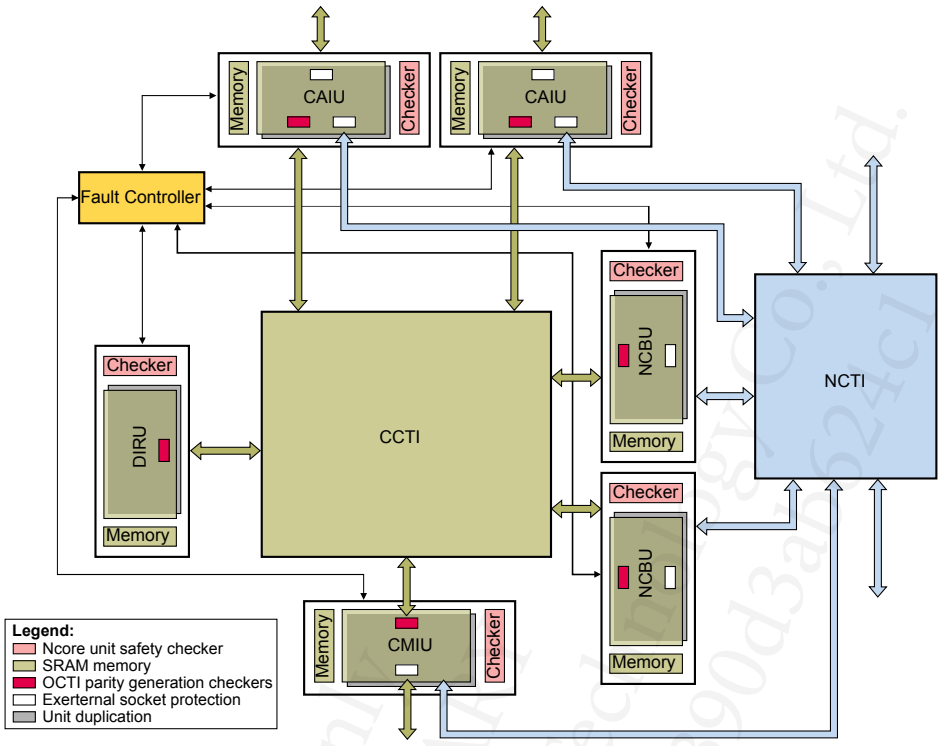

Figure 15. Ncore elements with resiliency

7.6.6.1 Component logic duplication

Ncore uses a mechanism called “component logic duplication” for providing its resiliency feature. This capability replicates the logic for all the Ncore components:

- CAI
- CMI
- DIR
- NCB

It creates logic for two identical modules of the logical component. The two identical modules are functional component and duplicated component. The replicated logic operates in lock-step with the original component logic and it is configured to operate one clock cycle apart.

Ncore uses an additional logic—checking logic—known as safety checker to ensure that the original and replicated logic operates in lockstep.

Ncore reports two types of faults to the fault controller:

- Mission fault

  The checker component receives one cycle delayed version of the same inputs as the functional component. The safety checker module receives the functional component outputs and delays it by one cycle, then compares them with the checker component outputs. Any discrepancy is reported as a mission fault.

  After a mission fault is detected, it remains logged inside the checker component until a BIST sequence clears it (See the BIST sequence).

- Latent fault

The safety checker module implements two identical comparator trees checking simultaneously that the output of the checker component is identical to the delayed version of the output of the functional component. A mismatch between the output of the comparator trees is reported as a latent fault.

7.6.6.2 Fault controller

The fault controller component monitors and logs faults reported by all safety checkers in the system, and drives an interrupt signal to notify the host system that a fault in the coherent interconnect has occurred. The fault controller hosts a register interface which allows you to identify the source of detected faults. (See Functional safety controller (FSC) register descriptions)

You can also use the fault controller to manage the BIST for the fault reporting logic. The fault controller has a BIST FSM that you use to:

- Communicate with the safety checkers
- Check the fault reporting logic
- Clear the mission and latent faults

After any faults are detected, you can execute a BIST sequence to debug the cause of the faults.

The SCBISTC register provides you the option of executing the BIST sequence automatically or manually depending on your requirement. If the automatic running of the BIST sequence fails, you can execute each step one by one to find out which step fails.

See BIST sequence for the procedure.

7.6.6.3 BIST sequence

The BIST sequence is as follows:

1. Reset safety checkers faults

   You reset all the safety checkers in this step.

   This step clears all the mission and latent faults from the safety checkers. On completion of this step, the SCMF*n*[MISSIONFAULT] and SCLF*n*[LATENTFAULT] must read as 0.

2. Force functional component comparator tree error

   You program the functional component output to 1 in this step.

   This step sets all the mission and latent faults from the safety checkers. On completion of this step, the SCMF*n*[MISSIONFAULT] and SCLF*n*[LATENTFAULT] must read as 1.

3. Reset safety checker faults, and force duplicated component comparator tree error

   You reset all the safety checkers and program the duplicated component output to 1 in this step.

   This step clears all the mission faults and sets all the latent faults from the safety checkers.

   On completion of this step, SCMF*n*[MISSIONFAULT] must read as 0 and SCLF*n*[LATENTFAULT] must read as 1.

4. Reset safety checker faults, and force both functional and duplicated component comparator tree error

   You reset all the safety checkers and program both the functional component and duplicated component outputs to 1 in this step.

   This step sets all the mission faults and clears all the latent faults from the safety checkers.

   On completion of this step, SCMF*n*[MISSIONFAULT] must read as 1 and SCLF*n*[LATENTFAULT] must read as 0.

5. Reset safety checkers faults

   You reset all the safety checkers in this step.

   This step clears all the mission and latent faults from the safety checkers. On completion of this step, SCMF*n*[MISSIONFAULT] and SCLF*n*[LATENTFAULT] must read as 0.

NOTE

Performing BIST sequence latches mission and latent faults in FCCU. You must clear the faults by running the FCCU fault clear mechanism. See the FCCU chapter in this Reference Manual for details.

7.6.7 Coherent read/write transactions

The various components in the Ncore work together to communicate and enforce cache coherence on shared transactions. Each coherent transaction initiates a series of protocol transactions and organizes all the operations to carry out the coherent transaction while ensuring the following:

- Maintains coherence amongst all coherent agents in the chip
- Updates the DIRU that oversees the cache state of all coherent agents in the chip

7.6.7.1 Coherent read transactions

To issue a coherent read transaction, you issue a coherent transaction to the CAI. Ncore performs the following operations on this request:

1. The CAI issues a command to the directory.
2. Ncore access the snoop filter in the directory to determine if the read data is resident in the cache of another coherent master connected to Ncore.
3. The directory issues a snoop message to all the coherent masters indicating the type of coherence operation to be performed.
4. The coherent masters receiving the snoop message responds by indicating the result of the snoop transaction.
    - If the data is found in cache, it is called a directory hit.
    - If the data is not found in any cache, it is called a directory miss.

On a directory hit, the snooped agent forwards the data to the requesting agent.

On a directory miss, the directory issues a memory read transaction through the CMI. The directory fetches the requested data from the main memory and forwards it to the requesting agent.

7.6.7.2 Coherent write transactions

To issue a coherent write transaction, you issue a coherent transaction to the CAI. Ncore performs the following operations on this request:

1. The CAI issues a command to the directory.
2. The directory issues a snoop message to all the coherent masters to invalidate the copies of the data resident in all the caches.
3. The directory issues the write to main memory through the CMI.

7.7 Reset and initialization

NOTE

You must perform the following before executing any cache coherence management operation:

- Initialize Ncore
- Move the chip modules connected with CAIU0 and CAIU1 out of reset. See the chip-specific Ncore information to know about the chip modules that are connected with CAIU0 and CAIU1.

Each structural unit must be in operational state, before processing any transaction.

For a component to be in an operational state, each structural unit within the component must be in operational state.

After a component is in operational state, it can be in either of the following states:

- Offline state
- Online state

A component processes coherent transactions only if it is in an online state.

For a component to be in an online state, each structural unit within the component must be in online state.

A component can be in either of the following states with respect to processing transactions:

- Active state
- Inactive state

A component is in the active state when it is tracking state pertaining to outstanding transactions, otherwise it is in the inactive state. Additionally, when a component is in an offline state, it is in the inactive state with respect to coherent transactions; however, with respect to non-coherent transactions, the component may be in either of the states.

In a configuration with only one coherent agent connected to the CAIUs as active, snoop activity is not required to maintain coherency between the CAIUs. So, when you configure to disable any of the coherent agent, you must ensure disabling of snoop messages (by using DIRUCASE0[CASNPEN*n*]) and DVM messages (by using CSADSE0[DVMSNPEN*n*]) to the CAI.

The following sections describes the sequences that you must perform for transitioning the various components to online state.

7.7.1 CAI initialization

Perform the following procedure for transitioning the CAI to online state:

1. Ensure that all the CAIUs within the interface are in operational state: read the CAIUID register here to identify the features and configuration information of the corresponding CAIU.

   Perform this step for each CAIU if the discovery routine is not performed. See Discovery routine for its procedure.
2. For a fully-coherent agent interface, enable snoop messages to the CAI for each DIRU by writing 1 to the DIRUCASE0[CASNPEN*n*] field corresponding to the CAIUs within the interface.
3. For a CAI that supports ACE DVM transactions on the address coherency channel, enable DVM messages to the CAI for each CAIU within the interface by writing 1 to the corresponding CSADSE0[DVMSNPEN*n*] field.

After CAI is transitioned to operational state, it may enter active state with respect to non-coherent transactions, but it remains in offline state until the above procedure completes.

7.7.2 CMI initialization

To transition the CMI to online state, ensure that all the CMIUs within the interface are in operational state: read the CMIUID register to identify the features and configuration information of the corresponding CMIU.

Perform this for each CMIU if the discovery routine is not performed. See Discovery routine for its procedure.

7.7.3 NCB initialization

To transition the NCB to online state, ensure that all the NCBUs within the interface are in operational state: read the NCBUID register to identify the features and configuration information of the corresponding NCBU.

Perform this for each NCBU if the discovery routine is not done. See Discovery routine for its procedure.

7.7.4 Directory initialization

To transition the directory to online state, ensure that all the DIRUs within the interface are in operational state.

The snoop filter (tag filter) in the directory is in offline state. Following is the procedure to transition the snoop filter to online state:

1. Ensure that the directory is in online state.
2. Ensure the following points for each caching agent associated with the snoop filter:
   a. All outstanding coherent transactions that may allocate cacheline in the agent's cache are complete.

b. Entire cache of the agent is clean and invalidated.

c. All the remaining outstanding coherent transactions from the agent are complete.

d. No new coherent transaction is initiated by the agent.

3. Perform an initialize all entries maintenance operation for each snoop filter in each DIRU within the directory by writing the appropriate values to the DIRUSFMC register. See Snoop filter maintenance for the maintenance operations.
4. Poll the DIRUSFMA[MNTOPACTV] field for each snoop filter in each DIRU within the directory until the field value equals 0.
5. Enable snoop filtering for each snoop filter in each DIRU within the directory by writing 1 to the corresponding DIRUSFE[SFENn] field.

After the directory is in online state, agents may issue coherent transactions via CAIs or NCBs in the online state to any CMI in the online state.

7.7.5 Discovery routine

After all the structural units are in operational state, execute the discovery routine to determine the:

- Number of snoop filters
- Number of each type of unit
- Various unit associations

The discovery routine procedure is as follows:

1. Validate the coherent subsystem release version by using the CSID[RELVER] field.
2. Identify the number of snoop filters in the coherent subsystem by using the CSID[NUMSFS] field.
3. Identify the configuration of each snoop filter in the coherent subsystem by using the corresponding CSSFIDRa register.
4. Identify the number of CAIUs, NCBUs, DIRUs, and CMIUs by using the CSUID register.
5. Read the following CAIUID register fields for each CAIU:
    a. CAIID: To identify the CAI with which the CAIU is associated.
    b. CA: To learn whether the CAIU is associated with a caching agent (that is, a fully-coherent agent). If it is associated, then this field also indicates that a corresponding DIRUCASE0[CASNPEN*n*] field is present.
    c. SFID: If you learn that the CAIU is associated with a caching agent, use this field to identify the snoop filter with which the caching agent is associated. Skip to the next step if the CAIU is not associated with a caching agent.
    d. TYPE: To learn whether the CAIU is associated with a DVM agent. If it is associated, then this field also indicates that a corresponding CSADSE[DVMSNPEN*n*] field is present.
6. Read the NCBUID[NCBID] field for each NCBU to identify the NCB associated with it.
7. Read the following CMIUID register fields for each CMIU:
    a. CMIID: To identify the CMI with which the CMIU is associated.

Discovery routine does not take into account the state of coherent agent connected to the CAIUs. If one of the coherent agent associated with a CAIU is in an inactive state, you must configure Ncore to avoid snoop activity towards the inactive caching agent. So, when you transition a CAIU to offline state, you must disable snoop messages (by using DIRUCASE0[CASNPEN*n*]) and DVM messages (by using CSADSE0[DVMSNPEN*n*]) to the CAI.

7.8 Maintenance operations

Use maintenance operations to initialize caching structures in the coherent subsystem and to manage those caching structures relative to non-coherent agents. The set of caching structures includes any snoop filters (tag filters) in DIRUs. Each set include the following registers:

- A maintenance control register (DIRUSFMC)
- A maintenance activity register (DIRUSFMA)
- A pair of maintenance location registers (DIRUSFMLR0 and DIRUSFMLR1)

Perform a maintenance operation by executing the following procedure:

1. Write the appropriate maintenance location registers with the location of the entry on which the operation is to be performed (if required for the operation).
2. Write the appropriate maintenance control register to initiate the maintenance operation.
3. Poll the maintenance operation active field (MNTOPACTV) in the appropriate maintenance activity register until the field value equals 0.

Successful completion of step 3 completes the maintenance operation.

For each DIRU, you can perform only one maintenance operation at a time. Writes to the maintenance operation registers while the corresponding MNTOPACTV field value equals 1 is ignored.

A maintenance operation operates only on the caching structure implemented by a unit.

7.8.1 Snoop filter maintenance

For a given DIRU, following is a list of maintenance operations that you could perform on a snoop filter:

- Initialize all entries: This operation invalidates all entries in the snoop filter and any associated victim buffer, and initializes the error protection bits in the entries.
- Flush all entries: This operation issues recall transactions for all valid entries in the snoop filter and any associated victim buffer, and leaves all entries in the invalid state.
- Flush entry at set and way: This operation issues a recall transaction for a valid entry at the specified physical set and way in the snoop filter, and leaves the entry in the invalid state.
- Flush entry at address: This operation issues a recall transaction for a valid entry at the specified address in any snoop filter and any associated victim buffer, and leaves the entry in the invalid state.
- Flush all victim buffer entries: This operation issues a recall transaction for all valid entries in the victim buffer associated with the designated snoop filter, and leaves all entries in the invalid state

The DIRUSFMC register corresponding to a DIRU contains the following fields to control the maintenance operation on its snoop filter:

- SFMNTOP: Write appropriate value to this field to specify the type of maintenance operation to be performed.
- SFID: This field identifies the snoop filter on which maintenance operation is performed.
- SFSECATTR: This field identifies the security attribute (secure versus non-secure) of the address on which the snoop filter maintenance operation is performed. A value of 1 indicates a secured configuration.

For the flush entry at set and way maintenance operation, the DIRUSFMLR0 register corresponding to a DIRU contains the following fields to identify the snoop filter entry on which maintenance operation is performed:

- MNTSET: This field identifies the physical set on which maintenance operation is performed.
- MNTWAY: This field identifies the physical way on which maintenance operation is performed.

This operation accesses the snoop filter directly, independent of whether permutation-based interleaving has been enabled for set selection. Additionally, the DIRUSFMLR0[MNTWORD] and DIRUSFMLR1[MNTADDR] field values are set to 0.

For flush entry at address maintenance operation, the DIRUSFMLR0 and DIRUSFMLR1 registers corresponding to a DIRU represents a directory cacheline address within the coherent subsystem address window. Following is the procedure to form this address:

1. Mask off the physical address bits above the most significant bit of the coherent subsystem address window.
2. Shift the result right by the number of bits in the directory cacheline offset.

3. Write the lower order 32 bits of the result into the DIRUSFMLR0 register and the remaining higher order bits into the DIRUSFMLR1 register. There may not be any high order bits for certain system configurations, and in such cases, you do not write anything to the DIRUSFMLR1 register.

The table below summarizes the location specifications based on the type of maintenance operation performed.

Table 21. Location specification

DIRUSFMC[SFMNTOP]	Maintenance operation	DIRUSFMLR1[MNTADDR]	DIRUSFMLR0[MNTWORD]	DIRUSFMLR0[MNTWAY]	DIRUSFMLR0[MNTSET]
0h	Initialize all entries	0	0	0	0
1h-3h	Reserved	N/A	N/A	N/A	N/A
4h	Flush all entries	0	0	0	0
5h	Flush entry at set and way	0	0	Way	Set
6h	Flush entry at address	Directory cacheline address			
7h	Reserved	N/A	N/A	N/A	N/A
8h	Flush all victim buffer entries	0	0	0	0
9h-Fh	Reserved	N/A	N/A	N/A	N/A

Ncore indicates status (whether in progress or have completed) of a maintenance operation by writing to the DIRUSFMA[MNTOPACTV] field.

- A field value of 1 indicates that maintenance operation is ongoing.
- A field value of 0 indicates completion of the maintenance operation.

For the following maintenance operations, you must perform the operation in each DIRU to flush the entire snoop filter:

- Initialize all entries
- Flush all entries
- Flush all victim buffer entries

For the following maintenance operations you must perform the operation only in the appropriate DIRU:

- Flush entry at set and way
- Flush entry at address

7.9 Power management

You reduce power consumption of the system by transitioning component from an operational state to non-operational state.

Before transitioning the units in the component into the non-operational state, you must transition all structural units of a component to an offline state or to the inactive state for non-coherent transactions.

After transitioning components in the coherent subsystem from online state to offline state, preserve the following order to transition the components from the operational state to the non-operational state:

1. Any or all of the following, as required:
   - CAI
   - NCB

- CMI

2. Directory and any tag filters after all of the above are in the offline state

The following sections describes the sequences that you must perform for transitioning the various components to offline state.

7.9.1 CAI power management

Perform the following procedure for transitioning a CAI to offline state:

1. Ensure the following conditions are fulfilled:
   - For fully-coherent agent interface, all outstanding coherent transactions that may allocate cacheline in the agent's cache are complete.
   - For fully-coherent agent interface, entire cache of the agent is clean and invalidated.
   - All the remaining outstanding coherent transactions from the agent are complete.
   - No new coherent transaction is initiated by the agent.
2. For a fully-coherent agent interface, disable snoop messages to the CAI for each DIRU by writing 0 to the DIRUCASE0[CASNPEN*n*] field corresponding to the CAIUs within the interface.
3. For a fully-coherent agent interface, poll the DIRUCASA0[CASNPACTV*n*] field corresponding to the CAIUs within the interface for each DIRU until the field value equals 0.
4. For a CAI that supports ACE DVM transactions on the AC channel, disable DVM messages to the CAI for each CAIU within the interface by writing 0 to the corresponding CSADSE0[DVMSNPEN*n*] field.
5. For a CAI that supports ACE DVM transactions on the AC channel, poll the CSADSA[DVMSNPACTV*n*] field corresponding to the CAIUs within the interface until the field value equals 0.
6. Poll the CAIUTA[SNPACTV] field for each CAIU within the CAI until the field value equals 0.

   Additionaly, for non-coherent transactions, perform the following procedure for transitioning a CAI to inactive state:
7. Ensure that the CAI is in offine state.
8. Ensure the following conditions are fulfilled:
   - All outstanding coherent transactions from all the agent are complete.
   - No new coherent transaction is initiated by any agent.
9. Poll the CAIUTA[TRANSACTV] field for each CAIU within the CAI until the field value equals 0.

See CAI initialization for the procedure to transition the CAI back to online state.

7.9.1.1 Isolated power state

CAI supports an additional state for power management—isolated power state.

In this state:

- Coherent read and write transactions are translated into non-coherent transactions.
- Certain other coherent transactions are terminated within CAI.

In the isolated power state, CAI does not require any additional coherent subsystem resources to process native agent transactions, thus it enables you to transition all other components in the coherent subsystem into offline state. The components in the offline state may then be transitioned into the non-operational state, depending on the configuration of the clock and voltage domains in the system.

The system power state in which a single CAI is in the isolated state and the rest of components in the coherent subsystem are in the offline state is known as the single-agent low-power state.

Perform the following procedure for transitioning a CAI to isolated power state:

1. Ensure the following conditions are fulfilled:

- All other CAIs are in the offline state.
- All NCBs are in the offline state.

2. For a fully-coherent agent interface, disable snoop messages to the CAI for each DIRU by writing 0 to the DIRUCASE0[CASNPEN*n*] field corresponding to the CAIUs within the interface.
3. For a fully-coherent agent interface, poll the DIRUCASA0[CASNPACTV*n*] field corresponding to the CAIUs within the interface for each DIRU until the field value equals 0.
4. For a CAI that supports ACE DVM transactions on the AC channel, disable DVM messages to the CAI for each CAIU within the interface by writing 0 to the corresponding CSADSE0[DVMSNPEN*n*] field.
5. For a CAI that supports ACE DVM transactions on the AC channel, poll the CSADSA[DVMSNPACTV*n*] field corresponding to the CAIUs within the interface until the field value equals 0.
6. Poll the CAIUTA[SNPACTV] field for each CAIU within the CAI until the field value equals 0.
7. Enable isolated power state for each CAIU within the CAI by writing 1 to CAIUTC[ISOLEN].
8. Poll the CAIUTA[COHACTV] field for each CAIU within the CAI until the field value equals 0.

After the CAI enters the Isolated power state, perform the following procedure to enter the single-agent low-power state:

1. Ensure the following conditions are fulfilled:
   - All other CAIs are in the offline state.
   - All NCBs are in the offline state.
2. Transition the CMI and Directory to the offline state.

You can also transition the components in the offline state into the non-operational state.

Perform the following procedure to exit the single-agent low-power state:

1. Transition the CMI and Directory to the online state.
2. Transition the CAI in Isolated power state to the offline state.

   Ncore writes 0 to CAIUTC[ISOLEN] on performing this step.

You can transition the CAIs and NCBs to the online state after exiting the single-agent low-power state.

7.9.2 NCB power management

Perform the following procedure for transitioning an NCB to offline state:

1. Ensure that the following conditions are fulfilled:
   - All outstanding non-coherent transactions from all the agents are complete.
   - No new non-coherent transaction is initiated by any agent.
2. Poll the NCBUTA[TRANSACTV] field for each NCBU within the interface until the field value equals 0.

See NCB initialization for the procedure to transition the NCB back to online state.

7.9.3 CMI power management

Perform the following procedure for transitioning a CMI to offline state:

1. Ensure that the following conditions are fulfilled:
   - All outstanding coherent transactions from all the agents are complete.
   - No new coherent transaction is initiated by any agent.
2. Poll the CMIUTA[TRANSACTV] field for each CMIU within the interface until the field value equals 0.

See CMI initialization for the procedure to transition the CMI back to online state.

7.9.4 Directory power management

Perform the following steps for transitioning a tag filter in a directory to online state:

1. Disable snoop filtering for each DIRU by writing 0 to the DIRUSFE[SFENn] field corresponding to the snoop filter.

Perform the following procedure for transitioning a directory to offline state:

1. Ensure that the following conditions are fulfilled:
   - All outstanding coherent transactions from all the agents are complete.
   - No new coherent transaction is initiated by any agent.
2. Poll the DIRUTA[TRANSACTV] field for each DIRU within the interface until the field value equals 0.

See Directory initialization for the procedure to transition the directory back to online state.

7.10 Memory map and register definition

Only full–word (32-bit) accesses are allowed on all registers in the Ncore memory space.

Fields

Field	Function
31-24 —	Reserved
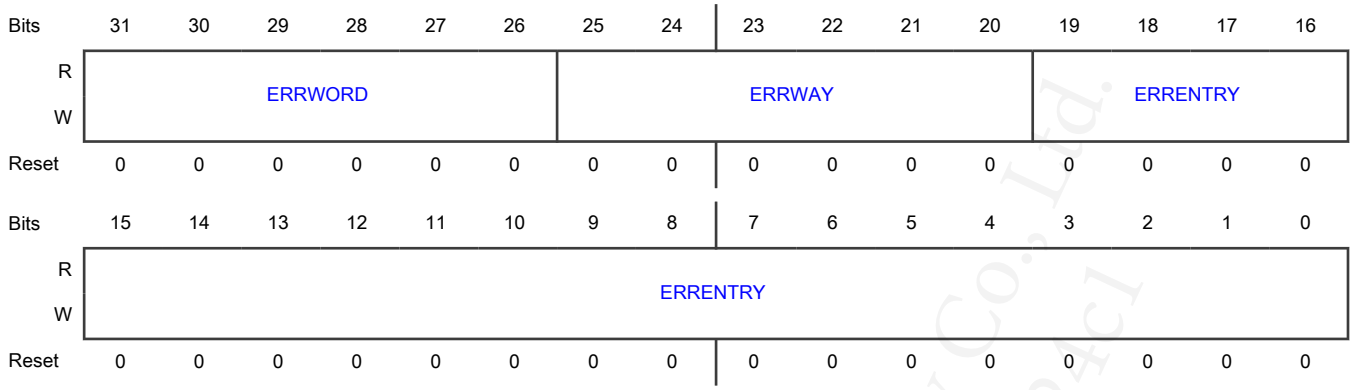
23-16 ERRINFO	Error Info Ncore write appropriate values to this field to indicate additional information about logged errors. Ncore writes to this field only when CMIUCES[ERRVLD] = 1; otherwise, the field is undefined.
15-12 ERRTYPE	Error Type Ncore write appropriate values to this field to indicate the type of logged error. Ncore writes to this field only when CMIUCES[ERRVLD] = 1; otherwise, the field is undefined. • 6h – CMIU data correctable error. When CMIUCES[ERRINFO] = 1h, it decodes to RTT data buffers
11-4 ERRCOUNT	Error Count This field indicates the number of correctable errors detected by the unit. The field value stops incrementing when you write 1 to CMIUCES[ERROVF].
3-2 —	Reserved
1 ERROVF	Error Overflow Ncore writes a 1 to this field to indicate that the number of correctable errors detected by the unit overflowed the value indicated by CMIUCES[ERRCOUNT]. You write a 1 to this field to clear the CMIUCES[ERRCOUNT] field, and it also clears this field.
0 ERRVLD	Error Valid Ncore writes a 1 to this field to indicate that the following registers have logged information about a correctable error; otherwise, certain fields in these registers are undefined. • CMIU Correctable Error Status (CMIUCES) • CMIU Correctable Error Location Register 0 (CMIUCELR0) • CMIU Correctable Error Location Register 1 (CMIUCELR1)

7.10.4.5 CMIU Correctable Error Location Register 0 (CMIUCELR0)



Offset

Register	Offset
CMIUCELR0	108h

Function

This register logs information about the correctable error locations in a CMIU.

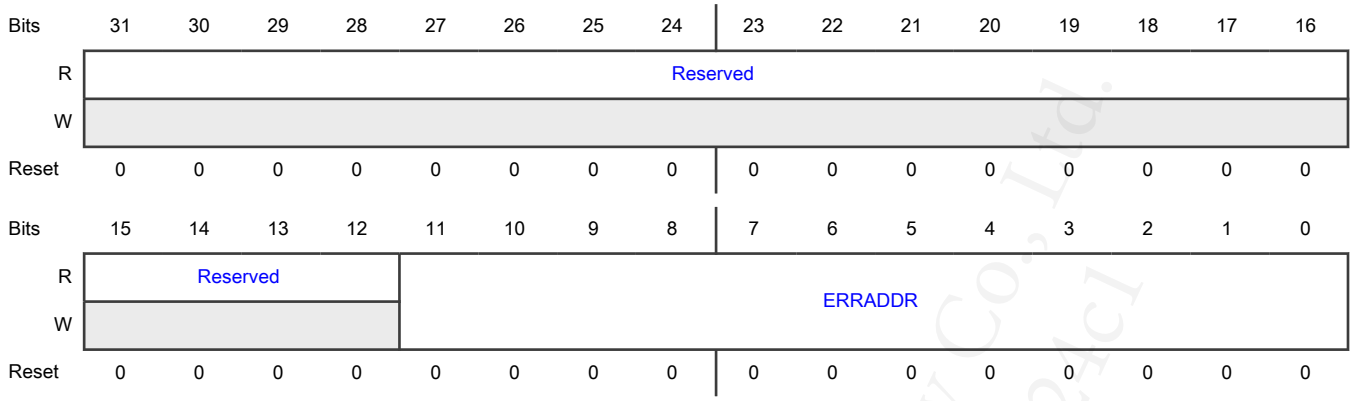
Diagram

Fields

Field	Function
31-26 ERRWORD	Error Word When CMIUCES[ERRVLD] = 1, this field indicates the data word in which the logged error was detected; otherwise, the field is undefined.
25-20 ERRWAY	Error Way When CMIUCES[ERRVLD] = 1, this field indicates the way on which the logged error was detected; otherwise, the field is undefined.
19-0 ERRENTRY	Error Entry or Set When CMIUCES[ERRVLD] = 1, this field indicates the entry or the set index on which the logged error was detected; otherwise, the field is undefined.

7.10.4.6 CMIU Correctable Error Location Register 1 (CMIUCELR1)

Offset



Register	Offset
CMIUCELR1	10Ch

Function

This register logs information about the correctable error locations in a CMIU.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

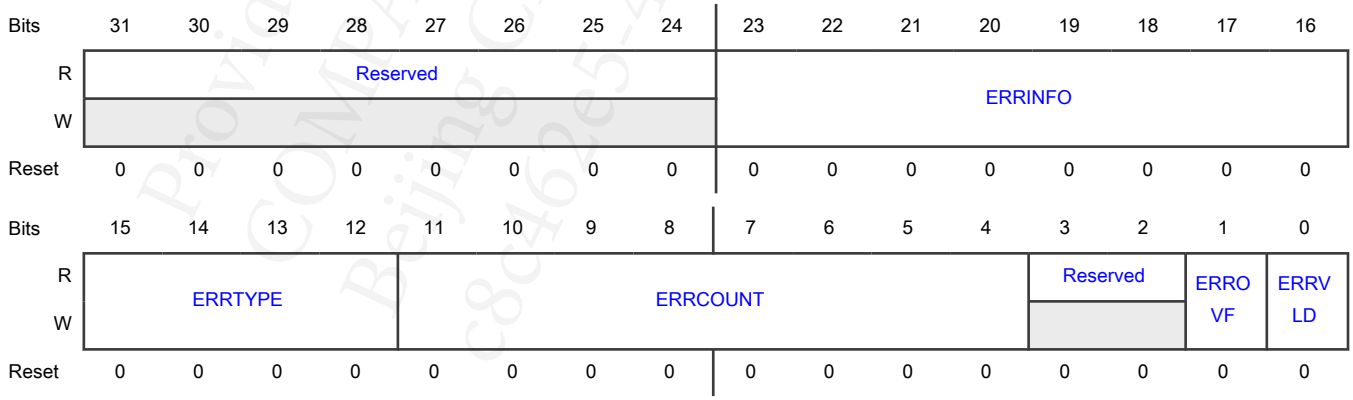
11-0 ERRADDR	Error Address When CMIUCES[ERRVLD] = 1, this field indicates the high-order address bits of the transaction that encountered the error; otherwise, the field is undefined.

7.10.4.7 CMIU Correctable Error Status Alias (CMIUCESA)



Offset

Register	Offset
CMIUCESA	124h

Function

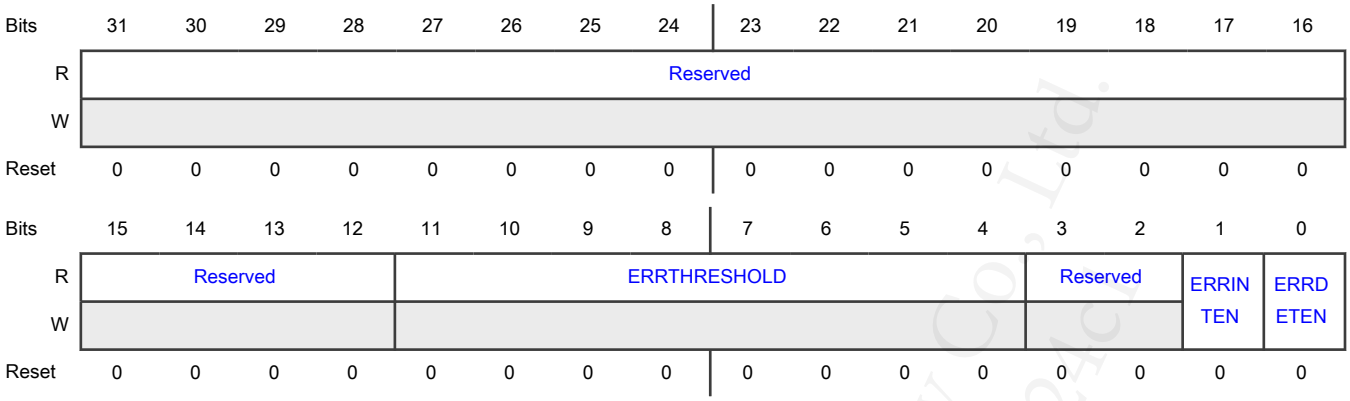
You use this register to have write access to the CMIU Correctable Error Status (CMIUCES) for diagnostic purposes.

Diagram

Fields

Field	Function
31-24 —	Reserved
23-16 ERRINFO	Error Info Ncore writes appropriate values to this field to indicate additional information about logged errors. Ncore writes to this field only when CMIUCESA[ERRVLD] = 1; otherwise, the field is undefined.
15-12 ERRTYPE	Error Type Ncore writes appropriate values to this field to indicate the type of logged error. Ncore writes to this field only when CMIUCESA[ERRVLD] = 1; otherwise, the field is undefined. • 6h – CMIU data correctable error. When CMIUCESA[ERRINFO] = 1, it decodes to RTT data buffers
11-4 ERRCOUNT	Error Count This field indicates the number of correctable errors detected by the unit. The field value stops incrementing when you write a 1 to CMIUCESA[ERROVF].
3-2 —	Reserved
1 ERROVF	Error Overflow Ncore writes a 1 to this field to indicate that the number of correctable errors detected by the unit overflowed the value indicated by CMIUCESA[ERRCOUNT]. You write a 1 to this field to clear the CMIUCESA[ERRCOUNT] field.
0 ERRVLD	Error Valid Ncore writes a 1 to this field to indicate that the following registers have logged information about a correctable error; otherwise, certain fields in these registers are undefined. • CMIU Correctable Error Status (CMIUCES) • CMIU Correctable Error Location Register 0 (CMIUCELR0) • CMIU Correctable Error Location Register 1 (CMIUCELR1)

7.10.4.8 CMIU Uncorrectable Error Control (CMIUUEC)



Offset

Register	Offset
CMIUUEC	140h

Function

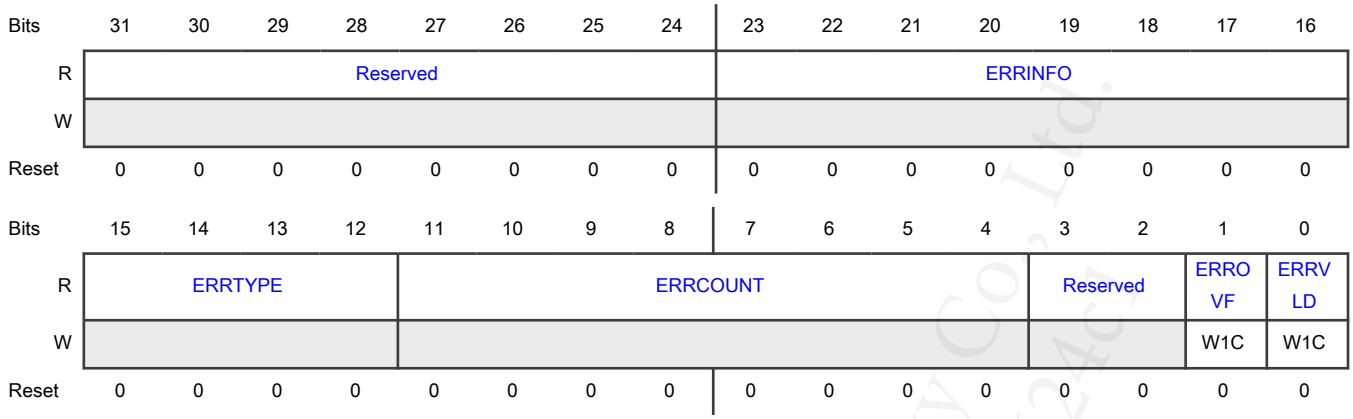
Use this register to control the detection and signaling of uncorrectable errors in a CMIU.

Diagram

Fields

Field	Function
31-12 —	Reserved
11-4 ERRTHRESHOLD	Uncorrectable Error Threshold Use this field to determine the threshold number of uncorrectable errors that must be detected before Ncore asserts the uncorrectable error interrupt signal.
3-2 —	Reserved
1 ERRINTEN	Uncorrectable Error Interrupt Enable Use this field to control the assertion of uncorrectable error interrupt signal on fulfilment of proper conditions. 0b - Disable assertion 1b - Enable assertion
0 ERRDETEN	Uncorrectable Error Detection Enable Use this field to control uncorrectable error detection and logging logic. 0b - Disable uncorrectable error detection and logging logic 1b - Enable uncorrectable error detection and logging logic

7.10.4.9 CMIU Uncorrectable Error Status (CMIUUES)



Offset

Register	Offset
CMIUUES	144h

Function

This register logs information about the uncorrectable errors in a CMIU.

Diagram

Fields

Field	Function
31-24 —	Reserved
23-16 ERRINFO	Error Info Ncore writes appropriate values to this field to indicate additional information about logged errors. Ncore writes to this field only when CMIUUES[ERRVLD] = 1; otherwise, the field is undefined.
15-12 ERRTYPE	Error Type Ncore writes appropriate values to this field to indicate the type of logged error. Ncore writes to this field only when CMIUUES[ERRVLD] = 1; otherwise, the field is undefined. • 6h – CMIU data uncorrectable error. When CMIUUES[ERRINFO] = 1h, it decodes to HTT data buffers
11-4 ERRCOUNT	Error Count This field indicates the number of uncorrectable errors detected by the unit. The field value stops incrementing when you write a 1 to CMIUUES[ERROVF].
3-2 —	Reserved
1 ERROVF	Error Overflow Ncore writes a 1 to this field to indicate that the number of uncorrectable errors detected by the unit overflowed the value indicated by CMIUUES[ERRCOUNT]. You write a 1 to this field to clear the CMIUUES[ERRCOUNT] field.
0 ERRVLD	Error Valid Ncore writes a 1 to this field to indicate that the following registers have logged information about an uncorrectable error; otherwise, certain fields in these registers are undefined.

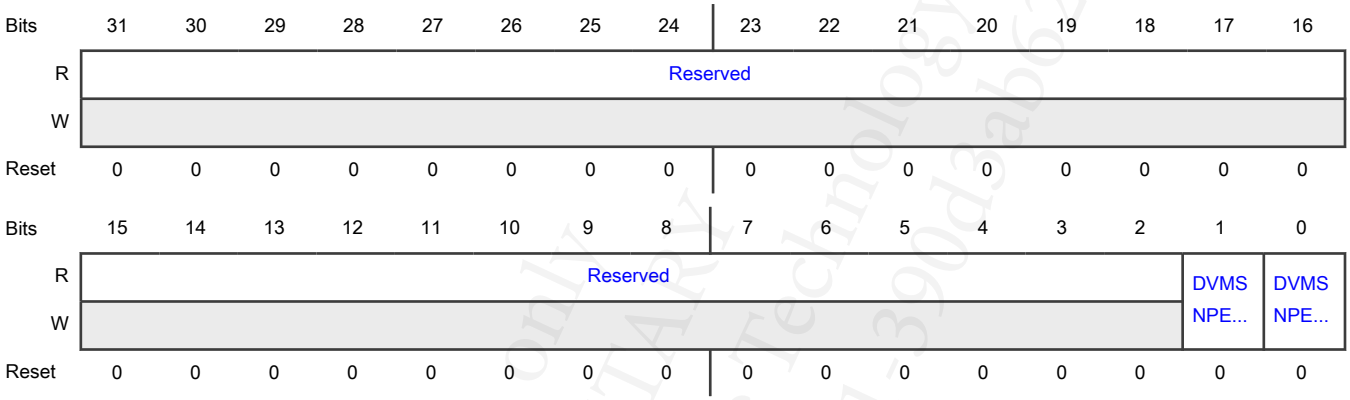
7.10.5.2 Coherent Subsystem ACE DVM Snoop Enable (CSADSE0)



Offset

Register	Offset
CSADSE0	40h

Function

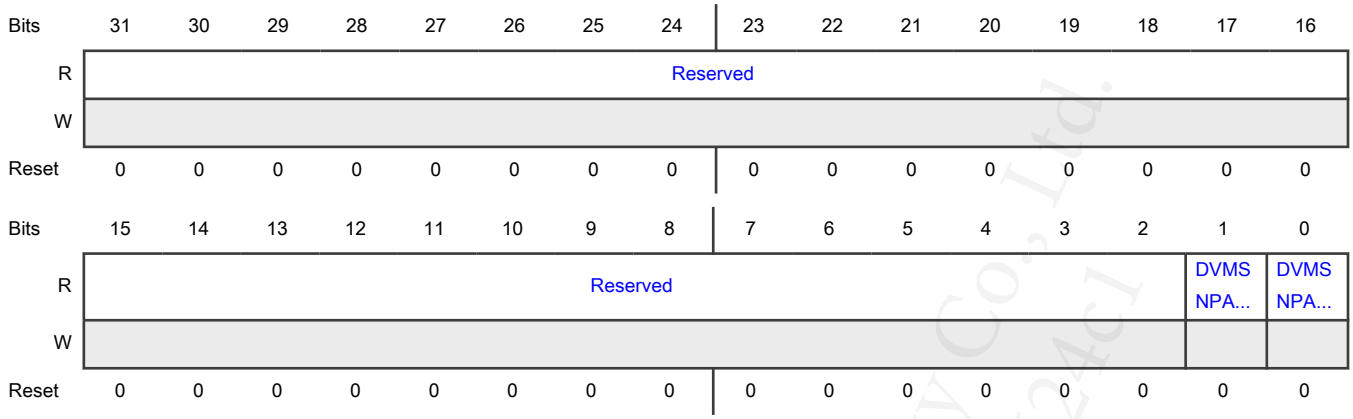
Use this register to enable DVM-related snoop messages to the CAIU associated with a snooped DVM agent.

Diagram

Fields

Field	Function
31-2 —	Reserved
1-0 DVMSNPENn	ACE DVM Snoop Enable n Use this field to control DVM-related snoop messages for the respective CAIU. 0b - Disable 1b - Enable

7.10.5.3 Coherent Subsystem ACE DVM Snoop Activity (CSADSA)



Offset

Register	Offset
CSADSA	50h

Function

Use this register to learn whether the DVM-related snoop messages to the CAIU that is associated with a snooped DVM agent is active or not.

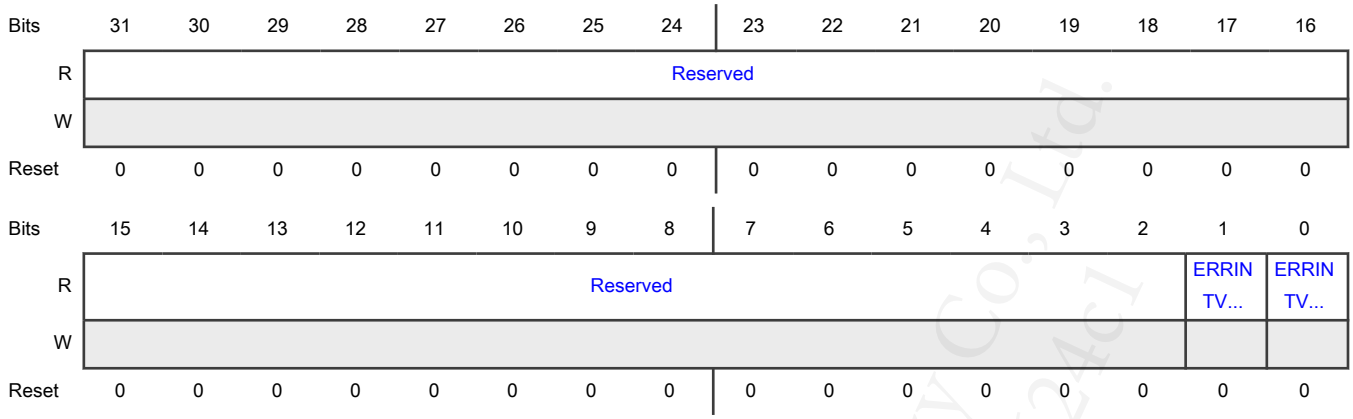
Diagram

Fields

Field	Function
31-2 —	Reserved
1-0 DVMSNPACTVn	ACE DVM Snoop Active Ncore writes a 1 to this field if DVM-related snoop messages are active for the respective CAIU.

7.10.5.4 Coherent Subsystem Correctable Error Interrupt Status (CSCEIS0 - CSCEIS3)

Offset



Register	Offset
CSCEIS0	100h
CSCEIS3	10Ch

Function

Use these registers to learn whether a unit has asserted a correctable error interrupt.

Provided under NDA only

Chapter 8
Miscellaneous System Control Module (MSCM)

8.1 Introduction

MSCM contains CPU configuration registers and on-chip memory controller registers.

8.1.1 Features

MSCM provides:

- Software-accessible processor core configuration information
- Interrupt router control registers
- Message-based interrupt configuration and management registers

8.2 Memory map and register definition

This section discusses the following topics:

- Core configuration registers
- Message-signaled interrupt (MSI) routing
  - Core-to-core MSIs
  - PCIe-to-core message-signaled interrupts
- Shared peripheral interrupt routing

8.2.1 Core configuration registers

These read-only registers contain data that defines the core setup for this chip. You can access the registers using 32-bit read references; other access sizes terminate with an error. Attempted write accesses to the read-only core configuration registers also terminate with an error.

The core configuration portion of the MSCM programming model map is organized based on the logical core number, and not on any type of physical port number. The following table shows how the configuration is partitioned.

Table 22. MSCM core configuration partitioning

Offset address range	Purpose
0h - 18h	Defines the generic core x configuration information. Only the Cortex-A53 and Cortex-M7 cores on this chip can access this region in either user or privileged mode; reads by non-core[1] bus masters (including the debugger) are treated as read as zero (RAZ) accesses. Write attempts are not permitted and terminate with an error.
20h - 38h	Defines the configuration information for core 0 (CP0). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.
40h - 58h	Defines the configuration information for core 1 (CP1). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.
60h - 78h	Defines the configuration information for core 2 (CP2). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.
80h - 98h	Defines the configuration information for core 3 (CP3). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.

Table continues on the next page...

Table 22. MSCM core configuration partitioning (continued)

Offset address range	Purpose
A0h - B8h	Defines the configuration information for core 4 (CP4). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.
C0h - D8h	Defines the configuration information for core 5 (CP5). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.
E0h - F8h	Defines the configuration information for core 6 (CP6). A bus master can access this region in either user or privileged mode. Write attempts are not permitted and terminate with an error.

1. A non-core bus master is one that is not Cortex-A53 or Cortex-M7.

NOTE

Attempted accesses to reserved locations are not permitted and terminate with an error. Debugger accesses referred to in this document are accesses from the system MEM-AP and not the core accesses through debugger.

8.2.2 Shared peripheral interrupt (SPI) routing

The SPI router portion of MSCM provides a set of memory-mapped registers defining the interrupt routing for all SPIs on this chip.

8.2.3 MSCM register descriptions

8.2.3.1 MSCM memory map

8.2.3.2 Processor X Type Register (CPXTYPE)

Offset

Register	Offset
CPXTYPE	0h

Function

This register provides a CPU-specific response indicating the personality of the core making the access. The 32-bit response includes four ASCII characters defining the CPU type (Cortex-A53 or Cortex-M7) along with a byte defining the logical revision number. This number follows Arm's rYpZ nomenclature.

A read from the Cortex-A53 or Cortex-M7 returns the appropriate processor information. Reads from any other bus master return all 0s. Attempted write accesses terminate with an error.

Access: Read by core masters Cortex-M7 and Cortex-A53 only

8.2.3.3 Processor X Number Register (CPXNUM)

Offset

Register	Offset
CPXNUM	4h

Function

This register provides a CPU-specific response indicating the logical processor number of the core making the access.

A read from the Cortex-A53 or the Cortex-M7 cores returns the appropriate processor information. Reads from any other bus master return all 0s. Attempted write accesses terminate with an error.

Access: Read by core masters Cortex-M7 and Cortex-A53 only

Fields

Field	Function
31-24 ICSZ	L1 Instruction Cache Size This field provides an encoded value of the instruction cache size. The capacity of the memory is derived using the formula 2^(8+SZ) and expressed as bytes. Here, SZ is a non-zero value, and SZ = 0 indicates that the memory is not present. **Table 26. L1 instruction cache size x ICSZ**

Instruction cache size	ICSZ
No instruction cache	0h
4 KB instruction cache	4h
8 KB instruction cache	5h
16 KB instruction cache	6h
32 KB instruction cache	7h
64 KB instruction cache	8h
128 KB instruction cache	9h
256 KB instruction cache	Ah
512 KB instruction cache	Bh
Cortex-A53 cores	7h (32 KB)
Cortex-M7 cores	7h (32 KB)

23-16 ICWY	L1 Instruction Cache Ways This field provides the number of cache ways for the instruction cache. • For the Cortex-A53 cores in this chip, ICWY = 2h (2-way set-associative). • For the Cortex-M7 cores in this chip, ICWY = 2h (2-way set-associative).
15-8 DCSZ	L1 Data Cache Size This field provides an encoded value of the data cache size. The capacity of the memory is derived using the formula 2^(8+SZ) and expressed as bytes. Here, SZ is a non-zero value, and SZ = 0 indicates that the memory is not present. **Table 27. Data cache size x DCSZ**

Data cache size	DCSZ
No data cache	0h
4 KB data cache	4h
8 KB data cache	5h
16 KB data cache	6h
32 KB data cache	7h
64 KB data cache	8h

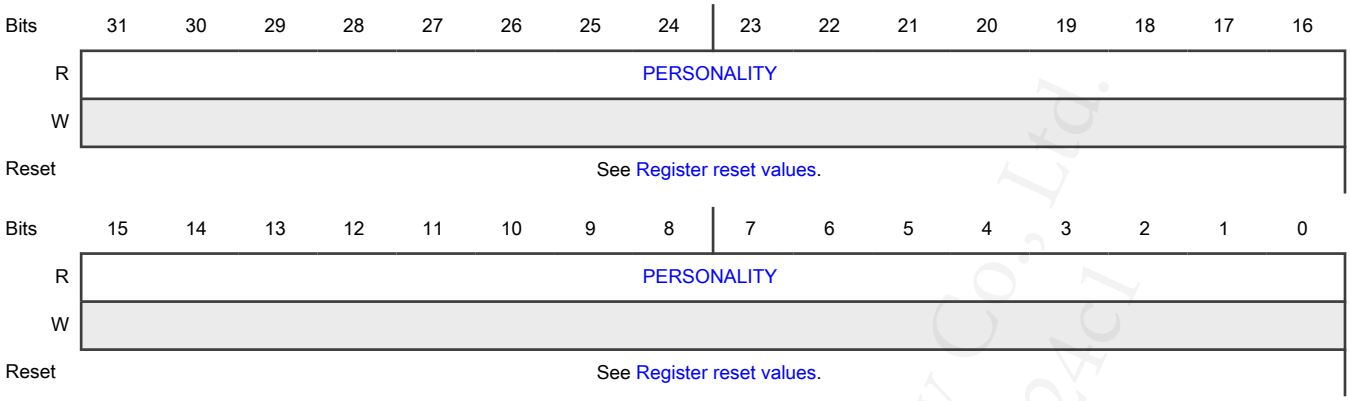
	• For the Cortex-A53 cores in this chip, MMU = 1h (supported). • For the Cortex-M7 cores in this chip, MMU = 0h (not supported).
1 SIMD	SIMD/Neon Instruction Support This field indicates if the instruction set extensions supporting SIMD and/or Neon capabilities are supported in the processor. • If SIMD/Neon support is not included, SIMD = 0h. • If SIMD/Neon support is included, SIMD = 1h. • For the Cortex-A53 cores in this chip, SIMD = 1h (supported). • For the Cortex-M7 cores in this chip, SIMD = 1h (supported).
0 HW_FPU	Floating Point Unit This field indicates if hardware support for floating point capabilities is supported in the processor. • If HW_FPU support is not included, HW_FPU = 0h. • If HW_FPU support is included, HW_FPU = 1h. • For the Cortex-A53 cores in this chip, HW_FPU = 1h (supported). • For the Cortex-M7 cores in this chip, HW_FPU = 1h (supported).

8.2.3.9 Processor Type Register (CP0TYPE - CP6TYPE)

Offset

Register	Offset
CP0TYPE	20h
CP1TYPE	40h
CP2TYPE	60h
CP3TYPE	80h
CP4TYPE	A0h
CP5TYPE	C0h
CP6TYPE	E0h

Function



This register defines the configuration information for CP0-6 . It has the same field definitions and functionality as provided in Processor X Type Register (CPXTYPE).

A read from any bus master returns the appropriate processor information and attempted write accesses terminate with an error.

NOTE

The reset value depends on the processor.

Preliminary Information COMPANY CONFIDENTIAL Beijing CHANGAN Automotive Technology Co., Ltd. c8d5e5_4a2f4818a2951390d3ab624c1

8.2.3.16 Interrupt Router CPa Interruptb Status Register (IRCP0ISR0 - IRCP6ISR2)

Offset

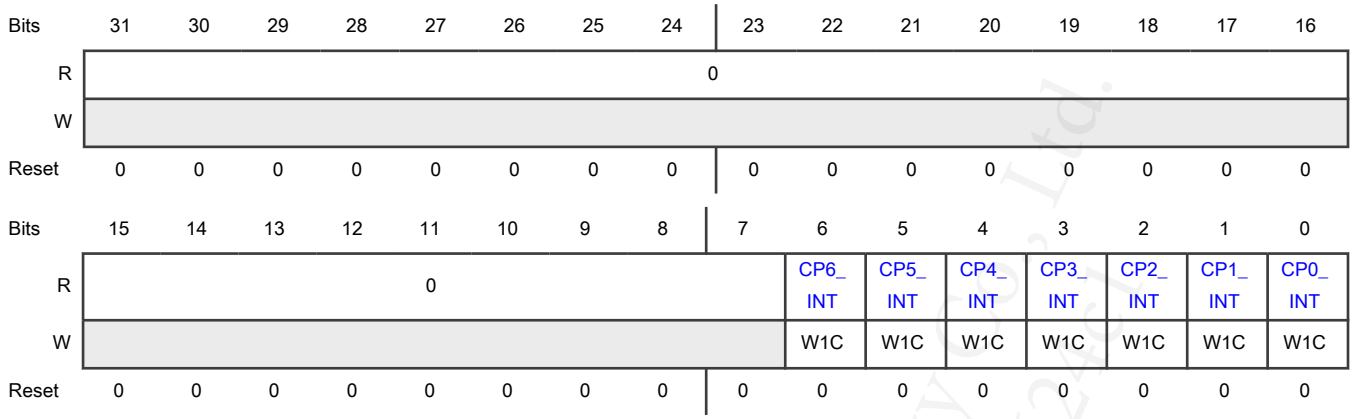
For a = 0 to 6; b = 0 to 2:

Register	Offset
IRCPaISRb	200h + (a × 20h) + (b × 8h)

Function

The IRCP*n*ISR{0,1,2} set of registers provides an interrupt bitmap, in which each bit defines the state of a unique MSI based on the initiating core. An MSI interrupt is cleared in an interrupt handler by writing a 1 to the appropriate field in the IRCP*n*ISR*x* register.

In this discussion, CP*m* represents the initiating core and CP*n* represents the target core for a core-to-core interrupt.



Read access

- Reads to IRCP*n*ISR{0,1,2} are only accessible in Privileged mode using 32-bit (word) accesses.
- Privileged, 32-bit read accesses from non-core (and non-debugger) bus masters are treated as Read-as-Zero (RAZ).
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- When CP*n* requests to read IRCP*n*ISR{0,1,2}, MSCM returns the entire content of IRCP*n*ISR{0,1,2}.
- When a trusted core, as indicated by IRCPCFG, requests to read IRCP*n*ISR{0,1,2}, MSCM returns the entire content of IRCP*n*ISR{0,1,2}.
- When the debugger requests to read IRCP*n*ISR{0,1,2}, MSCM returns the entire content of IRCP*n*ISR{0,1,2}.
- When CP*m* requests to read IRCP*n*ISR{0,1,2}, MSCM only returns the value of the corresponding status, CP*m*_INT, while not exposing all other pending interrupts initiated by the other cores.
- When CP*m* requests to read IRCP*n*ISR{0,1,2}, MSCM returns the value of the corresponding status, CP*m*_INT, in bit position 0, reflecting how CP*m* set the MSI when it wrote to IRCP*n*IGR{0,1,2}. All other fields on the returned read value are zero-filled.

Write access

- Writes to IRCP*n*ISR{0,1,2} are only accessible in Privileged mode using 32-bit (word) accesses.
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- Writes to IRCP*n*ISR{0,1,2} follow the Write 1 to Clear (W1C) protocol, whereby writing a 1 clears the corresponding field, and writing 0 is ignored.
- PCIe_0 access is restricted to registers IRCPnIGR3 and IRCPnISR3, and PCIe_1 access is restricted to registers IRCPnIGR4 and IRCPnISR4.
- The target core, CP*n*, has full access to write to all the fields of IRCP*n*ISR*x*.
- A trusted core, as indicated by IRCPCFG, has full access to write to all the fields of IRCP*n*ISR{0,1,2}.
- When CP*m* is different from CP*n*, the W1C action by CP*m* only clears IRCP*n*ISR{0,1,2}[CP*m*_INT].
- The CP*m* field must present W1C in bit position 0 to clear its corresponding interrupt. Write data bits 1-31 that CP*m* presents are ignored.
- The privileged write accesses from non-core (and non-debugger) bus masters are treated as Writes Ignored (WI).
- The privileged write accesses from the debugger are treated as WI.

Diagram

Fields

Field	Function
31-7 —	Reserved
6 CP6_INT	CP6-to-CPn Interrupt This field generates a directed interrupt initiated by core 6 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 6 writes a 1 to clear the field. 0b - CP6 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP6, is asserted.
5 CP5_INT	CP5-to-CPn Interrupt This field generates a directed interrupt initiated by core 5 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 5 writes a 1 to clear the field. 0b - CP5 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP5, is asserted.
4 CP4_INT	CP4-to-CPn Interrupt This field generates a directed interrupt initiated by core 4 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 4 writes a 1 to clear the field. 0b - CP4 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP4, is asserted.
3 CP3_INT	CP3-to-CPn Interrupt This field generates a directed interrupt initiated by core 3 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 3 writes a 1 to clear the field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - CP3 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP3, is asserted.
2 CP2_INT	CP2-to-CPn Interrupt This field generates a directed interrupt initiated by core 2 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 2 writes a 1 to clear the field. 0b - CP2 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP2, is asserted.
1 CP1_INT	CP1-to-CPn Interrupt This field generates a directed interrupt initiated by core 1 targeting core *n*, if the appropriate interrupt routing field is enabled. The interrupt is negated when the target core, a trusted core, or core 1 writes a 1 to clear the field. 0b - CP1 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP1, is asserted.
0 CP0_INT	CP0-to-CPn Interrupt This field generates a directed interrupt initiated by core 0 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 0 writes a 1 to clear the field. 0b - CP0 does not assert any interrupt to CPn. 1b - Interrupt to CPn, initiated by CP0, is asserted.

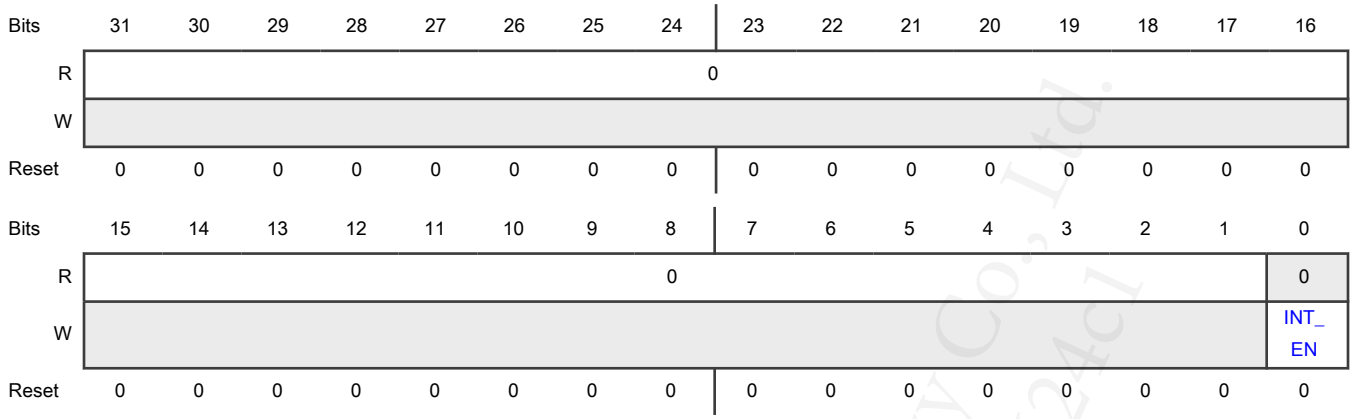
8.2.3.17 Interrupt Router CPa Interruptb Generation Register (IRCP0IGR0 - IRCP6IGR2)

Offset

For a = 0 to 6; b = 0 to 2:

Register	Offset
IRCPaIGRb	204h + (a × 20h) + (b × 8h)

Function



The IRCP*n*IGR{0,1,2} set of registers provides a mechanism for cores to initiate an MSI to another core in the system.

Privileged, 32-bit accesses from the:

- Cortex-A53 or Cortex-M7 cores are treated as RAZ/W
- Debugger are treated as RAZ/WI
- Non-core (and non-debugger) bus masters are treated as RAZ/WI

Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.

Diagram

Fields

Field	Function
31-1 —	Reserved
0 INT_EN	Interrupt Enable A write to this field by CP*m* initiates a core-to-core interrupt targeting CP*n*.

8.2.3.18 Interrupt Router CPa Interruptb Status Register (IRCP0ISR3 - IRCP6ISR4)

Offset

For a = 0 to 6; b = 3 to 4:

Register	Offset
IRCPaISRb	-E8h + (a × 20h) + (b × 100h)

Function

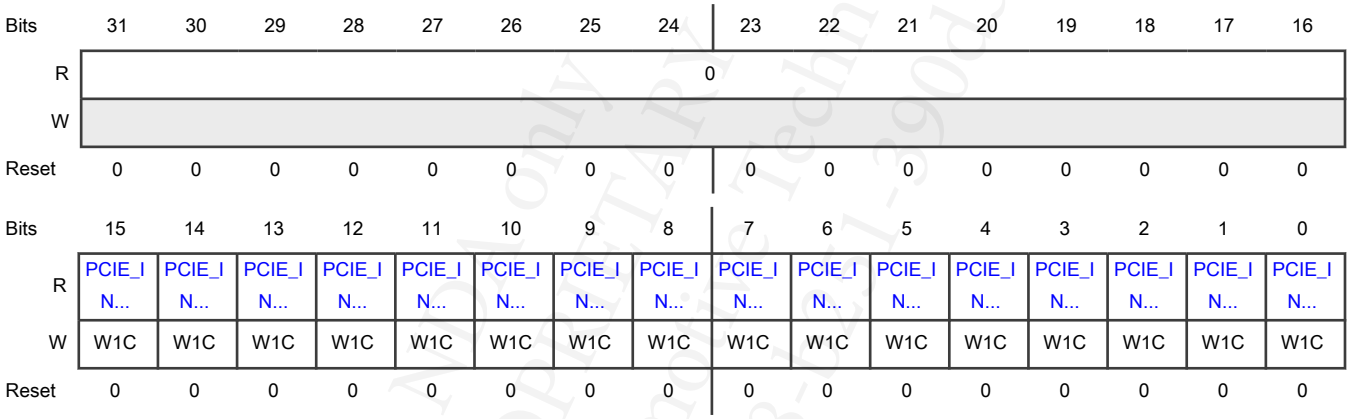
CP*n* represents the target core for a PCIe-to-core interrupt.

The fields of this register generate a directed interrupt initiated by PCIe, targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core or a trusted core writes 1 to clear the field.

NOTE

IRCPnISR3 and IRCPnIGR3 correspond to the PCIe_0 interrupt; IRCPnISR4 and IRCPnIGR4 correspond to the PCIe_1 interrupt.

Read access



- Reads to IRCP*n*ISR*p* are only accessible in Privileged mode using 32-bit (word) accesses.
- Privileged, 32-bit read accesses from non-core (and non-debugger) bus masters are treated as Read-as-Zero (RAZ).
- Privileged, 32-bit read accesses from any other core, except CP*n*, are treated as RAZ.
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.

- When CP*n* requests to read IRCP*n*ISR*p*, MSCM returns the entire content of IRCP*n*ISR*p*.
- When the debugger requests to read IRCP*n*ISR*p*, MSCM returns the entire content of IRCP*n*ISR*p*.
- When a trusted core, as indicated by IRCPCFG, requests to read IRCP*n*ISR*p*, MSCM returns the entire content of the IRCP0ISR*p* register.

Write access

- Writes to IRCP*n*ISR*x* are only accessible in Privileged mode using 32-bit (word) accesses.
- Writes to IRCP*n*ISR*x* follow the W1C protocol, whereby writing 1 clears the corresponding field and writing 0 is ignored.
- Privileged, 32-bit write accesses from the debugger are treated as WI.
- Privileged, 32-bit write accesses from non-core (and non-debugger) bus masters are treated as WI.
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- The target core, CP*n*, has full access to write to all the fields of the IRCP0ISR*x* register.
- A trusted core, as indicated by IRCPCFG, has full access to write to all the fields of IRCP*n*ISR*x*.

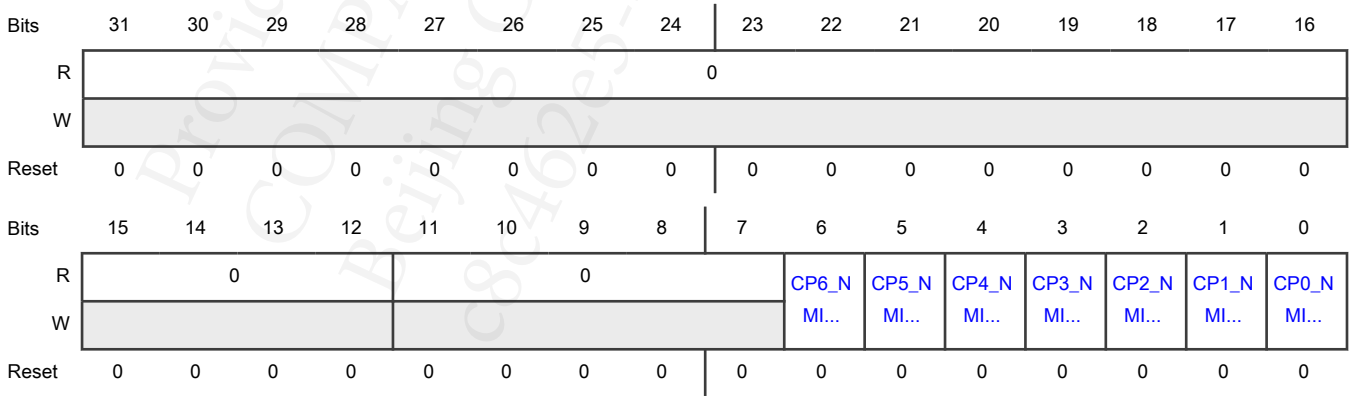
8.2.3.22 Interrupt Router Non-Maskable Interrupt Control Register (IRNMIC)



Offset

Register	Offset
IRNMIC	800h

Function

This register enables the routing control for the non-maskable interrupt (NMI) request to specific cores. For this chip, each interrupt request can be routed using the enable fields in this register. If the value of all the fields is 0, the interrupt request is disabled. Privileged accesses from non-core (and non-debug) bus masters are treated as RAZ/WI and any attempted User mode reference is terminated with an error.

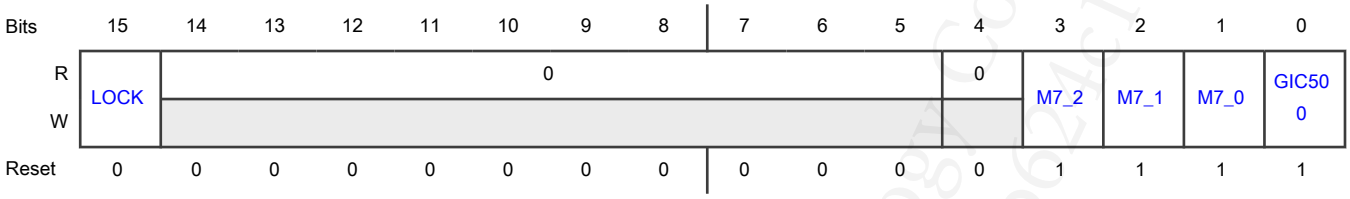
8.2.3.23 Interrupt Router Shared Peripheral Routing Control Register (IRSPRC0 - IRSPRC239)

Offset

For a = 0 to 239:

Register	Offset
IRSPRCa	880h + (a × 2h)

provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c46265-4821-4aa8-2513-9003ab624c1



Function

This register provides an array of halfword (16-bit) registers, where each register defines the routing control for the corresponding interrupt request. For this chip, each interrupt request can be routed using the bit-mapped fields in IRSPRC*n*. If all the CP*x*E*n* bits are cleared, the interrupt request is disabled. For each routing control, halfword can be locked by asserting the LOCK field.

Non-core, non-debugger accesses to these registers receive errors and the read data is undefined.

Access: Privileged read/write

Diagram

Fields

Field	Function
15 LOCK	Lock Interrupt Request This field provides a mechanism to lock the routing of the corresponding interrupt request. After the field is asserted, attempted writes to the IRSPRC*n* register are ignored until the next reset clears the flag. 0b - Writes to the IRSPRCn are allowed. 1b - Writes to the IRSPRCn are ignored.
14-5 —	Reserved
4 —	Reserved
3 M7_2	Enable Cortex-M7_2 Interrupt Steering This field enables the routing of the corresponding interrupt request to Cortex-M7_2.

1 M7_0	Enable Cortex-M7_0 Interrupt Steering This field enables the routing of the corresponding interrupt request to Cortex-M7_0.
0 GIC500	Enable GIC500 Interrupt Steering This field enables the routing of the corresponding interrupt request to GIC500 associated with the Cortex-A53 clusters.

8.3 Functional description

This section discusses the following topics:

- MSI routing

— Core-to-core MSIs

— PCIe-to-core MSIs

- Interrupt steering and semaphores
  - — Interrupt handling overview
  - — MSCM interrupt router functional description

8.3.1 MSI routing

MSIs are interrupts that are indirectly broadcast to a target core by writing configuration bits in MSCM. These interrupts can either be initiated by one core targeting another core in the system (known as core-to-core interrupts), or by PCIe targeting a core in the system (known as PCIe-to-core interrupts).

These MSIs are initiated via writes to IRCP*n*IGR*x* and managed through the IRCP*n*ISR*x* registers, where *n* indicates the logical core number (0-6) and *x* represents the interrupt number (0-3). Each of the seven cores can support up to three outstanding core-to-core interrupts and one outstanding PCIe-to-core interrupt.

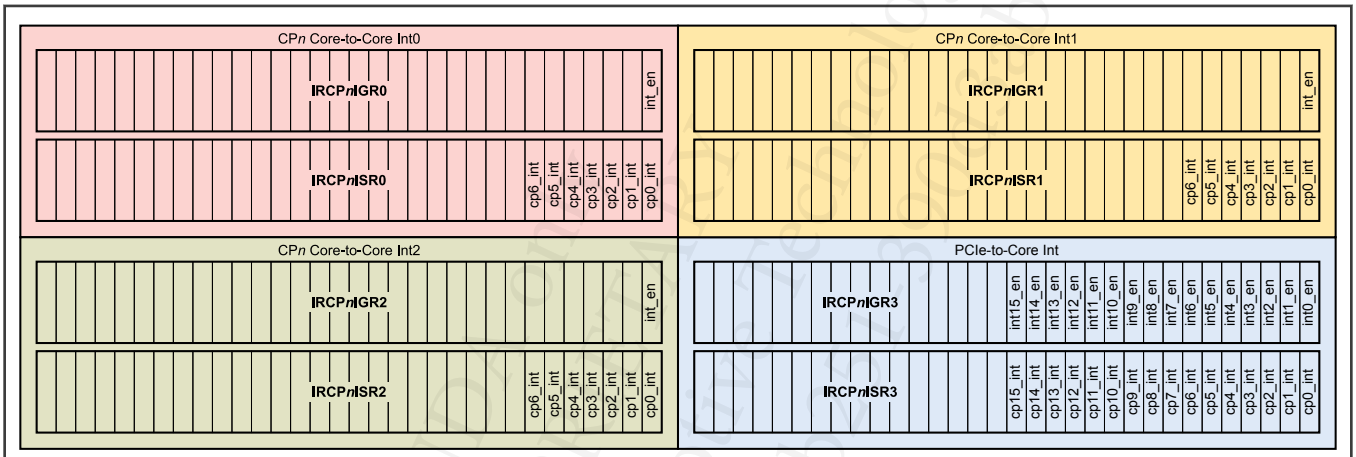

Figure 16. IRCP*n*IGR*x*/IRCP*n*ISR*x* pairs for one core

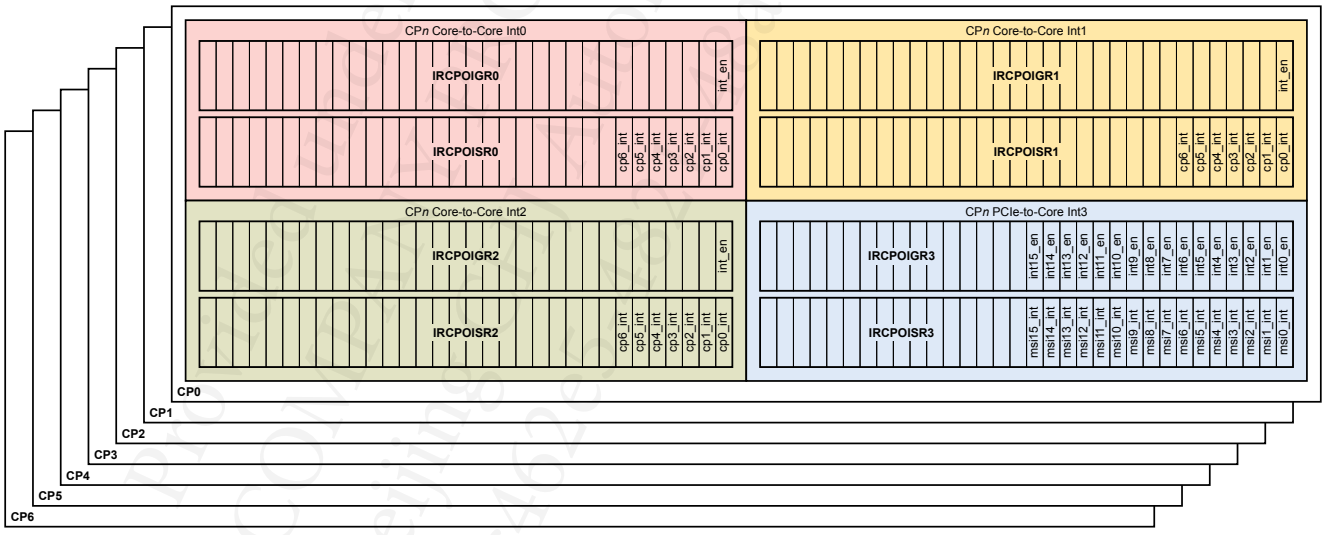

Figure 17. IRCP*n*IGR*x*/IRCP*n*ISR*x* pairs per core

8.3.1.1 Core-to-core MSIs

The next figure depicts the sequence for initiating a core-to-core MSI, in which CP*m* represents the initiating core, CP*n* represents the target core, and CP*x* indicates the MSI number. CP*m* writes to the IRCP*n*IGR*x* to initiate an MSI. The outstanding MSI that CP*m* initiates, targeting CP*n*, is reflected in the corresponding bit-mapped field in IRCP*n*ISR*x*. For example, an MSI is initiated by CP6 by writing to IRCP*n*IGR[INT_EN], and then reflected in IRCP*n*ISR*x*[CP6_INT].

At any given time, there can be up to three pending MSIs initiated by different cores.

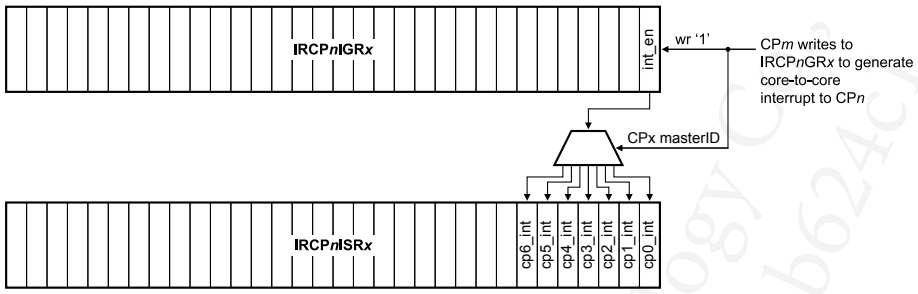

Figure 18. Initiating a core-to-core MSI via IRCP*n*IGR{0,1,2}/IRCP*n*ISR{0,1,2}

8.3.1.2 PCIe-to-core MSIs

The following figure depicts the sequence for initiating a PCIe-to-core interrupt, in which CP*n* represents the target core. PCIe writes to IRCP*n*IGR*p* to initiate an MSI. The outstanding MSI targeting CP*n* is reflected in IRCP*n*ISR3. This register contains bit-mapped fields indicating the initiating source of the MSI. A given core can support up to 16 outstanding PCIe-initiated MSIs.

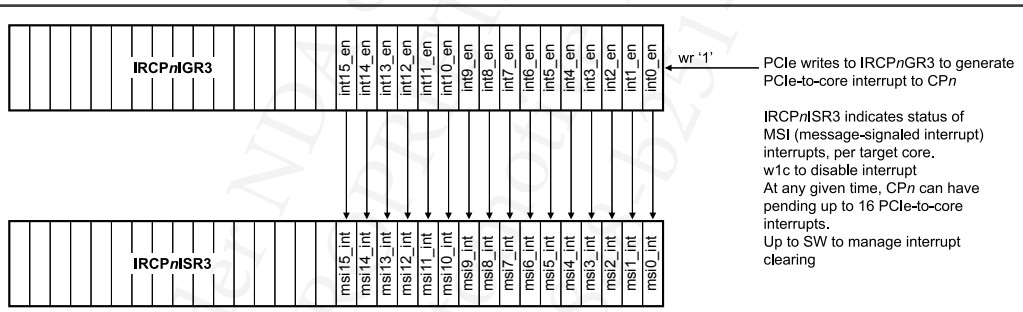

Figure 19. Initiating a core-to-core MSI via IRCP*n*IGR*p*/IRCP*n*ISR*p*

8.3.2 Interrupt steering and semaphores

This section discusses these topics:

- Interrupt handling overview
- MSCM interrupt router functional description

8.3.2.1 Interrupt handling overview

The interrupt handling mechanisms of the Cortex-A53 and Cortex-M7 cores differ significantly. The Cortex-A53 processor uses a simple, two-interrupt request mechanism: fast interrupt request(FIQ) and interrupt request (IRQ), with two corresponding exception vector instructions, while the Cortex-M7 has a nested vector interrupt controller (NVIC) tightly coupled to the processor core. The real-time performance of Cortex-M7 means that the NVIC directly provides the appropriate interrupt vector, in the form of the starting instruction address for the interrupt handler, to the core. These Cortex-M7 architectural features directly translate into faster interrupt status register (ISR) entries and exit capabilities, with an improved runtime performance. See the Arm core technical reference manuals for details.

In the Cortex-A53 core complex, a generic interrupt controller (GIC) manages the IRQ collection and prioritization for the processor and provides a functionality similar to the NVIC of Cortex-M7. To minimize software complexity, a common view of the interrupt requests and their routing mechanisms is implemented, although it must be recognized that the differences between the NVIC and the GIC do require the ISRs to be customized for the appropriate processor.

In this architecture, a total of 240 IRQs are supported where this parameter is defined by the realistic limits of the NVIC implementation, both in terms of silicon size and supported frequency of operation. These 240 IRQs are split into a total of eight directed requests and 232+ shared peripheral requests. Unless noted otherwise, let the directed requests be defined as INT[7:0] and the shared peripheral requests as INT[239:8]. The association of the interrupt request bit number and its corresponding position within the IRQ vectors is needed for both the NVIC and GIC service routines.

8.3.2.2 MSCM interrupt router functional description

As described in MSCM register descriptions, the interrupt routing registers enable the steering of requests to the processor cores.

Chapter 9
Miscellaneous Control Module (MCM)

9.1 Introduction

The Miscellaneous Control Module (MCM) provides miscellaneous control functions and contains Cortex-M7 local memory descriptors.

NOTE

MCM is accessible using the Private Peripheral Bus of Cortex-M7.

9.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Floating Point Exception monitor and interrupt control
- Local memory descriptors:
  - ITCM
  - D0TCM
  - D1TCM
  - ICACHE
  - DCACHE

9.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

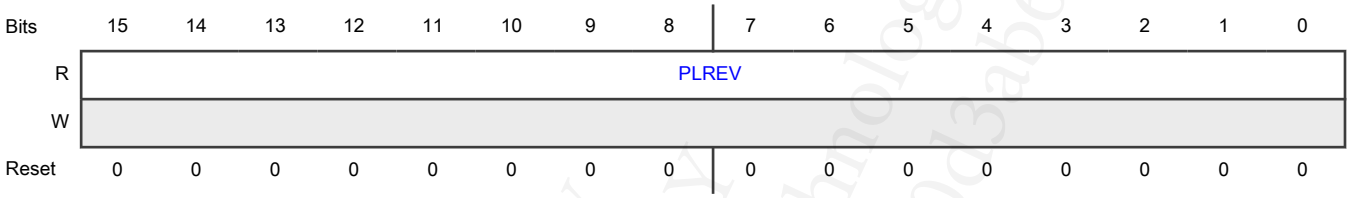
9.2.1 MCM register descriptions

9.2.1.1 MCM memory map

MCM base address: E008_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	SoC-defined Platform Revision (PLREV)	16	RO	0000h
2h	Processor Core Type (PCT)	16	RO	AC70h
Ch	Core Platform Control (CPCR)	32	RW	0000_0200h
10h	Interrupt Status and Control (ISCR)	32	RW	0000_0000h
400h	Local Memory Descriptor 0 (LMEM_DESC_0)	32	RW	0000_0000h
404h - 408h	Local Memory Descriptor a (LMEM_DESC_1 - LMEM_DESC_2)	32	RW	8604_2000h
40Ch	Local Memory Descriptor 3 (LMEM_DESC_3)	32	RW	8626_4000h
410h	Local Memory Descriptor 4 (LMEM_DESC_4)	32	RW	8644_6000h

9.2.1.2 SoC-defined Platform Revision (PLREV)



Offset

Register	Offset
PLREV	0h

Function

The PLREV is a 16-bit read-only register specifying an SoC-defined platform revision number. The state of this register is defined by a platform input signal; it can only be read from the IPS programming model. Any attempted write is ignored.

Diagram

Fields

Field	Function
15-0 PLREV	The PLREV[15:0] field is specified by a platform input signal to define a software-visible revision number.

9.2.1.3 Processor Core Type (PCT)

Offset

Register	Offset
PCT	2h

Function

The PCT is a 16-bit read-only register specifying the architecture of the processor core within the platform on the device. The state of this register is defined by a module input signal, which can only be read from the IPS programming model. Any attempted write is ignored.

9 —	Reserved
8-0 —	Reserved

1. For more information see Cortex-M7 documentation: Arm Cortex-M7 Processor Technical Reference Manual at www.arm.com.

9.2.1.5 Interrupt Status and Control (ISCR)

Offset

Register	Offset
ISCR	10h

Function

The MCM_ISCR register defines the configuration of, and reports status for, a number of core-related interrupt exception conditions. It includes:

- Enable and status fields associated with the core's floating-point exceptions
- Bus errors associated with the core's cache write buffer
- Events associated with the debug ETB module

The individual event indicators are first qualified with their exception enables, and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these fields are ignored. When these flags are 1, they retain this value until software clears the corresponding FPSCR field. For more information see Cortex-M7 documentation: Arm Cortex-M7 Processor Technical Reference Manual at www.arm.com.

25 FDZCE	FPU Divide-by-Zero Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
24 FIOCE	FPU Invalid Operation Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 WABE	TCM Write Abort Interrupt Enable 0b - Disable interrupt 1b - Enable Interrupt
20-16 —	Reserved
15 FIDC	FPU Input Denormal Interrupt Status This read-only field is a copy of the core's FPSCR[IDC] field. It indicates that an input denormalized number has been detected in the processor's FPU. When this field is 1, it retains this value until software clears the FPSCR[IDC] field. 0b - No interrupt 1b - Interrupt occurred
14-13 —	Reserved
12 FIXC	FPU Inexact Interrupt Status This read-only field is a copy of the core's FPSCR[IXC] field. It indicates that an inexact number has been detected in the processor's FPU. When this field is 1, it retains this value until software clears the FPSCR[IXC] field. 0b - No interrupt 1b - Interrupt occurred
11 FUFC	FPU Underflow Interrupt Status This read-only field is a copy of the core's FPSCR[UFC] field. It indicates that an underflow has been detected in the processor's FPU. When this field is 1, it retains this value until software clears the FPSCR[UFC] field. 0b - No interrupt 1b - Interrupt occurred
10 FOFC	FPU Overflow Interrupt Status This read-only field is a copy of the core's FPSCR[OFC] field. It indicates that an overflow has been detected in the processor's FPU. When this field is 1, it retains this value until software clears the FPSCR[OFC] field. 0b - No interrupt 1b - Interrupt occurred
9	FPU Divide-by-Zero Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
FDZC	This read-only field is a copy of the core's FPSCR[DZC] field. It indicates that a divide-by-zero operation has been detected in the processor's FPU. When this field is 1, it retains this value until software clears the FPSCR[DZC] field. 0b - No interrupt 1b - Interrupt occurred
8 FIOC	FPU Invalid Operation Interrupt Status This read-only field is a copy of the core's FPSCR[IOC] field. It indicates that an illegal operation has been detected in the processor's FPU. When this field is 1, it retains this value until software clears the FPSCR[IOC] field. 0b - No interrupt 1b - Interrupt occurred
7 —	Reserved
6 WABSO	Write Abort on Slave Overrun The overrun conditions are reported only if WABE=1. 0b - No write abort overrun 1b - Write abort overrun occurred
5 WABS	Write Abort on Slave This field indicates when a write abort has occurred on the AHBS interface. 0b - No write abort occurred on AHBS interface 1b - Write abort occurred on AHBS interface
4-0 —	Reserved

9.3 Functional description

9.3.1 Interrupts

MCM generates an interrupt if any of the following are true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC).
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC).
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC).
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC).
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC).
- FPU invalid operation interrupt is enabled (FDZCE) and an invalid operation occurs (FDZC).
- Write abort interrupt is enabled (WABE) and a write abort occurs (CM7 WABORTS INDICATOR).

Determining interrupt source

To determine the exact source of the interrupt for Cortex-M7 core, qualify the interrupt status flags with the corresponding interrupt enable fields.

- MCM_ISCR[31:16] && MCM_ISCR[15:0]
- Search the result for asserted flags, which indicate the exact interrupt sources.

9.4 Glossary

ITCM	Instruction Tightly Coupled Memory
DTCM	Data Tightly Coupled Memory
ICACHE	Instruction Cache Memory
DCACHE	Data Cache Memory

Chapter 10
A53 Cluster General Purpose Registers (A53_GPR)

10.1 Introduction

The Cortex-A53 cluster GPRs provide status and control the configuration of the Cortex-A53 clusters/cores and GIC500.

10.2 Technical reference

Many of the register fields in this chapter are documented in more detail in *Arm® Cortex®-A53 MPCore Processor Technical Reference Manual*, Revision r0p4, at https://www.arm.com.

10.3 A53_CLUSTER_GPR register descriptions

10.3.1 A53_CLUSTER_GPR memory map

A53_GPR base address: 4007_C400h

7-2 —	Reserved
1 WFE_EVT_CA53_CLUSTER1	WFE Event for Cortex-A53 Cluster1 Generates a wake-up event for cluster1 to exit from WFE retention state. It is particularly useful for heterogeneous cores in the system to wake the cluster from WFE state. Writing a 1 to this field generates an event. If you write a 1 to this field, you must then write a 0 to this field.
0 WFE_EVT_CA53_CLUSTER0	WFE Event For Cortex-A53 Cluster0 Generates a wake-up event for cluster0 to exit from WFE retention state. It is particularly useful for heterogeneous cores in the system to wake the cluster from WFE state. Writing a 1 to this field generates an event. If you write a 1 to this field, you must then write a 0 to this field.

Chapter 11
Cortex-M7 Cluster General Purpose Registers (CM7_GPR)

11.1 Introduction

CM7_CLUSTER_GPR configures certain Cortex-M7 features.

11.2 CM7_CLUSTER_GPR register descriptions

11.2.1 CM7_CLUSTER_GPR memory map

CM7_GPR_0 base address: 4007_C100h

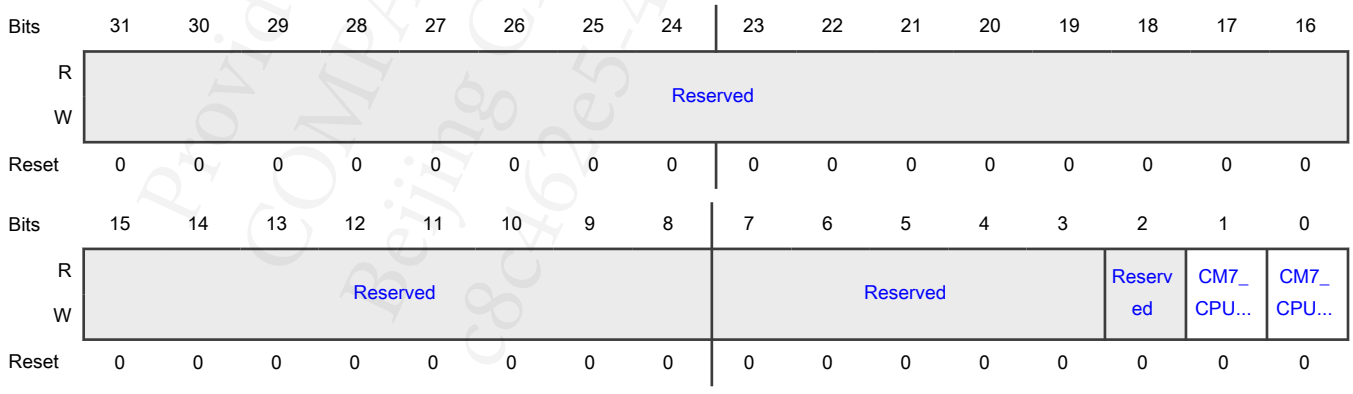
CM7_GPR_1 base address: 4007_C200h

CM7_GPR_2 base address: 4007_C300h

Offset	Register	Width (In bits)	Access	Reset value
0h	Cortex-M7 GPR0 (CORTEXM7_GPR0)	32	RW	0000_0000h

11.2.2 Cortex-M7 GPR0 (CORTEXM7_GPR0)

Offset



Register	Offset
CORTEXM7_GPR0	0h

Function

Configures Cortex-M7 memory retention, wait assertion, and WFE behavior.

You must access this register using only 32-bit accesses.

Diagram

Fields

Field	Function
31-8 —	Reserved. Writes to this field result in transfer error.
7-3 —	Reserved
2 —	Reserved
1 CM7_CPU_EVENT_GENERATE	Cortex-M7 Event Generate Sets the Event register in the processor that is defined in the Arm v7-M architecture. This causes a WFE instruction to complete. It also wakes up the processor, if it is sleeping, because it executed a WFE instruction. 0b - Do not set event 1b - Set event
0 CM7_CPU_WAIT	Cortex-M7 CPU Wait Asserts wait after reset during TCM initialization. See "Preloading TCM" section in Arm Cortex-M7 Processor Technical Reference Manual, DDI 0489D Revision r1p1 at www.arm.com. 0b - Do not assert wait 1b - Assert wait

Chapter 12
Enhanced Direct Memory Access (eDMA)

12.1 Chip-specific eDMA information

12.1.1 eDMA instances

This device has the following system eDMA instances:

- eDMA_0
- eDMA_1

Each of these instances also has a shadow instance tied to it in delayed lockstep and CRC is integrated with each of them.

As the following figure shows:

- The system eDMA instances, eDMA_0 and eDMA_1, each have a "shadow" eDMA instance that operates in delayed lockstep. All four of these instances have 32 channels.
- The delayed-lockstep pair eDMA_0 and its "shadow" instance integrate with DMAMUX_0 and DMAMUX_1.
- The delayed-lockstep pair eDMA_1 and its "shadow" instance integrate with DMAMUX_2 and DMAMUX_3.

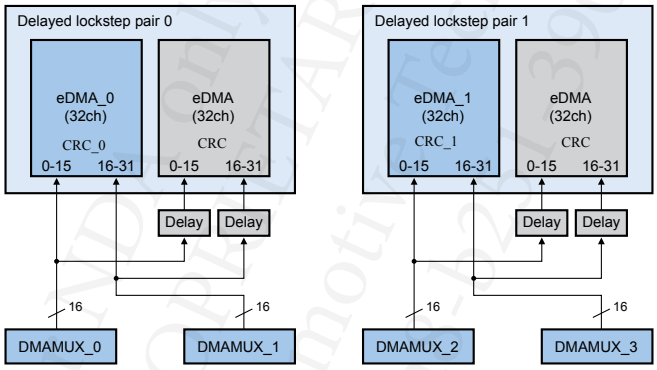

Figure 20. eDMA instances and DMAMUX integration

12.1.2 ECC support

TCD memory is covered by 8-bit ECC on a 64-bit basis using the H-matrix that includes address in the syndrome calculation, which enables single-error correction, double-error detection (SECDED), and allows for error injection.

12.1.3 eDMA bandwidth management

The eDMA bandwidth is shared across peripherals, limiting how much bandwidth the eDMA can support simultaneously on all peripherals. For example, if all four SPI modules are operating together in full-duplex mode with 8-bit frame size, they might get only up to 4 Mbit/s per SPI module for transmit/receive. Therefore, to increase the efficiency of high-bandwidth SPI transfers, use larger transfer frame sizes.

12.2 Introduction

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations

— Data-movement operations

- Local memory containing transfer control descriptors for each of the 32 channels

12.2.1 eDMA system block diagram

Figure 21 illustrates the components of the eDMA system, including the eDMA module (engine).

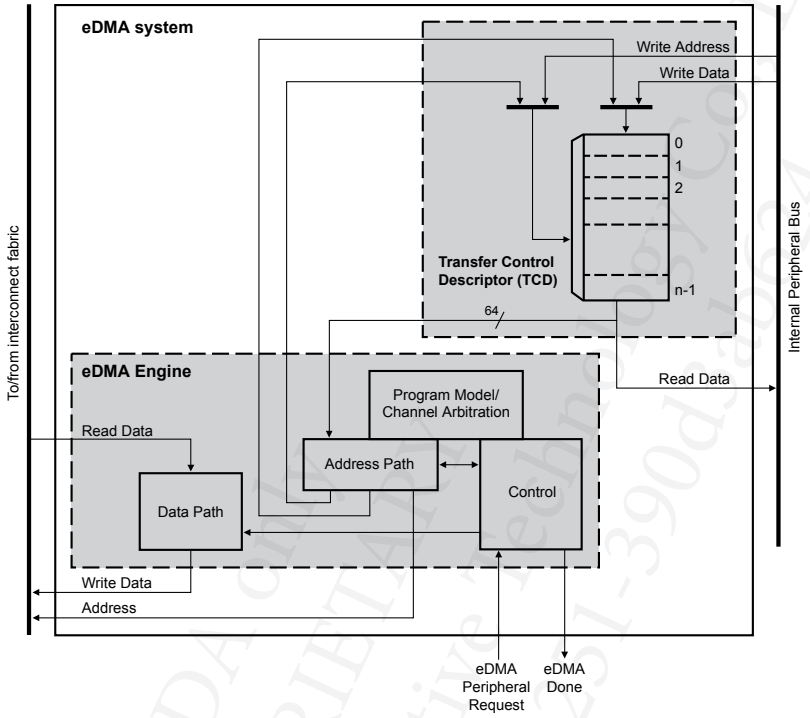

Figure 21. eDMA system block diagram

12.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 39. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all master bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 39. eDMA engine submodules (continued)

Submodule	Function
	When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 40. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

12.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

  - Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

12.3 Modes of operation

The eDMA operates in the following modes:

Table 41. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the eDMA attempts to complete an active channel. After the channel completes, no other channels are allowed to start and the device enters Wait mode.

12.4 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.

3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits.

TCD initialization

The TCD memory is in an unknown state after reset. Only the TCD START bit is initialized to 0. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

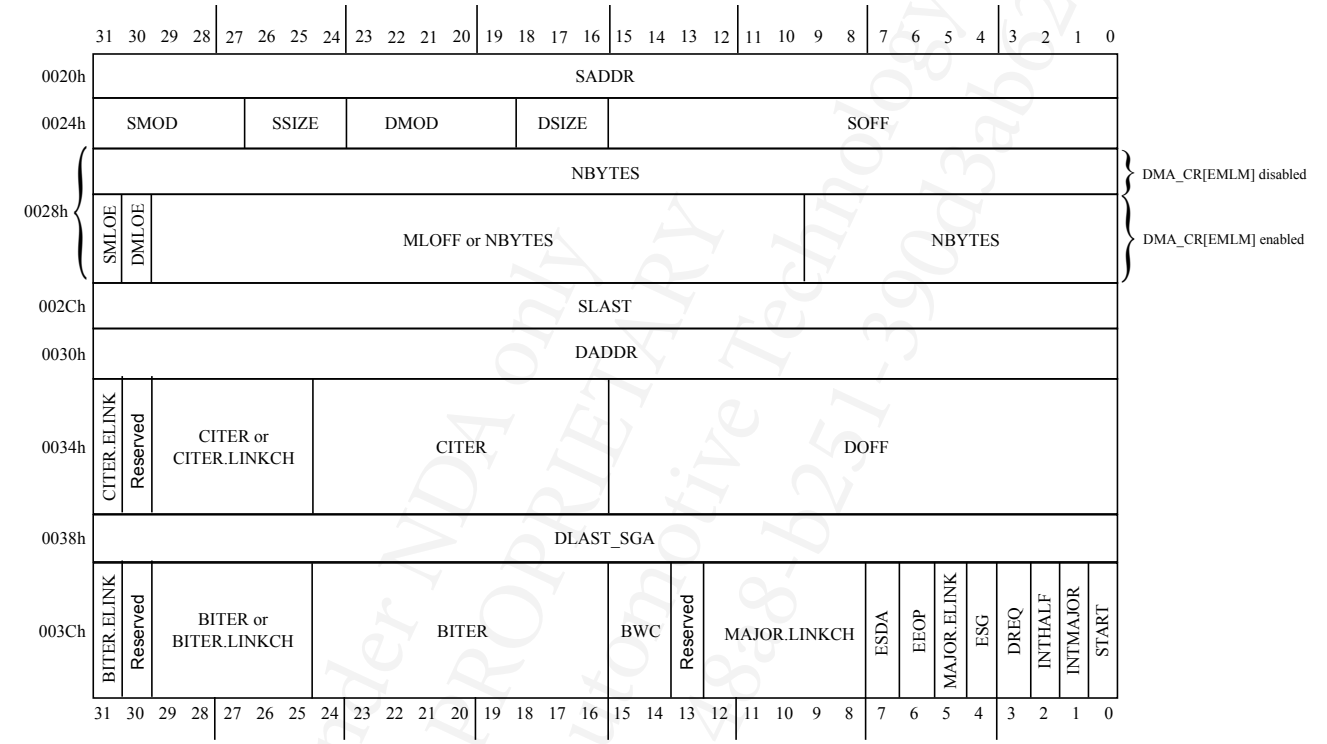

Figure 22. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

12.4.1.2 Management Page Control (CSR)

Offset

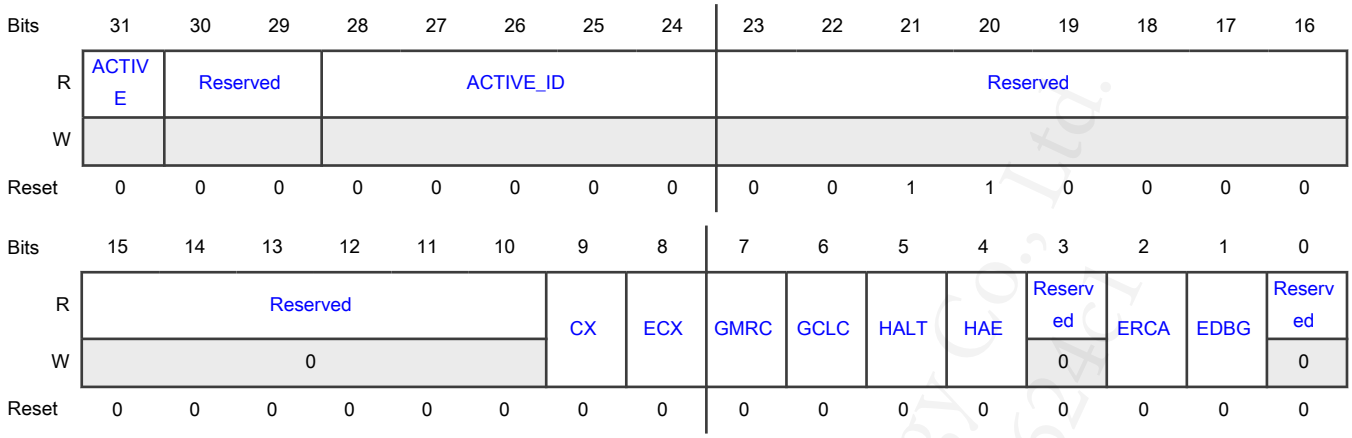
Register	Offset
CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.



When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

NOTE

For correct operation, changes to the CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the CSR[ACTIVE] field is 0.

Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel
30-29 —	Reserved
28-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to

Table continues on the next page...

Table continued from the previous page...

Field	Function
	cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Master ID Replication Control **NOTE** If master ID replication is disabled, the privileged protection level (Supervisor mode) for DMA transfers is used. 0b - Master ID replication disabled for all channels 1b - Master ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5 HALT	Halt DMA Operations This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Fixed priority arbitration used for channel selection within each group 1b - Round-robin arbitration used for channel selection within each group
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - When in debug mode, the DMA continues to operate

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

12.4.1.3 Management Page Error Status (ES)

Offset

Register	Offset
ES	4h

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

31	Valid Logical OR of all ERR status fields.

Table continues on the next page...

Table continued from the previous page...

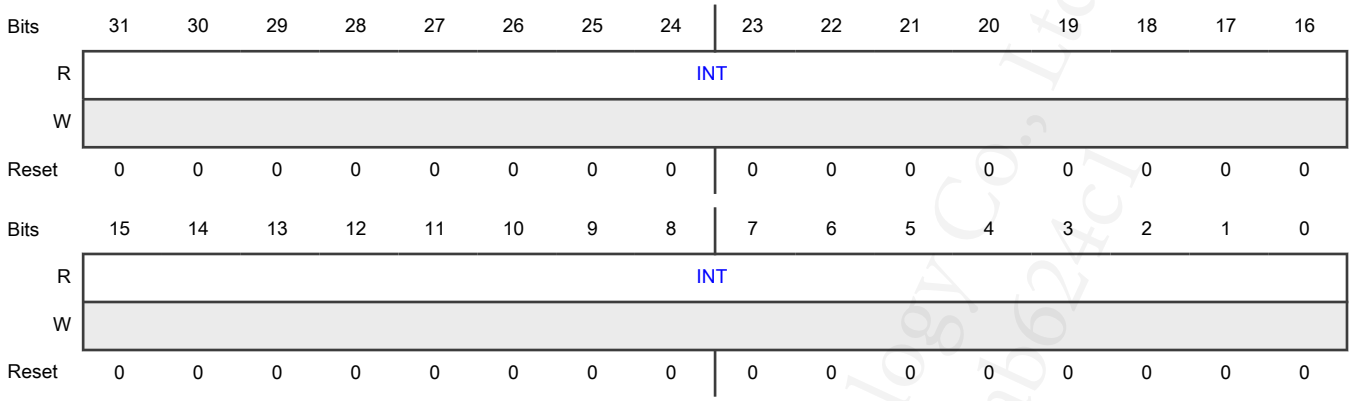
Field	Function
VLD	0b - No ERR fields are set to 1 1b - At least one ERR field is set to 1, indicating a valid error exists that software has not cleared
30-29 —	Reserved
28-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-10 —	Reserved
9 UCE	Uncorrectable TCD Error During Channel Execution UCE is set to 1 only when an uncorrectable ECC error occurs on an access generated by the DMA. If a CPU access to the TCD causes an uncorrectable ECC error, then that access receives a bus error response. **NOTE** When the eDMA sees a RAM error on an IPS access (when you are accessing a TCD), it reports the error as a bus abort. When the DMA engine receives a RAM error (the execution engine is accessing a TCD) it is recorded in the Error Status register, ES[UCE], along with the channel number. 0b - No uncorrectable ECC error 1b - Last recorded error was an uncorrectable TCD RAM error
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the ERR field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5	Destination Address Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
DAE	When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

12.4.1.4 Management Page Interrupt Request Status (INT)



Offset

Register	Offset
INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

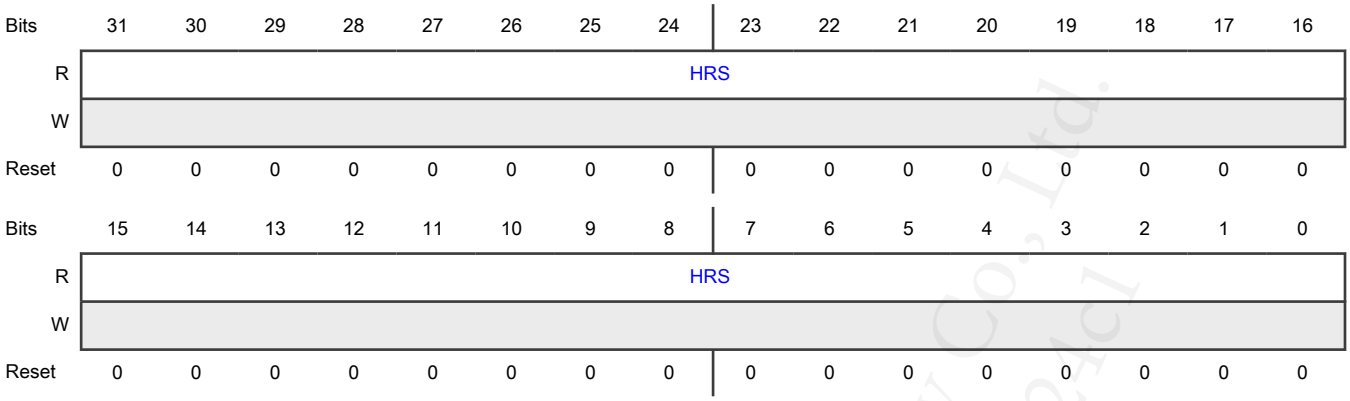
Diagram

Fields

Field	Function
31-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

12.4.1.5 Management Page Hardware Request Status (HRS)

Offset



Register	Offset
HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram

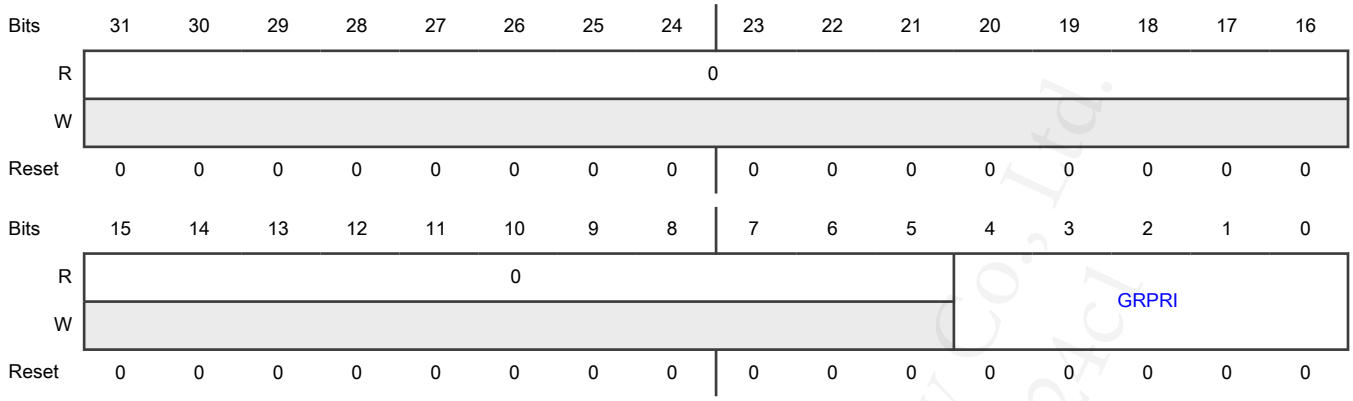
Fields

Field	Function
31-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and the channel is free, the hardware automatically clears the corresponding HRS bit to 0. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

12.4.1.6 Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)

Offset

For n = 0 to 31:



Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

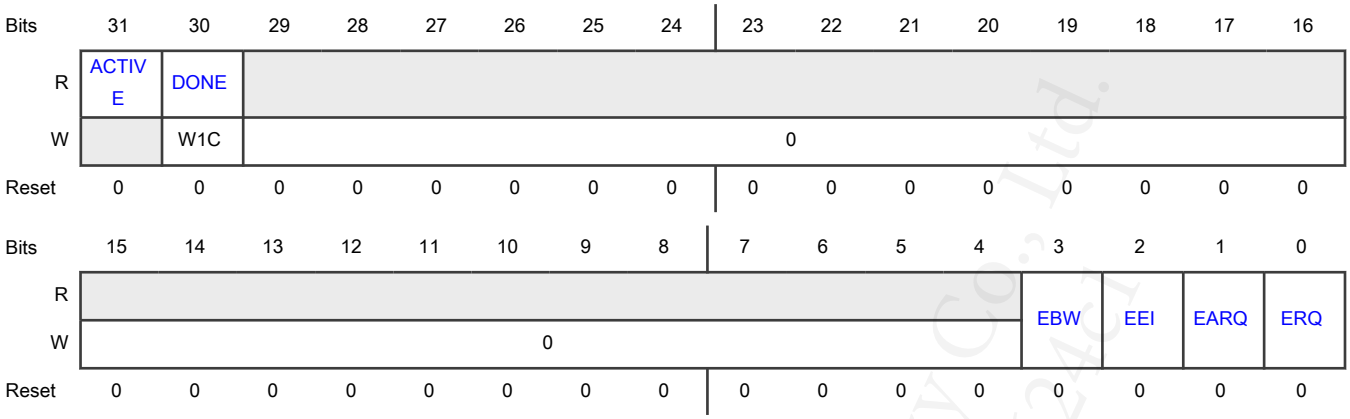
12.4.2.2 Channel Control and Status (CH0_CSR - CH31_CSR)

Offset

For n = 0 to 31:



Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Provided under NXP COMPANY CONFIDENTIAL Beijing CHJ Automotive Technology Co., Ltd. c84625-482-4a-b251-290da6741

Diagram

Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled 1b - Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 EARQ	Enable Asynchronous DMA Request In Stop Mode For Channel The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

12.4.2.3 Channel Error Status (CH0_ES - CH31_ES)

Offset

For n = 0 to 31:

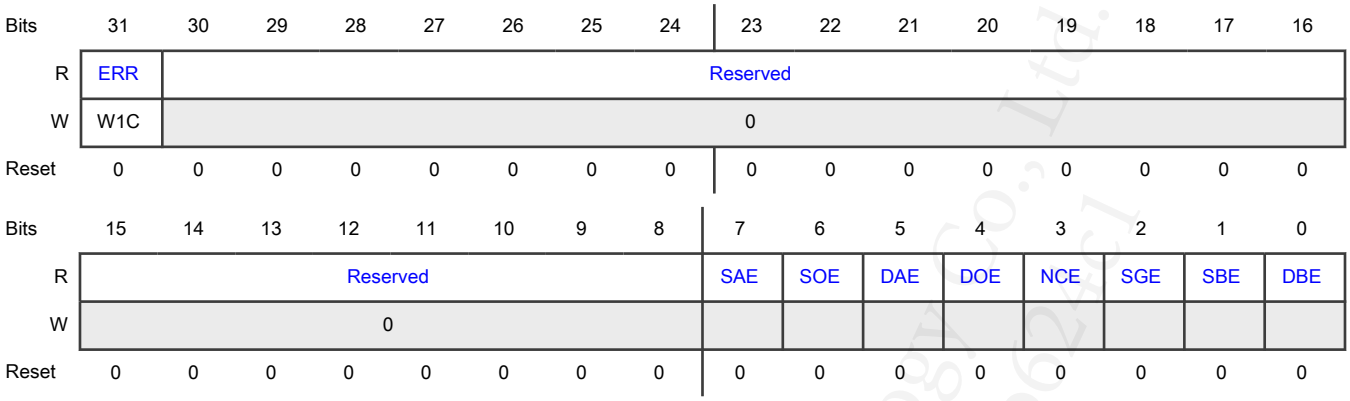
Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.



During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error or else an uncorrectable TCD error occurred. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram

Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved

4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error

Table continues on the next page...

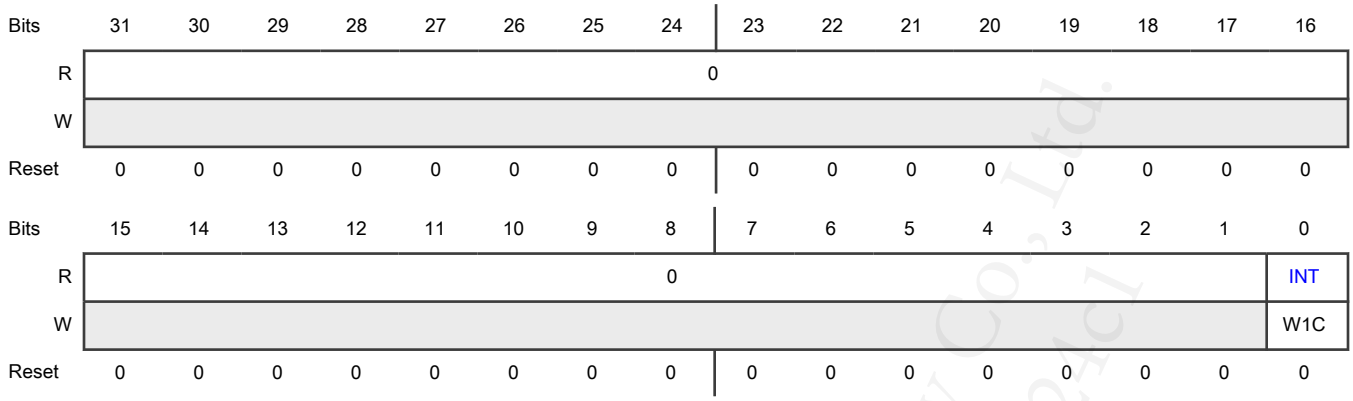
Table continued from the previous page...

Field	Function
	1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

12.4.2.4 Channel Interrupt Status (CH0_INT - CH31_INT)

Offset

For n = 0 to 31:



Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfe control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Diagram

Fields

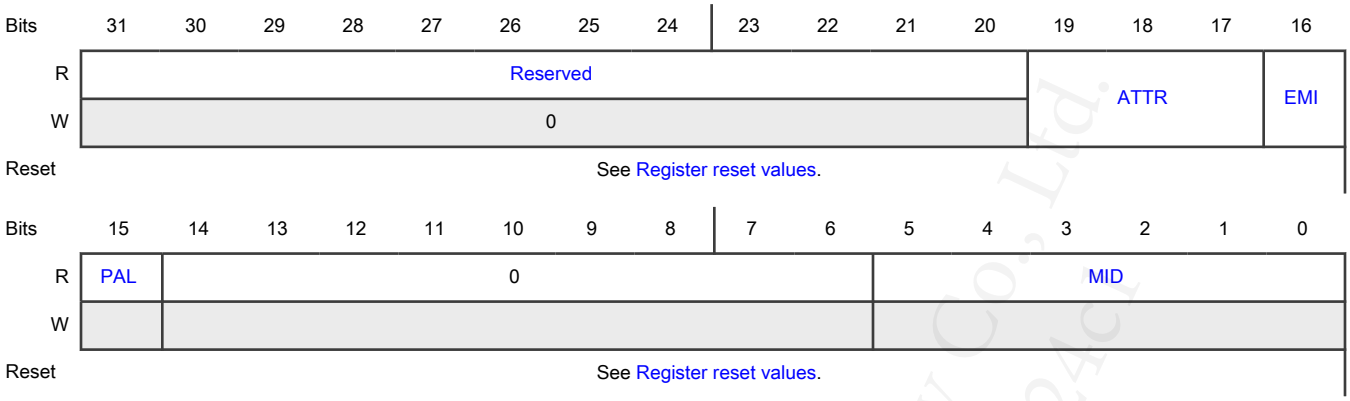
Field	Function
31-1 —	Reserved
0 INT	Interrupt Request 0b - Interrupt request for corresponding channel cleared 1b - Interrupt request for corresponding channel active

12.4.2.5 Channel System Bus (CH0_SBR - CH31_SBR)

Offset

For n = 0 to 31:

Register	Offset
CHn_SBR	Ch + (n × 1000h)



Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

The ATTR register outputs the register values onto the system bus interface for further decoding by the security system.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

Diagram

Register reset values

Register	Reset value
CH0_SBR–CH31_SBR	eDMA_0_TCD: 0000_8006h eDMA_1_TCD: 0000_8007h

Fields

Field	Function
31-20 —	Reserved
19-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Master ID Replication The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID and protection level are captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the privileged protection level (Supervisor mode) for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15	Privileged Access Level

Table continues on the next page...

Table continued from the previous page...

Field	Function
PAL	This field controls DMA's protection level on the system bus when the channel is active. **NOTE** When you enable master ID replication, the value captured in this register is the privilege level of the core or other master writing the channel's transfer control descriptor, which is the lower byte of TCD*n*_CSR. 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14-6 —	Reserved
5-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's control attributes, which are in the lower byte of TCD*n*_CSR.

12.4.2.6 Channel Priority (CH0_PRI - CH31_PRI)

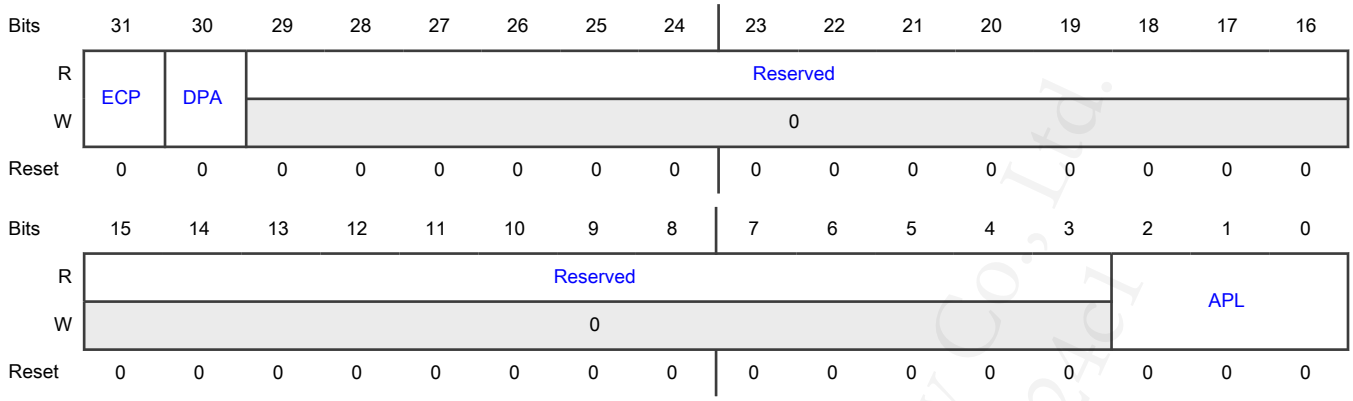
Offset

For n = 0 to 31:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).



The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram

Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Diagram

Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 00000b - Source address modulo feature disabled 00001b - Source address modulo feature enabled for any non-zero value [1-31]

12.4.2.10 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD31_NBYTES_MLOFFNO)

Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

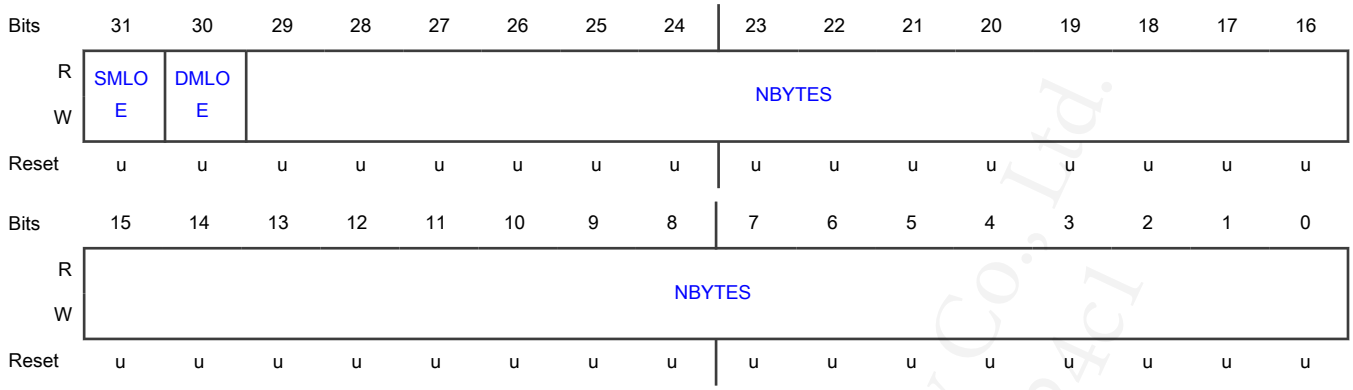
Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)



The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram

Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

12.4.2.11 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD31_NBYTES_MLOFFYES)

Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

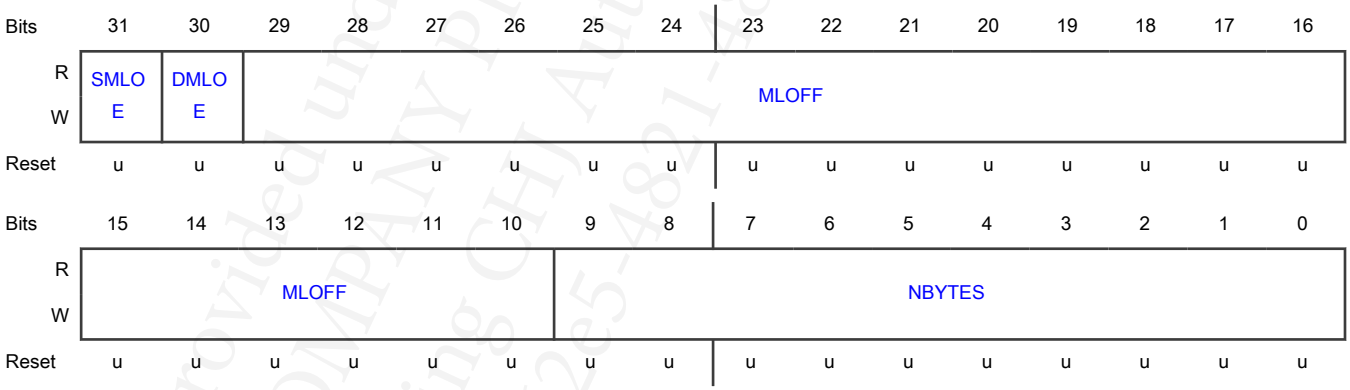
Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.



When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram

Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

12.4.2.13 TCD Destination Address (TCD0_DADDR - TCD31_DADDR)

Offset

For n = 0 to 31:

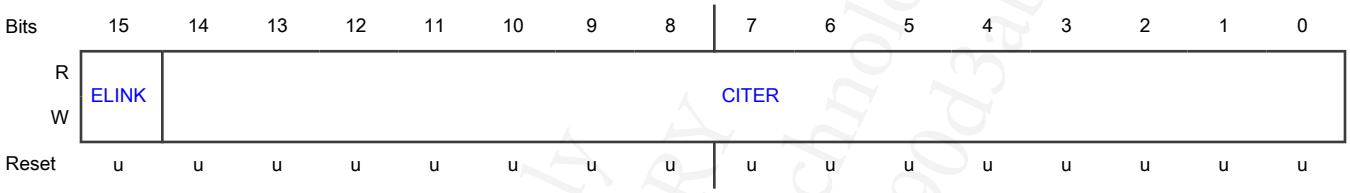
12.4.2.15 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO)

Offset



For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram

Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

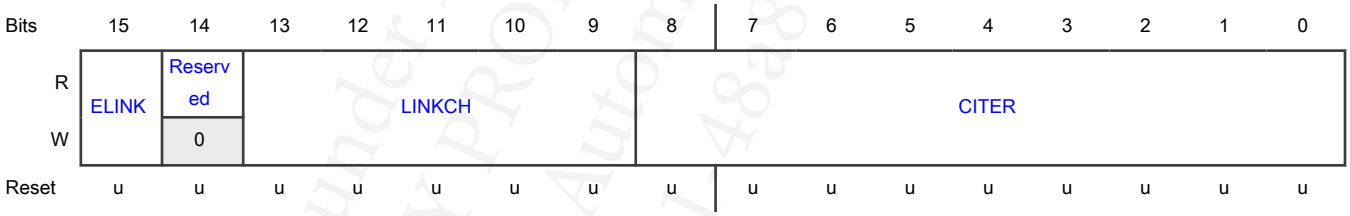
Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

12.4.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES)

Offset



For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram

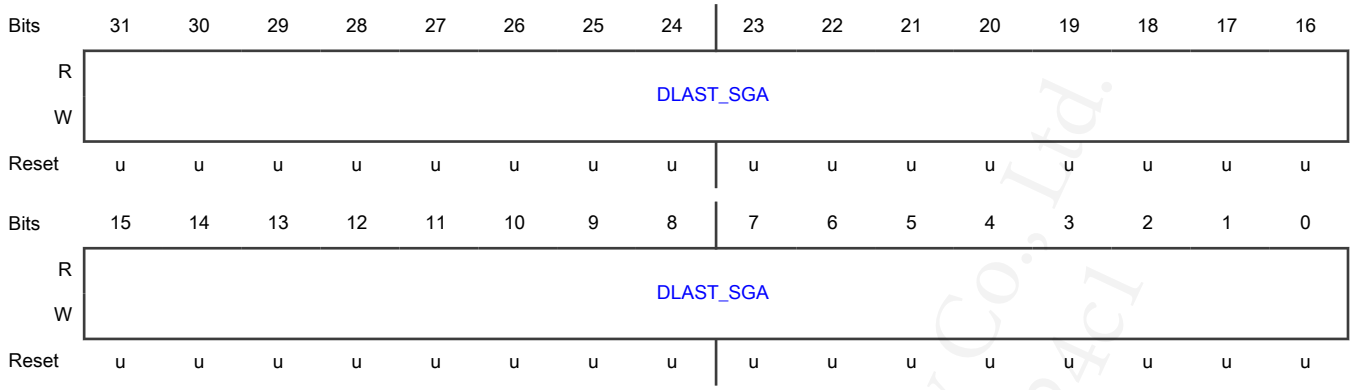
Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.



12.4.2.17 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD31_DLAST_SGA)

Offset

For n = 0 to 31:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Diagram

Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

12.4.2.18 TCD Control and Status (TCD0_CSR - TCD31_CSR)

Offset

For n = 0 to 31:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Provided under NDA
COMPANY PRIVATE
Beijing CHJ Automotive Technology Co.,Ltd.
c8c4625-4821-48a-b25-1390d3ab624c1

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BWC			MAJORLINKCH					ESDA	EEOP	MAJOREL...	ESG	DREQ	INTHALF	INTMAJOR	START
W			0													
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Enable eDMA master high-priority elevation (HPE) mode. No eDMA engine stalls. 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the SDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - Channel's ERQ field not affected 1b - Channel's ERQ field cleared to 0 when major loop complete
2 INTHALF	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

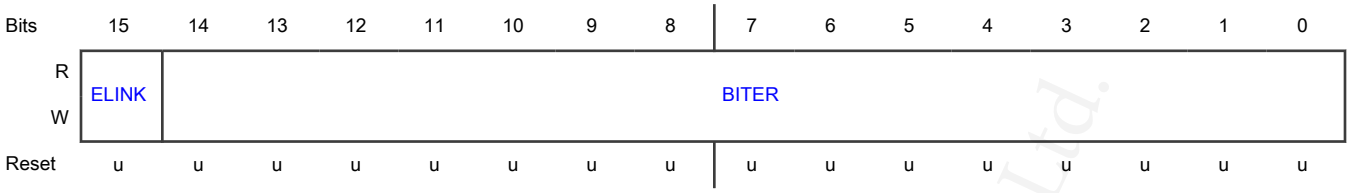
Table continued from the previous page...

Field	Function
	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

12.4.2.19 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD31_BITER_ELINKNO)

Offset

For n = 0 to 31:



Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

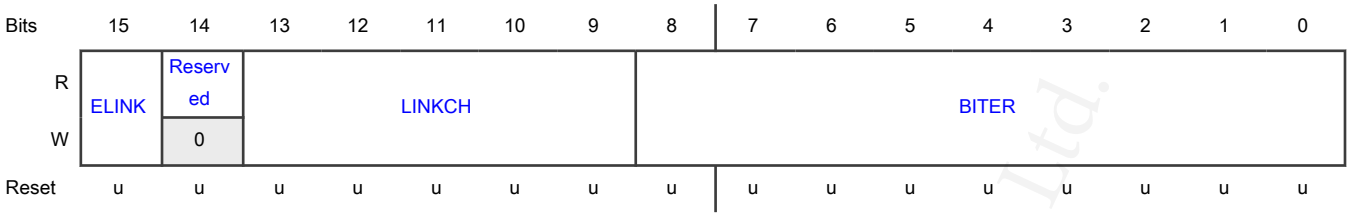
Diagram

Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

12.4.2.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD31_BITER_ELINKYES)

Offset



For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

12.5 Functional description

The operation of eDMA is described in the following subsections.

12.5.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

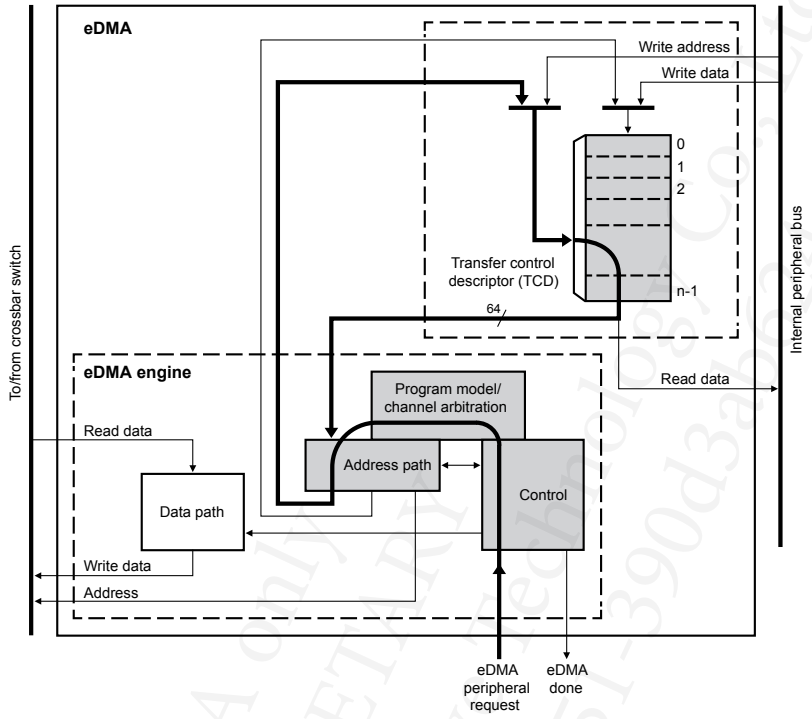

Figure 23. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

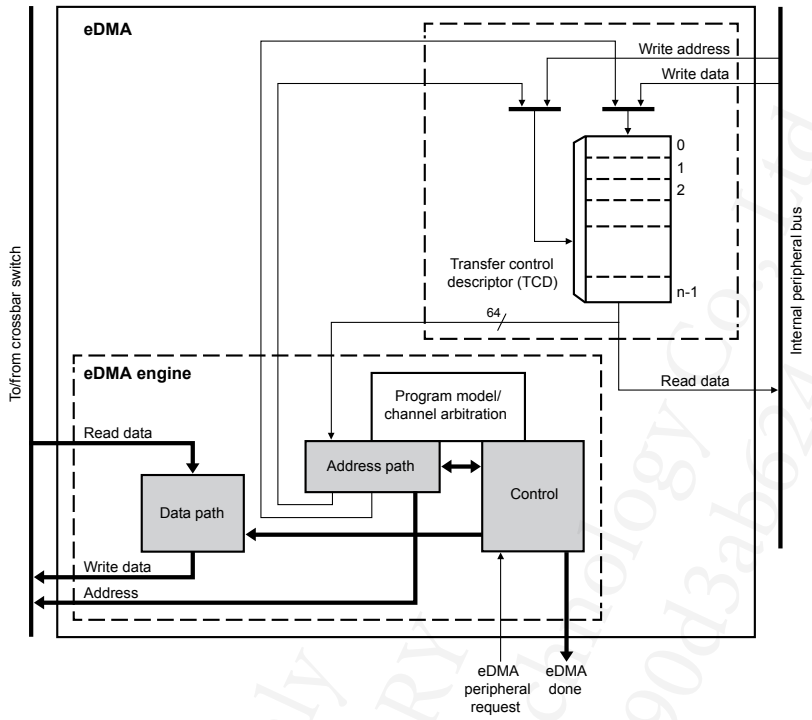

Figure 24. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

12.5.2 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_CSR and TCDn_CSR) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- A TCD memory error
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

e0462a-4821-48a8-b251-390d3ab924c1

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_CSR and TCDn_CSR). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. The valid field (VLD) is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved any errors and cleared all of the error interrupt fields, the valid field is cleared to 0 but the cause of the last error is still indicated.

12.5.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel’s data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel’s ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel’s preempt ability is disabled, that channel cannot suspend a lower-priority channel’s data transfer, regardless of the lower-priority channel’s ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

12.6 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

12.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.

4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 42, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 42. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 43. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

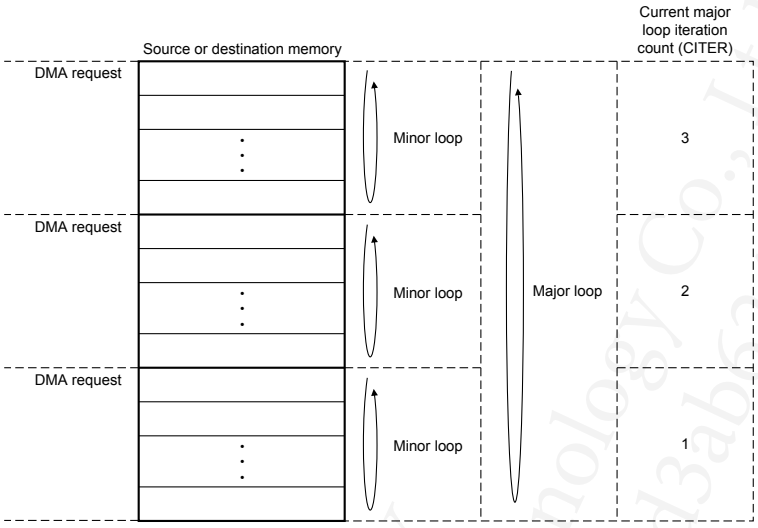

Figure 26. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

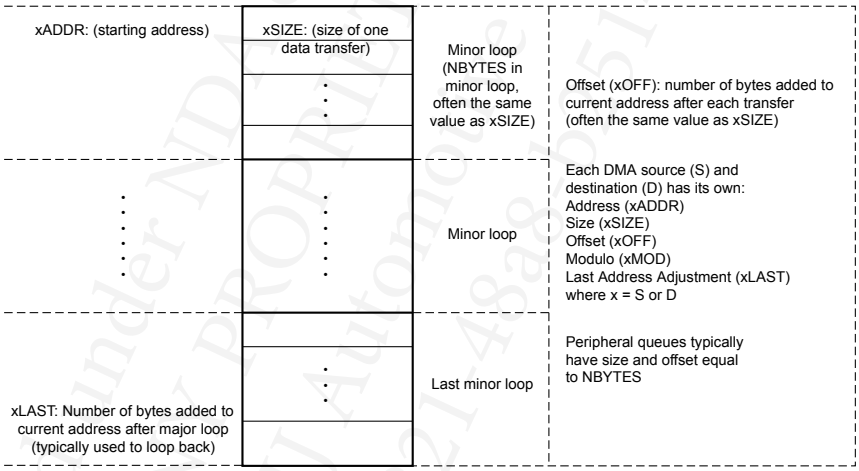

Figure 27. Memory array terms

12.6.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 44. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers.

Table continues on the next page...

Table 44. eDMA arbitration priorities (continued)

Priority	Scheme	Description
		Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is giver to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

12.6.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_CSR and TCDn_CSR). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent reoccurrence of the error.

12.6.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

12.6.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

12.6.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

12.6.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

12.6.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
```

```
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

12.6.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
h. Write 32 bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

12.6.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 45. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

12.6.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

12.6.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Beijing CHJ Automotive Technology Co., Ltd. COMPANY PROPRIETARY Provided under NDA only c8c42e-4821-4a8-b25-390d3ab624c1

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

12.6.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

12.6.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

12.6.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field

2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 46. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

12.6.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

12.6.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

12.6.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.

2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

12.6.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

12.6.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.

- If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
- If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

12.6.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

12.6.9 Lockstep

This chip contains an eDMA Checker which, when enabled, operates in Lockstep mode with the primary eDMA, executing the exact same transfer profiles. The eDMA Checker checks to ensure the primary eDMA is operating correctly. A block diagram is shown below.

Provided under IDA only, COMPANY PROPRIETARY Beijing CHJ Automotive Technology Co., Ltd. c8c462e5-4821-48a8-b251-390d3ab624

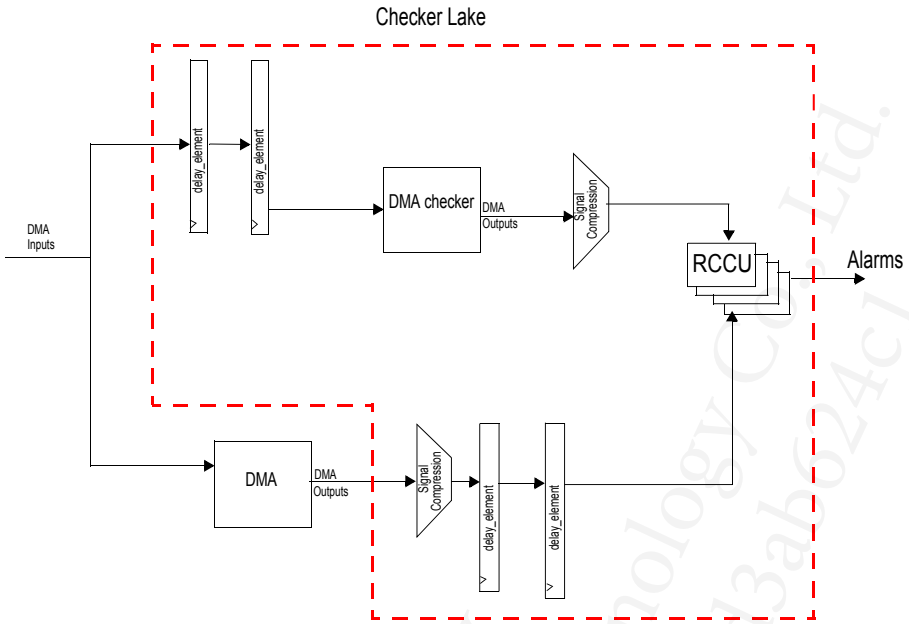

Figure 28. Lockstep block diagram

Initialization

To prevent the eDMA Checker from generating a false comparison error after power-on-reset, the eDMA's data output buffer must be initialized prior to enabling the Checker. To initialize the eDMA data output buffer, the eDMA must perform one or more 64-bit data transfers using any data value.

Errors

To handle source-address errors (SAE), perform the following steps.

1. Fix the addressing error.
2. Clear the ERR bit in the appropriate Channel Error Status (CH0_ES - CH31_ES). Management Page Error Status (ES) indicates the presence, location, and type of the last recorded channel error.
3. Start the channel in a normal fashion.

12.6.10 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

12.6.10.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the SPI by verifying that HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

12.6.10.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

Chapter 13
DMA CRC Module (DMA_CRC)

13.1 Introduction

This section provides an overview of the CRC unit and DMA Controller. The CRC unit is capable of calculating the CRC checksum in parallel with the DMA transfers. The CRC unit supports up to eight out of 64 DMA channels that are selectable through a programmable register. The CRC calculation is performed on the read data transfers. It is cumulatively calculated with each transfer until the DMA transfer is completed. The DMA CRC module supports aligned 32-bits and 64-bits data transfers. The unaligned transfer produces unpredictable checksum. All control/status registers inside the unit support the 32-bit peripheral interface protocol.

13.1.1 Block diagram

Here is the block diagram of the DMA_CRC module:

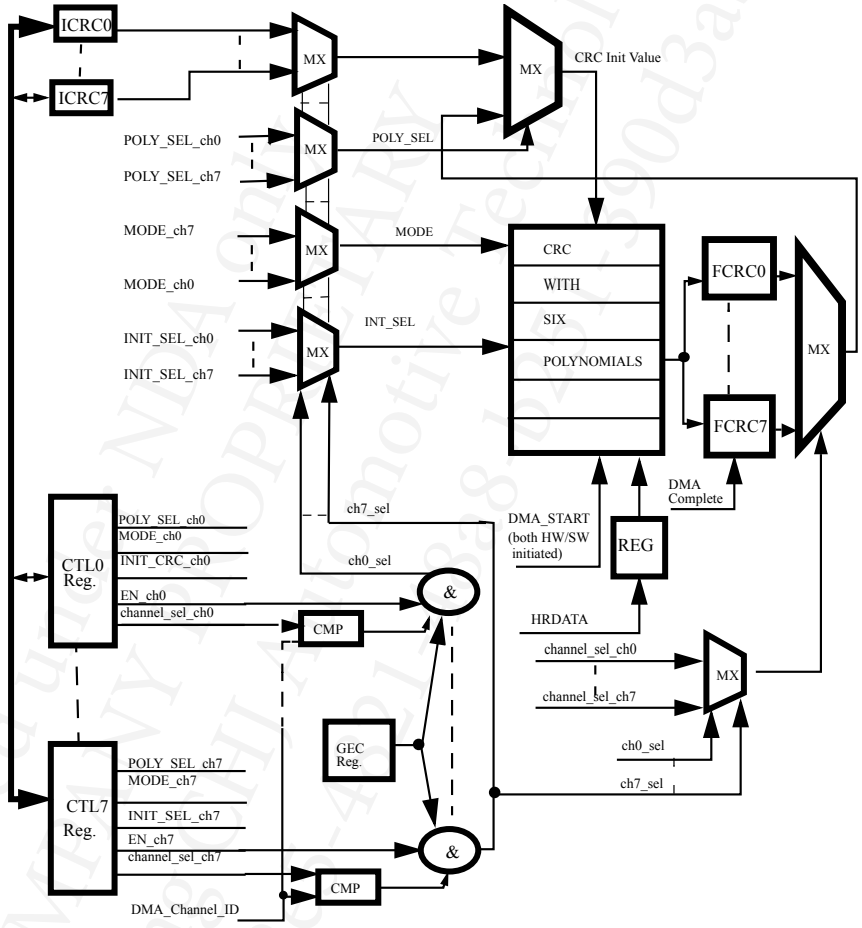

Figure 29. Block diagram

13.1.2 Features

The following list summarizes the key features of the DMA_CRC module:

- Contains peripheral interface for accessing CRC's control and status registers
- Supports up to eight channels

- Supports up to six different polynomials (8-bit, 16-bit, and 32-bit). Each channel can have its own polynomial or share the same polynomial. The supported polynomials are:
  - Ethernet (IEEE 802,3) CCITT32 CRC-32 0x04C11DB7
  - CASTAGNOLI, iSCSI CRC-32C 0x1EDC6F41
  - E2E Profile 4 CRC-32 P4 0xF4ACFB13
  - x.25. CCITT16 CRC-16 0x1021
  - H2F, AUTOSAR 4.0 CRC-8 0x2F
  - VDA CAN, SAE-J1850 CRC-8 0x1D
- Can enable/disable CRC functionality per channel
- Can use global CRC enable to safeguard against the accidental enablement
- Can preload CRC register at the start of the DMA transfers with an initial value (ICRC register) or continue with the accumulated CRC value from previous read transactions. The software can preload the ICRC register with a pre-calculated checksum value and check for a zero-checksum value at the end of the DMA transfers
- Makes the intermediate and final result of the CRC accessible through the Final CRC Value Register (FCRC). Each channel has its own FCRC register
- Supports all capabilities of the current eDMA, such as TCDs, channel linking, scatter-gather, and so on

13.1.3 Mode of operation

The DMA_CRC module supports only the normal mode. It uses CTL[MODE] to select the normal mode. In the normal mode, the DMA controller performs its normal operation which is reading from its source address and writing to its destination address. The CRC checksum is calculated on the read data (HRDATA[63:0] or HRDATA[31:0]).

NOTE

For this device, the data used in the CRC computation is in little endian.

13.2 DMA_CRC register descriptions

The DMA_CRC module provides a programming model mapped to a standard 16 KB on-platform peripheral slot.

The programming model can be referenced using a 32-, 16-, or 8-bit accesses. The attempted references to undefined (reserved) addresses generate an error termination. Each DMA channel with CRC provides three architected registers: Initial CRC Value Register (ICRC), Final CRC Value Register (FCRC), and CRC Control Register (CTL). In addition, an architected register, Global Enable CRC Register (GEC), is present to enable the CRC logic globally on all the eight channels.

13.2.1 DMA_CRC memory map

DMA_CRC_0 base address: 4013_C000h

DMA_CRC_1 base address: 4023_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Enable CRC Register (GEC)	32	RW	0000_0000h
10h	CRC Control Register (CTL0)	32	RW	0000_0000h
14h	Initial CRC Value Register (ICRC0)	32	RW	FFFF_FFFFh

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
18h	Final CRC Value Register (FCRC0)	32	RO	0000_0000h
20h	CRC Control Register (CTL1)	32	RW	0000_0000h
24h	Initial CRC Value Register (ICRC1)	32	RW	FFFF_FFFFh
28h	Final CRC Value Register (FCRC1)	32	RO	0000_0000h
30h	CRC Control Register (CTL2)	32	RW	0000_0000h

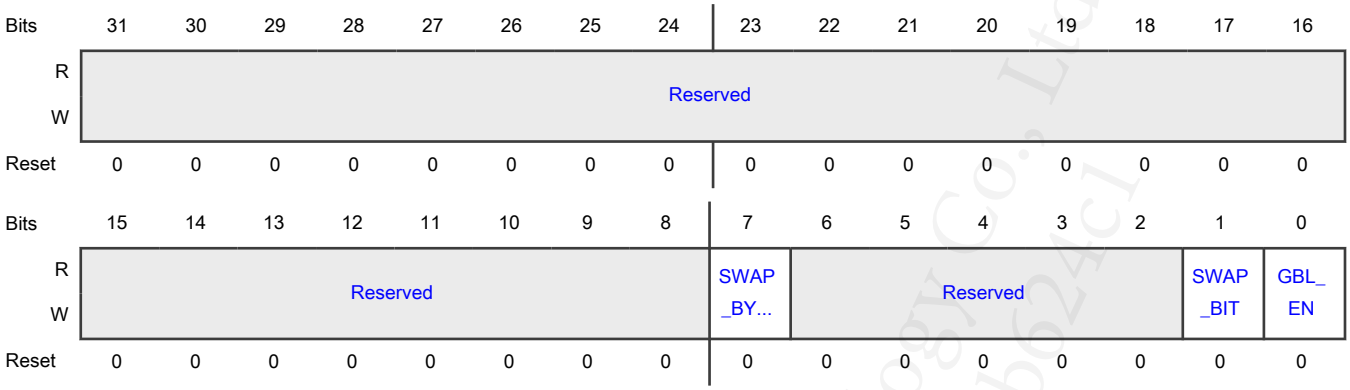
68h	Final CRC Value Register (FCRC5)	32	RO	0000_0000h
70h	CRC Control Register (CTL6)	32	RW	0000_0000h
74h	Initial CRC Value Register (ICRC6)	32	RW	FFFF_FFFFh
78h	Final CRC Value Register (FCRC6)	32	RO	0000_0000h
80h	CRC Control Register (CTL7)	32	RW	0000_0000h
84h	Initial CRC Value Register (ICRC7)	32	RW	FFFF_FFFFh
88h	Final CRC Value Register (FCRC7)	32	RO	0000_0000h

13.2.2 Global Enable CRC Register (GEC)

Offset



Register	Offset
GEC	0h

Function

The bit 0 of the Global Enable CRC Register (GEC) enables the CRC logic in all the eight channels. A write to any of the CRC Control Register (CTLn) clears this bit and disables the CRC logic. This bit should be set as the last step in enabling the CRC logic.

This register safeguards against the accidental enablement of the CRC function or accidental configuration update of the CTLn in the middle of a DMA transfer.

Diagram

Fields

Field	Function
31-8 —	Reserved
7 SWAP_BYTE	Swap Byte This field swap the DMA data byte-wise. 0b - Do not swap. 1b - Byte-wise swap on the input data.
6-2 —	Reserved
1 SWAP_BIT	Swap Bit This field swap the DMA data bit-wise. 0b - Do not swap. 1b - Bit-wise swap on the input data.
0 GBL_EN	Global Enable bit This bit globally enables/disables CRC logic in all channels. Writing to any of the CTLn register clears this bit. 0b - Disable CRC in all channels. 1b - Enable CRC in all channels.

13.2.3 CRC Control Register (CTL0 - CTL7)

Offset

For a = 0 to 7:

Register	Offset
CTLa	10h + (a × 10h)

Function

The CRC Control Register (CTLn) allows the user to set the following functions (n indicates channel 0 through 7):

- Selecting one of the 64 channels to monitor
- Selecting one of the six available polynomials
- Selecting an initial seed value of the CRC
- Enabling/disabling the CRC logic
- Selecting the CRC mode

To initiate the CRC calculation on the read data, this control register must be set up prior to any DMA transfer. Updating the CTL register in the middle of the DMA transfers results in non-deterministic behavior and corrupts the CRC checksum. This register can be accessed in byte, half-word, or word. The CRC control register must be set prior to selecting the functionalities of the CRC, such as enabling/disabling it, selecting the polynomial, preloading of the CRC, and so on.

NOTE

Writing to the reserved bits does not generate error and is ignored. Reading the reserved bits returns zeroes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continued from the previous page...

Field	Function
	111110b - Select Channel 62. 111111b - Select Channel 63.

13.2.4 Initial CRC Value Register (ICRC0 - ICRC7)

Offset

For a = 0 to 7:

Register	Offset
ICRCa	14h + (a × 10h)

Function

The Initial CRC Value Register (ICRC) is one of the options to initialize the CRC at the start of a DMA transfer. When CTL[INIT_SEL] is '1', the content of ICRC is used as the starting seed of the CRC. Software can use this feature to check for a zero-checksum value at the end of the DMA transfer by preloading the CRC with a certain value. The CTL[POLY_SEL] determines the values to be loaded in this register. Example, for a "16 bits polynomial x.25. CCITT16 CRC-16 0x1021", bits 15:0 are used to preload the CRC seed. The rest of the bits[31:16] are treated as don't care.

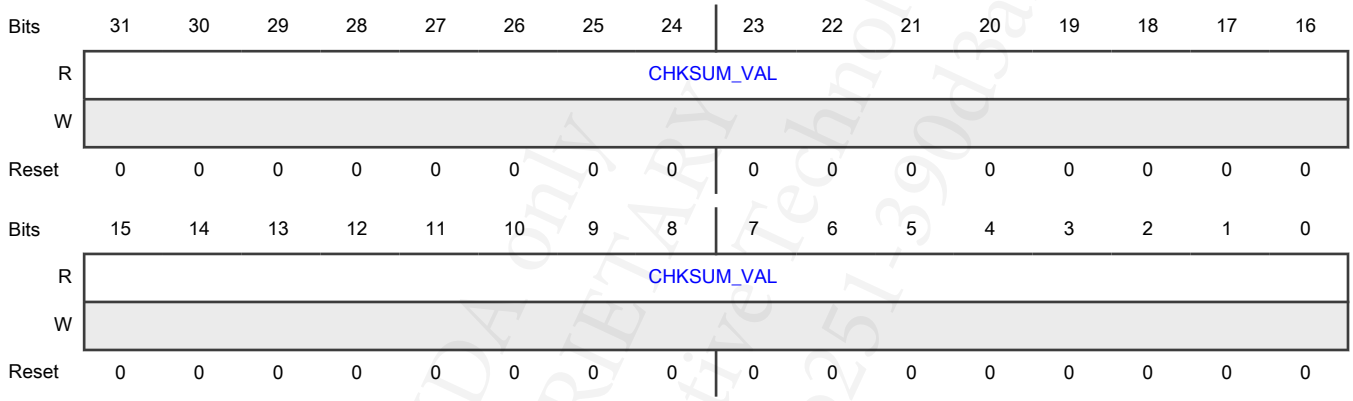
13.2.5 Final CRC Value Register (FCRC0 - FCRC7)

Offset



For a = 0 to 7:

Register	Offset
FCRCa	18h + (a × 10h)

Function

The Final CRC Value register holds the checksum at the end of the DMA transfer. In a channel linking, it is updated on the completion of every minor loop and major loop. The valid checksum bits depend on the size of the polynomial. Example, for an 8-bit polynomial H2F, AUTOSAR 4.0 CRC-8 0x2F, the resulting checksum resides in FCRC[7:0].

Diagram

Fields

Field	Function
31-0 CHKSUM_VAL	Final CRC Value Contains the final value of the CRC (Checksum)

13.3 Functional description

The CH_SEL[5:0] bits of CTL0 through CTL7 are compared to the incoming DMA_CHANNEL_ID[5:0] signal. When a match is detected and both the CTL[EN] and GEC[GBL_EN] bits for the matched channels are set, a CRC calculation is initiated on the incoming read data (HRDATA[63:0] or HRDATA[31:0]) depending on the size of data that the DMA transfers. The CRC calculation is performed on all the read data until the DMA engine completes its transfer, but excluding any transfer for TCD updates. The content of CH_SEL[5:0] bits for CTL0 through CTL7 must be unique if their EN bit is set or a non-deterministic checksum is generated. The match signal along with the assertion of the EN and CRC Global Enable signals selects other attributes corresponding to each channel, such as CTL[POLY_SEL], CTL[MODE], and CTL[INIT_SEL].

The CTL[POLY_SEL] selects one of the six polynomials. The non-selected polynomials should be kept static to minimize power. The CTL[POLY_SEL] bits should never be set to '110' and '111'; otherwise, a non-deterministic checksum is generated. The CRC is calculated by XORing the registered values of HRDATA[63:0] or HRDATA[31:0] with the seed value of CRC selected by INIT_SEL.

The checksum value is stored in the Final CRC Value Register (FCRC). For a 16-bit polynomials, the checksum is stored in FCRC[15:0], and for 8-bit polynomials, it is stored in FCRC[7:0]. The software must verify the correctness of the checksum

value in the Final CRC Value register. The checksum calculation for 64-bit or 32-bit data using any polynomial completes in one clock cycle.

Examples of input data and expected output checksum:

Initial value ICRC [31:0] = FFFFFFFFh

SWAP_BIT = 0

SWAP_BYTE = 1 or littleEndian

Final XOR value: 32'h0

Table 47. Example of input data and expected output checksum

Chapter 14
Direct Memory Access Multiplexer (DMAMUX)

14.1 Chip-specific DMAMUX information

14.1.1 DMAMUX-to-eDMA channel mapping

The following table shows the channel mapping between DMAMUX instances and eDMA instances.

DMAMUX instance channels	eDMA instance (lockstep pair) channels
DMAMUX_0 channels 0–15	eDMA_0 channels 0–15
DMAMUX_1 channels 0–15	eDMA_0 channels 16–31
DMAMUX_2 channels 0–15	eDMA_1 channels 0–15
DMAMUX_3 channels 0–15	eDMA_1 channels 16–31

NOTE

See DMA Map file attached to this document for details on the channel mapping.

14.2 Introduction

14.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. See the chip-specific information to know the detailed source numbers. This process is illustrated in the following figure.

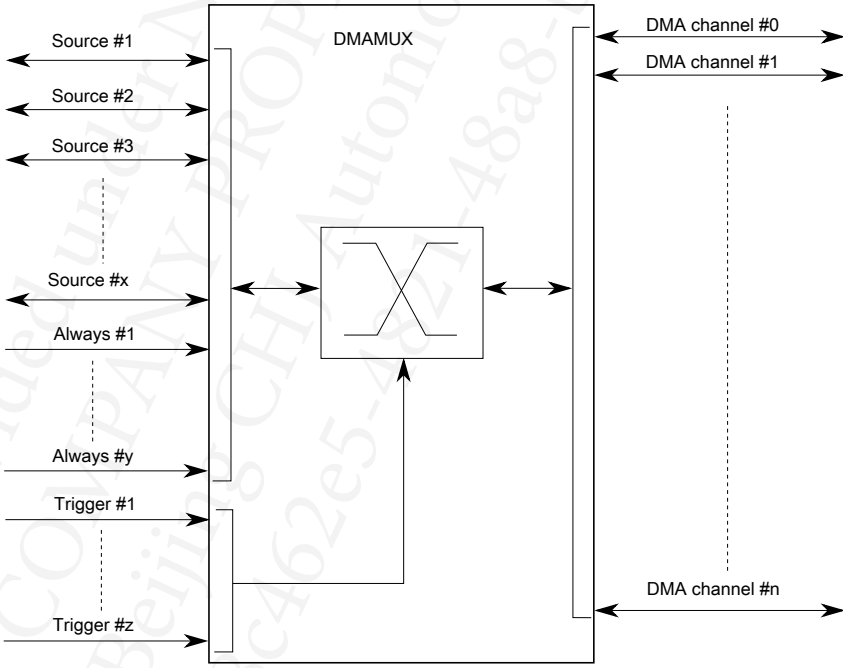

Figure 30. DMAMUX block diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHY Automotive Technology Co., Ltd.
c8c462e5-4f21-48a8-b251-390d3b0c4af1

14.2.2 Features

Following are the features of DMAMUX module.

- Up to 59 peripheral slots and up to 4 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first 5 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

14.2.3 Modes of operation

The DMAMUX module supports the following operating modes.

- Disabled mode: In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.
- Normal mode: In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.
- Periodic Trigger mode: In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done by an external periodic interrupt timer (PIT). This mode is available only for channels 0–4.

14.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

14.3.1 DMAMUX register descriptions

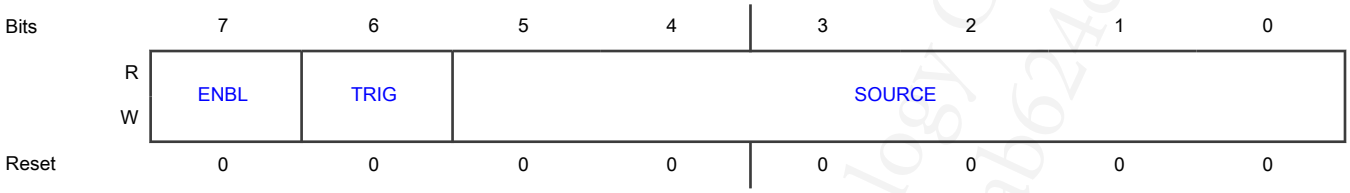
Function



Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Diagram

Fields

Field	Function
7 ENBL	DMA Channel Enable Enables the DMA channel. 0b - DMA channel is disabled. This mode is primarily used during configuration of the DMAMUX. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1b - DMA channel is enabled
6 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0b - Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1b - Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
5-0 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

14.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

14.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first five channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by an external periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done by configuring the external periodic timer.

NOTE

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

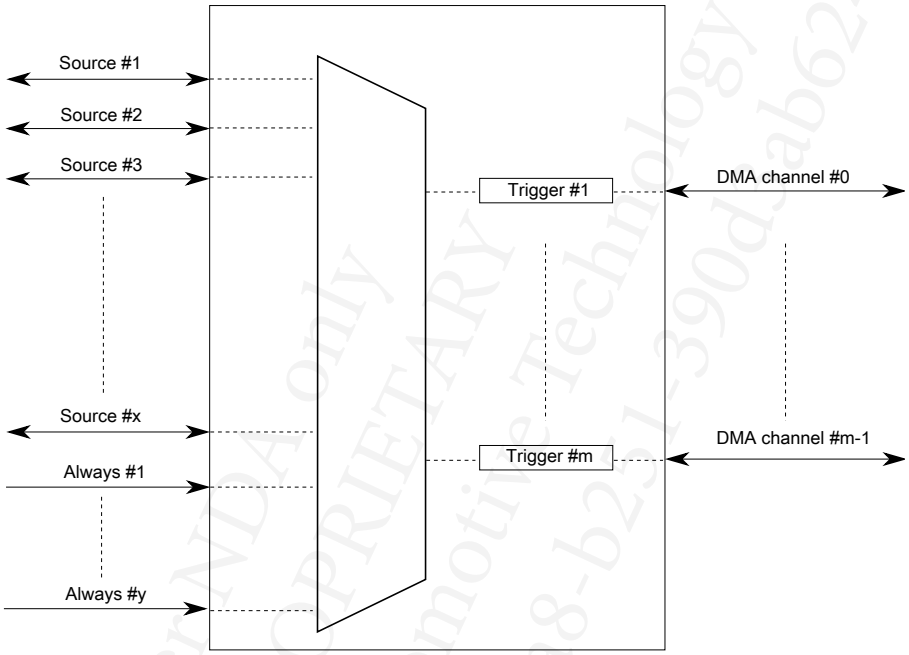


Figure 31. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

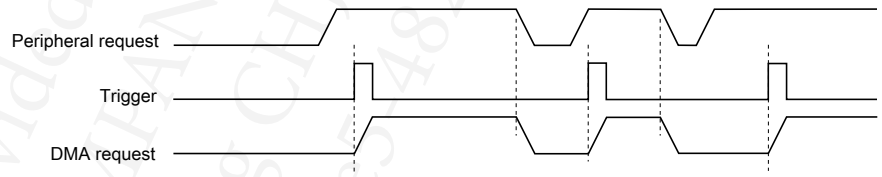

Figure 32. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral negates its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

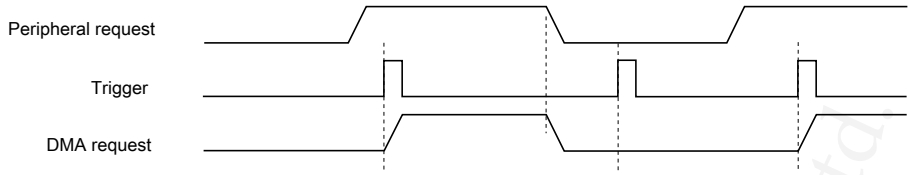

Figure 33. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful in the following two situations.

- Periodically polling external devices on a particular bus: As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI requests DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO ports to drive or sample waveforms: By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

14.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

14.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are 4 additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory: Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa: Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation: Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are as follows.

- Transfer all data in a single minor loop: By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use explicit software reactivation: In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers after every minor loop. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use an always-enabled DMA source: In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and

pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

14.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

14.5.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

14.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine the DMA channel with which the source will be associated. Note that only the first five DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip-specific information for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
```

```
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;                                 /* Clear all the fields of CHCFG1 register */
*CHCFG1 = 0xC5;                                 /* ENBL = 1  DMA Channel is enabled */
                                                /* TRIG = 1  Triggering is enabled */
                                                /* SOURCE = 5  DMA Source 5 is selected */
```

To enable a source, without periodic triggering:

1. Determine the DMA channel with which the source will be associated. Note that only the first five DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is setwhile CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;                                 /* Clear all the fields of CHCFG1 register */
*CHCFG1 = 0x85;                                 /* ENBL = 1  DMA Channel is enabled */
                                                /* TRIG = 0  Triggering is disabled */
                                                /* SOURCE = 5  DMA Source 5 is selected */
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the eDMA chapter for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
```

```
*CHCFG8 = 0x00;                                 /* Clear all the fields of CHCFG1 register */
*CHCFG8 = 0x87;                                 /* ENBL = 1  DMA Channel is enabled */
                                                /* TRIG = 0  Triggering is disabled */
                                                /* SOURCE = 7  DMA Source 7 is selected */

Chapter 15
Extended Resource Domain Controller (XRDC)

15.1 Chip-specific XRDC_0 information

15.1.1 XRDC instances

This chip has two XRDC instances:

- XRDC_0 is the system instance.
- XRDC_1 is the Accelerator subsystem instance.

Features shared by both instances include:

- Access rights computed by MRCs and PACs can be determined by the SEMA42 module (hardware semaphore).
- The XRDCs have no interrupts of their own. An access violation triggers a Data Abort exception on the core performing the access.

NOTE

In this chapter:

- SDAC and MRC are interchangeable terms.
- PDAC and PAC are interchangeable terms.

15.1.2 XRDC_0 submodule configurations

XRDC consists of multiple submodules. See the "Block diagram" section for a list and descriptions of the submodules.

The following tables summarize the submodules and their configurations in this chip.

- MDAC configurations
- MRC configurations
- PAC configurations

The global XRDC configuration defines eight domains. Unimplemented domain numbers read as zero, provide no access, and cannot be written.

Additional global configuration includes:

- The width of the PIDs is defined as the low-order 6 bits.
- The implemented number of low-order address bits included in the memory region descriptor start and end address evaluations is 20.
- Upper address bits in the start address are read as zeros and cannot be written. In the end address, they read as ones and cannot be written.

15.1.2.1 MDAC configurations

Table 48. MDACn configurations

Submodule instance	Configuration	Number of MDA_W*x*_*y*_DFMT*z* registers	Bus master	Non-secure input[1]
XRDC_MDAC0	Processor	8	Cortex-A53 C0	Input from master

Table continues on the next page...

Table 48. MDACn configurations (continued)

Submodule instance	Configuration	Number of MDA_W*x*_*y*_DFMT*z* registers	Bus master	Non-secure input[1]
XRDC_MDAC1	Processor	8	Cortex-A53 C1	Input from master
XRDC_MDAC2	Nonprocessor	1	Debug ETR	Input from master
XRDC_MDAC3	Nonprocessor	1	GIC-500	Input from master
XRDC_MDAC4	Nonprocessor	1	Reserved	1
XRDC_MDAC5	Nonprocessor	1	SerDes_0	Input from master
XRDC_MDAC6	Nonprocessor	1	eDMA_0	1
XRDC_MDAC7	Nonprocessor	1	eDMA_1	1

XRDC_MDAC20	Nonprocessor	1	uSDHC	Input from master
XRDC_MDAC21	Nonprocessor	1	Debug trace	Input from master

1. The MDAC has a non-secure input for the bus master. Entries in this column mean:
   - 1: The bus master is always a non-secure input.
   - 0: The bus master is always a secure input.
   - Input from master: The bus master determines whether the input is 1 or 0.

NOTE

Input DID is 0 for all masters except DMA MDAC which takes input from DMA.

15.1.2.2 MRC configurations

Table 49. MRCn configurations

Submodule instance	Region format	Number of region descriptors	Slaves protected, module (port number)
XRDC_MRC0	Auto	16	DRAM0_A53(0), DRAM0_M7_EDMA(1), DRAM0_GENERAL(2)

Table continues on the next page...

Table 49. MRCn configurations (continued)

Submodule instance	Region format	Number of region descriptors	Slaves protected, module (port number)
XRDC_MRC1	Auto	16	unused

XRDC_MRC13	Auto	16	S_DBG_APB(0)

NOTE

- For MRC2/3, SRAM{0-7} work together to support the interleaved SRAM scheme and are mapped to the 4MB address range 0x34000000 – 0x343FFFFF.
- For MRC4/5, SRAM{8-15} work together to support the interleaved SRAM scheme and are mapped to the 4MB address range 0x34400000 – 0x347FFFFF.

15.1.2.3 PAC configurations

Table 50. PACn configurations

Module name	Slaves protected
XRDC_PAC0	Peripheral group 0
XRDC_PAC1	Peripheral group 1
XRDC_PAC2	Peripheral group 2
XRDC_PAC3	Peripheral group 3

For details about the modules in each peripheral group, see the chip's memory map.

15.1.3 XRDC_0 MRCs and SRAM interleaving

Due to the granularity of SRAM interleaving, MRC2,MRC3 and MRC4,MRC5 for SRAM behave as a single MRC respectively. Hardware mirrors the two MRCs.

- Sixteen MRGDs for MRC2, MRC3 for first half of SRAM memory address space, and sixteen MRGDs for MRC4,MRC5 for the second half of SRAM are usable.
- Software can write to any of the two MRC instances and the write replicates to the other MRC automatically.
- Software can read from any of the two MRCs and get the same result.

15.1.4 XRDC_1 Introduction

This chip contains an additional XRDC manager, also known as XRDC_1, to support region protection for the off-CC NoC masters. The following table shows the ports that have XRDC_1 protection associated with them. Refer to the XRDC chapter for more details.

Table 51. XRDC_1 MDACn configurations

Submodule instance	Configuration	Number of MDA_W*x_y*_DFMT*z* registers	Bus master	Non-secure input[1]
XRDC_MDAC0	Nonprocessor	1	PCIe_1	input from master
XRDC_MDAC1	Nonprocessor	1	PFE_HIF0 (PFE_HIF BD fetch)	1
XRDC_MDAC2	Nonprocessor	1	PFE_HIF1 (PFE_HIF BD update)	1
XRDC_MDAC3	Nonprocessor	1	PFE_HIF2 (PFE_HIF data write)	1
>XRDC_MDAC4	Nonprocessor	1	PFE_HIF3 (PFE_HIF data read)	1
XRDC_MDAC5	Nonprocessor	1	PFE_DDR (PFE_PKT_MASTER)	1
XRDC_MDAC6	Nonprocessor	1	PFE_UTIL	1
XRDC_MDAC7	Nonprocessor	1	USB	1

1. The MDAC has a non-secure input for the bus master. Entries in this column mean:
   - 1: The bus master is always a non-secure input.
   - 0: The bus master is always a secure input.
   - Input from master: The bus master determines whether the input is 1 or 0.

Table 52. XRDC_1 MRCn configurations

Submodule instance	Region format	Number of descriptors	Slaves protected, module (port number)
XRDC_MRC0	Auto	4	STDBY_SRAM
XRDC_MRC1	Auto	4	LLCE
XRDC_MRC2	Auto	16	Concerto
XRDC_MRC3	Auto	4	PCIe_1

15.2 Introduction

XRDC provides an integrated, scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions, and slave peripherals for processing domains to support enforcement of robust operational environments. First, each bus mastering resource is assigned to a DID . For processors, there are additional fields that can optionally be used to assign each core to multiple domains. Next, the access control policies for the individual domains are programmed into slave memory region descriptors and slave peripheral domain access control registers. Finally, all accesses throughout the chip are monitored concurrently to determine the validity of each and every access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme defined by XRDC supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure and nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism, where:

SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser

with different access control policies that are based on read and write references. Combined with the user or privileged and secure or nonsecure attributes, a DID is associated with every system bus transaction and forms the hardware basis for implementation of the XRDC's access control mechanisms.

Access to shared memory regions and slave peripherals can be dynamically controlled with the optional inclusion of a hardware semaphore. This semaphore, if enabled for a given address space or peripheral, allows writes to the targeted address space only if the requesting domain owns the semaphore. This capability allows the access control policy for a given resource to be dynamically revised based on hardware semaphore ownership.

Each core contains its own local memory protection unit to control permissions and manage resources among the various tasks executing on that core. The XRDC adds a second layer of protection for the shared resources in a multicore system by providing an integrated, scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions, and slave peripherals to processing domains to support enforcement of robust operational environments.

15.2.1 Features

The key features of XRDC include:

- Assignment of chip resources to processing domains
  - Resources are categorized into four groups:
    - Processor cores
    - Non-core bus masters
    - Slave memories
    - Slave peripherals
  - Each processing domain is assigned a unique DID
  - DID is a new attribute associated with every system bus transaction
  - Used in conjunction with user/privileged, secure/nonsecure attributes
- Access rights to slave targets defined in region descriptor registers for memories and access control registers for peripherals
- Support for sharing of memory and peripherals with optional inclusion of hardware semaphores to dynamically determine access rights

- Built upon a four-level hierarchical access control model
  - SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
  - Encoded into a three-bit per-domain ACP used throughout the XRDC
  - Certain processors do not support the NonsecurePriv state. For these cores, the model simplifies to a three-state definition: SecurePriv > SecureUser > NonsecureUser
- Programming model and hardware implementation is distributed across multiple submodules
  - Support for a broad, highly-configurable architecture definition
  - Memory region descriptors support a format leveraged from earlier System Memory Protection Units (SMPUs)

15.2.2 Block diagram

As previously noted, the XRDC implementation is distributed across multiple submodules instantiated throughout the chip. The XRDC submodules include:

- MGR
  - The MGR submodule provides hardware management for all programming model reads and writes
- MDAC
  - The MDAC handles resource assignments and generation of the domain identifiers
- MRC
  - The MRC implements the access controls for slave memories based on the pre-programmed region descriptor registers
- PAC
  - The PAC implements the access controls for slave peripherals based on the pre-programmed domain access control registers

For chip-specific implementation details of this module's instances, see the chip configuration information.

See Figure 34 for a simplified XRDC block diagram focusing on topology and connections.

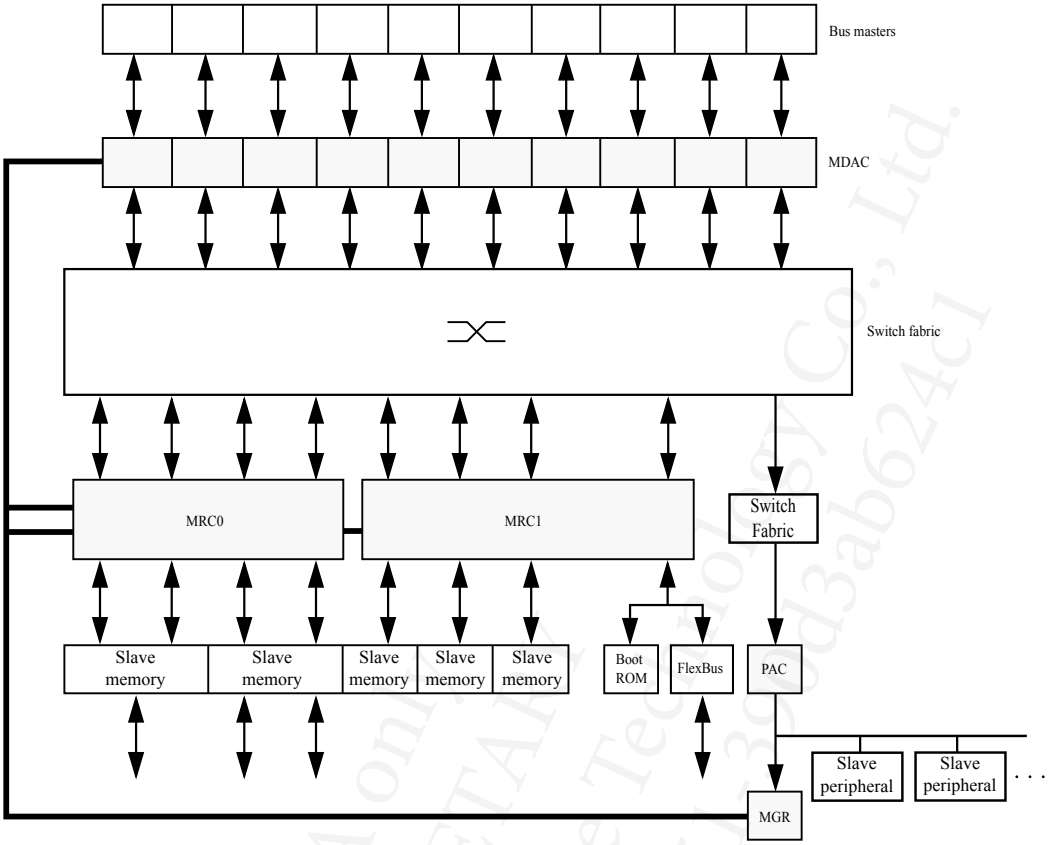

Figure 34. Simplified XRDC block diagram

15.2.3 Modes of operation

The XRDC module does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it strictly responds on the basis of the memory addresses of the connected system buses. The slave peripheral bus is used to access XRDC's distributed programming model; these references are only allowed if the requesting bus master is operating in the secure, privileged mode. Domain assignment and access control functions are evaluated on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s). The implementation of the MRC submodule supports either AMBA-AHB or AMBA-AXI system bus protocols.

15.3 External signal description

The XRDC module does not directly support any external interfaces.

The internal interfaces include a standard 32-bit slave bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses, and connections to the slave peripheral buses as shown in Figure 34.

15.4 Memory map/register definition

The XRDC module supports a large number of architecturally defined, program-visible registers distributed across four 4 KB address slots. The actual registers are chip-specific.

The register resources of the XRDC programming model can only be accessed while in secure, privileged mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads, and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, and writes to read-only resources or to reserved spaces are terminated with an error unless noted otherwise.

Accesses to these memory map holes return an error:

- Any access to an MDAC, PDAC, or MRC that does not exist
- Holes in the 0h-F0h and DERR to PID register space
- For MDAC, gaps in the registers
- For MRCs, RGD gaps; thus, if there are four RGDs, an attempted access to RGD5 fails

Accesses to these memory map holes do not return a bus error:

- For MRCs, current RGDs are four words but have eight words of address available; words 4-7
- For PDAC, reserved slots

The XRDC programming model is partitioned into five groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Master domain assignments
- Peripheral domain access controls
- Memory region descriptors

It should be noted that many of the programming model registers in the XRDC are organized as two-dimensional data structures. These generic arrays contain *m* words representing the columns and *n* instances of the structure representing the rows, and may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout; that is, the *m* words representing the column appear sequentially with the entire row replicated *n* times. The XRDC register structure uses the naming convention of *<regname>_Wm_n*, where the column number *m* appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier *n* appears as the final numerical suffix.

The architectural definition of the complete XRDC programming model is presented in this section. Each implementation is SoC-specific and highly dependent on the chip's requirements.

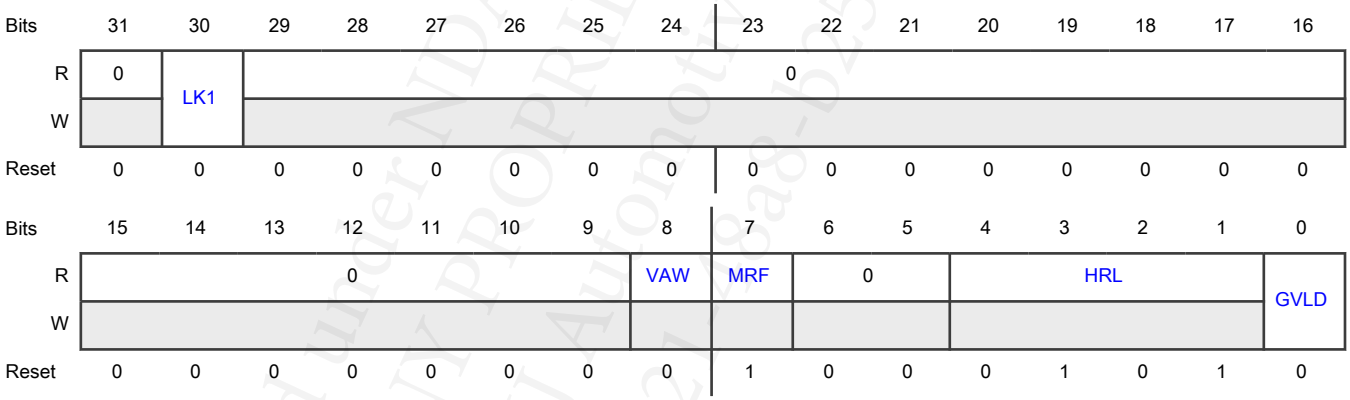
15.4.1.2 Control (CR)

Offset



Register	Offset
CR	0h

Function

This register provides the read-only status of the XRDC and a global enable bit for the entire module's operation.

Access: Secure privileged read/write

Diagram

Fields

Field	Function
31 —	Reserved
30 LK1	Lock This field provides a locking mechanism that can be used to prohibit the ability to write to this register. After you write 1 to this field, it remains asserted until the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Register can be written to by any secure privileged write 1b - Register is locked (read-only) until the next reset
29-9 —	Reserved
8 VAW	Virtualization Aware This field indicates that the domain assignments support the optional inclusion of a logical partition identifier (also known as an operating system number). 0b - Implementation is not virtualization-aware 1b - Implementation is virtualization-aware
7 MRF	Memory Region Format This field indicates that the format of the memory region descriptors and is defined by SoC requirements. 0b - Reserved 1b - SMPU family format
6-5 —	Reserved
4-1 HRL	Hardware Revision Level This field specifies XRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module. It is hardwired to the value 0101b as it represents an architectural descendent from previous {system} memory protection units ({S}MPU).
0 GVLD	Global Valid (XRDC Global Enable/Disable) 0b - XRDC disabled; all accesses from all bus masters to all slaves allowed 1b - XRDC enabled

15.4.1.3 Hardware Configuration 0 (HWCFG0)

Offset

Register	Offset
HWCFG0	F0h

Function

This read-only register contains information on XRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory region controllers (MRCs) and peripheral access controllers (PACs). The register value at reset is chip-specific. Attempted writes are error-terminated.

Access: Secure privileged read

MDACFG17	111h
MDACFG18	112h
MDACFG19	113h
MDACFG20	114h
MDACFG21	115h

Function

This register defines the number of implemented domain assignment registers for bus master *m*, where *m*+1 can specify bus masters from 1 to 64. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error-terminated.

Typically, processor bus masters include one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: Secure privileged read

MRCFG13	10h

Fields

Field	Function
7-5 —	Reserved
4-0 NMRGD	Number Of Memory Region Descriptors For Memory Region Controller *n* Number of memory region descriptors for MRC*r*. This field specifies the number of memory region descriptors associated with a given memory region controller instance. The value is limited to the range [0-16], where 0 indicates a non-existent MRC instance and non-zero values indicate the number of implemented memory region descriptors [4, 8,12,16] associated with the MRC*r* submodule.

15.4.1.8 Domain Error Location (DERRLOC0 - DERRLOC7)

Offset

For d = 0 to 7:

Register	Offset
DERRLOCd	200h + (d × 4h)

Function

This array of read-only registers provide the instance number of the submodule where an access violation occurred. These registers are organized as a word array, which is indexed by the faulting domain number, *d*. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance

numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i*, and DERR_W3_*i* register arrays. See Domain error capture management for details.

When an access violation is detected by either a memory region controller (MRC) or a peripheral access controller (PAC), address and attribute information of the offending access is captured. Using the faulting DID number as the index, *d*, this array of read-only registers provides additional information signaling the instance number of the submodule where the access violation(s) occurred. Because the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error-terminated.

Access: Secure privileged read

DERR_W0_16	500h
DERR_W0_17	510h
DERR_W0_18	520h
DERR_W0_19	530h

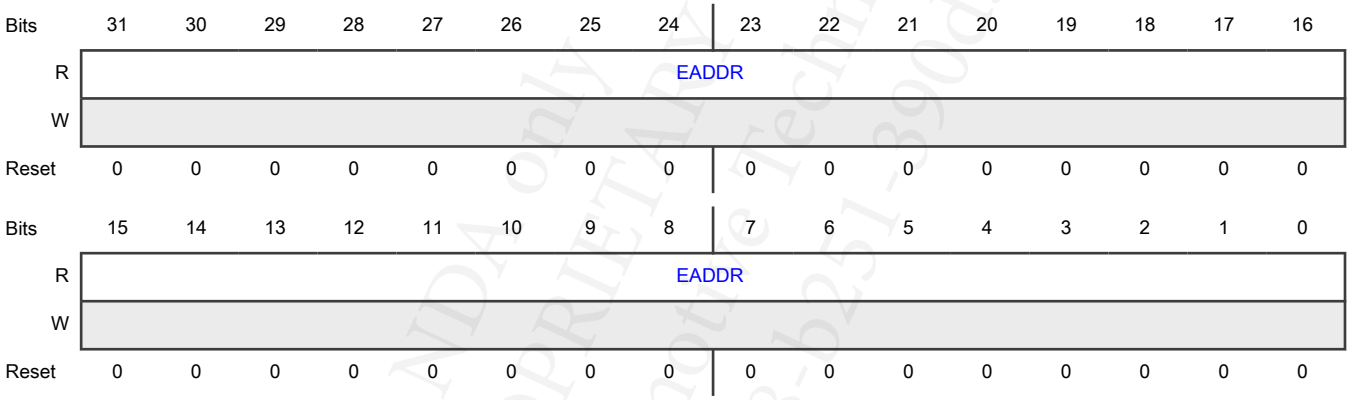
Function

This read-only register array provides the address of an access violation detected by either an MRC or a PAC. These registers are organized as a word array, which is indexed by the violating submodule instance number. That is, the index, *i*, of this array is the instance number of the submodule that detected the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory-mapped error capture detail registers are organized as 20 sequential 16-byte entries. The

first 16 register sets are associated with the MRCs. The following four register sets are associated with the PACs. Each 16-byte structure contains DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i*, and DERR_W3_*i*.

The error capture registers in the MRC and PAC submodules contain physical registers for each domain, but are organized in the DERR_W0_*i* and DERR_W1_*i* registers to provide the information for the requesting domain only. Thus, the access violation exception handler for each domain only has visibility into the captured error information for its own domain. See Domain error capture management for details.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_*i* register. At that time, this register is cleared and re-enabled to capture the next access violation.



Attempted writes are error-terminated as are attempted reads of an MRC or PAC instance that is not physically present.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W0_*i* records only the error of the lowest slave index.

Access: Secure privileged read

Function

This is a word-sized location in the domain error details data structure. The registers are organized in a data structure based on instance number, that is, n = the instance number of the submodule which detected the access violation, and are read using information directly extracted from the DERRLOCn registers. The memory-mapped capture error detail registers are organized as 20 sequential 16-byte entries. The first 16 register sets are associated with the memory region controllers. The following four registers sets are associated with the peripheral access controllers. Each 16-byte record contains DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i* and DERR_W3_*i*. See Domain error capture management for more details. A read of this location returns zeroes. Attempted writes are error-terminated as are attempted reads of an MRC or PAC instance that is not physically present.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W2_*i* will record only the error of the lowest slave index.

Access: Secure Privileged Read

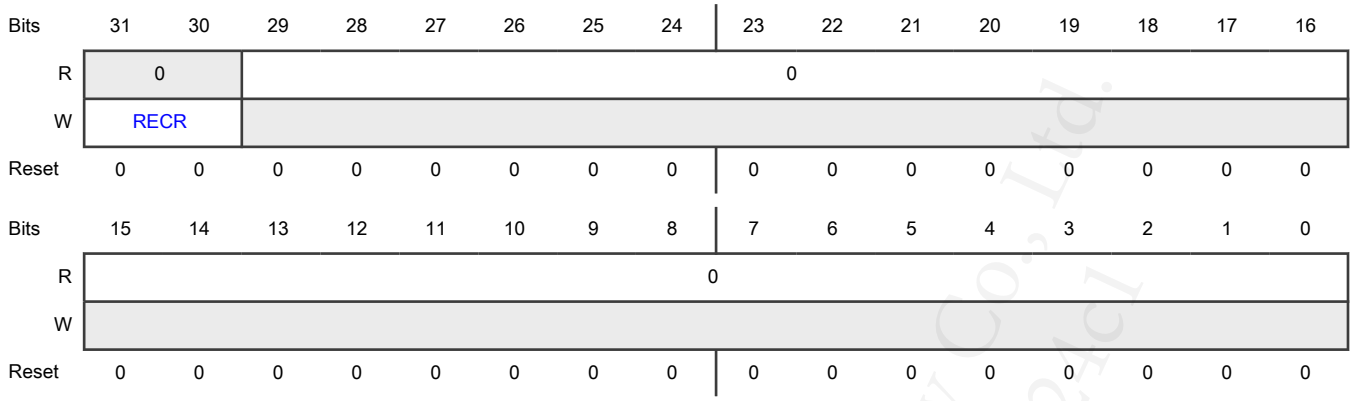
Function

This register rearms the error capture logic and clears the DERR_W0_*i* and DERR_W1_*i* registers. After the domain access violation error details are read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

It also clears the corresponding field in DERRLOC*n* register.

A read of this location returns a value of 0000h. Attempted reads of an MRC or PAC instance that is not physically present are error-terminated.



See Domain error capture management for details.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W3_*i* records only the error of the lowest slave index.

Function

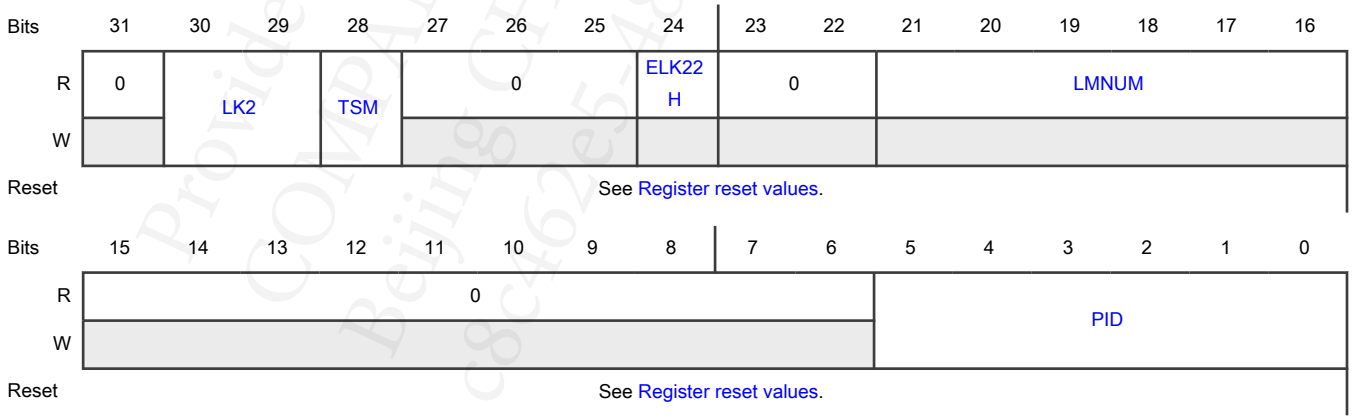
In XRDC's access control definition, each processor has a corresponding process identifier (PID) that performs two important functions: the PID[5] bit defines the secure/nonsecure attribute associated with an executing task, and the entire value can be used to group tasks into different domains.

While certain processors include this register in their programming model definitions, others do not. This register is provided for those processors that do not include a PID register in their programming models. Secure privileged software saves and restores the PID as part of any context switch.

This data structure defines an array of 32-bit values, one per MDA module, that define the PID. Because this register resource is only applicable to processor cores, the data structure is typically sparsely populated. The HWCFG2 register provides a bitmap of the implemented PID*n* registers. This data structure is indexed using the corresponding MDA instance number.

For processors only supporting the 3-state access control model (SecurePriv, SecureUser, NonsecureUser), the nonsecure[n] output signal from the MDAC submodule is forced to 0 while being in privileged mode to enable precise state transitions between user and privileged modes. Specifically, the MDAC logic for bus master *n* forms the nonsecure attribute output signal as a function of two configuration bits: PID*m*[TSM] and HWCFG{2,3}[*n*]. See the following table that provides details on generation of the nonsecure_out[*n*] attribute.

Depending on the operating clock domain of each MDAC instance, there may be optional information stored in the corresponding PID*m* register to properly implement the LK2 = 2 functionality.



Specifically, if PIDm[ELK22H] = 1, then the MDAC hardware loads PIDm[LMNUM] with the bus master number of the processor that set PIDm[LK2] = 2. The LMNUM field is subsequently used to qualify attempted writes to the PIDm register. The LMNUM field is cleared when LK2 = [0,1,3].

Reads of the PID*n* register either return the contents of this register, or the PID*n* value directly sourced from a processor. For non-processor bus masters, this register does not exist and any attempted read is error-terminated.

Table 54. Generation of the nonsecure_out[*n*] attribute

Configuration {PID*n*[TSM], HWCFG{2,3}[*n*]}	local_nonsecure[*n*]	nonsecure_out[*n*]

Register reset values

Register	Reset value
PID0–PID1	0100_0000h
PID2–PID7	Register not supported
PID8–PID18	0000_0000h
PID11–PID15	Register not supported

Fields

Field	Function
31 — 	Reserved
30-29 LK2 	Lock This field provides a locking mechanism that can be used to limit the ability to write to the register. After you write 1 to the bits of this field, they individually remain asserted until the next reset. If the processor sources its PID*m* directly, that is, HWCFG{2-3}[PIDP*m* = 1], then secure privileged reads of this memory location return 0 for this field. 00, 01b - Register can be written to by any secure privileged write 10b - Register can only be written by a secure privileged write from bus master m 11b - Register locked (read-only) until the next reset
28 TSM 	Three-State Model If asserted, this field indicates that the associated processor core only supports the three-state access control model. This indicator is sticky; that is, after it is set to 1, it remains at that value until the next reset. For processors only supporting the three-state access control model, this field must be set before loading any nonsecure value into the PID. See table: Generation of the nonsecure_out[*n*] attribute for the specifications of the privileged and nonsecure attributes generated by MDAC.
27-25 — 	Reserved
24 ELK22H 	Enable (LK2 = 2) Special Handling 0b - LK2 is in its standard form. The LMNUM field of this register is reserved and always read as 0. 1b - This read-only field signals an MDAC instance clocking configuration where the special handling of the LK2 = 2 state is required and LMNUM will capture the current lock owner.
23-22 — 	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 LMNUM	Locked Master Number This field is only enabled when ELK22K = 1. It is written by the MDAC instance with the bus master number of the locking processor that set LK2 = 2 and is used to qualify subsequent attempted writes to the register. The field is cleared to 0 when LK2 = [0,1,3] or ELK22H = 0.
15-6 —	Reserved
5-0 PID	Process Identifier This field determines the secure (0) or nonsecure (1) attribute for transactions associated with the corresponding processor. If the processor sources its PID*n* directly, then secure privileged reads of this memory location return the processor register for this field. See Cache coherency interconnect (CCI) for more information.

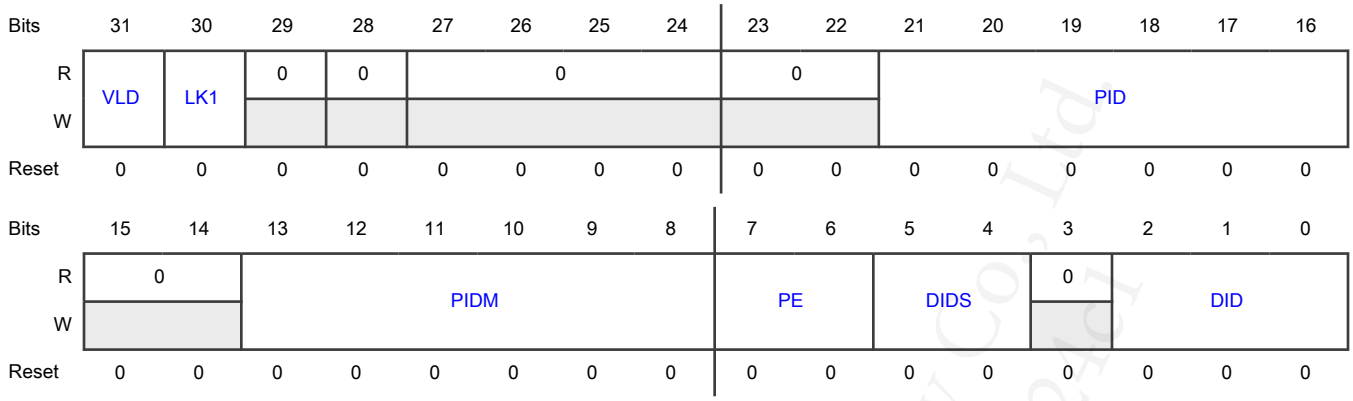
Function

This set of registers provide a two-dimensional data structure for assigning bus masters to domains. The number of implemented registers is defined by MDACFG*m*[NMDAR]. This per-master domain assignment is then repeated for each bus master (MDA*m*). Thus, *m* specifies the master number and *r* refers to the specific MDA register for a given bus master.



Each W*r* within the MDA*m* structure is a word-sized definition; there are two formats supported: one for processor cores and the other for non-processors. Processor masters typically support one or more W*r* domain definitions, while non-processor masters support a single W*r*.

The MDAC submodule is responsible for the generation of domain identifiers for every transaction from every bus master. If there is a single W*r* for a given master, then the specified domain identifier is used directly. If there are multiple W*r* values for a given master, then the MDAC evaluates the conditional terms to determine a “hit.” For all W*r* hits, their corresponding domain identifiers are logically summed together (using boolean OR). Use cases are typically expected to hit a single W*r* for a processor master. Special care is needed if none of the conditional terms hit any W*r* evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_W*r*_*m* register has one of two programming models depending on the state of the domain format field, DFMT, in this register. The model described in this section is applicable if DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Master Domain Assignment (MDA_W*r*_*m*_DFMT1).

Access: Secure privileged read/write

Diagram

Fields

Field	Function
31 VLD	Valid This field indicates that the domain assignment is valid. It is further qualified if the value of CR[GVLD] is 1. If the value of CR[GVLD] is 0, the DID output is defined by the chip-specific default DID value. See the XRDC chip configuration section for details. If both MDA_W*r_m*[VLD] and CR[GVLD] are asserted, the DID output is defined by the remaining contents of this register. 0b - W*r* domain assignment invalid 1b - W*r* domain assignment valid
30 LK1	Lock This field provides a locking mechanism that can be used to limit the ability to write to the register. After this field is set to 1, it remains at that value until the next reset. 0b - Register can be written to by any secure privileged write 1b - Register locked (read-only) until the next reset

15.4.1.16 Peripheral Domain Access Control (PDAC_W0_0 - PDAC_W0_408)

Offset

Register	Offset
PDAC_W0_(c * 128) + s	1000h + (c × 400h) + (s × 8h)

Function

This register array, PDAC_W*r*_*s*, provides a two-dimensional data structure for defining access control policies per domain for each implemented slave peripheral. In the offset equation above, *c* is the instance number and *s* is the slot number. See Table 55 for access control policies. There are two word-sized registers assigned for each peripheral address slot (W*r*).

Each W*r* within the PDAC*s* structure is a word-sized definition; a total of two words (64 bits) is needed to define the access control policies for all the domains.

These registers also allow a hardware semaphore to be optionally included in the access control evaluation for peripherals shared by multiple domains. If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain owning it has write permission into the peripheral. The write permissions for all other domains are revoked based on the semaphore state. If the semaphore is not owned by any domain, the D*x*ACP fields are evaluated normally.

The PAC submodule uses the peripheral access address to select the appropriate PDAC*s* register, and then uses the domain identifier associated with the access to select the appropriate D*x*ACP field. The selected D*x*ACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP evaluation for details. If allowed, the access proceeds, else an access violation is signaled, the transfer error-terminated, and the appropriate address and attribute information captured in the corresponding error detail registers.

15.4.1.18 Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_223)

Offset

Register	Offset
MRGD_W0_n * 16 + m	2000h + (n × 200h) + (m × 20h)

Function

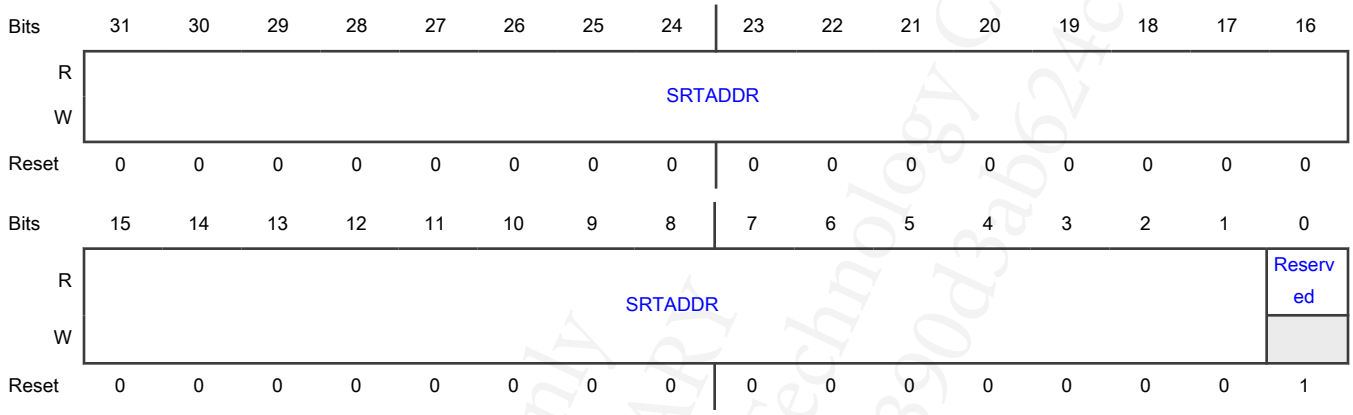
This set of registers provide a two-dimensional data structure for defining access control policies (see Table 56) per domain for each supported memory region. There are four word-size registers (W*o*) defined in each memory region. There are up to 16 memory region controllers (MRCs), *n*, each supporting up to 16 memory region descriptors (MRGD), *m*. The number of MRCs is defined by HWCFG0[NMRC].

Each instance of an MRC submodule can monitor up to eight system buses concurrently.

NOTE

An AXI port counts as two system buses because the read address and write address channels operate independently.

Each W*o* within the MRGD*m* structure is a word-sized definition; a total of four words (128 bits, W0-W3) are needed to completely define the memory region descriptor.



XRDC uses separate start (W0) and end addresses (W1) to define memory regions and leverages capabilities formerly provided in SMPUs.

The region descriptor also allows a hardware semaphore to be optionally included in the access control evaluation for memory regions shared by multiple domains. If enabled, the state of the semaphore dynamically modifies the access control policies so

that only the domain owning it has write permission into the region. The write permissions for all other domains are revoked based on the semaphore state. If the semaphore is not owned by any domain, the D*x*ACP fields are evaluated normally.

The MRC submodule evaluates multiple system bus access addresses versus the programmed address ranges to determine a region hit. After a region hit is determined, the MRC uses the domain identifier associated with the access to select the appropriate D*x*ACP field from the corresponding MRGD*n*. The selected D*x*ACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See Memory region descriptor hit determination and Memory region DxACP evaluation for details. If allowed, the access proceeds, else an access violation is signaled, the transfer error terminated, and the appropriate address and attribute information captured in the corresponding error detail registers.

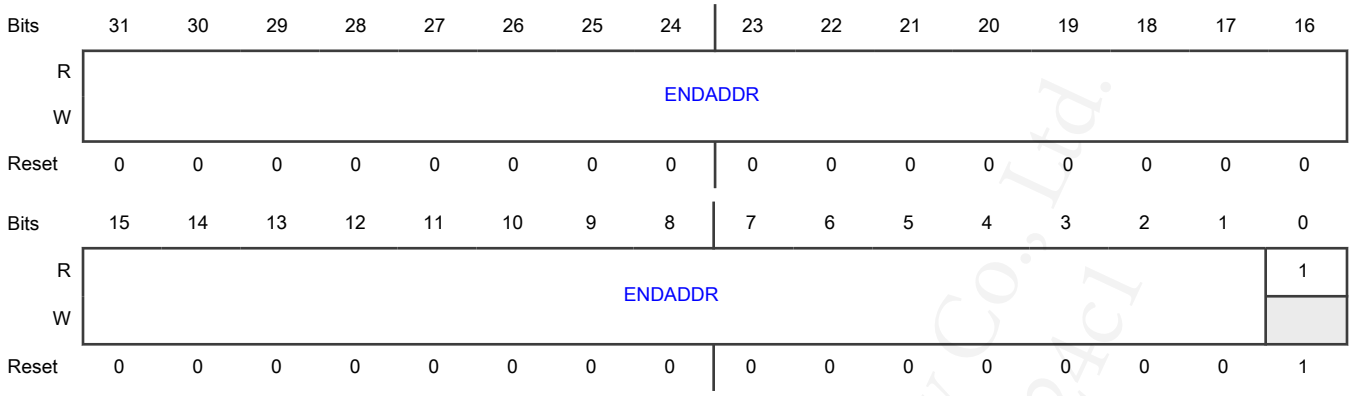
Diagram

Fields

Field	Function
31-1 SRTADDR	Start Address This field defines bits 35:5 of the 0-modulo-32-byte start address of the memory region. The minimum region size is 32 bytes. This field expects the address to be entered 4 bits shifted to the right.
0 —	Reserved

15.4.1.19 Memory Region Descriptor (MRGD_W1_0 - MRGD_W1_223)

Offset



Register	Offset
MRGD_W1_n * 16 + m	2004h + (n × 200h) + (m × 20h)

Function

See Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_223) for description.

Fields

Field	Function
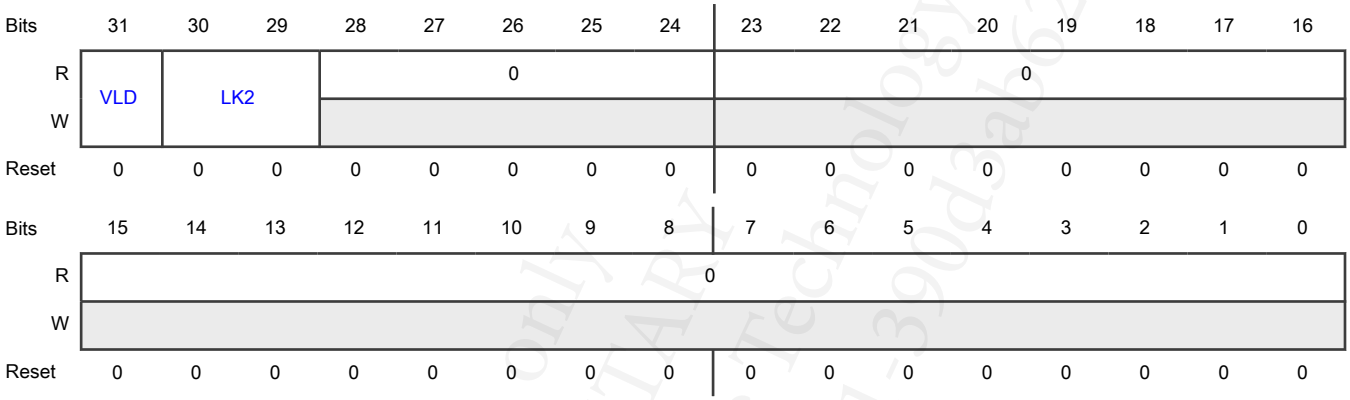
31 —	Reserved
30 SE	Semaphore Enable This field indicates if a semaphore, SNUM, is to be included in the D*x*ACP access evaluation. 0b - Do not include a semaphore in the D*x*ACP evaluation. 1b - Include the semaphore defined by SNUM in the D*x*ACP evaluation.
29-28 —	Reserved
27-24 SNUM	Semaphore Number Include this hardware semaphore in the D*x*ACP access evaluation.
23-21: D7ACP 20-18: D6ACP 17-15: D5ACP 14-12: D4ACP 11-9: D3ACP 8-6: D2ACP 5-3: D1ACP 2-0: D0ACP	Domain *n* Access Control Policy This field defines the access control rights for the selected domain. The encodings specify read and write access capabilities based on the four operating states. These fields are only implemented for supported DIDs; unsupported DIDs are not implemented and default to a zero value, providing no access rights. See the Access control policy table above.

15.4.1.21 Memory Region Descriptor (MRGD_W3_0 - MRGD_W3_223)



Offset

Register	Offset
MRGD_W3_n * 16 + m	200Ch + (n × 200h) + (m × 20h)

Function

See Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_223) for description.

Diagram

Fields

Field	Function
31 VLD	Valid This field indicates that the memory region descriptor definition is valid. It is further qualified if the value of CR[GVLD] is 1. If the value of CR[GVLD] is 0, then all accesses to the memory region are allowed. Any write to MRGD_W[0-2]_*n* clears the MRGD_W3_*n*[VLD] indicator, so a coherent register state can be supported. 0b - The MRGD*n* assignment is invalid. 1b - The MRGD*n* assignment is valid.
30-29 LK2	Lock This field provides a mechanism to limit writes to the MRGD*n* register to protect its contents. After you write 1 to the bits of this field, they individually remain asserted until the next reset. 00b - All MRGD*n* registers can be written to 01b - Reserved 10b - Domain *x* can only update the D*x*ACP field for domain *x*; no other ACP fields can be written to 11b - MRGD*n* registers are locked (read-only) until the next reset

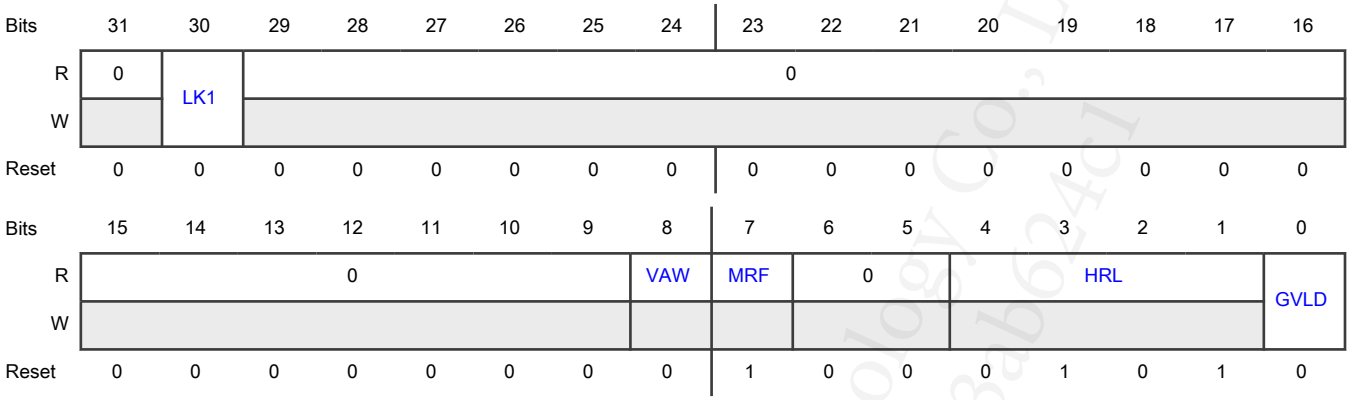
15.4.2.2 Control (CR)

Offset



Register	Offset
CR	0h

Function

This register provides the read-only status of the XRDC and a global enable bit for the entire module's operation.

Access: Secure privileged read/write

Diagram

Fields

Field	Function
31 —	Reserved
30 LK1	Lock This field provides a locking mechanism that can be used to prohibit the ability to write to this register. After you write 1 to this field, it remains asserted until the next reset. 0b - Register can be written to by any secure privileged write 1b - Register is locked (read-only) until the next reset
29-9 —	Reserved
8 VAW	Virtualization Aware This field indicates that the domain assignments support the optional inclusion of a logical partition identifier (also known as an operating system number). 0b - Implementation is not virtualization-aware 1b - Implementation is virtualization-aware
7 MRF	Memory Region Format This field indicates that the format of the memory region descriptors and is defined by SoC requirements. 0b - Reserved 1b - SMPU family format
6-5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4-1 HRL	Hardware Revision Level This field specifies XRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module. It is hardwired to the value 0101b as it represents an architectural descendent from previous {system} memory protection units ({S}MPU).
0 GVLD	Global Valid (XRDC Global Enable/Disable) 0b - XRDC disabled; all accesses from all bus masters to all slaves allowed 1b - XRDC enabled

15.4.2.3 Hardware Configuration 0 (HWCFG0)

Offset

Register	Offset
HWCFG0	F0h

Function

This read-only register contains information on XRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory region controllers (MRCs) and peripheral access controllers (PACs). The register value at reset is chip-specific. Attempted writes are error-terminated.

Access: Secure privileged read

Fields

Field	Function
31-0 PIDPn	Process Identifier Process identifier present from bus master *n*. This field provides a bitmap to signal that bus master *n* sources a process identifier register to the MDAC logic. 0b - Bus master *n* does not source a process identifier register; MDAC logic provides the needed PID for processor cores 1b - Bus master *i* sources a process identifier register to MDAC logic

15.4.2.6 Master Domain Assignment Configuration (MDACFG0 - MDACFG7)

Offset

For m = 0 to 7:

Register	Offset
MDACFGm	100h + (m × 1h)

Function

This register defines the number of implemented domain assignment registers for bus master *m*, where *m*+1 can specify bus masters from 1 to 64. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error-terminated.

Typically, processor bus masters include one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: Secure privileged read

Provided under NDA only
COMMERCIAL IN CONFIDENCE

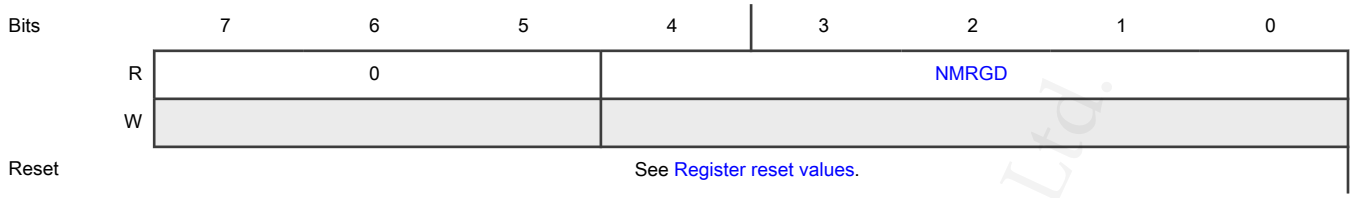
R	NCM	0			NMDAR			
W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Function
7 NCM	Non-CPU Master This field indicates that bus master *m* is a non-CPU master. It specifies that the format of the associated MDA_W*r_m* register defines a non-processor domain assignment. The value of the field is 0 for a non-existent bus master. 0b - Bus master is a processor 1b - Bus master is a non-processor
6-4 —	Reserved
3-0 NMDAR	Number Of Master Domain Assignment Registers For Bus Master *m* This field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where 0 indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDA*m*.

15.4.2.7 Memory Region Configuration (MRCFG0 - MRCFG5)

Offset



Register	Offset
MRCFG0	140h
MRCFG1	141h
MRCFG2	142h
MRCFG3	143h
MRCFG4	144h
MRCFG5	145h

Function

This read-only register defines the number of implemented memory region descriptors for each MRC*r*, where *r*+1 can specify up to 16 instances. These registers are organized as byte-sized data arrays and can be read using 8-, 16- or 32-bit accesses. A zero value indicates a non-existent memory region controller instance. Attempted writes are error-terminated.

Access: Secure Privileged Read

Diagram

Register reset values

Register	Reset value
MRCFG0–MRCFG1	04h
MRCFG2	10h
MRCFG3–MRCFG5	04h

Fields

Field	Function
7-5 —	Reserved
4-0 NMRGD	Number Of Memory Region Descriptors For Memory Region Controller *n* Number of memory region descriptors for MRC*r*. This field specifies the number of memory region descriptors associated with a given memory region controller instance. The value is limited to the range [0-16], where 0 indicates a non-existent MRC instance and non-zero values indicate the number of implemented memory region descriptors [4, 8,12,16] associated with the MRC*r* submodule.

15.4.2.8 Domain Error Location (DERRLOC0 - DERRLOC7)

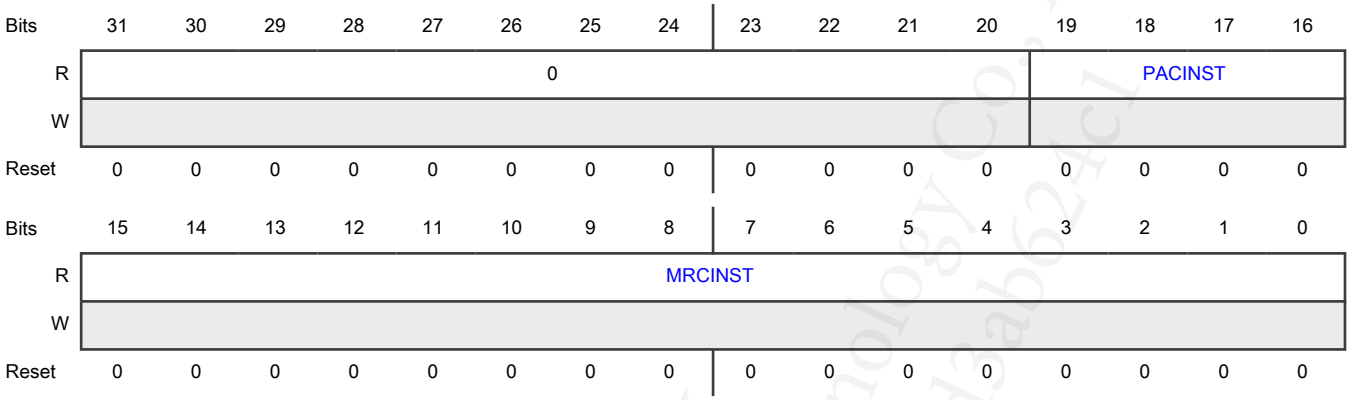
Offset

For d = 0 to 7:

Register	Offset
DERRLOCd	200h + (d × 4h)

Function

This array of read-only registers provide the instance number of the submodule where an access violation occurred. These registers are organized as a word array, which is indexed by the faulting domain number, *d*. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i*, and DERR_W3_*i* register arrays. See Domain error capture management for details.



When an access violation is detected by either a memory region controller (MRC) or a peripheral access controller (PAC), address and attribute information of the offending access is captured. Using the faulting DID number as the index, *d*, this array of read-only registers provides additional information signaling the instance number of the submodule where the access violation(s) occurred.

Because the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error-terminated.

Access: Secure privileged read

Diagram

Fields

Field	Function
31-20 —	Reserved
19-16 PACINST	PAC Instance This field is a bitmap indicating the presence of a detected access violation for domain *d* in the implemented instances of the PAC. The least-significant bit of this field (bit 16) corresponds to PAC instance 0. The most-significant bit of this field (bit 19) corresponds to PAC instance 3, and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the PACs. **NOTE** When a memory slot controller (MSC) is present, it appears here in the same way as a PAC instance. For each bit in this field: • 0 - The peripheral access controller has not detected an access violation or is not physically present. • 1 - The peripheral access controller has detected one or more access violations for this domain.
15-0 MRCINST	MRC Instance This field is a bitmap indicating the presence of a detected access violation for domain *d* in the implemented instances of the MRC. The least-significant bit of this field (bit 0) corresponds to MRC instance 0. The most-significant bit of this field (bit 3) corresponds to MRC instance 3, and so on. Multiple bits can be set at any time to indicate access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0 - The memory region controller has not detected an access violation or is not physically present. • 1 - The memory region controller has detected one or more access violations for this domain.

15.4.2.9 Domain Error Word0 (DERR_W0_0 - DERR_W0_16)

Offset

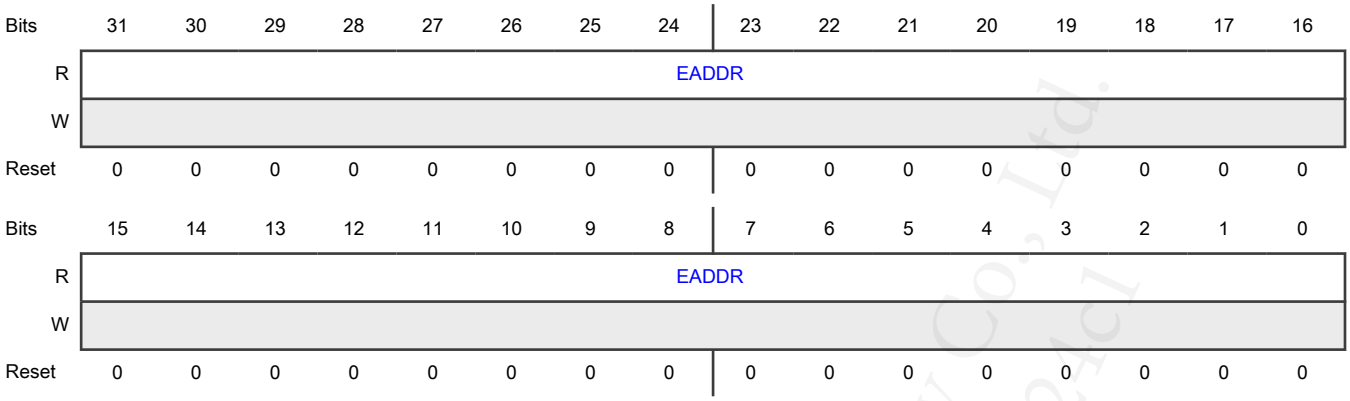
Register	Offset
DERR_W0_0	400h
DERR_W0_1	410h
DERR_W0_2	420h
DERR_W0_3	430h
DERR_W0_4	440h
DERR_W0_5	450h
DERR_W0_16	500h

Function

This read-only register array provides the address of an access violation detected by either an MRC or a PAC. These registers are organized as a word array, which is indexed by the violating submodule instance number. That is, the index, *i*, of this array is the instance number of the submodule that detected the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory-mapped error capture detail registers are organized as 20 sequential 16-byte entries. The first 16 register sets are associated with the MRCs. The following four register sets are associated with the PACs. Each 16-byte structure contains DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i*, and DERR_W3_*i*.

The error capture registers in the MRC and PAC submodules contain physical registers for each domain, but are organized in the DERR_W0_*i* and DERR_W1_*i* registers to provide the information for the requesting domain only. Thus, the access violation exception handler for each domain only has visibility into the captured error information for its own domain. See Domain error capture management for details.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_*i* register. At that time, this register is cleared and re-enabled to capture the next access violation.



Attempted writes are error-terminated as are attempted reads of an MRC or PAC instance that is not physically present.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W0_*i* records only the error of the lowest slave index.

Access: Secure privileged read

Diagram

Fields

Field	Function
31-0 EADDR	Error Address This is the access address that generated an access violation.

15.4.2.10 Domain Error Word1 (DERR_W1_0 - DERR_W1_16)

Offset

Register	Offset
DERR_W1_0	404h

Provided under NDA to Beijing CHJ Automotive Technology Co., Ltd. COMPANY PROPRIETARY c8c462e5-4821-4aa8-b251-390d3ab624c1

Function

This is a word-sized location in the domain error details data structure. The registers are organized in a data structure based on instance number, that is, n = the instance number of the submodule which detected the access violation, and are read using information directly extracted from the DERRLOCn registers. The memory-mapped capture error detail registers are organized as 20 sequential 16-byte entries. The first 16 register sets are associated with the memory region controllers. The following four registers sets are associated with the peripheral access controllers. Each 16-byte record contains DERR_W0_*i*, DERR_W1_*i*, DERR_W2_*i* and DERR_W3_*i*. See Domain error capture management for more details. A read of this location returns zeroes. Attempted writes are error-terminated as are attempted reads of an MRC or PAC instance that is not physically present.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W2_*i* will record only the error of the lowest slave index.

Access: Secure Privileged Read

Table continued from the previous page...

Register	Offset
DERR_W3_3	43Ch
DERR_W3_4	44Ch
DERR_W3_5	45Ch
DERR_W3_16	50Ch

Function

This register rearms the error capture logic and clears the DERR_W0_*i* and DERR_W1_*i* registers. After the domain access violation error details are read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

It also clears the corresponding field in DERRLOC*n* register.

A read of this location returns a value of 0000h. Attempted reads of an MRC or PAC instance that is not physically present are error-terminated.

See Domain error capture management for details.

NOTE

If masters with the same DID cause simultaneous error accesses, DERR_W3_*i* records only the error of the lowest slave index.

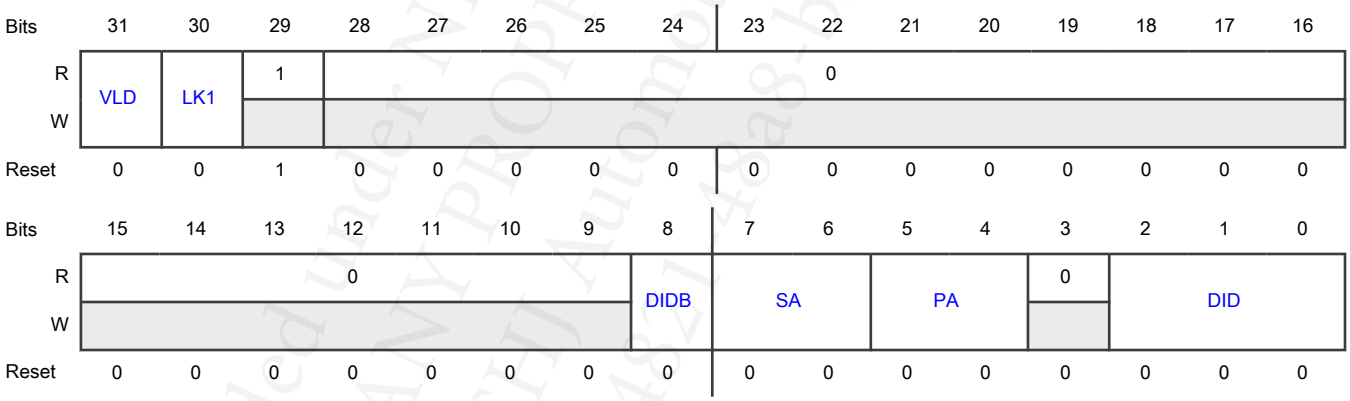
15.4.2.13 Master Domain Assignment (MDA_W0_0_DFMT1 - MDA_W0_7_DFMT1)

Offset

For m = 0 to 7:



Register	Offset
MDA_W0_m_DFMT1	800h + (m × 20h)

Function

This register is identical to Master Domain Assignment (MDA_W*r_m*_DFMT0) except that the value of the domain format field, DFMT, is 1. This format supports two different specifications of DID for non-core bus masters.

Access: Secure privileged read/write

Diagram

Fields

Field	Function
31 VLD	Valid This field indicates that the domain assignment is valid. It is further qualified if the value of CR[GVLD] is 1. If the value of CR[GVLD] is 0, the DID output is defined by the chip-specific default DID value. See the XRDC chip configuration section for details. If both MDA_W*r_m*[VLD] and CR[GVLD] are asserted, the DID output is defined by the remaining contents of this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - The W*r* domain assignment is invalid 1b - The W*r* domain assignment is valid
30 LK1	Lock This field provides a locking mechanism that can be used to limit the ability to write to the register. After this bit is set, it remains asserted until the next reset. 0b - Register can be written to by any secure privileged write 1b - Register is locked (read-only) until the next reset
29 DFMT	Domain Format Identifies this register's domain assignment. 1b - Non-processor domain assignment
28-9 —	Reserved
8 DIDB	DID Bypass If asserted, this field enables the bypassing of an input DID value as the domain identifier for this non-processor bus master. This capability allows non-processor bus masters (for example, a DMA) to masquerade as a processor. After this field is set to 1, it remains at that value until the next reset. 0b - Use MDA*n*[3:0] as the domain identifier 1b - Use the DID input as the domain identifier
7-6 SA	Secure Attribute This field defines the secure/nonsecure attribute for non-processor cores. **NOTE** The bus master's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. 00b - Force the bus attribute for this master to secure. 01b - Force the bus attribute for this master to nonsecure. 1xb - Use the bus master's secure/nonsecure attribute directly.
5-4 PA	Privileged Attribute This field defines the privileged/user attribute for non-processor cores. **NOTE** The bus master's input privileged or user attribute is used if PA = 1X, or this VLD = 0. 00b - Force the bus attribute for this master to user. 01b - Force the bus attribute for this master to privileged.

15.4.2.14 Peripheral Domain Access Control (PDAC_W0_0 - PDAC_W0_15)

Offset

Register	Offset
PDAC_W0_(0 * 128) + s	1000h + (s × 8h)

Function

This register array, PDAC_W*r*_*s*, provides a two-dimensional data structure for defining access control policies per domain for each implemented slave peripheral. In the offset equation above, *c* is the instance number and *s* is the slot number. See Table 57 for access control policies. There are two word-sized registers assigned for each peripheral address slot (W*r*).

Each W*r* within the PDAC*s* structure is a word-sized definition; a total of two words (64 bits) is needed to define the access control policies for all the domains.

These registers also allow a hardware semaphore to be optionally included in the access control evaluation for peripherals shared by multiple domains. If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain owning it has write permission into the peripheral. The write permissions for all other domains are revoked based on the semaphore state. If the semaphore is not owned by any domain, the D*x*ACP fields are evaluated normally.

The PAC submodule uses the peripheral access address to select the appropriate PDAC*s* register, and then uses the domain identifier associated with the access to select the appropriate D*x*ACP field. The selected D*x*ACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP evaluation for details. If allowed, the access proceeds, else an access violation is signaled, the transfer error-terminated, and the appropriate address and attribute information captured in the corresponding error detail registers.

Access: Secure privileged read/write

15.4.2.16 Memory Region Descriptor (MRGD_W0_0 - MRGD_W0_83)

Offset

Register	Offset
MRGD_W0_n * 16 + m	2000h + (n × 200h) + (m × 20h)

Function

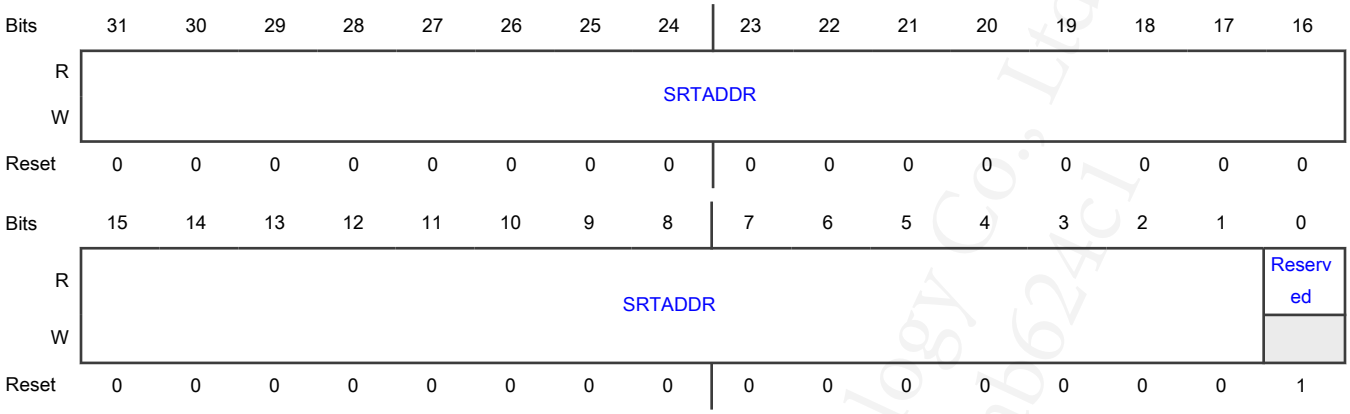
This set of registers provide a two-dimensional data structure for defining access control policies (see Table 58) per domain for each supported memory region. There are four word-size registers (W*o*) defined in each memory region. There are up to 16 memory region controllers (MRCs), *n*, each supporting up to 16 memory region descriptors (MRGD), *m*. The number of MRCs is defined by HWCFG0[NMRC].

Each instance of an MRC submodule can monitor up to eight system buses concurrently.

NOTE

An AXI port counts as two system buses because the read address and write address channels operate independently.

Each W*o* within the MRGD*m* structure is a word-sized definition; a total of four words (128 bits, W0-W3) are needed to completely define the memory region descriptor.



XRDC uses separate start (W0) and end addresses (W1) to define memory regions and leverages capabilities formerly provided in SMPUs.

The region descriptor also allows a hardware semaphore to be optionally included in the access control evaluation for memory regions shared by multiple domains. If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain owning it has write permission into the region. The write permissions for all other domains are revoked based on the semaphore state. If the semaphore is not owned by any domain, the D*x*ACP fields are evaluated normally.

The MRC submodule evaluates multiple system bus access addresses versus the programmed address ranges to determine a region hit. After a region hit is determined, the MRC uses the domain identifier associated with the access to select the appropriate D*x*ACP field from the corresponding MRGD*n*. The selected D*x*ACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See Memory region descriptor hit determination and Memory

region DxACP evaluation for details. If allowed, the access proceeds, else an access violation is signaled, the transfer error terminated, and the appropriate address and attribute information captured in the corresponding error detail registers.

15.5 Functional description

This section provides details on the operation and implementation of the XRDC submodules.

15.5.1 Manager (MGR)

The MGR submodule is responsible for coordinating XRDC's programming model reads and writes.

The complete programming model is large, requiring four 4 KB slave peripheral address space slots, although most chips define a sparsely populated subset. Additionally, the programming model is distributed across the various submodule instances (MDAC, MRC, and PAC). The MGR submodule provides the required hardware management for all programming model accesses, generating and distributing the appropriate address decodes and write data to the MDAC, MRC, and PAC submodule instances, and collecting and combining all the register read data buses and responses.

MGR implements the Control Register, all the read-only hardware configuration registers (HWCFG[0-3], MDACFG*n*, and MRCFG), and the program-visible versions of the domain error capture registers. To support the domain error reporting functionality, the MGR submodule collects the individually captured error indicator output signals from all the submodule instances and remaps them so they are organized into an instance bitmap by domain, as specified by the DERRLOC*n* register array.

15.5.2 Master domain assignment controller (MDAC)

The MDAC submodule is responsible for the generation of the domainID on every memory transaction for every bus master in the chip. The resulting domainID and {nonsecure, privileged} signals are generated. They are then treated as address attributes and associated with each transaction as a given transaction moves through the system.

MDAC modules that drive the DIDs for processor cores include an option of processor-identifier (PID) matching to select between DIDs. This is accomplished by first enabling PID checking by setting MDA_W*m_n*[PE] = [2,3]. With PID matching enabled, a domain hit is determined by matching MDA_W*m_n*[PID] with the PID input or PID in the PID register. The PIDM field can be used to match specific groups of PIDs.

As a simple example, assume a system with two DIDs.

- DID 1 is for critical tasks (criticality is system-specific and may refer to timing, safety, and so on).
- DID 2 is for non-critical tasks.
- Two DIDs require two MDA_W*m_n* registers, MDA_W0 and MDA_W1.

Further, assume that the processor's task identifier defines whether a task is critical or non-critical, as defined by system software.

- PIDs [0-15] are assigned to critical tasks.
- PIDs != [0-15] are assigned to noncritical tasks.

During startup, software initializes the MDA_W[0-1] registers. MDA_W0 defines DID = 1 for PIDs [0-15] and MDA_W1 defines DID = 2 for PIDs != [0-15].

- MDA_W0 value is 8000_0F81h, which corresponds to these individual field values:
  - VLD = 1

  - PID = 0h
  - PIDM = Fh
  - PE = 2
  - DIDS = 0
  - DID = 1
- MDA_W1 value is 8000_0FC2h, which corresponds to these individual field values:
  - VLD = 1
  - PID = 0h
  - PIDM = Fh
  - PE = 3
  - DIDS = 0
  - DID = 2

When the processor executes, it loads the appropriate task ID into its PID register. The processor's PID register value is input for the corresponding MDAC module and is used by the MDA_W*m* comparison logic. The system then dynamically generates two DIDs, and the downstream XRDC access check logic can distinguish and enforce different access control rights based on the different DIDs.

A special mode is provided for driving the DID of non-processor masters. This is enabled with the DID bypass field, MDA_W0_*n*_DFMT1[DIDB]. The MDAC has a DID input that can be driven by a master and used directly as the DID output. This allows variability in the DID, which is dictated by the master and is intended to be used by DMA masters that masquerade as (that is, drive the DID of) the master that programmed it.

15.5.3 D*x*ACP evaluation

Fundamental to XRDC's operation is the actual access violation check performed by the MRC and PAC controllers.

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the DID as an address attribute through the system bus switching fabric(s). As transactions reach the slave memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or peripheral access control register. After the appropriate register is selected, the next function is the actual access evaluation.

For this step, the DID of the current transaction selects the appropriate 3-bit D*x*ACP (domain *x* access control policy) from the source register. The D*x*ACP field defines the access rights for the domain based on the four-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, user = 0/privileged = 1).

The four-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as follows:

```
if {nonsecure, privileged} == 01b, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 00b, then level = SecureUser
if {nonsecure, privileged} == 11b, then level = NonsecurePriv(ileged)
if {nonsecure, privileged} == 10b, then level = NonsecureUser
```

The resulting hierarchical access control model specifies the following:

```
SecurePriv(ileged) > SecureUser > NonsecurePriv(ileged) > NonsecureUser
```

Table 59 defines XRDC's evaluation of the access control policy.

Table 59. Domain *x* access control policy definition

Policy	Allowable accesses			
	Secure Priv	Secure User	Nonsecure Priv	Nonsecure User
111	r, w	r, w	r, w	r, w
110	r, w	r, w	r, w	none
101	r, w	r, w	r	r
100	r, w	r, w	r	none
011	r, w	r, w	none	none
010	r, w	none	none	none
001	r	r	none	none
000	none	none	none	none

Unimplemented domains default to the D*x*ACP field value of 000b in the above table, which provides no access rights.

After the D*x*ACP evaluation is complete and the access error signal is generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

XRDC optionally supports the inclusion of a hardware semaphore to dynamically alter the access control policy of a memory region or peripheral access. See Hardware semaphores and dynamic access rights for details.

15.5.4 Hardware semaphores and dynamic access rights

Both memory region descriptors and peripheral access control registers support the ability to optionally include a hardware semaphore in their access evaluations. This capability is provided to allow hardware enforcement of dynamic access rights based on the state of the semaphore for shared memory regions and/or shared peripherals.

If enabled (MRGD_W2_*n*[SE] = 1 or PDAC_W0_*n*[SE] = 1), the state of the specified hardware semaphore, as defined by MRGD_W2_*n*[SNUM] or PDAC_W0_*n*[SNUM]), is checked before the normal D*x*ACP evaluation. On a write transaction, if the semaphore is not idle, that is, the semaphore state is non-zero and not owned by the requesting domain, the access is aborted and error-terminated. Stated differently, writes into a semaphore-enabled address space are only allowed if the semaphore is idle, or is owned by the requesting domain. See the Semaphores2 (SEMA42) chapter for more information.

The semaphore check is detailed in lines 84-92 of the C code description contained in MRC C code description. The comparable function in the PAC C code in Peripheral access controller (PAC) is found in lines 38-45.

An additional note on this capability is that because the semaphore module only supports up to 15 domains, that is, DIDs [0-14], DID 15 cannot be used for this function.

15.5.5 Memory region controller (MRC)

The XRDC's memory region controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed region descriptors that define memory spaces and their associated access rights per DID, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The XRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support {4, 8, 12, 16} region descriptors, concurrently monitoring up to eight slave memory ports. Note that monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 35. In this figure, a single slave bus port is shown. When the remaining slave ports are considered, the two-dimensional connection matrix of the MRC hardware is the resulting structure. The basic access evaluation macro is shown as the replicated submodule block. Each system bus slave port access is broadcast across the implemented memory region descriptors. In Figure 35, the system bus fabric slave port is shown on the left, the memory region descriptor registers are in the center, and the peripheral bus interface is on the right. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and access violations. These violations are based on the DID associated with the reference.

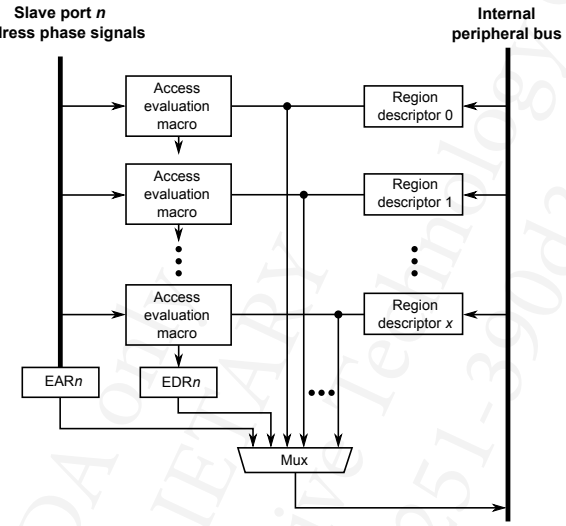

Figure 35. MRC access evaluation macro hardware structure

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the DID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in DxACP evaluation.

15.5.5.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as follows:

```
region_hit_n =
   ((addr >= start_addr) & (addr <= end_addr)) & valid
```

Here, `addr` is the current system reference address, `start_addr]` and `end_addr` are the start and end addresses, respectively, and `valid` is the valid bit, all from memory region descriptor *n*.

You must ensure that end_addr ≥ start_addr. There are no hardware checks to verify this. The software must properly load appropriate values into these fields of the region descriptor.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

15.5.5.2 Memory region D*x*ACP evaluation

For each region descriptor hit, the MRC logic then evaluates the access rights defined by the MRGD_W*m_n* registers. Specifically, the domainID attribute selects the appropriate D*x*ACP field from the MRGD_W{2,3}_*n* registers and then the {write, nonsecure,

privileged} address attributes are compared with the access policy defined by the selected D*x*ACP. See DxACP evaluation for additional details on this function.

When CR[GVLD] = 1, and for each bus slave port being monitored, MRC performs a reduction-AND of all the individual *(no_hit | error)* terms from each access evaluation macro. As specified in Memory region descriptor hit determination, an invalid MRGD_W*m_n* (MRGD_W3_*n*[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

- If the access does not hit a region descriptor
- If the access hits a single region descriptor and that region signals a domain violation
- If the access hits multiple (overlapping) regions and all regions signal violations

The third condition reflects that priority is given to *permission granting over access denying* for overlapping regions as this approach provides more flexibility to system software in the region descriptor assignments.

Unimplemented domain identifiers default to all-zero D*x*ACP fields providing no access rights. Additionally, these fields are RAZ/WI.

15.5.5.3 MRC C code description

The functionality of the MRC evaluation is described in the C code below. This code begins with the description of the data structures corresponding to the MRC-associated registers (lines 1-12). Note that the memory region descriptors are described as three-dimensional, unsigned 32-bit integer arrays indexed by the MRC instance number, the RGD number within the instance, and then the word offset within the region descriptor.

The access evaluation consists of four basic functions: a check of the XRDC's global valid bit (lines 43-45), the address hit/miss determination (lines 73-78), the selection of the D*x*ACP field and its evaluation (lines 80-96), and the combination of all the individual MRGD_W*m_n* hit and error indicators to determine the final state of the memory reference (lines 99-134).

```
 1  //  MRC  registers
 2 unsigned int      xrdc_hwcfg0;          // contains NMRC -> # of MRC's
 3 unsigned char     xrdc_mrcfg[16];       // defines NMRGD -> # of RGD's
 4
 5 #define RGD_ADDR_MASK   0xfffffffe0     // force sysAddr to modulo-32
 6 //
 7 // the memory region descriptors are modeled as a 3-dimensional array
 8 //  xrdc_mrgd[x][y][z] where:
 9 //      [x] = MRC instance number defined by xrdc_hwcfg0[nmrc]
10 //      [y] = RGDn within a given instance, defined by xrdc_mrcfgn[nmrgd]
11 //      [z] = Wordm within a given region descriptor
12 unsigned int      xrdc_mrgd[16][16][4]; // memory region descriptors
13
14 evaluate_MRC (MRCn, NMRGD, sysAddr, write, nonsecure, privileged, did)
15   unsigned int    MRCn;                 // MRCn instance number
16   unsigned int    NMRGD;                // number of RGDs for this MRC
17   unsigned int    sysAddr;              // system address
18   unsigned int    write;                // read   (=0), write      (=1)
19   unsigned int    nonsecure;            // secure (=0), nonsecure  (=1)
20   unsigned int    privileged;           // user   (=0), privileged (=1)
21   unsigned int    did;                  // domain identifier
22 {
23   unsigned int    mrgd_vld;             // local RGDn valid
24   unsigned int    mrgd_w2;              // local RGDn Word2
25   unsigned int    mrgd_w3;              // local RGDn Word3
26   unsigned int    mrgd_hit;             // calculated RGD "hit" signal
27   unsigned int    mrgd_error;           // calculated RGD "error" signal
28   unsigned int    mrgd_sema4;           // local copy of RGDn semaphore
29   unsigned int    mrc_hit;              // bitmask of RGDn hit signals
```

```
 30   unsigned int    mrc_error;            // bitmask of RGDn access errors
 31   unsigned int    final_error_state;    // final error state
 32   unsigned int    memory_access_error;  // final access error indicator

 38   unsigned int    i;                    // loop counter
 39
 40   mrc_hit   = 0;
 41   mrc_error = 0;
 42
 43   if (xrdc_cr_gvld == 0) {              // check global valid
 44       memory_access_error = 0;
 45   } else {
 46
 47       for (i = 0; i < xrdc_mrcfg[MRCn]; i++) {
 48           mrgd_hit    = 0;
 49           mrgd_error  = 0;
 50
 51           // extract the region descriptor valid indicator
 52           mrgd_vld = (xrdc_mrgd[MRCn][i][3] & 0x80000000) >> 31;
 53
 73           // first, determine if system address "hits" in the given MRDGn
 74           if (((sysAddr & RGD_ADDR_MASK) >=
 \                    (xrdc_mrgd[MRCn][i][0] & RGD_ADDR_MASK)) &&
 75               ((sysAddr & RGD_ADDR_MASK) <=
 \                    (xrdc_mrgd[MRCn][i][1] & RGD_ADDR_MASK)) &&
 76                (mrgd_vld == 1)) {
 77               mrgd_hit = 1;
 78           }
 79
 80           // second, if there was a hit, evaluate DxACP including any sema4
 81           if (mrgd_hit == 1) {
 82               mrgd_w2 = xrdc_mrgd[MRCn][i][2];
 83               mrgd_w3 = xrdc_mrgd[MRCn][i][3];
 84               // semaphore check using a local copy
 85               mrgd_sema4 = sema4[(mrgd_w2 & 0x3f000000) >> 24];
 86               // check if it is enabled on write and
 87              //       if not idle, nor equal to (did+1)
 88               if (((mrgd_w2 & 0x40000000) == 0x40000000) &&  // se
 89                    (write == 1)                          &&  // wt
 90                    (mrgd_sema4 != 0)                     &&  // sema4 !=idle
 91                    (mrgd_sema4 != (did+1)))              {   // sema4 !=did
 92                   mrgd_error = 1;
 93               } else {
 94                   // perform standard DxACP check
 95                   mrgd_error = evaluate_DxACP(mrgd_w2, mrgd_w3, did,
 \                                    nonsecure, privileged, write);
 96               }
 97           }
 98
 99           // accumulate the hit and error indicators
100           mrc_hit   = (mrc_hit   | (mrgd_hit   << i)) & 0xffff;
101           mrc_error = (mrc_error | (mrgd_error << i)) & 0xffff;
102       }
103
104
105       For each slave port monitored, MRC performs a reduction-AND of all
106       the individual (~hit | error) terms from each access evaluation.
107       This expression then terminates the bus cycle with an error & reports
108       an access error for three conditions:
109
```

```
110       1) If the access does not hit in *any* region descriptor,
111             then an access error is reported.
112       2) If the access hits in one region descriptor and
113          that region signals a violation,
114             then an access error is reported.
115       3) If the access hits in multiple (overlapping) regions and *all*
116          regions signal violations,
117             then an access error is reported.
118
119       The third condition reflects that priority is given to "permission
120       granting over access denying" for overlapping regions as this
121       approach provides more flexibility to system software in region
122       descriptor assignments.
123       */
124
125       final_error_state   = ((mrc_hit   ^ 0xffff)  // form ~mrc_hit
126                           |  mrc_error) & 0xffff;  // factor in error flags
127
128       if (final_error_state == 0xffff)
129           memory_access_error = 1;
130       else
131           memory_access_error = 0;
132    }
133    return memory_access_error;
134 }
```

15.5.6 Peripheral access controller (PAC)

The peripheral access controller performs an access control evaluation similar to that of the memory region controller (Memory region controller (MRC), but using dedicated memory region descriptors with a unique PDAC_W[0-1]_*n* register per slave peripheral slot. The presence of one region descriptor per slave peripheral address space slot in the PAC simplifies the required functionality compared to the MRC.

The functionality of the PAC evaluation is described in the C code shown below. This code begins with the description of the data structures corresponding to the PAC-associated registers (lines 1-3). It then performs a check of the global valid bit (CR[GVLD]) (lines 25-27), followed by the extraction of the peripheral slot number from the system address (line 32), and then followed by the access of the selected PDAC_W[0-1]_*n* registers (lines 33-34). Next, a check of the optional inclusion of a hardware semaphore and its current state is performed (lines 37-46). Finally, if the access is still allowed, an evaluation of the appropriate D*x*ACP permission field is done (line 48). This is detailed in DxACP evaluation and the state of the peripheral access error control signal is returned (line 52).

```
 1   // PAC registers
 2   unsigned int    xrdc_cr_gvld;
 3   unsigned int    xrdc_pdac[512][2];
 4
 5   evaluate_PAC (sysAddr, write, privileged, nonsecure, did)
 6       unsigned int    sysAddr;                  // system address
 7       unsigned int    write;                    // read/write attribute
 8       unsigned int    privileged;               // user/privileged attribute
 9       unsigned int    nonsecure;                // secure/nonsecure attribute
10       unsigned int    did;                      // domain identifier
11   {
12       unsigned int    ips_slot_number;          // f(system address)
13       unsigned int    pdacw0;                   // selected PAC_W0_n register
14       unsigned int    pdacw1;                   // selected PAC_W1_n register
15       unsigned int    pac_sema4;               // local copy of referenced sema4
16       unsigned int    peripheral_access_error;
17
```

```
18      // the evaluation of the PACn involves a 4-step process:
19      //   1) select the appropriate PDACn using the system address
20      //   2) using the DID for the access, select the appropriate DxACP field
21      //   3) evaluate the state of the (optional) SEMA4 for this access
22      //   4) using the {secure/nonsecure, user/priviledged} attributes, eval DxACP
23
24      // first, check the global XRDC valid bit
25      if (xrdc_cr_gvld == 0) {
26          peripheral_access_error = 0;
27          }
28
29      else {
30          // Extract the peripheral slot number from the system memory map.
31          // Example for a standard 4k slot assignment:
32          // sysAddr[20:12] = slot select [0-511]
33          ips_slot_number = (sysAddr & 0x001ff000) >> 12;
34          pdacw0 = xrdc_pdac[ips_slot_number][0];
35          pdacw1 = xrdc_pdac[ips_slot_number][1];
36          peripheral_access_error = 0;
37          if ((pdacw1 & 0x80000000) == 0x80000000) {         // PDACn is valid
38              // semaphore check
39              pac_sema4 = sema4[(pdacw0 & 0x3f000000) >> 24]; // local copy
40              // check if it is enabled on a write and if not idle, nor == (did+1)
41              if (((pdacw0 & 0x40000000) == 0x40000000)   &&  // se
42                   (write == 1)                           &&  // wt
43                   (pac_sema4 != 0)                        &&  // sema4 != idle
44                   (pac_sema4 != (did+1)))                {     // sema4 != did
45                  peripheral_access_error = 1;
46              } else {
47                  // perform the standard DxACP check
48                  peripheral_access_error = evaluate_DxACP(pdacw0, pdacw1, did,
\                                                  nonsecure, privileged, write);
49              }
50          }
51      }
52      return peripheral_access_error;
53  }
```

15.6 Initialization information

Out of reset, the value of CR[GVLD] is 0 and XRDC is disabled, allowing secure privileged startup code to configure the entire programming model. The initialization process typically is performed in three steps:

1. You read the various hardware configuration registers (HWCFG{0-3}, MDACFG*n*, and MRCFG*n*) to obtain the implemented hardware capabilities for the chip.
2. Using the information retrieved in step 1 coupled with the desired domain architecture, you program all the register data structures for domain assignment (MDA_W*m_n*), memory region descriptors (MRGD_W*m_n*), and peripheral access control registers (PDAC_W*m_n*). There are individual valid bits included in all these registers that are typically asserted. Additionally, there are lock mechanisms available if register settings need to be configured and marked as read-only.
3. After the XRDC programming model is loaded, the CR is written with GVLD asserted. At that point, the XRDC is fully operational.

In this context, XRDC being fully operational means the MDAC modules are generating the DIDs and the slave memory and peripheral responders (MRC, PAC) are checking the access rights. Because of the distributed design hierarchy and the pipelined nature of the hardware system bus fabric, it can take multiple cycles for a generated DID to propagate through the entire design. Any previous DID is based on the master's default DID, and depending on the programmed access policies, could generate an access error response.

If incorrect error responses are being generated, the following approaches can be used to minimize or eliminate these extraneous access errors:

- Minimize the amount of system bus traffic when the value of CR[GVLD] is 1.
- Guarantee that all addresses being accessed provide sufficient access rights for the default DID(s) as well as the newly programmed DID(s). After XRDC is fully operational, as confirmed by a read of HWCFG1, the permissions for the default DID(s) can be removed.
- Try to have the bus master that is programming and configuring the XRDC registers use the same DID, that is, its default DID, for both initialization and configuration as well as normal system operation. You do this when you define the DID assignments for the system.

15.7 Application information

As described in Introduction, the XRDC architecture is intended to provide a broad, highly capable framework for access control, system memory protection, and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, and is highly configurable via hardware design parameters and software programmability. This considerable number of hardware design parameters allows the XRDC architecture to be a very scalable solution, capable of servicing a wide spectrum of chips from ultra-low end MCUs to multi-core, high-performance embedded microprocessors.

15.7.1 Master domain assignments

The typical use case related to master domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus master devices such as DMA. The definition of a domain may be static, based on the combination of a processor and other optional bus masters. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains. The maximum number of possible CPU domain definitions is limited by the MDACFG*n* value. In particular, the optional inclusion of PID value(s) can be used to create multiple classes of CPU with different domain values.

For example, critical tasks, whether safety-critical, performance-critical, and so on, can be grouped together in one domain and all other tasks into the second domain. Non-processor bus masters typically have a single MDA_W*m_n* configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can inherit attributes from a processor programming it (from certain modules such as DMAs).

The MDA_W*m_n* registers, along with the memory region descriptors and the peripheral domain access control registers, have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

15.7.2 Cache coherency interconnect (CCI)

For multi-core clusters built with Cortex-A cores, the cluster and optional cache coherency interconnect (CCI) logic tags each system bus transaction with a read identifier (RID) or write identifier (WID), depending on the transaction type. The precise identification of the source processor core is complicated by the fact that there is a shared write buffer and transactions can be generated by the snoop control unit in the cluster. These complicating factors remove the ability to precisely associate certain write operations with a specific processor. For this chip, precise source identification of the system bus transaction is therefore limited to the cluster number, an SCU transaction.

Accordingly, there is logic associated with the Master Domain Assignment function that uses the read and write identifiers to dynamically select a domainID using the PID and PID mask functions in the MDA_W*m_n* registers.

For this chip, the {R,W}ID outputs from the core are remapped into a 2-bit encoded ID that is subsequently input to the XRDC MDAC modules to support generation of the domainID.

The following steps detail the hardware operation of using the core {R,W}IDs and the required software configuration to dynamically generate the domainID in the XRDC MDAC logic for the two dual-core Cortex-A53 clusters, cluster0 and cluster1:

1. The hardware remaps the core read and write IDs to the following 2-bit encoded values:

remapped_{r,w}id[1:0]	Description
00b	Signals a cluster0 access
01b	Signals a cluster1 access
10b	Signals an SCU or ACP access

2. The MDAC instances of the core clusters are configured to enable a PID input value, and the remapped 2-bit read and write IDs are connected to the PID_IN[3:0] input signal as follows:

```
PID_IN[3:0] = {remapped_wid[1:0], remapped_rid[1:0]}
```

That is, PID_IN[3:2] represents the remapped write ID and PID_IN[1:0] is the remapped read ID. In addition, PID_IN[4] is used to signal a read (PID_IN[4] = 0) or a write (PID_IN[4] = 1).

Each MDA_W*m_n* register associated with this system bus master port then calculates, on a cycle-by-cycle basis, a dynamic 6-bit PID (PID_dyn) value defined as follows:

```
PID_dyn[5:0] = {PID_REG[5], write, remapped_wid[1:0], remapped_rid[1:0]}
```

Here, PID_REG[5] is the register bit from the associated PID*n* register, and the low-order 5 bits are the concatenation of the write indicator and the remapped write and read identifiers, which are read-only-zero.

3. The dynamic PID_dyn[5:0] value is compared against the MDA_W*m_n*[PIDMDIDB] field, which provides a static PID and PID mask for the comparison. If the combined dynamic PID input matches the MDA_W*m_n*[PIDMDIDB] field, there is a register "hit" and the domainID is generated based on the remaining fields in the MDA_W*m_n* register.
4. From a software configuration perspective, six MDA_W*m_n* registers can be used to generate the required domain IDs: three registers define the domain IDs for reads and three for the ccwrite domain ID. As specific examples, consider the following hex values for these six MDA_W*m_n* registers:

Hex value	Description
MDA_W0_*n* = c000_2c8wh	Domain *w* for cluster0 reads (valid, locked)
MDA_W1_*n* = c001_2c8yh	Domain *y* for cluster1 reads (valid, locked)
MDA_W2_*n* = c002_2c8zh	Domain *z* for SCU reads (valid, locked)
MDA_W3_*n* = c010_238wh	Domain *w* for cluster0 writes (valid, locked)
MDA_W4_*n* = c014_238yh	Domain *y* for cluster1 writes (valid, locked)
MDA_W5_*n* = c018_278zh	Domain *z* for SCU writes (valid, locked)

In this case, the three domainIDs (*w*,*y*,*z*) are arbitrary within the supported [0-7] set.

The above MDA_W*m_n* register definitions can be further refined to utilize the DIDSPA = 2 (DFMT = 0) setting to include the processor number (where possible) as the low-order 2 bits of the domain ID. The lower-order two bits of the input DID to the MDAC instance are configured to generate the value "2" to indicate cp0, and the value "3" to indicate cp1. Then the following domain IDs are generated:

DID[3:0]	Description
2	cluster0, cp0
3	cluster0, cp1
6	cluster1, cp0
7	cluster1, cp1
5	SCU transactions

In this case, domains {*w*, *y*, *z*} = {2, 6, 5}. These values are selected as they align with the default DIDs.

The corresponding MDA_W*m*_*n* register values are specified in the following table:

MDA_W0_*n* = c000_2ca0h	Domains 2/3 for cluster0 {cp0, cp1} read
MDA_W1_*n* = c001_2ca4h	Domains 6/7 for cluster1 {cp0, cp1} read
MDA_W2_*n* = c002_2d85h	Domain 5 for SCU read
MDA_W3_*n* = c010_23a0h	Domains 2/3 for cluster0 cp*x* write
MDA_W4_*n* = c014_23a4h	Domains 6/7 for cluster1 cp*x* write
MDA_W5_*n* = c018_2785h	Domain 5 for SCU write

Finally, it should be noted that the cluster specifically identifies cp0 or cp1 on certain classes of transactions: writes to non-reorderable device memory, store exclusives, and barrier operations have the correct processor identifier. However, the most common processor system bus writes to normal memory or reorderable device memory do not precisely identify the source processor because of the presence of write buffers within the cluster.

15.7.3 Memory region descriptor management

There are two important concepts to consider in managing the memory region descriptors.

First, the association between each MRC*n* instance and the slave memory regions it monitors is chip-specific. This chip-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the slave memories being monitored.

Second, as detailed in Memory region DxACP evaluation, after the XRDC is enabled, every memory reference must hit one or more regions, else an access violation is reported. There are two other conditions for which access errors are reported:

- If the access hits a single region descriptor and that region signals a domain violation
- If the access hits multiple (overlapping) regions and all regions signal violations

15.7.4 Domain error capture management

When either a memory region controller or a peripheral access controller detects a domain access violation, the address and attribute information of the offending access is captured. The DERRLOC*n* read-only registers provide additional information by signaling the instance number of the submodule for which the access violation(s) occurred. Because the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*n* and DERR_W1_*n*, the DERRLOC*n* registers provide the instance number details.

These registers are organized as a word array, indexed by the faulting domain number, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begins by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOC*n* array. The resulting DERRLOC*n* value is then examined to determine the instance number of the reporting MRC and/or PAC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handlers use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. After the instance number is determined, the captured error address (DERR_W0_*n*) and attribute information (DERR_W1_*n*) can easily be retrieved from the domain error registers. The 2-bit DERR_W1_*n*[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_*n* is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this two-step retrieval of the domain error address and attributes is shown in Figure 36.

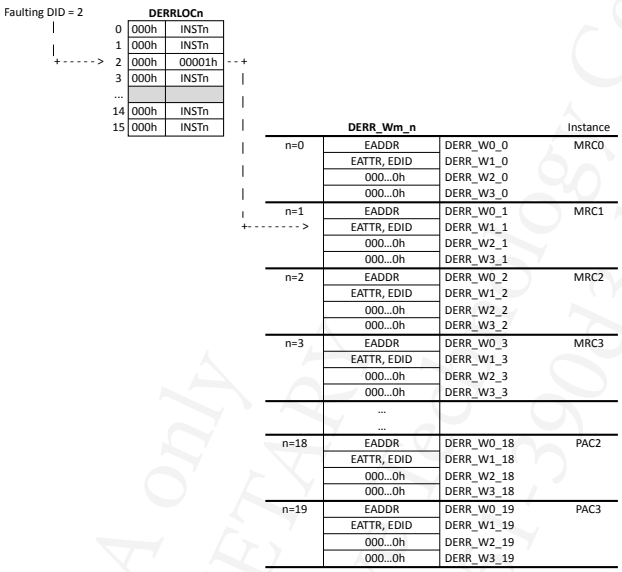

Figure 36. Two-step retrieval of domain error address and attributes

Chapter 16
System Integration Unit Lite2 (SIUL2)

16.1 Chip-specific SIUL2 information

16.1.1 SIUL2 memory map

The SIUL2 memory map is split into two regions, one for SIUL2_0 and one for SIUL2_1. The global memory map space for the SIUL2 modules is specified in the attached IOMUX spreadsheet. That spreadsheet refers to SIUL2_0 and SIUL2_1 as SIUL_CC and SIUL_OFFCC, respectively.

16.1.2 Register configuration

SIUL2_0 is mapped to MSCRs 0–101 and 512–595. SIUL2_1 is mapped to MSCRs 112–190 and 631–1023. This means, for example, that the first SIUL2_1 MSCR register is MSCR112, and that has an offset of 1C0h (112d×4) relative to the MSCR0 address of SIUL2_1. Thus the MSCR112 address is at 400h (1C0h+240h) relative to the SIUL2_1 base address. The attached IOMUX spreadsheet defines the mapping of MSCRs to port pins. This spreadsheet also shows that the MSCR[RCVR], MSCR[DSE], MSCR[SRE], MSCR[INV], MSCR[ODE], and MSCR[OBE] fields are reserved for all GPI pads.These fields on PAD_010, PAD_036, PAD_038, and PAD_043 are writable, but writing any value to those fields has no impact on pad function. MSCR[SLEEP] is reserved for all pads.

NOTE

PAD 10, 36, 38, 43, 146, 148, 150, 152, 154, 156, 158, 160, 162, 164, 166, 168, 170, 172, 174, 176, 179, 182, and 183 on this chip are implemented as GPIs. To know the exact implementation, see the IO Signal Table tab in the attached IOMUX spreadsheet.

NOTE

CR values above 511 in IOMUX spreadsheet refer to IMCR registers. The equivalent IMCR number is CR number minus 512.

16.1.3 Interrupts and DMA requests

SIUL2_0 has no interrupt or DMA requests. SIUL2_1 has a single interrupt that is an OR of all EIRQ fields. After the interrupt has been triggered, the ISR can check the interrupt status flag to find which particular EIRQ pin triggered the interrupt. SIUL2_1 also has eight DMA requests that are mapped to EIRQ[0:7]. The SIUL2_1 DIRSR0 implements only fields EIRE0–EIRE7. Bits 8:31 are reserved and do not correspond to any valid DMA request.

16.1.4 MIDR1 and MIDR2 Reset Values

The reset values for the SIUL2 MCU ID registers (MIDR) will change with the product variant. The following table contains the reset values for each product varient.

Table 60. MIDR reset values for S32G product family

Product Variant	SIUL2_CC_MIDR1	SIUL2_CC_MIDR2	SIUL2_OFF_CC_MIDR 1	SIUL2_OFF_CC_MIDR 2
S32G274A	0x1D12_000X[1]	0x48BB_0000	0x4C20_0412	0x0X12_C000[2]
S32G254A	0x1CFE_000X[1]	0x48BB_0000	0x4C20_0412	0x0XFE_C000[3]
S32G233A	0x1CE9_000X[1]	0x48BB_0000	0x4C20_0411	0x0XE9_C000[3]
S32G234M	0x1CEA_000X[1]	0x48B8_0000	0x4C20_3412	0x0XEA_C000[3]

1. X= 2-bit MAJOR_MASK bit field and 2-bit MINOR_MASK bit field which will change depending upon part revision.

2. X=4'bnn01, where n is the 2-bit SUBMINOR_MASK field which will change depending upon part revision.
3. X=4'bnn00, where n is the 2-bit SUBMINOR_MASK field which will change depending upon part revision.

NOTE

The part revision information is contained in the following bit fields:

- SIUL2_0_MIDR1[MAJOR_MASK]
- SIUL2_0_MIDR1[MINOR_MASK]
- SIUL2_1_MIDR2[SUBMINOR_MASK]

The revision information follows the order: Revision MAJOR.MINOR.SUBMINOR

16.2 Introduction

16.2.1 Overview

SIUL2 provides control over all electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. SIUL2 enables you to select the functions and electrical characteristics that appear on external chip pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration.

The block diagram shows the functional blocks of the module and its interfaces to other system components.

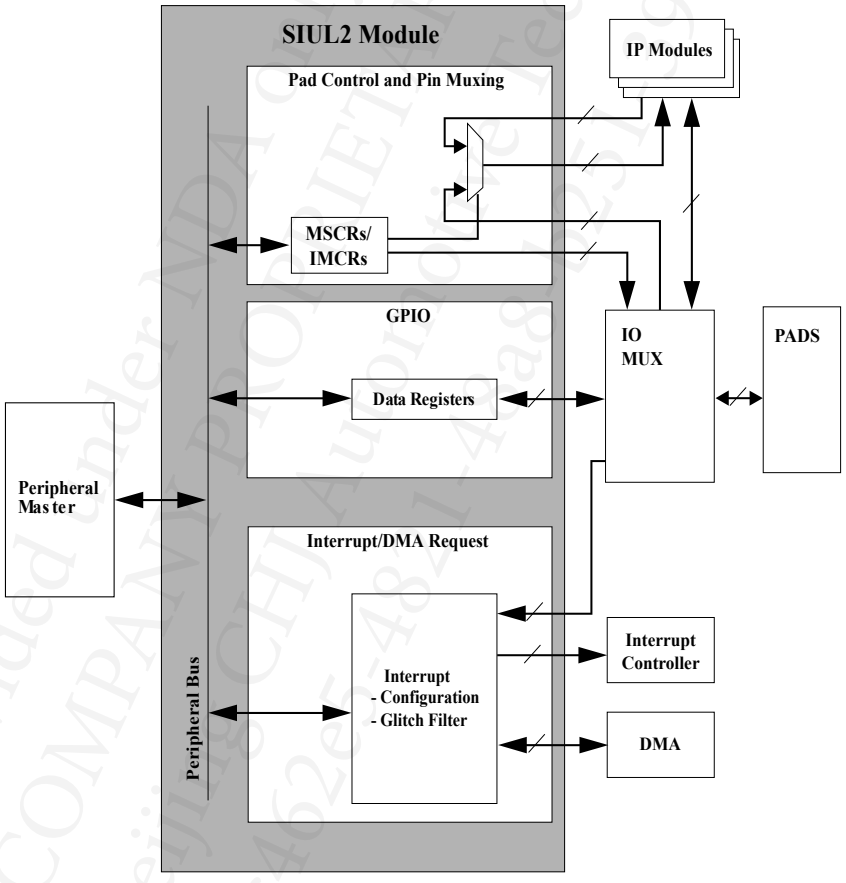

Figure 37. SIUL2 block diagram

SIUL2 provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. It provides registers for you to read values from GPIO pads configured as inputs and to write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back to check if the written value appeared on the pad.

You can access GPIO data registers in various ways to allow port access and bit manipulation without read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask using single 32-bit access

You can configure external interrupt sources at the chip level to be used with any chip pad. You can configure interrupt sources to have a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the REQ pins in the chip packages.

16.2.2 Features

SIUL2 supports:

- One to 32 GPIO ports with data control
  - Drives data to as many as 16 independent I/O channels
  - Samples data from as many as 16 independent I/O channels
- Read or write of two 16-bit registers with one access for a 32-bit port
- External interrupt/DMA requests:
  - One to 12 programmable digital glitch filters, one for each REQ pin
  - Edge detection
- Multiplexed Signal Configuration Registers (MSCR) to configure the electrical parameters and settings for as many as 512 functional pads.

See the interrupt map file and the DMAMUX map file attached to this document for mapping of interrupt and DMA sources to interrupt vectors and DMA channels.

16.3 SIUL2_0 register descriptions

This section describes the SIUL2 registers.

NOTE

- Undocumented register spaces in the SIUL2 memory map, including addresses shown as blanks, are Reserved.
  - Reserved registers or spaces are read as 0.
  - Writes to Reserved registers or spaces generate a transfer error.
- Writes to read-only registers generate a transfer error.

NOTE

- For the array of 8-bit registers GPDO*n* and GPDI*n*:
  - An 8-bit access to an unimplemented address (a "hole") within the array region will generate a transfer error.
  - However, if you do a 16-bit or a 32-bit access and if any register instance is implemented within the accessed range, a transfer error will not be generated even if the range includes a hole.
- For the array of 16-bit registers PGPDO*n* and PGPDI*n*:
  - A 16-bit access to an unimplemented address (a "hole") within the array region will generate a transfer error.
  - However, if you do a 32-bit access and if a register instance is implemented on the other 16-bit range, a transfer error will not be generated even if the range includes a hole.

16.3.2 SIUL2 MCU ID Register #1 (MIDR1)

Offset

Register	Offset
MIDR1	4h

Function

This register holds identification information about the device.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

16.3.4 SIUL2 DMA/Interrupt Status Flag Register0 (DISR0)

Offset

Register	Offset
DISR0	10h

Function

DISR0 contains flag bits that record an event on the external IRQ pins. When an event as defined in IREER0 and IFEER0 occurs, the corresponding flag bit is set. The IRQ flag bit is set regardless of the state of the corresponding DIRER0[EIRE*n*] bit. The IRQ flag bit remains set until you clear it or is cleared by servicing of a DMA request. The IRQ flag bits are cleared by writing a 1 to the bits. A write of 0 has no effect.

This register supports 8-, 16-, and 32-bit accesses.

2 EIF2	External Interrupt Status Flag 2 If enabled (DIRERR2 = 1) causes an interrupt. This flag can be cleared only by writing 1. Writing 0 has no effect. 0b - No interrupt event has occurred on the pad. 1b - An interrupt event as defined by IREER2 and IFEER2 has occurred.
1 EIF1	External Interrupt Status Flag 1 If enabled (DIRERR1 = 1) causes an interrupt. This flag can be cleared only by writing 1. Writing 0 has no effect. 0b - No interrupt event has occurred on the pad. 1b - An interrupt event as defined by IREER1 and IFEER1 has occurred.
0 EIF0	External Interrupt Status Flag 0 If enabled (DIRERR0 = 1) causes an interrupt. This flag can be cleared only by writing 1. Writing 0 has no effect. 0b - No interrupt event has occurred on the pad. 1b - An interrupt event as defined by IREER0 and IFEER0 has occurred.

16.3.5 SIUL2 DMA/Interrupt Request Enable Register0 (DIRER0)

Offset

Register	Offset
DIRER0	18h

Function

DIRER0 enables the assertion of DMA or interrupt request to the interrupt controller if the corresponding DISR0[EIF*n*] bit is set. The type of request is determined by the corresponding DIRSR0[DIRSR*n*] bit.

This register supports 8-, 16-, and 32-bit accesses.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
ca462e5-4821-42a8-b251-3901ab624c1

NOTE

DMA requests cannot be enabled or disabled.

16.3.6 SIUL2 DMA/Interrupt Request Select Register0 (DIRSR0)

Offset

Register	Offset
DIRSR0	20h

Function

DIRSR0 selects between the DMA or interrupt request. The DIRSR0[DIRSR*n*] bit determines whether DMA or an interrupt request asserts the corresponding DISR0[EIF*n*] bit.

This register supports 8-, 16-, and 32-bit accesses.

16.3.7 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (IREER0)

Offset

Register	Offset
IREER0	28h

Function

IREER0 enables the rising-edge triggered events on the corresponding interrupt pads.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

If both the IREE and IFEE bits are cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

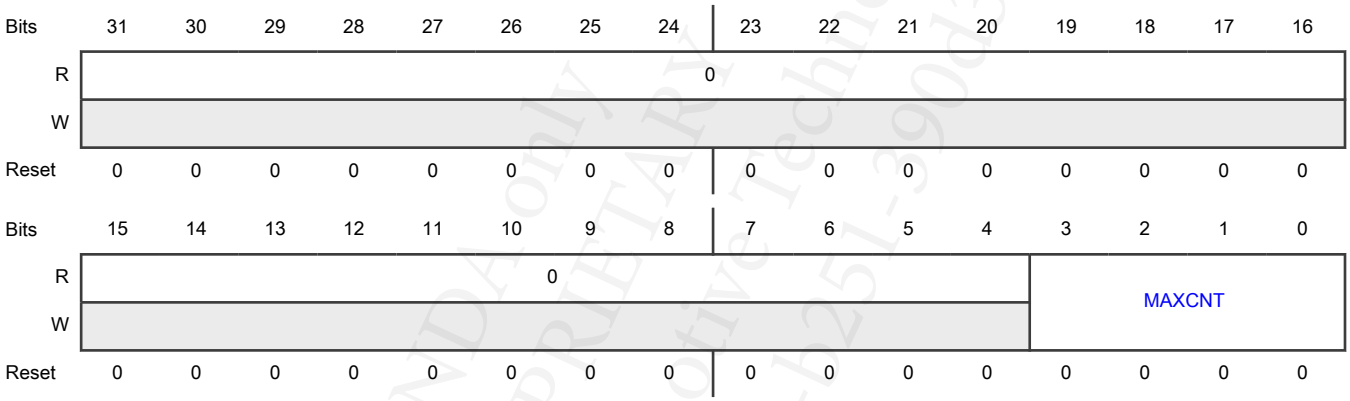
16.3.10 SIUL2 Interrupt Filter Maximum Counter Register (IFMCR0 - IFMCR11)

Offset

For a = 0 to 11:

Register	Offset
IFMCRa	40h + (a × 4h)



Function

IFMCR*n* registers configure the filter counter associated with each digital glitch filter.

NOTE

These registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Diagram

Fields

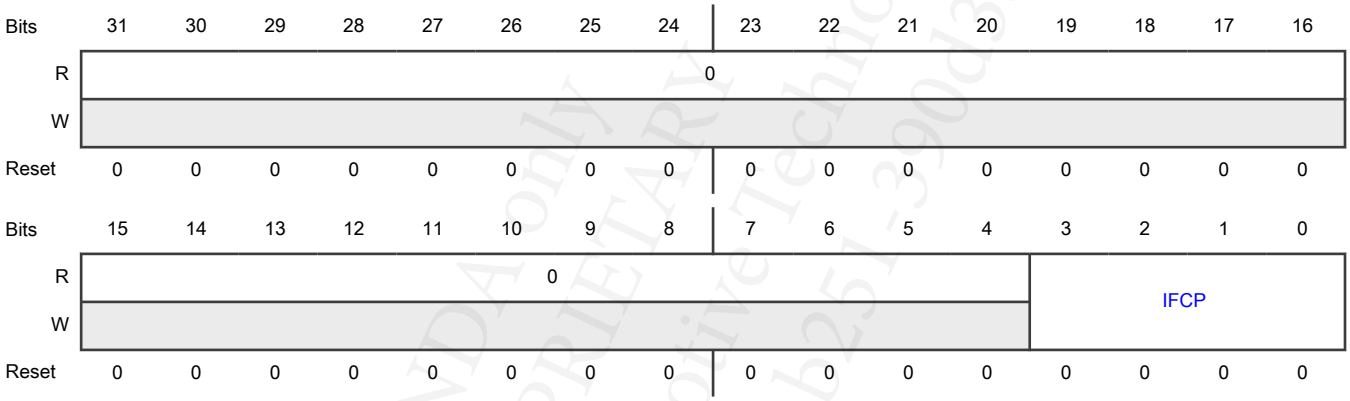
Field	Function
31-4 —	Reserved
3-0 MAXCNT	Maximum Interrupt Filter Counter setting MAXCNT can be 0d to 15d. • A value of 0d, 1d, or 2d sets the filter as an all pass filter. • A value of 3d to 15d sets the filter period to TCK × MAXCNT + *n* × TCK, where: — *n* is 0, 1, 2, 3, or 4. — TCK is the prescaled filter clock period, which is the IRC clock prescaled to the IFCP value specified in IFCPR.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4e2e5-4821-48a8-b251-290d3ab624c1

16.3.11 SIUL2 Interrupt Filter Clock Prescaler Register (IFCPR)

Offset

Register	Offset
IFCPR	C0h



Function

IFCPR configures the clock prescaler which selects the clock for all digital filters. A prescaler is applied to the input clock to SIUL2, which is the peripheral clock counter in the SIUL2.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

Diagram

Fields

Field	Function
31-4 —	Reserved
3-0 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock period is T_{IRC} × (IFCP + 1), where: • T_{IRC} is the internal oscillator period. • IFCP is 0 to 15.

16.3.12 SIUL2 Multiplexed Signal Configuration Register (MSCR0 - MSCR101)

Offset

For a = 0 to 101:

Register	Offset
MSCRa	240h + (a × 4h)

Function

MSCR*n* registers select the source signal connected to the register's associated destination, which is a chip output pin or a chip pin that can be configured as an output.

MSCR*n* also specifies the electrical properties of the associated pin.

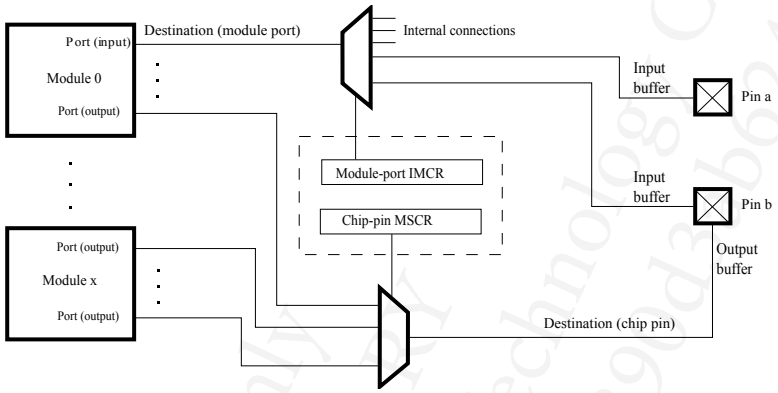


Figure 38. MSCR and IMCR port and pin connection

For chip-pin MSCR assignments and pin types, see the IOMUX file attached to this document.

NOTE

- MSCR*n* registers support only 32-bit accesses. Byte and half-word write accesses are not supported.
- MSCR*n* registers must be configured only during application initialization and must not be modified during application runtime.
- Accessing a reserved MSCR*n* register generates a transfer error.

Function

IMCR*n* registers select the source signal connected to the register's associated destination, which is an internal module port that is an input port or can be configured as an input.

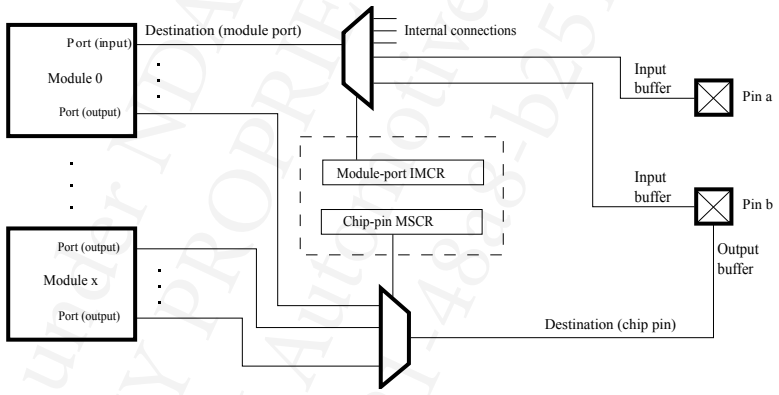

Figure 39. MSCR and IMCR port and pin connection

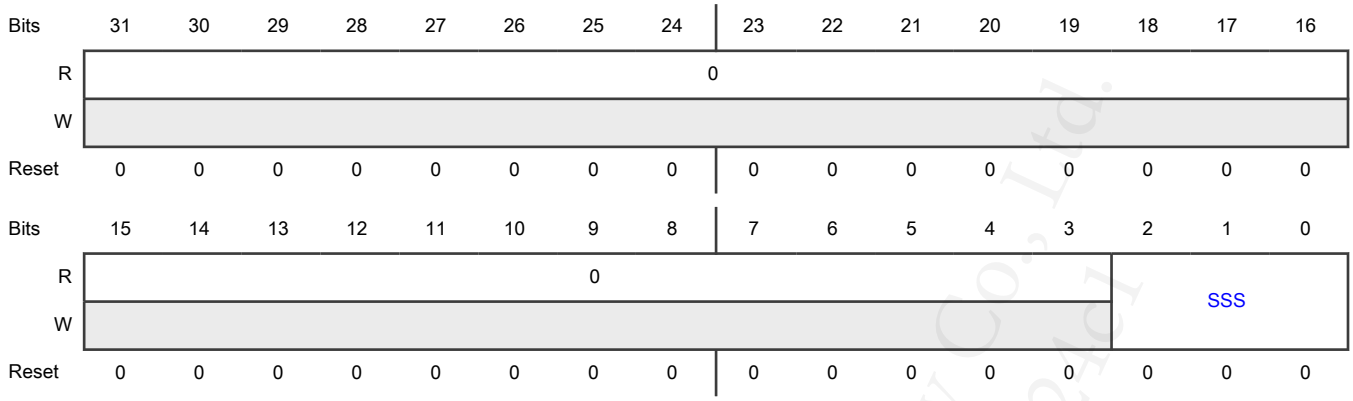

For IMCR assignments and field values, see the IOMUX file attached to this document.

NOTE

- IMCR*n* registers support only 32-bit accesses. Byte and half-word write accesses are not supported.
- IMCR*n* registers must be configured only during application initialization and must not be modified during application runtime.
- Accessing a reserved IMCR*n* register generates a transfer error.

c8c462e5-4821-48a8-b251-390d3ab624c1

Function

Each PGPDO*n* register sets or clears the respective pads of the chip.

PGPDO*n* registers can set the values of all output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* registers set the value on a specific pin with byte writes.

Each bit writes or reads the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPDO*n*.

For a given PGPDO*x*[PPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

PGPDO*n* registers access the same physical resource as the PDO and MPGPDO address locations.

These registers support 8-, 16-, and 32-bit accesses.

NOTE

MPGPDO*n* registers must only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error. Read access will return 0.

NOTE

MPGPDO*n* registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Accesses to each MPGPDO*n* register location is coherent with access to the bit-wise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

16.3.21 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO6)

Offset

Register	Offset
MPGPDO6	1798h

Function

Each MPGPDO*n* register selectively modifies the pad values associated with PGPDO*n*.

NOTE

MPGPDO*n* registers must only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error. Read access will return 0.

NOTE

MPGPDO*n* registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Accesses to each MPGPDO*n* register location is coherent with access to the bit-wise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

16.4 SIUL2_1 register descriptions

This section describes the SIUL2 registers.

NOTE

- Undocumented register spaces in the SIUL2 memory map, including addresses shown as blanks, are Reserved.
  - Reserved registers or spaces are read as 0.
  - Writes to Reserved registers or spaces generate a transfer error.
- Writes to read-only registers generate a transfer error.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

NOTE

- For the array of 8-bit registers GPDO*n* and GPDI*n*:
  - An 8-bit access to an unimplemented address (a "hole") within the array region will generate a transfer error.
  - However, if you do a 16-bit or a 32-bit access and if any register instance is implemented within the accessed range, a transfer error will not be generated even if the range includes a hole.
- For the array of 16-bit registers PGPDO*n* and PGPDI*n*:
  - A 16-bit access to an unimplemented address (a "hole") within the array region will generate a transfer error.
  - However, if you do a 32-bit access and if a register instance is implemented on the other 16-bit range, a transfer error will not be generated even if the range includes a hole.

16.4.4 SIUL2 DMA/Interrupt Status Flag Register0 (DISR0)

Offset

Register	Offset
DISR0	10h

Function

DISR0 contains flag bits that record an event on the external IRQ pins. When an event as defined in IREER0 and IFEER0 occurs, the corresponding flag bit is set. The IRQ flag bit is set regardless of the state of the corresponding DIRER0[EIRE*n*] bit. The IRQ flag bit remains set until you clear it or is cleared by servicing of a DMA request. The IRQ flag bits are cleared by writing a 1 to the bits. A write of 0 has no effect.

This register supports 8-, 16-, and 32-bit accesses.

Field	Function
EIF2	This flag can be cleared only by writing 1. Writing 0 has no effect. 0b - No interrupt event has occurred on the pad. 1b - An interrupt event as defined by IREER2 and IFEER2 has occurred.
1 EIF1	External Interrupt Status Flag 1 If enabled (DIRERR1 = 1) causes an interrupt or DMA request. This flag can be cleared only by writing 1. Writing 0 has no effect. 0b - No interrupt event has occurred on the pad. 1b - An interrupt event as defined by IREER1 and IFEER1 has occurred.
0 EIF0	External Interrupt Status Flag 0 If enabled (DIRERR0 = 1) causes an interrupt or DMA request. This flag can be cleared only by writing 1. Writing 0 has no effect. 0b - No interrupt event has occurred on the pad. 1b - An interrupt event as defined by IREER0 and IFEER0 has occurred.

16.4.5 SIUL2 DMA/Interrupt Request Enable Register0 (DIRER0)

Offset

Register	Offset
DIRER0	18h

Function

DIRER0 enables the assertion of DMA or interrupt request to the interrupt controller if the corresponding DISR0[EIF*n*] bit is set. The type of request is determined by the corresponding DIRSR0[DIRSR*n*] bit.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

DMA requests cannot be enabled or disabled.

16.4.6 SIUL2 DMA/Interrupt Request Select Register0 (DIRSR0)

Offset

Register	Offset
DIRSR0	20h

Function

DIRSR0 selects between the DMA or interrupt request. The DIRSR0[DIRSR*n*] bit determines whether DMA or an interrupt request asserts the corresponding DISR0[EIF*n*] bit.

This register supports 8-, 16-, and 32-bit accesses.

16.4.7 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (IREER0)

Offset

Register	Offset
IREER0	28h

Function

IREER0 enables the rising-edge triggered events on the corresponding interrupt pads.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

If both the IREE and IFEE bits are cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

16.4.9 SIUL2 Interrupt Filter Enable Register 0 (IFER0)

Offset

Register	Offset
IFER0	38h

Function

IFER0 enables a digital filter counter on the corresponding interrupt pads to filter out glitches on the inputs.

This register supports 8-, 16-, and 32-bit accesses.

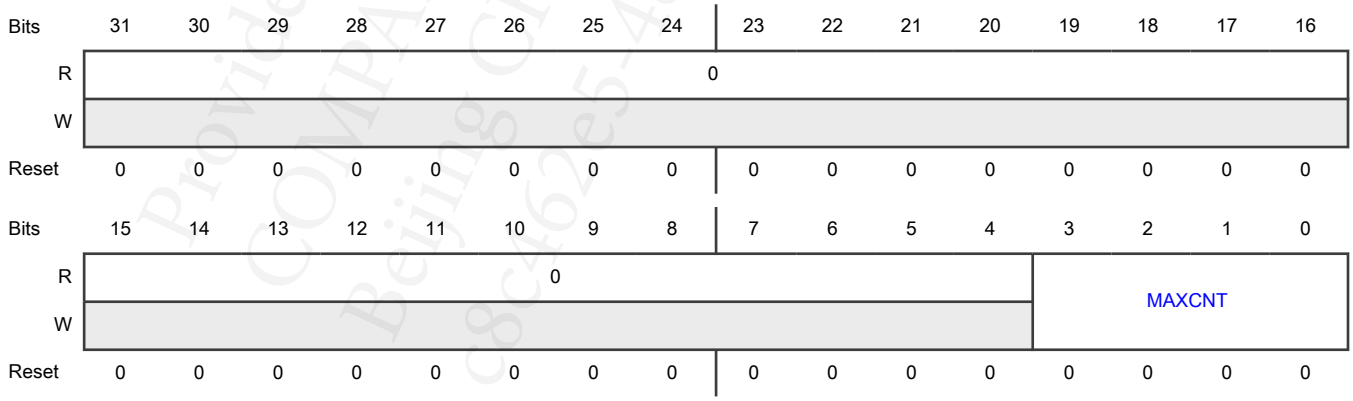
16.4.10 SIUL2 Interrupt Filter Maximum Counter Register (IFMCR0 - IFMCR31)

Offset

For a = 0 to 31:

Register	Offset
IFMCRa	40h + (a × 4h)



Function

IFMCR*n* registers configure the filter counter associated with each digital glitch filter.

NOTE

These registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
08c462e5-4821-4a8-b251-300d3ab624c1

Fields

Field	Function
31-4 —	Reserved
3-0 MAXCNT	Maximum Interrupt Filter Counter setting MAXCNT can be 0d to 15d. • A value of 0d, 1d, or 2d sets the filter as an all pass filter. • A value of 3d to 15d sets the filter period to TCK × MAXCNT + *n* × TCK, where: — *n* is 0, 1, 2, 3, or 4. — TCK is the prescaled filter clock period, which is the IRC clock prescaled to the IFCP value specified in IFCPR.

16.4.11 SIUL2 Interrupt Filter Clock Prescaler Register (IFCPR)

Offset

Register	Offset
IFCPR	C0h

Function

IFCPR configures the clock prescaler which selects the clock for all digital filters. A prescaler is applied to the input clock to SIUL2, which is the peripheral clock counter in the SIUL2.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

Function

MSCR*n* registers select the source signal connected to the register's associated destination, which is a chip output pin or a chip pin that can be configured as an output.

MSCR*n* also specifies the electrical properties of the associated pin.

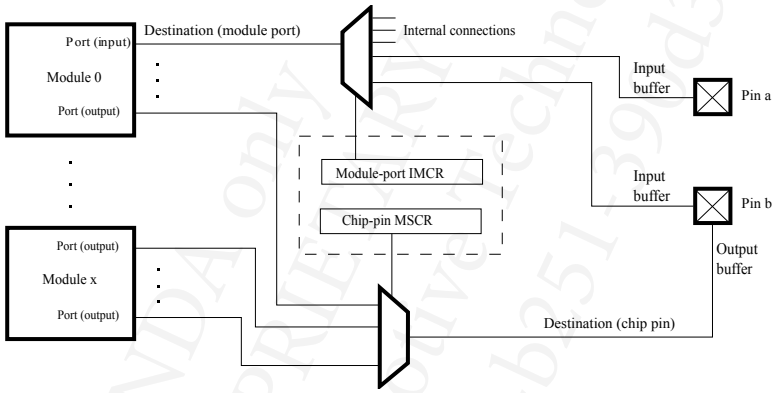

Figure 40. MSCR and IMCR port and pin connection

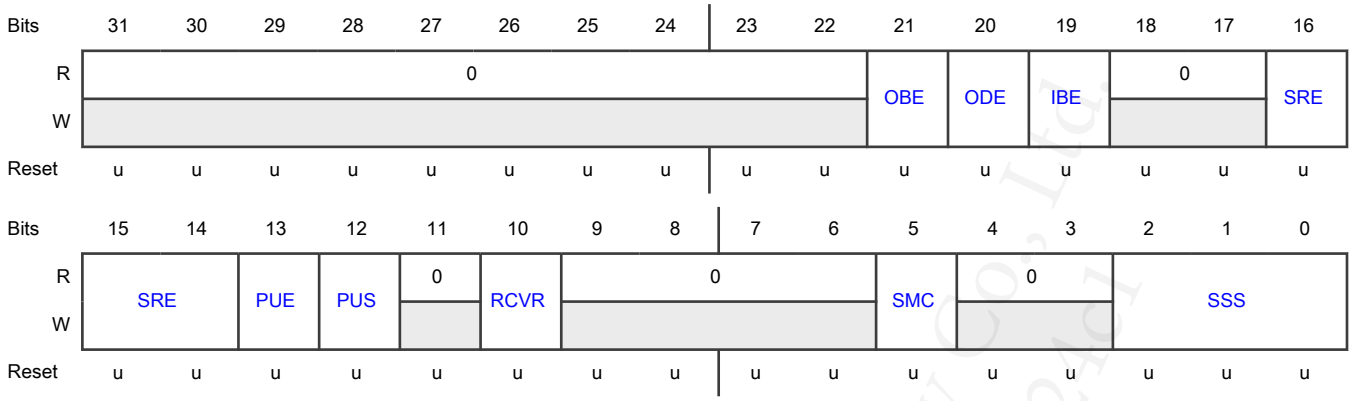

For chip-pin MSCR assignments and pin types, see the IOMUX file attached to this document.

NOTE

- MSCR*n* registers support only 32-bit accesses. Byte and half-word write accesses are not supported.
- MSCR*n* registers must be configured only during application initialization and must not be modified during application runtime.
- Accessing a reserved MSCR*n* register generates a transfer error.

16.4.16 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO7)

Offset

Register	Offset
PGPDO7	170Ch

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHY Automotive Technology Co., Ltd.
c8c46265-482-48a8-b251-590d3ab624c1

Function

Each PGPDO*n* register sets or clears the respective pads of the chip.

PGPDO*n* registers can set the values of all output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* registers set the value on a specific pin with byte writes.

Each bit writes or reads the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPDO*n*.

For a given PGPDO*x*[PPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

PGPDO*n* registers access the same physical resource as the PDO and MPGPDO address locations.

These registers support 8-, 16-, and 32-bit accesses.

16.4.17 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO9)

Offset

Register	Offset
PGPDO9	1710h

Function

Each PGPDO*n* register sets or clears the respective pads of the chip.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CJJ Automotive Technology Co., Ltd.
8c462e5-4821-48a8-b251-390d3ab624c1

PGPDO*n* registers can set the values of all output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* registers set the value on a specific pin with byte writes.

Each bit writes or reads the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPDO*n*.

For a given PGPDO*x*[PPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

PGPDO*n* registers access the same physical resource as the PDO and MPGPDO address locations.

These registers support 8-, 16-, and 32-bit accesses.

16.4.24 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO7)

Offset

Register	Offset
MPGPDO7	179Ch

Function

Each MPGPDO*n* register selectively modifies the pad values associated with PGPDO*n*.

NOTE

MPGPDO*n* registers must only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error. Read access will return 0.

NOTE

MPGPDO*n* registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Accesses to each MPGPDO*n* register location is coherent with access to the bit-wise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

16.4.25 SIUL2 Masked Parallel GPIO Pad Data Out Register (MPGPDO9 - MPGPDO10)

Offset

Register	Offset
MPGPDO9	17A4h
MPGPDO10	17A8h

Function

Each MPGPDO*n* register selectively modifies the pad values associated with PGPDO*n*.

NOTE

MPGPDO*n* registers must only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error. Read access will return 0.

NOTE

MPGPDO*n* registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Accesses to each MPGPDO*n* register location is coherent with access to the bit-wise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

16.5 Functional description

16.5.1 Pad Control

SIUL2 can control the electrical characteristics of as many as 512 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis.

The setting of each pad out of reset is fixed per chip but can be configured individually. This way you can select special pull settings or peripheral pad ownership.

You can configure each pad independently of all other pads on the chip or other pads grouped within a single port. Thus you can group different pad types together in ports and operate the pads individually. Grouping the various functions for each pad into a single register allows you to configure each pad with a single write to a register, which further allows you to duplicate software for similar pads with index changes.

16.5.2 General Purpose Input and Output pads (GPIO)

SIUL2 allows each pad to be configured as either of the following:

- General Purpose Input or Output pad (GPIO)
- A pad for one or more alternate functions (input or output) determined by the peripheral that uses the pad

GPIO pads can also be implemented without any alternate function.

SIUL2 can manage as many as 512 GPIO pads organized as ports that can be accessed for data reads and writes as 8-bit, 16-bit, or 32-bit.

All port accesses are identical, with each read or write performed only at a different location to access a different port width:

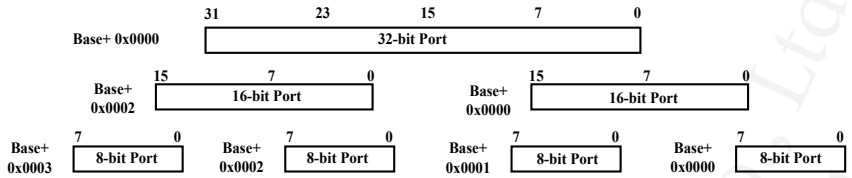

Figure 42. Data Port example arrangement showing configuration for different port width accesses

SIUL2 has separate data input and data output registers for all pads. You can thus directly read back an input or output value of a pad to validate what is actually present on the pad instead of confirming the value that was written to the data input registers.

- The data output registers support both read and write operations.
- The data input registers support read access only.

When a pad is configured to use one of its alternate functions, the data input values reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until re-configured to GPIO. All general purpose pads are implemented as bidirectional.

If bidirectional operation impacts performance or is not required for a pad function, you can limit the functionality of the pad to input only.

16.5.3 External interrupts/DMA requests (REQ Pins)

SIUL2 supports one to 32 external interrupts allocated to pads by the chip.

See the interrupt map file and the DMAMUX map file attached to this document for mapping of interrupt and DMA sources to interrupt vectors and DMA channels.

SIUL2 supports one to four interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support as many as eight external interrupt sources from the chip pads.

All the external interrupt pads within a single group have equal priority. You are responsible for searching through the group of sources in the appropriate way for the application.

NOTE

Glitch filters appplied to external interrupts require a running internal oscillator clock. If such a clock is not available, enabling the glitch filter on an external interrupt will disable the interrupt.

16.5.3.1 External interrupt initialization

Follow these steps to enable external interrupts:

NOTE

If you do not follow these steps you may get a false interrupt flag during interrupt initialization.

1. Clear the DIRER0[EIRE*n*] bits to mask interrupts.
2. Set the appropriate IREER0[IREE*n*] bits and IFEER0[IFEE*n*] bits as needed to select the pin polarity.
3. Configure the appropriate bits in the MSCR register instances for the external interrupt pin(s):
    a. Clear the OBE and ODE bits to disable output.
    b. Set the IBE bit to enable the input buffer of the pin.
    c. If you are using the internal pullup or pulldown, configure the appropriate PUE and PUS fields.

4. Write the appropriate DIRSR0[DIRS*n*] bits to select a request between DMA or interrupt.
5. Select the desired glitch filter setup for the pins:
    a. Write the appropriate value to IFMCR*n*[MAXCNT] register for the respective external interrupt to the filter counter.
    b. Write the appropriate value to IFCPR[IFCP] to set the filter clock prescaler.
    c. Set the appropriate IFER0[IFE*n*] bits to enable the glitch filter for the external interrupt pins.
6. Write to the appropriate DISR0[EIF*n*] bits to clear any flags.
7. Set the appropriate DIRER0[EIRE*n*] bits to enable the interrupt pins.

16.5.3.2 External interrupt management

You can enable or disable each interrupt independently using a single rolled up register, DIRER0.

You can configure a pad defined as an external interrupt to recognize interrupts with an active rising edge, an active falling edge, or both, using the IREER and IFEER registers.

NOTE

You must not disable both edge events of a given interrupt.

Each external interrupt has an individual flag, held in the DISR0 register. DISR0 is a clear-by-write-1 register, which prevents inadvertent overwriting of other flags in the same register.

This figure provides an overview of the external interrupt implementation:

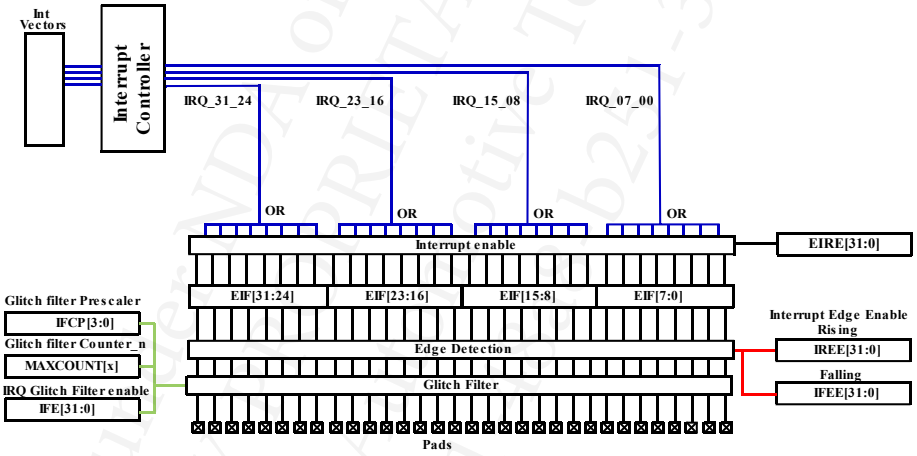

Figure 43. External interrupt pad diagram

16.5.3.3 External interrupt request

The REQ input pins on the chip are sources for interrupt or DMA requests. The chip provides four possible interrupt vectors for the SIUL2. The 32 interrupt request sources map to vectors and channels as follows:

Table 61. Interrupt source mapping to SIUL2 interrupt request output for 32 interrupt sources

Vector/Channel #	Interrupt vector source
0	REQ[07] | REQ[06] | REQ[05] | REQ[04] | REQ[03] | REQ[02] | REQ[01] | REQ[00]
1	REQ[15] | REQ[14] | REQ[13] | REQ[12] | REQ[11] | REQ[10] | REQ[09] | REQ[08]

Table continues on the next page...

Table 61. Interrupt source mapping to SIUL2 interrupt request output for 32 interrupt sources (continued)

Vector/Channel #	Interrupt vector source
2	REQ[23] | REQ[22] | REQ[21] | REQ[20] | REQ[19] | REQ[18] | REQ[17] | REQ[16]

Chapter 17
Semaphores2 (SEMA42)

17.1 Introduction

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

17.1.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: Domain X enters a section of code where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

17.1.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains. In this chapter, dm*X* represents domain *X*.
  - Gates appear as a 16-entry byte-size array with read and write accesses.
    - Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.
    - After the gate locks, the locking domain unlocks the gate by writing zeroes.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      If gate = 0h, then state = unlocked

      if gate = 1h, then state = locked by domain (master) 0

      if gate = 2h, then state = locked by domain (master) 1

      …

      if gate = Fh, then state = locked by domain (master) 14

- SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.
- After a gate locks, the locking domain must unlock the gate by writing zeroes.

— Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability

- Memory-mapped slave peripheral that offers programming-model accesses

The following figure shows a simplified SEMA42 block diagram. In the diagram, the register blocks named gate0, gate1,…, gate (n-2) and gate (n-1) include the finite state machines implementing the semaphore gates.

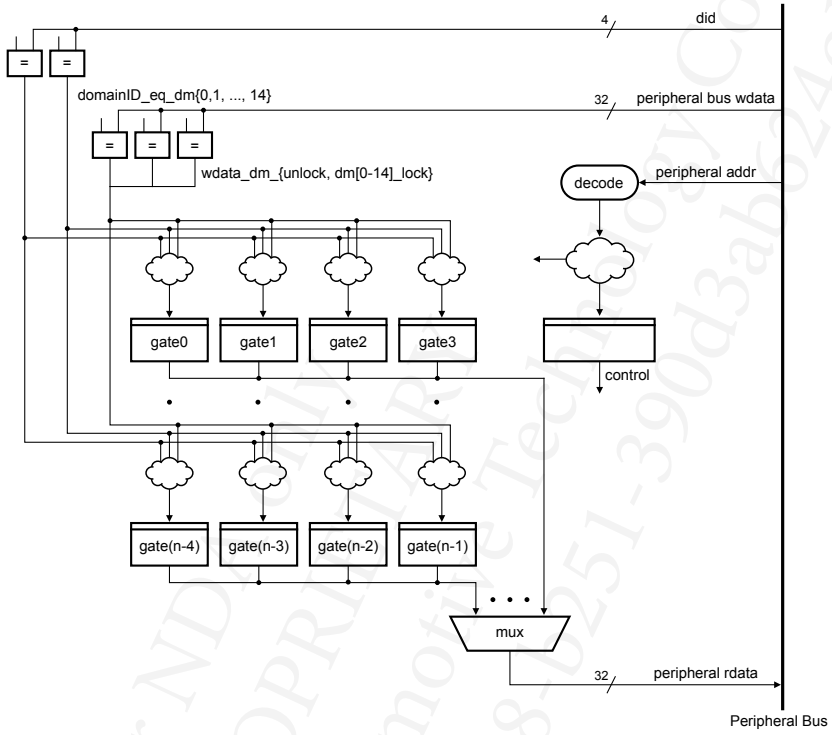

Figure 44. SEMA42 block diagram

17.2 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

17.2.1 SEMA42 register descriptions

17.2.1.1 SEMA42 memory map

SEMA42 base address: 4029_8000h

Offset	Register	Width (In bits)	Access	Reset value

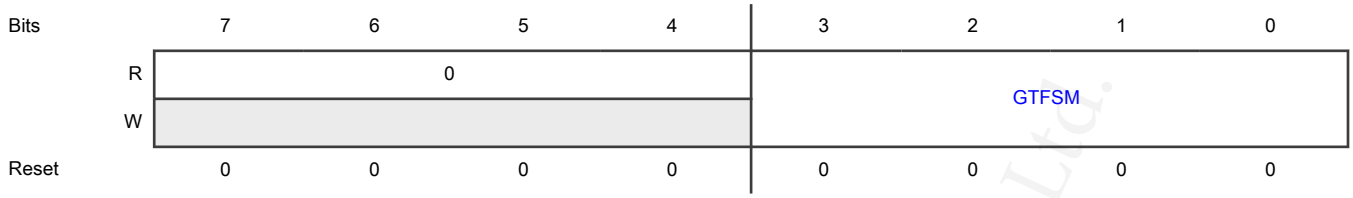
GATE11	8h
GATE10	9h
GATE9	Ah
GATE8	Bh
GATE15	Ch
GATE14	Dh
GATE13	Eh
GATE12	Fh



Function

SEMA42 implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain masters can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

17.2.1.3 Reset Gate Read (RSTGT_R)

Offset

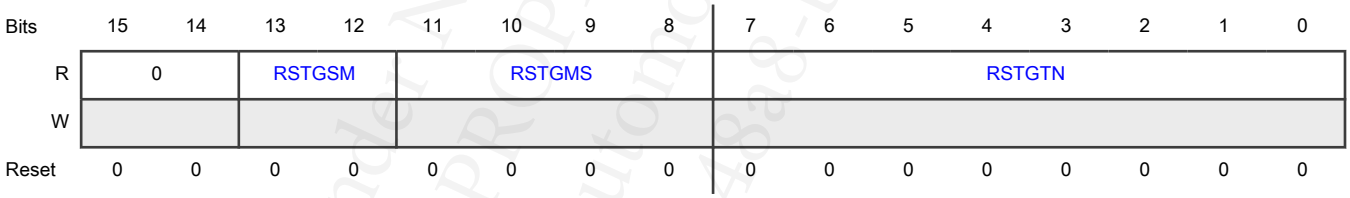
Register	Offset
RSTGT_R	42h

Provided under NDA to COMPANY PROPRIETARY Beijing CarRobotics Automotive Technology Co., Ltd. c8c462e5-4821-48a8-b251-390d3ab624c1

Function

This section and Reset Gate Write (RSTGT_W) describe the same register. This section describes the general operation of the register and also shows how the register fields appear when you read the register. Reset Gate Write (RSTGT_W) shows how the register fields appear when you write to the register.

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:



- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 aborts the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

Diagram

Fields

Field	Function
15-14 ROZ	ROZ This field always returns the value 0 when you read it.
13-12 RSTGSM	Reset gate finite state machine Reads of the RSTGT register return the encoded state machine value. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset gate domain This field records the logical number of the domain performing the gate reset function. The logical number is the domain number. This domain number is determined by the XRDC's Master Domain Assignment Controller (XRDC_MDAC). To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset gate number This field specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

17.2.1.4 Reset Gate Write (RSTGT_W)

Offset

Register	Offset
RSTGT_W	42h

Function

This section describes how the RSTGT fields appear when the register is written. See Reset Gate Read (RSTGT_R) for the description of the register's overall operation and how the register fields appear when you read the register.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W	RSTGDP								RSTGTN							
Reset [1]	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset gate data pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset gate number This field specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

17.3 Functional description

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

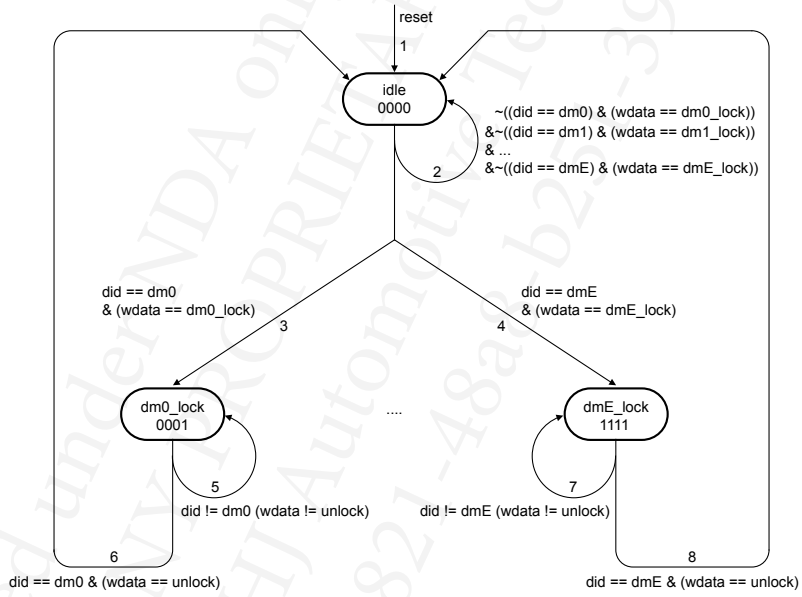


Figure 45. GATE*n* state machine

In the figure above, "did" is the domain identifier and "dm" is the domain number. The domain number identifies core domain *X* (dm*X*). Thus, for example, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 62. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

0 HSE_CM7_SLEEP_STAT	HSE Cortex-M7 Core Sleep Status Indicates the sleep state of the HSE Cortex-M7 core. 0b - Not in Sleep mode 1b - In Sleep mode

18.2.5 CMU Status 1 (CMU_STATUS_REG1)

Offset

Register	Offset
CMU_STATUS_REG1	28h

Function

Shows the status of these CMU events:

- If a monitored clock frequency is higher than high frequency reference (FHH)
- If a monitored clock frequency is lower than low frequency reference (FLL)

Reset phase: Destructive

NOTE

Immediately after the functional reset, do not read the content of the CMU_STATUS_REG1 for diagnosing the clock monitoring errors. Before entering the normal operation, you must clear the register.

1 CA53_0_DBGL1RSTDISABLE	DBGL1RSTDISABLE Driver Input Of Cortex-A53 Cluster 0 Enables or disables the automatic invalidation of L1 data cache at reset. 0b - Enable 1b - Disable
0 DEBUG_CLK_DISABLE	Disable Clocks Of Debug And Trace Components In Functional Mode Writing 1 to this field disables all the clocks related to debug and trace (except clocks related to DAP and JTAGC to save run-time power. This field takes effect only when no debug is authorized (such as external or self-hosted debug). 0b - Enable clock 1b - Disable clock

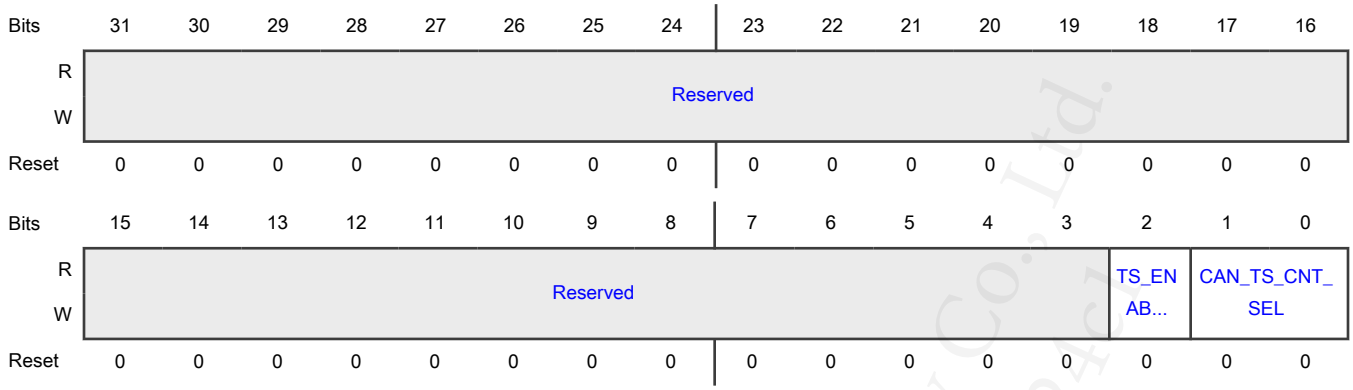
18.2.10 Timestamp Control (TIMESTAMP_CONTROL_REGISTER)

Offset

Register	Offset
TIMESTAMP_CONTROL_REGISTER	F0h

Function

Control the following operations:



- Select the Timestamp counter source
- Enable Timestamp

This register helps Timestamp to distribute and synchronize up to three counter sources from different clock domains to one common domain, for use by communication peripherals such as FlexCAN and LLCE. See the Timestamp chapter for more information on the sources.

Reset phase: Functional

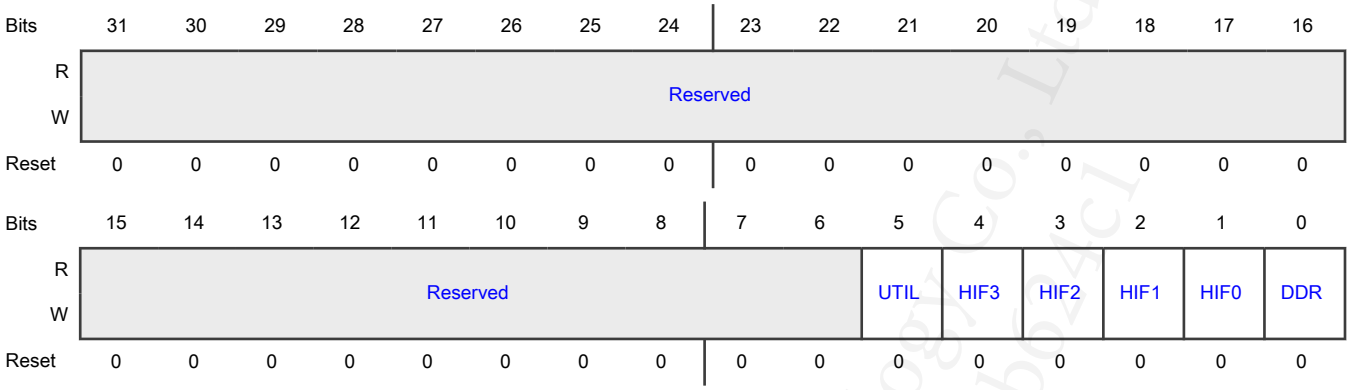
19.2.1.2 PFE Port Coherency Enable (PFE_COH_EN)



Offset

Register	Offset
PFE_COH_EN	0h

Function

Enables coherency for PFE ports. See "PPFE ports" in the S32GACCELNOCRM document.

Diagram

Fields

Field	Function
31-6 —	Reserved
5 UTIL	PFE UTIL Coherency Enable 0b - PFE UTIL interface not coherent 1b - PFE UTIL interface coherent to A53
4 HIF3	PFE HIF3 Coherency Enable 0b - PFE HIF3 interface not coherent 1b - PFE HIF3 interface coherent to A53
3 HIF2	PFE HIF2 Coherency Enable 0b - PFE HIF2 interface not coherent 1b - PFE HIF2 interface coherent to A53

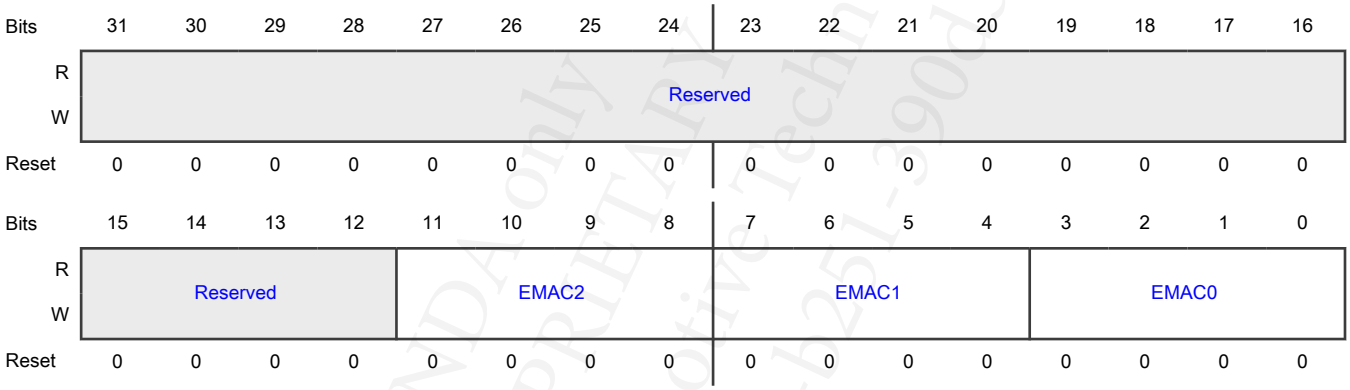
19.2.1.3 PFE EMAC Interface Mode (PFE_EMACX_INTF_SEL)

Offset

Register	Offset
PFE_EMACX_INTF_SEL	4h



Function

Selects the PFE EMAC interface mode on a per-MAC basis. PFE samples these fields at reset, and therefore must be programmed before bringing PFE out of reset.

The EMAC*n* fields select the Ethernet interface and PHY. 0000b selects the PCIE_0 PHY. The other three valid values route the Ethernet signals to the GPIOs.

Modes not listed are reserved and are not supported.

Diagram

Fields

Field	Function
31-12 —	Reserved
11-8 EMAC2	EMAC2 Interface Select 0000b - Selects GMII and PCIE_0 PHY 0001b - Selects MII and external pads/PHY 0010b - Selects RGMII and external pads/PHY 1001b - Selects RMII and external pads/PHY
7-4 EMAC1	EMAC1 Interface Select 0000b - Selects GMII and PCIE_0 PHY 0001b - Selects MII and external pads/PHY

Table continues on the next page...

Table continued from the previous page...

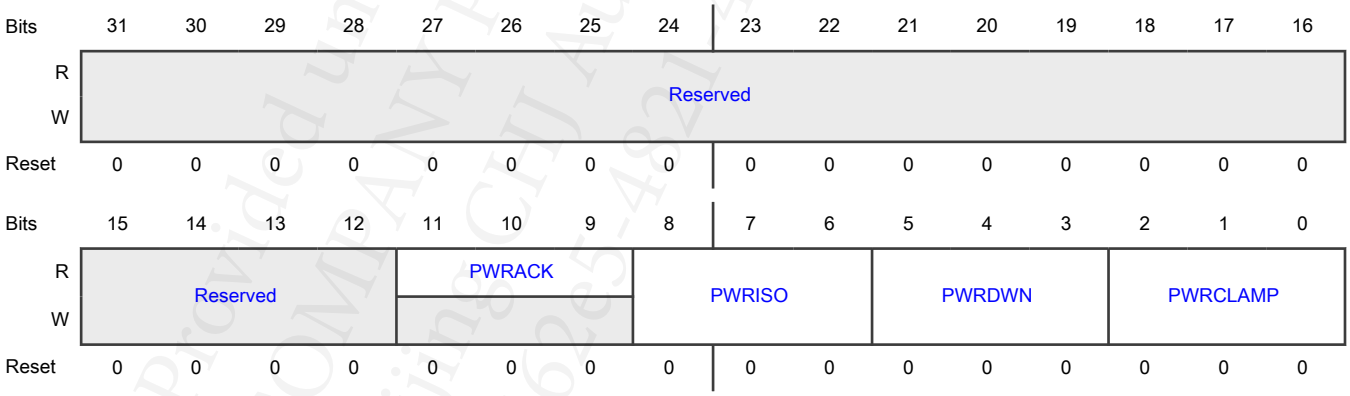
19.2.1.4 PFE EMACX Power Control (PFE_PWR_CTRL)

Offset

Register	Offset
PFE_PWR_CTRL	20h



Function

Drives PFE signals:

- emacx_pwr_clamp[2:0]
- emacx_pwr_down_ctrl[2:0]
- emacx_pwr_isolate[2:0]

It also captures the value of the emacx_sbd_pwr_down_ack[2:0] pins.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

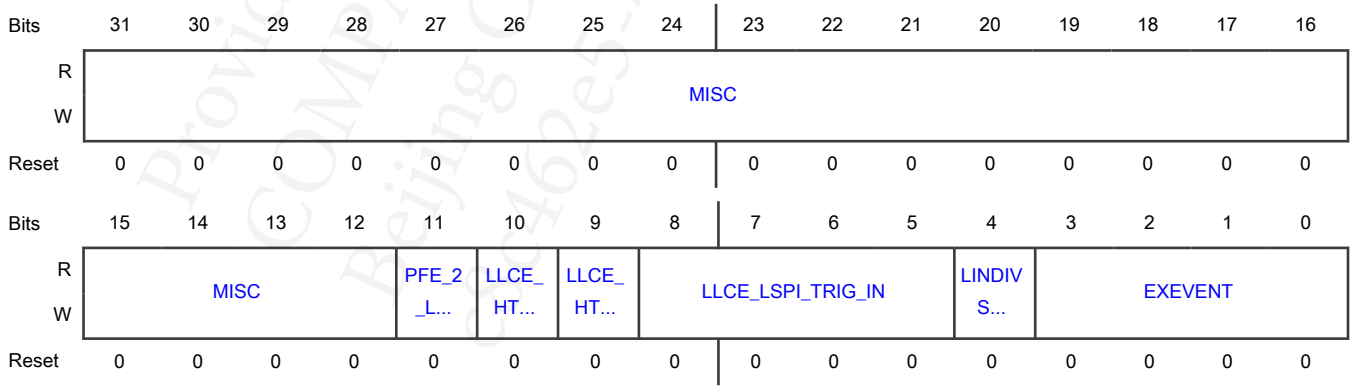
Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e6-4221-48a8-b251-390d3ab624c1

Fields

Field	Function
31-16 MISC	Reserved
15-12 LLCE_LSPI_TRIG_FM	LLCE LSPI Trigger Frame Status of the llce_lspi_trig_frame[3:0] output bus.
11-8 LLCE_LSPI_TRIG_RX	LLCE LSPI Trigger Receive Status of the llce_lspi_trig_receive[3:0] output bus.
7-4 SYSRESETREQ	System Reset Request Status of the LLCE M0+ core's SYS_RESET_REQ status. Each bit in this field represents the status of one of the LLCE cores. The least significant bit corresponds to the c0 SYS_RESET_REQ output signal and the most significant bit corresponds to the c3 SYS_RESET_REQ output signal. The bit value is the corresponding output signal's value.
3-0 SLEEPING	Sleeping SLEEPING status of the LLCE M0+ cores. Each bit in this field represents the status of one of the LLCE cores. The least significant bit corresponds to the c0 SLEEPING output signal and the most significant bit corresponds to the c3 SLEEPING output signal. The bit value is the corresponding output signal's value.

19.2.1.6 LLCE Power Control (LLCE_CTRL)



Offset

Register	Offset
LLCE_CTRL	44h

Function

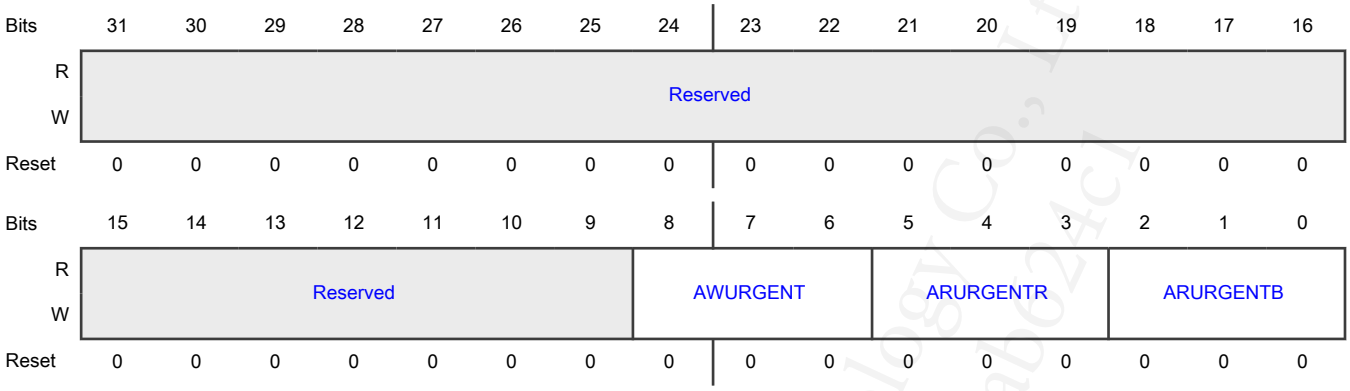
Controls the LLCE subsystem and its M0+ cores.

Diagram

Fields

Field	Function
31-12 MISC	Reserved
11 PFE_2_LLCE_INT_HS_BP	PFE 2 LLCE Interrupt Bypass Controls the PFE-to-LLCE interrupt bypass enable. If this field equals 1, PFE does not clear the interrupt immediately. Instead, it reads the buffer descriptor status (for example, in LLCE RAM) prior to clearing interrupt. Interrupt-stretching logic is bypassed, but synchronization is still required. If this field equals 0, PFE clears its own LLCE interrupt. Logic holds the interrupt long enough for LLCE to latch it in NVIC. 0b - Interrupt bypass disabled 1b - Interrupt bypass enabled
10 LLCE_HTM1_TRC_DIS	LLCE HTM1 Trace Disable Drives the LLCE HTM1 tracedisable input. This functionality can be used by software and not with the debugger attached as the debugger might overwrite this bit.
9 LLCE_HTM0_TRC_DIS	LLCE HTM0 Trace Disable Drives the LLCE HTM0 tracedisable input. This functionality can be used by software and not with the debugger attached as the debugger might overwrite this bit.
8-5 LLCE_LSPI_TRIG_IN	LLCE LSPI Trigger Drives the llce_lspi_trg_input[3:0] bus.
4 LINDIVSEL	LINFlexD Divide Select Selects which clock drives the LLCE ipg_clk_lin_pe_div2 clock. 0b - LIN_CLK (a divided-by-2 version of LIN_BAUD_CLK) drives ipg_clk_lin_pe_div2 1b - LIN_BAUD_CLK drives the ipg_clk_lin_pe_div2xE2 pin
3-0 EXEVENT	External Event Controls the external event inputs of the LLCE M0+ cores. Each bit in this field corresponds to the external event input for a particular core and can be programmed to wake up a core from WFE. The least significant bit corresponds to the c0 EXEV input signal. Bits 1, 2, and 3 correspond to c1, c2, and c3 EXEV input signals, respectively. The value written to this field is written to the input signals.

19.2.1.7 DDR Urgent Control (DDR_URGENT_CTRL)



Offset

Register	Offset
DDR_URGENT_CTRL	48h

Function

Controls the values of the arurgent and awurgent inputs of the DDR controller. See the "DDR Subsystem Reference Manual" for more information.

Diagram

Fields

Field	Function
31-9 —	Reserved
8-6 AWURGENT	awurgent Control Drives the following: • Bit 0 - ddr_awurgent_0 • Bit 1 - ddr_awurgent_1 • Bit 2 - ddr_awurgent_2
5-3 ARURGENTR	arurgentr Control Drives the following: • Bit 0 - ddr_arurgentr_0 • Bit 1 - ddr_arurgentr_1 • Bit 2 - ddr_arurgentr_2
2-0 ARURGENTB	arurentb Control Drives the following: • Bit 0 - ddr_arurgentb_0 • Bit 1 - ddr_arurgentb_1 • Bit 2 - ddr_arurgentb_2

Chapter 21
Register Protection (REG_PROT)

21.1 Introduction

The REG_PROT module offers a mechanism to protect defined memory-mapped address locations, in a module under protection, from being written. The address locations that can be protected are module specific.

The module is located between the module under protection and the platform peripheral interface. This is shown in the following figure.

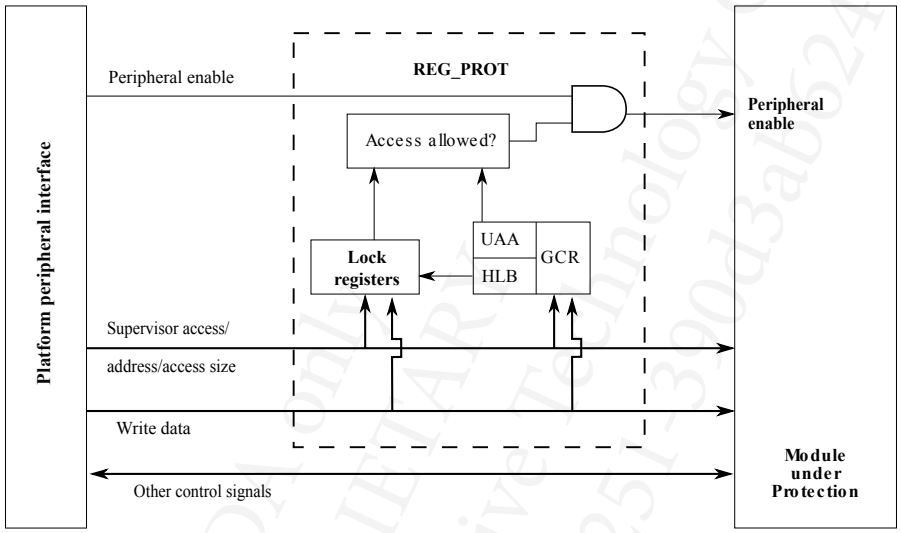

Figure 46. Block diagram

21.2 Features

REG_PROT includes these distinctive features:

- Write accesses for the module under protection are restricted to the supervisor mode only.
- Registers with 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory map and register definition.
- Write to address mirror automatically sets the corresponding lock bit.
- After the lock bits are configured, they can be protected from changes.

21.3 Modes of operation

The REG_PROT module is operable when the module under protection is operable.

21.4 External signal description

There are no external signals.

21.5 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection.

Following is the memory map for a module that is protected by the REG_PROT module.

Table 66. Module memory map

Protection size/ PROT_MEM	Area	Area size	Use	Offset
1 kB	Area 1	1 kB	Module Register MR0 — MR1023	0x0000-0x03FF

32 kB	Area 1	32 kB	Module Register MR0 — MR32767	0x0000-0x7FFF
	Area 2	32 kB	Module Register MR0 — MR32767 Set Soft Lock Bit LMR0 — LMR32767	0x8000-0xFFFF
	Area 3	8 kB	Soft Lock Bit Register SLBR0 — SLBR8191	0x10000-0x11FFF
	Area 4	**4 kB**	Global Configuration Register (GCR)	**0x12000-0x12FFC**

NOTE

Reserved registers in area #1 are handled as specified in the protected module's documentation.

NOTE

There is a single register in configuration space that corresponds to Area 4 while the size mentioned in Area size column is to turn the whole area multiple of 4 KB. See the Offset column to know the exact area for GCR registers.

- Area 1 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB, which holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB and is a mirror of Area 1. For an example, if Area 1 takes 8 KB of memory space, then read/write access to an offset 0x2000+X reads/writes the register at offset X. However, a write access to offset 0x2000+X additionally sets the optional soft lock bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in Area 1 need to have protection defined by the associated soft lock bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y are identical to accesses at offset Y.
- Area 3 can take the memory space of 256 KB/512 KB/1 KB/2 KB/4 KB/8 KB and hold soft lock bits, one bit per byte in Area 1. The four soft lock bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 4 can take the memory space of 1.75 KB/3.5 KB/3 KB/2 KB/4 KB/4 KB and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the soft lock bits and can only be cleared by a system reset after it is set. If other bits are set, they allow user access to the protected module.

If you access a locked byte with a write transaction, a transfer error is issued to the system and the write transaction is not executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Area 3 results in a transfer error. In Area 4, there will not be any transfer error for the address range mentioned in the table shown below because these address spaces of Area 4 are mapped to the GCR register. Accesses in Area 4, beyond the address range mentioned in the Module memory map, are prohibited and might or might not result into a bus abort.

21.5.1 Memory map

21.5.2 Module registers (MR)

Each functional module has its own unique set of registers. This chapter refers to these registers generically as module registers (MR), which exist in the lower module memory space, and receive protection from the REG_PROT module.

21.5.3 MR and set soft lock bit (LMR)

This is memory area #2 that provides mirrored access to module registers with the side-effect of setting soft lock bits in case of a write access to a register that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in SLBRn [SLBm], according to the mapping described in Soft Lock Bit Register (SLBRn).

21.6 REG_PROT register descriptions

This register information documents memory areas #3 and #4. To extrapolate to registers for other PROT_MEM values, see the information in Memory map and register definition.

NOTE

REG_PROT registers do not have their own base address. They occupy a portion of the memory space of each module instance that has REG_PROT protection. As a result, this information presents the REG_PROT "base address" as 0h.

21.6.1 REG_PROT memory map

REG_PROT base address: 0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Soft Lock Bit Register (SLBRn)	8	RW	00h
900h	Global Configuration Register (GCR)	32	RW	0000_0000h

21.6.2 Soft Lock Bit Register (SLBRn)

Offset

Register	Offset
SLBRn	0h

Function

NOTE

This register information represents the case where PROT_MEM is 1.

These registers hold the Soft Lock Bits (SLBs) for the protected registers in memory area #1, which is the normal register address space of the protected module. As many number of Soft Lock Bit Registers (SLBR*n*) can be implemented, depending on the number of protected module register bytes. Each SLBR*n* has four soft lock fields (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each soft lock field also has a corresponding write enable field in the same register that controls whether the soft lock field can be written. The following table shows the mapping between the soft lock fields to the bytes in memory area #1. See Module memory map table for SLBRn address offsets. For SLBRn address offsets, see the REG_PROT sheet attached to this document.

Table 67. SLBs vs. protected address

All the write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module. 1b - The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions.
22-0 —	Reserved

21.7 Functional description

The following sections describe the functional characteristics of the REG_PROT module.

21.7.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32 bits (address == multiples of 4)
- 16 bits (address == multiples of 2)
- 8 bits (address == multiples of 1)

The addresses that are protected and the protection size depends on the chip and/or module.

For all addresses that are protected, there are SLBRn[SLBm] bits that specify whether the address is locked. When an address is locked, it can only be read but not written in any mode (supervisor/normal). If an address is unprotected, the corresponding SLBRn[SLBm] bit is always 0b0, no matter what software is writing to.

NOTE

For more information on register protection specification, see the REG_PROT sheet attached to this document.

21.7.2 Change lock settings

To change the setting whether an address is locked or unlocked, the corresponding SLBRn.SLBm bit needs to be changed. This can be done using the following methods:

- Modify the SLBRn[SLBm] directly by writing to area #3
- Set the SLBRn[SLBm] bit(s) by writing to the mirror module space (area #2)

Both methods are explained in the following sections.

21.7.2.1 Change lock settings directly via area #3

In memory area #3, the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m*, which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

The following figure shows two modification examples for 8-bit wise protected area. In the example on the left, there is a write access to the SLBR*n* register specifying a mask value that allows modification of all SLBR*n*.SLBm bits. The example on the right specifies a mask that only allows modification of the bits SLBR*n*.SLB[1:3].

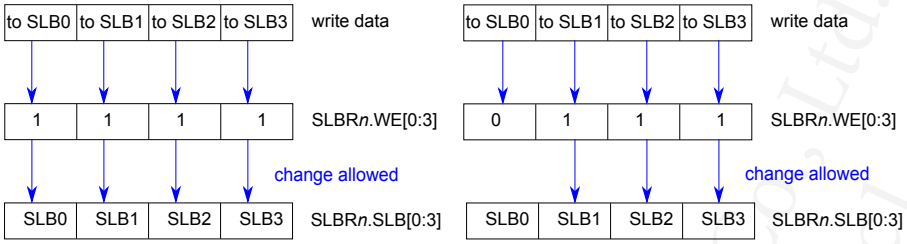

Figure 47. Change lock settings directly via area #3

The following figure shows two modification examples for 16-bit wise protected area. On the right side of the figure, it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] as well. This is done because the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case, the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[2:3] are cleared, the lock bits SLBR*n*.SLB[2:3] remain unchanged.

In the example on the left side of the figure, the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3]. This is done because the address reflected by SLBR*n*.SLB[0] and SLBR*n*.SLB[2] are protected 16-bit wise. Note that in this case, the write enable SLBR*n*.WE[0] and SLBR*n*.WE[2] must be set while SLBR*n*.WE[1] and SLBR*n*.WE[3] don't matter.

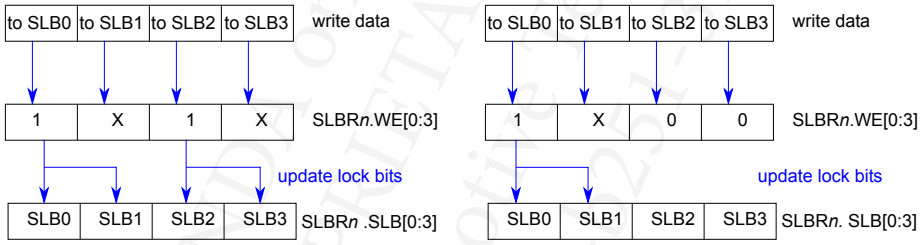

Figure 48. Change lock settings for 16-bit protected addresses

The following figure shows modification example for 32-bit wise protected area. When SLBR*n*.WE[0] is set, the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1:3] as well. Otherwise, SLBR*n*.SLB[0:3] remains unchanged. Note that in this case, the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1:3] does not matter.

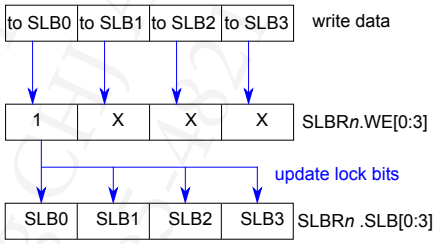

Figure 49. Change lock settings for 32-bit protected addresses

The following figure shows a mixed protection size configuration.

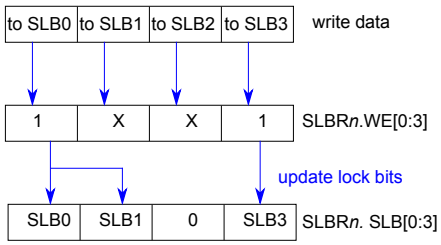

Figure 50. Change lock settings for mixed protection

The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked because the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3] as the corresponding register is 8-bit protected.

21.7.2.2 Enable locking via mirror module space (area #2)

It is possible to enable locking for a register after writing to it. See below examples for 8kB protection size (offset of the mirrored registers 0x2000). To do so, the mirrored module address space must be used. The following figure shows an example.

When writing to address 0x0008, the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (see the left part of the following figure).

When writing to address 0x2008, the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[0:1] are set while the lock bits SLBR2.SLB[2:3] remain unchanged (see the right part of the following figure).

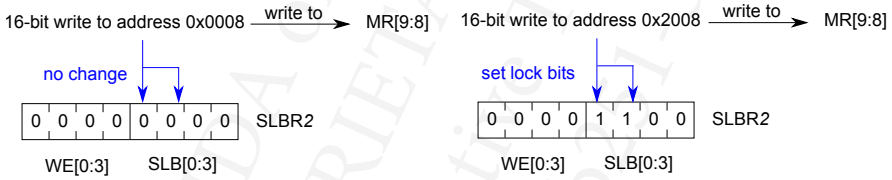

Figure 51. Enable locking via mirror module space (area #2)

The following figure shows an example where some addresses are protected and some are not. Addresses 0x0C and 0x0D are unprotected. Therefore, their corresponding lock bits SLBR3.SLB[0:1] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C, only lock bits SLBR3.SLB[2:3] are set while bits SLBR3.SLB[0:1] stay 0b0.

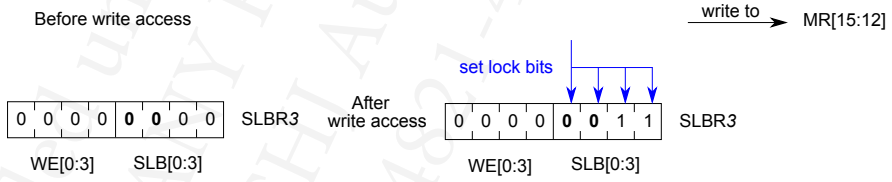

Figure 52. Enable locking for protected and unprotected addresses

NOTE

Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space do not change the lock bits.

21.7.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings directly via area #3 and Enable locking via mirror module space (area #2) is only possible as long as the field GCR.HLB is cleared. After you write 1 to this field, the locking bits cannot be modified until there is a system reset.

21.7.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition, seeMemory map and register definition.

- If accessing area #1 or area #2, the protection module passes on access error from the underlying module under protection.
- If the user mode is not allowed, the user writes to all areas, asserts a transfer error, and the writes get blocked.
- If accessing unimplemented 32-bit registers in area #3 and area #4, a transfer error is asserted.
- If writing to a register in area #1 and area #2 with Soft Lock field set for any of the affected bytes, a transfer error is asserted and the write will get blocked. Also, the complete write operation to non-protected bytes in this word is ignored.
- If writing to a Soft Lock Register in area #3 with the Hard Lock field being set, a transfer error is asserted.
- For any write operation in any access mode to area #2 while Hard Lock field GCR.HLB is set

21.7.4 Sequence

You must configure the REG_PROT first. And then, you need to write 1 to the HLB field in REG_PROT. This ensures that registers under protection are not updated in the user access mode. You need to follow these steps:

1. Enable XRDC protection for the module to enable writes in the supervisor mode only. This step is mandatory, if protected registers of the module are expected to be configured multiple times.
2. Configure REG_PROT to enable write on registers of module under protection.
3. Configure the registers of module under protection.
4. Configure the REG_PROT for the required SLB fields.
5. Set the HLB field in REG_PROT. This step is mandatory, if protected registers of module are expected to be configured only once.

21.8 Initialization/application information

The following sections contain information related to initialization and use of the Register Protection module in applications.

21.8.1 Reset

The reset state of each individual bit is shown within the Register Description section. In summary, after reset, locking for all MRn registers is disabled. You can access the registers only in the Supervisor mode.

Chapter 22
Wakeup Unit (WKPU)

22.1 Chip-specific WKPU information

22.1.1 WKPU configuration

The following table shows the WKPU configuration on this chip.

Table 68. WKUP expose pads

Number of	Value
NMI sources	1
Internal interrupt sources	1
External interrupt sources	23
Glitch filters for external interrupts	23
External interrupt vectors	3

NOTE

Wake-up sources 0 to 22 map to the pads with the corresponding WKPUx signal and I/O supplies are described in the attached IOMUX spreadsheet, IO Signal tab. Wake-up source 31 is mapped to the internal RTC module. For the IO voltage supply range, refer to the Absolute Maximum Ratings section in the chip DataSheet.

22.1.2 Chip-specific NMI Configuration Register (NCR)

The NMI Configuration Register (NCR) does not support the NDSS0 and NWRE0 fields.

Although these fields support read/write access, writing a value other than the reset value is prohibited, and can produce unexpected results.

22.1.3 Interrupts

WKPU allows an external NMI pin to assert non-maskable interrupts in this chip.

- Control the NMI destination interrupt by configuring the NMI Destination Source Select fields of the NMI Configuration register (NCR[NDSSn]).
- Control enabling of rising edge, falling edge, or either edge reaction to the NMI pin for each core independently with the NMI Falling-edge Events Enable (NCR[NFEEn]) and NMI Rising-edge Events Enable (NCR[NREEn]) fields.
- WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.
- The NMI supports a status flag and an overrun flag with the NMI Status Flag and NMI Overrun Status Flag fields of the NMI Status Flag register (NSR[NOVFn] and NSR[NOVFn]).

22.1.4 NMI on Standby exit

Entering Standby mode always resets the NMI Configuration register (NCR). Therefore, exiting Standby mode does not generate NMI from WKPU. To generate NMI, software must first initialize the NCR.

NOTE

Only NCR[NLOCK0] is reset by STANDBY mode. The NMI from WKPU will not be generated on STANDBY as software need to disable NMI before standby entry, and NMI pads will be powered off during standby.

22.1.5 Asynchronous wake-up sources for various modes

In this chip, the following modules can provide wake-up in Standby mode:

- WKPU
- RTC

NOTE

This chip only supports the rising-edge detection of RTC wake-up.

22.1.6 Pull control of wake-up pads

This table shows how the PULL value of WKPU pads are controlled by SIUL2 and WKPU configuration.

Device Mode	SIUL2_MSCRn[PUE]	SIUL2_MSCRn[PUS]	WKUP_PUS[WKUP_PU_OVERRIDE]	WKPU_WIPER[IPUE]	WKPU_PUS[WKUP_PUS]	Affect on WKPU PAD
All except STANDBY modes	0	x	0	x	x	Highz
	x	x	1	0	x	Highz
	x	x	1	1	0	Pull down
	x	x	1	1	1	Pull up
	1	0	0	x	x	Pull down
	1	1	0	x	x	Pull up

NOTE

Wake-up pads pull controls must be configured via the WKPU and not by the SIUL during STANDBY. The proper procedure for managing the wake-up pads pulls is described in the "Wake-up pin pullup/pulldown control during Run and Standby modes" section of the Power chapter.

22.1.7 Enabling wakeup pads

Before enabling a wakeup using the Wakeup Request Enable Register (WRER) register, enable the input buffer (IBE) for the corresponding wakeup pin using SIUL*.MSCR[IBE] control field.

22.1.8 Wakeup/Interrupt Pull Enable Register (WIPUER_WIPDER)

This register is used to enable a Pull on the corresponding interrupt pads to pull an unconnected wakeup/interrupt input to a specified voltage level. The register is described in the WKPU register descriptions in this chapter.

NOTE

Enabling pull-ups on the wake-up pins during the Standby mode will increase the overall standby power consumption.

NOTE

If a wake-up source is not being used, then the software should ensure that the corresponding wake-up interrupt is disabled.

22.2 Introduction

The WKPU supports 32 external sources that can generate interrupts or wakeup events and 1 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from other wakeup sources to supply a single wakeup to the system. The block diagram of WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See chip-specific WKPU for more information.

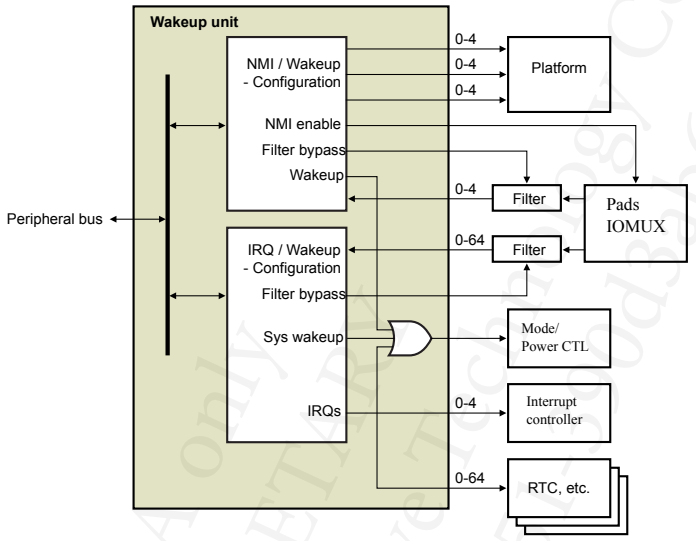

Figure 53. WKPU and connected system components

22.3 Features

The WKPU supports these features:

- Non-maskable interrupt support with:
  - 1 NMI source
  - 1 analog glitch filter
  - Active (rise/fall) edge selection control for events
  - Configurable system wakeup triggering from NMI source
- External wakeup/interrupt support with:
  - System interrupt vector for interrupt sources
  - 31 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources
  - Configurable pullup
- On-chip wakeup support:
  - wakeup sources

— Wakeup status mapped to same register as external wakeup/interrupt status

22.4 WKPU memory map and registers

22.4.1 WKPU register descriptions

This section provides a detailed description of all the registers accessible in the WKPU module.

NOTE

Reserved registers read as zero and writes have no effect. A transfer error is generated when trying to access a completely reserved register space. The field length of external pad control registers depends on the number of WKPU channels implemented in a chip.

22.4.1.1 WKPU memory map

WKPU base address: 4009_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	NMI Status Flag Register (NSR)	32	W1C	0000_0000h

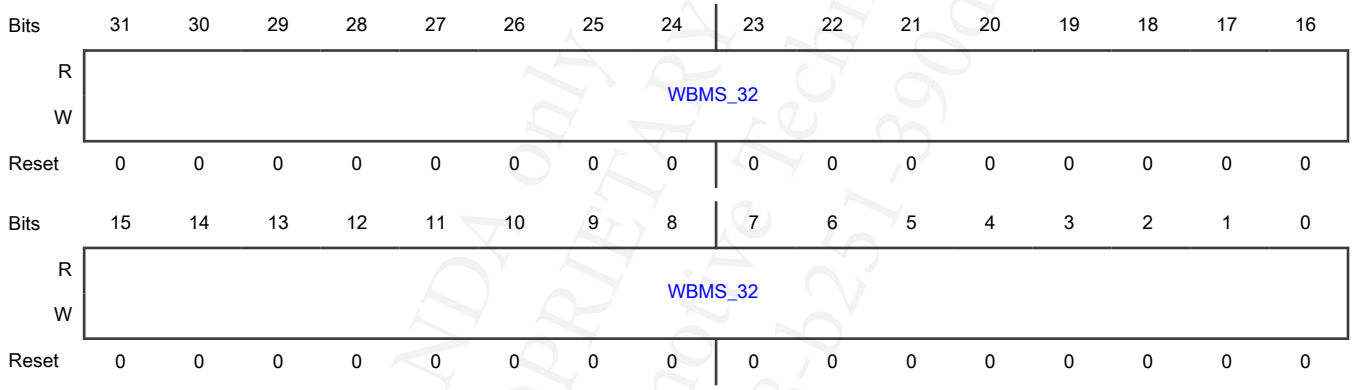
WBMSR	10h

Function



This register is used by the boot software to select between a short boot or a full boot. Application software should write '0' or '1' for each wakeup event in this register. You must ensure that the selected Boot mode matches the corresponding wakeup source.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Diagram

Fields

Field	Function

22.4.1.5 Wakeup/Interrupt Status Flag Register (WISR)

Offset

Register	Offset
WISR	14h

Function

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located at the left of the external wakeup/interrupt status bits and are read-only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source.

Access: User read/write

22.5 Functional description

This section provides functional description of WKPU.

22.5.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, although it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be performed when NMI is disabled, to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

c8c462e3-4824-4888-b251-390d3ab624c1

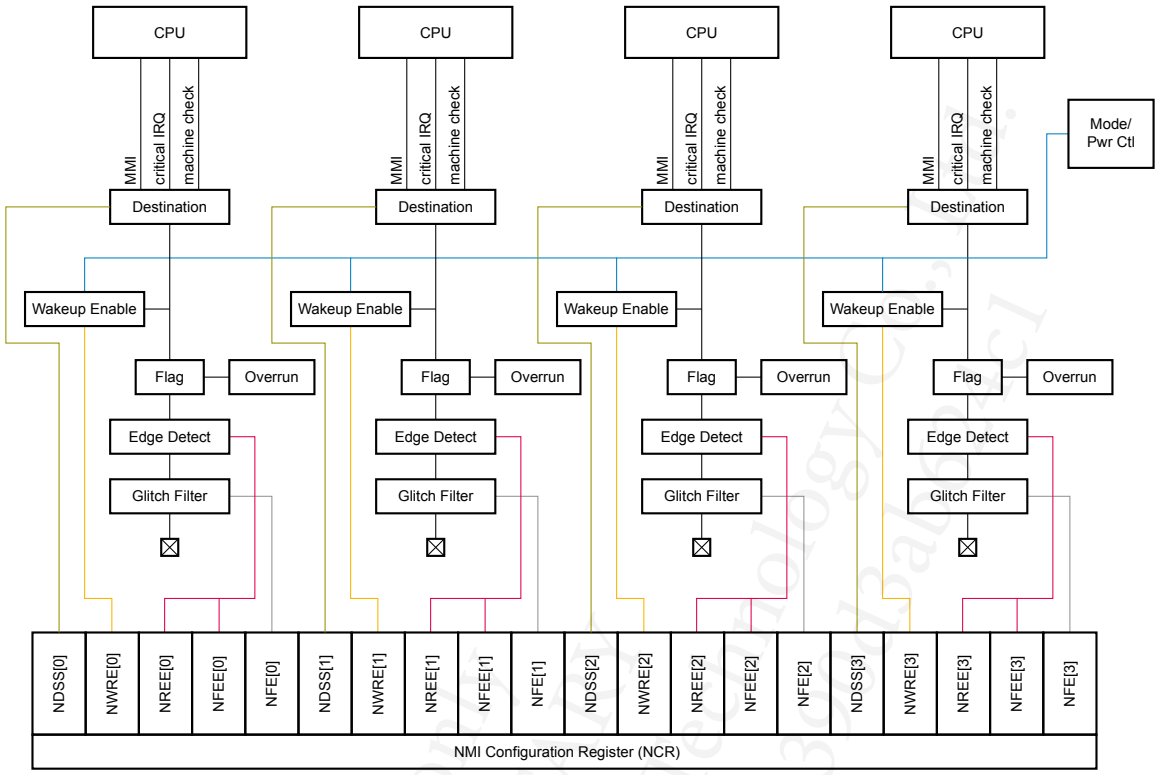

Figure 54. NMI pad diagram

22.5.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NCR[NREEn] and NCR[NFEEn] bits.

NOTE

After reset, NREE and NFEE are set to '0'; therefore, the NMI functionality is disabled after reset and must be enabled explicitly by software.

After a pad's NMI functionality is enabled, the pad cannot be reconfigured to override or disable the NMI. See the chip-specific WKPU information for details of NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NCR[NDSSn] bits. See NMI Configuration Register (NCR) for details.

Each NMI supports a status flag and an overrun flag, which are located in the NSR register (see NMI Status Flag Register (NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (that is, status flag has not been cleared).

NOTE

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt is not cleared.

During an NMI ISR, on wakeup of the chip from an NMI, any writes to the ECC-protected memory must have the correct ECC.

22.6 External wakeups/interrupts

The WKPU supports 1 interrupt vector to the interrupt controller of the chip. Each interrupt vector can support up to the number of external interrupt sources from the device pads, with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt source is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

See the following figure for an overview of the external interrupt implementation, showing an example of four interrupt vectors with eight external interrupt sources each.

NOTE

The figure below shows a generic representation of WKPU. See the chip-specific WKPU information for details on how this device's configuration might differ from this figure.

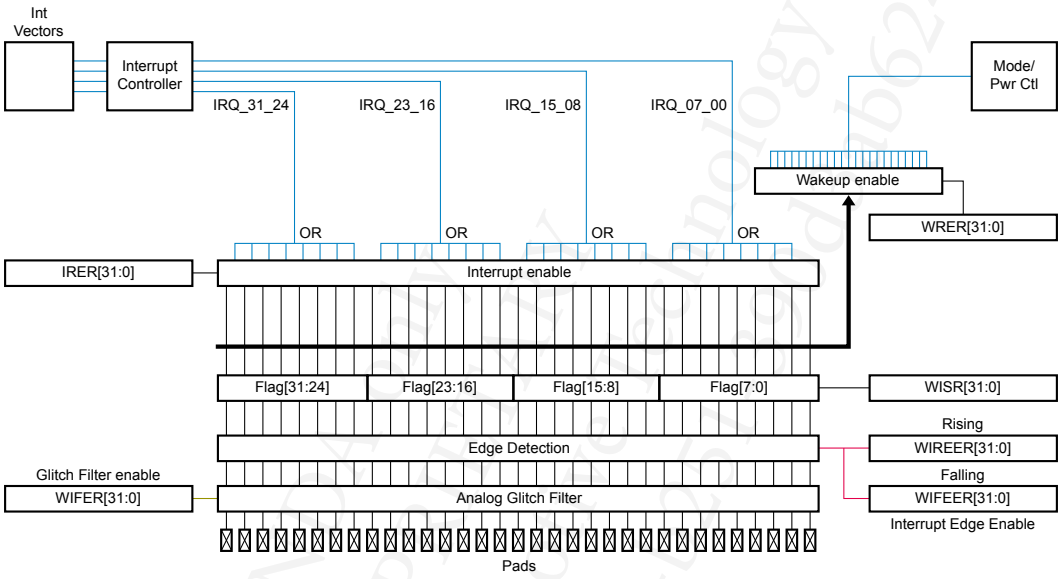

Figure 55. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is set based on the platform and the interrupt controller's priority levels, but the allocation of pads to each group of interrupts can be independently configured by the chip.

External interrupt lines have a digital glitch filter applied to them.

22.6.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled-up register (Interrupt Request Enable Register (IRER)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active.

NOTE

Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (that is, no system wakeup or interrupt is generated on any activity of that pad).

The active IRQ edge is controlled by users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag, which is held in the flag register, WISR. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

22.7 On-chip wakeups

The WKPU supports on-chip wakeup sources. WKPU and on-chip wakeup sources interrupt simultaneously if wakeup from on-chip wakeup sources and WKPU (that is, Wakeup Request Enable Register (WRER)) is configured in Stop and Low-Power modes. Alternatively, in Standby mode a single wakeup is generated to the system through WKPU.

22.8 Initialization information

This section discusses initialization for the following features:

- Glitch filter and pad configuration
- Non-maskable interrupts

22.8.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed when the NMI is disabled. This is to avoid erroneous triggering by glitches caused by the configuration process.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NCR[NREE], NCR[NFEE], NCR[RREE], and NCR[RFEE] bits in the same register write.

22.8.2 Non-maskable interrupts

If the IBE of NMI is controlled by the NFEE or NREE fields of NMI Configuration Register (NCR) when an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. You must follow the following sequence to enable the NMI interrupt on a rising edge event on the NMI pin:

1. Write 1 to NCR[NFEE0]
2. Write 1 to NCR[NREE0]
3. Write 0 to NCR[NFEE0]

If the IBE of NMI is tied off to 1, no false interrupt is expected.

Chapter 23
Clocking

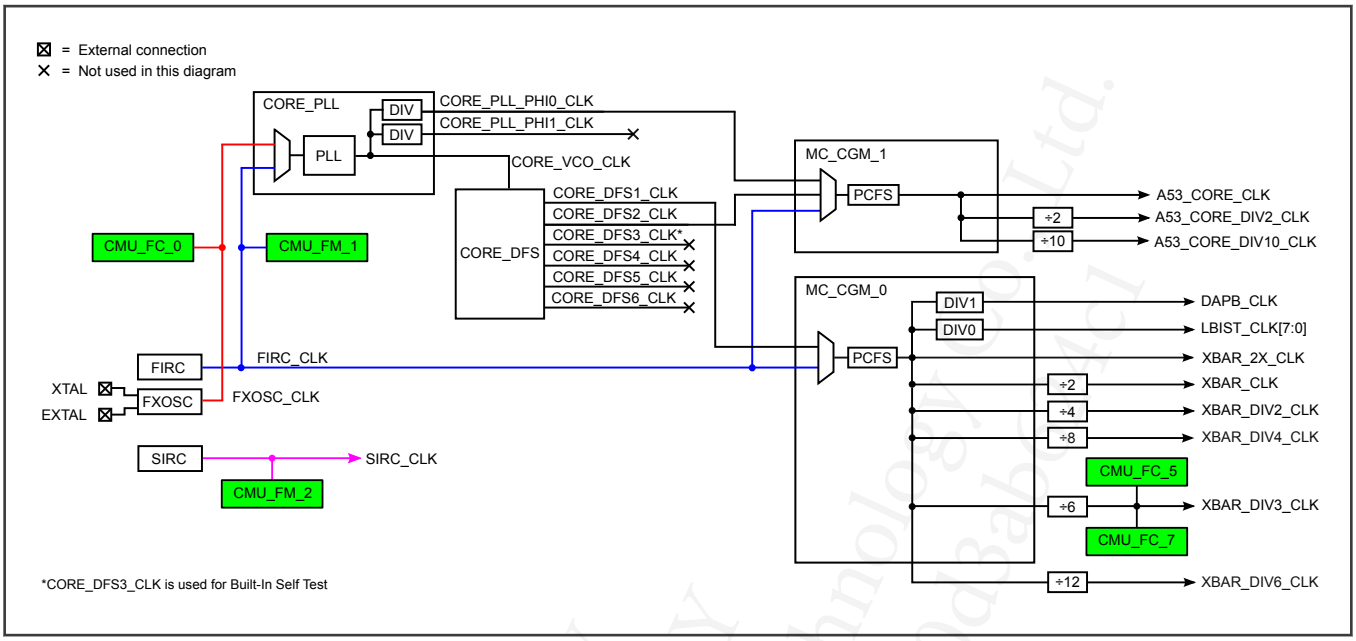
23.1 Introduction

This chapter describes the architecture of the system-level clocks and includes the following:

- System clock specifics
- Clock sources
- Clock architecture
- Clock control registers
- Clock monitoring
- Clock gating
- Module clocking

The chapter covers information related to clocks generated on the chip. Protocol clocks provided by external chips are covered in the respective chapters where they are used.

23.1.1 Features



The chip-clocking architecture supports the following features:

- Multiple clock sources supported for clock generation:
  - Fast Internal RC Oscillator (FIRC)
  - Slow Internal RC Oscillator (SIRC)
  - Fast External Crystal Oscillator (FXOSC)
  - Phase-Locked Loops (PLLs)
  - Digital Frequency Synthesizer (DFS) modules
- Frequency Modulated (FM) clock to reduce electromagnetic emissions
- Precise clocks for timers and communication functions
- Glitchless clock switching of Clock Generation Module (MC_CGM) clock selectors
- Progressive Clock Frequency Switching (PCFS) for system clocks driving cores
- Clock monitor units to check the integrity of the clocks
- Module clock gating using the MC_ME Partition *n* Process Configuration registers

23.1.2.7.4 PFE clocking

23.2 Clock sources

23.2.1 Introduction

The internal clocks are generated from one of these input clock sources:

- FIRC — 48 MHz (mainly used as a backup clock) (see note)
- SIRC — 32 kHz (see note)
- FXOSC — 20–40 MHz (see note)
- PLLs:
  - CORE_PLL (FM)
  - PERIPH_PLL (Non-FM)
  - DDR_PLL (FM)
  - ACCEL_PLL (FM)
  - AURORA_PLL (Non-FM)
- DFS blocks:
  - CORE_PLL DFS
  - PERIPH_PLL DFS

NOTE

Nominal frequencies are shown in the list above. Detailed clock operating parameters can be found in this chip's data sheet.

The PLL outputs (direct output or DFS outputs), FXOSC, SIRC, and FIRC can be selected to drive system peripherals, cores, and infrastructure depending on MC_CGM configuration.

23.2.2 Input clock pins

Description	Pin
FXOSC pins	XTAL
	EXTAL
FTM_0 external reference clock	FTM0_EXT_REF
FTM_1 external reference clock	FTM1_EXT_REF
SPI_*n* clock	DSPI*n*_SCK_I
Ethernet timestamp clock	GMAC_TS_CLK_I
Ethernet TX clock	GMAC0_TX_CLK_I
Ethernet RX clock	GMAC0_RX_CLK_I
Ethernet RMII REF clock	GMAC0_RMII_REF_CLK_I
Aurora reference clock (differential)	AUR_CLK_P, AUR_CLK_N
JTAG clock	TCK
RTC external clock	RTC_EXT_CLK
PFE_MAC_0 Ethernet TX clock	PFE_MAC0_TX_CLK_I
PFE_MAC_0 Ethernet RX clock	PFE_MAC0_RX_CLK_I
PFE_MAC_0 Ethernet RMII REF clock	PFE_MAC0_RMII_REF_CLK_I
PFE_MAC_1 Ethernet TX clock	PFE_MAC1_TX_CLK_I
PFE_MAC_1 Ethernet RX clock	PFE_MAC1_RX_CLK_I
PFE_MAC_1 Ethernet RMII REF clock	PFE_MAC1_RMII_REF_CLK_I
PFE_MAC_2 Ethernet TX clock	PFE_MAC2_TX_CLK_I
PFE_MAC_2 Ethernet RX clock	PFE_MAC2_RX_CLK_I
PFE_MAC_2 Ethernet RMII REF clock	PFE_MAC2_RMII_REF_CLK_I

23.2.3 Output clock pins

Description	Pin
Output clock	CLKOUT0
Output clock	CLKOUT1

23.2.4 FIRC

This chip has a 48 MHz FIRC (output FIRC_CLK) with the following features:

- Always enabled
- PLL clock source when FXOSC is not available
- Clock source for the following modules:
  - Power Management Controller (PMC)

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
c8c462e5-4821-48a8-b251-2

- Reset Generation Module (MC_RGM)
- Fault Collection and Control Unit (FCCU)
- FCCU Output Supervision Unit (FOSU)
- Software Watchdog Timer (SWT)
- System Integration Unit Lite2 (SIUL2) (input filter)

- Default system clock after reset
- Serves as the system clock source in case loss of lock or loss of clock detection
- Turned off while entering the Standby mode

23.2.5 SIRC

This chip has a 32 kHz SIRC (output SIRC_CLK) with the following features:

- Always enabled
- Used as a clock source for the following modules:
  - Real-time clock (RTC)
  - POR_WDOG

23.2.6 FXOSC

This chip has a 20—40 MHz FXOSC (output FXOSC_CLK) with the following features:

- Reference for the chip PLLs
- Reference clock source for the following:
  - FlexCAN
  - FlexRay
- Available to drive the CLKOUT pin
- Allows a crystal or external clock source reference clock for the chip
- Uses crystals with a fundamental frequency range of 20–40 MHz
- Supports the following input clock modes:
  - Crystal
  - Single-ended bypass
  - Differential bypass

23.2.6.1 FXOSC register interface

Please see the "FXOSC" chapter for details.

23.2.7 PLL

This chip contains the following PLLs:

- CORE_PLL - Programmable FM PLL (SSCG) used for the following:
  - Cortex-A53 clusters
  - Cortex-M7 clusters
  - HSE_H
  - High-speed chip interconnect

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

- PERIPH_PLL - For peripherals including the following:
  - GMAC
  - FlexCAN
  - FlexRay (non-FM)
  - ...
- ACCEL_PLL - Programmable accelerators supporting FM (SSCG)
- DDR_PLL - For DRAM interface (FM)
- AURORA_PLL - For Aurora interface (non-FM)

These PLLs have the following features:

- One or all of the following modes of operation:
  - Normal PLL mode with crystal reference
  - Normal PLL mode with external reference
  - Normal PLL mode with internal RC oscillator (FIRC) input (used during boot)
- Lock status indication from the monitoring circuitry
- Option to turn on/off frequency modulation (applies to CORE_PLL, DDR_PLL, ACCEL_PLL)
- Fractionally divided outputs using Digital Frequency Synthesizer (DFS) for additional clock domains

23.2.7.1 PLL input clocks

Clock sources for the PLLs can be either the 20-40 MHz FXOSC or 48 MHz FIRC. During boot, FIRC_CLK is used as the default PLL reference clock. After boot, the PLL reference must be changed to FXOSC_CLK.

23.2.7.2 PLL output clocks

PLLs have VCO and multiple PHI*n* output clocks. PLL output clocks can be configured to be divided for use by modules (see Overview for details).

23.2.7.3 PLL register interface

See chapter "PLL digital interface (PLLDIG)" for details.

23.2.7.4 DFS

The chip includes two DFS modules:

- CORE_PLL DFS
- PERIPH_PLL DFS

DFS uses the VCO output clock of the PLLs as its source clock.

DFS modules provide the following features:

- Multiple-phase divider outputs
- Phase divider outputs that are controlled independently
- Phase dividers that have independent resets
- CORE_PLL DFS that supports six outputs
- PERIPH_PLL DFS that supports six outputs

The DFS clocks are mapped to the DFS ports as follows:

Table 69. DFS clock and port mapping

DFS instance	Clock	Port
CORE_DFS	CORE_DFS1_CLK	CORE_DFS_DVPORT0
	CORE_DFS2_CLK	CORE_DFS_DVPORT1
	CORE_DFS3_CLK	CORE_DFS_DVPORT2
	CORE_DFS4_CLK	CORE_DFS_DVPORT3

MC_CGM_5	Clock mux 0 Selector	DDR_PLL_PHI0_CLK

1. The default clock selected for all clock mux selectors is FIRC_CLK (out of reset).

NOTE

Current and target clocks must be operational before switching source clocks.

23.3.4 System clock frequency limitations

The maximum operating frequency of system level clocks is shown in the product data sheet. The limits shown in the data sheet must not be exceeded.

23.3.5 Default clock configuration

FIRC_CLK is the default clock for the entire system at power-up. All system clock dividers are set to their default or reset values.

23.3.6 Standby clock configuration

SIRC_CLK is the only clock available during the Standby mode. FIRC_CLK is the clock used after Standby mode exit.

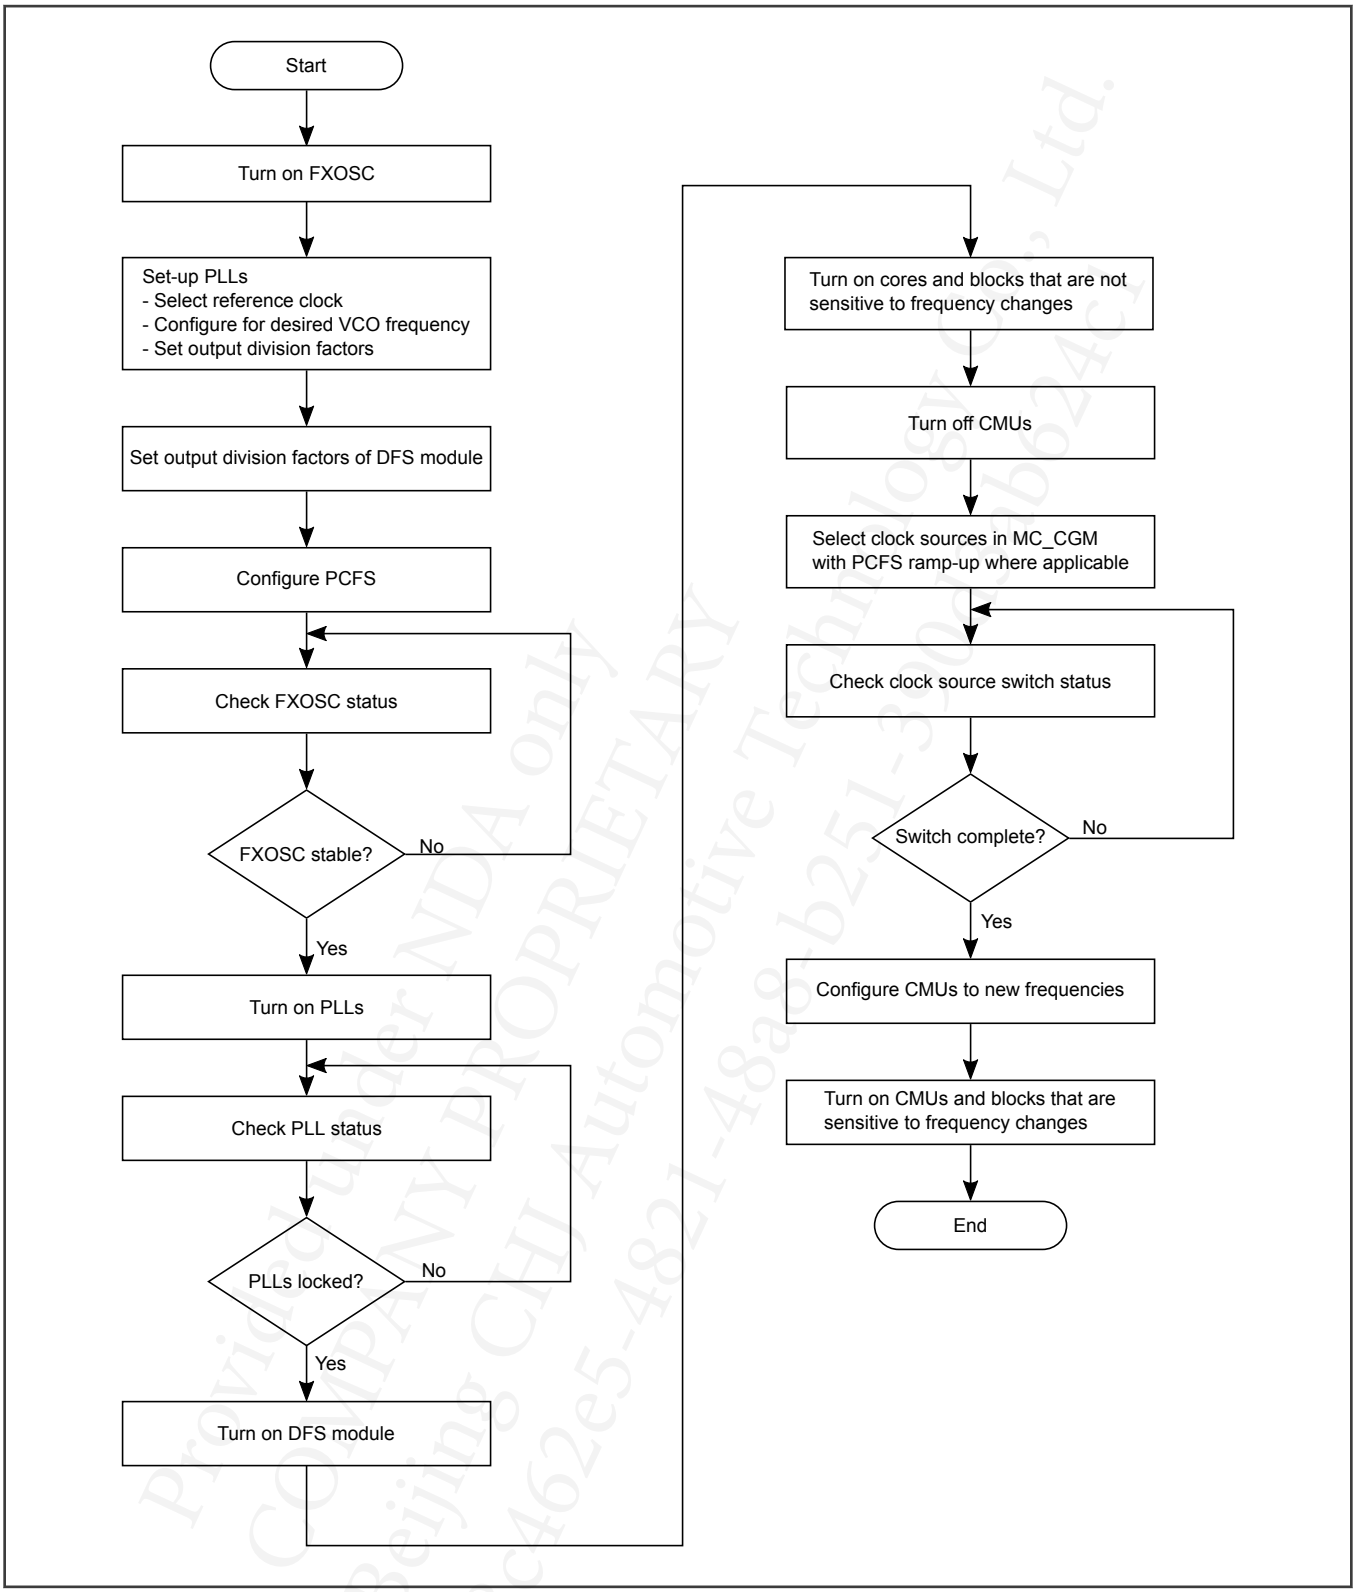
23.4 Software resettable domain

Before deassertion of software resettable domain 1, you must switch the input source of MC_CGM_1 mux 0 (A53_CORE_CLK output) to FIRC_CLK. After switching the clock, deassert the reset of software domain 1.

Before deassertion of software resettable domain 2, you must switch the input source of MC_CGM_2 mux [0:9] to FIRC_CLK. After switching the clocks, deassert the reset of software domain 2.

Before deassertion of software resettable domain 3, you must switch the input source of the following to FIRC_CLK:

- MC_CGM_0 mux_3 (PER_CLK)
- MC_CGM_0 mux_6 (FLEXRAY_PE_CLK)
- MC_CGM_0 mux_7 (CAN_PE_CLK)
- MC_CGM_0 mux_8 (LINFLEXD_CLK, LIN_BAUD_CLK)



After switching the clocks, deassert the reset of software domain 3.

23.5 Clock on/off procedures

The sections below describe the correct procedures for turning clock signals on and off.

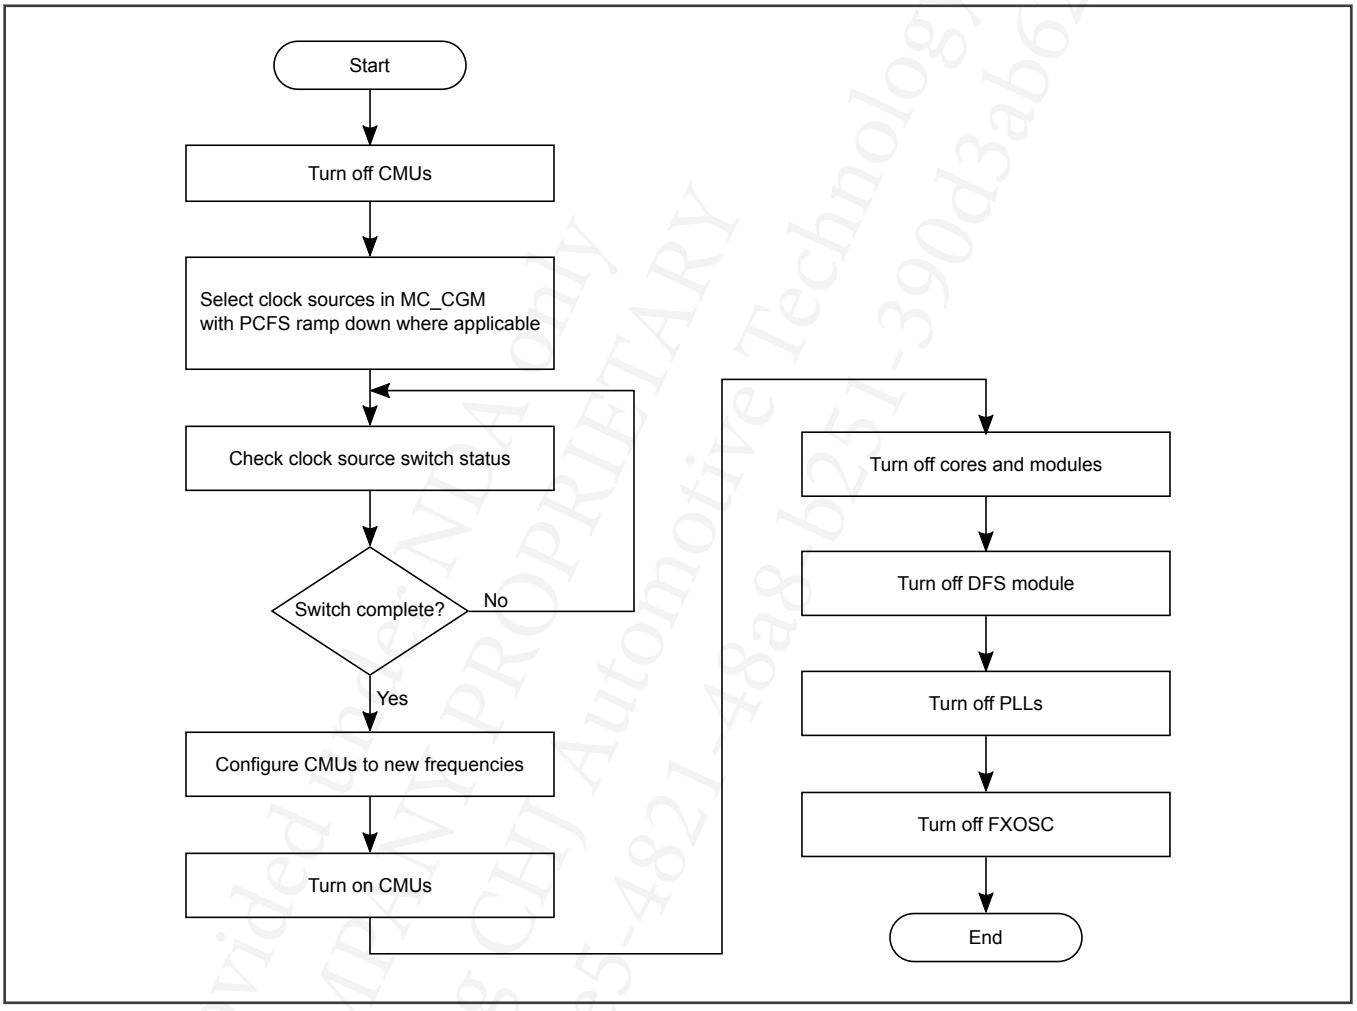
Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab6240d

23.5.1 Clock-on

NOTE

See PLL turn on sequence for details on correct PLL turn on sequencing.

23.5.1.1 PLL SSCG Setup



Some PLL instances support SSCG via frequency modulation (FM) to help reduce EMI. See PLL for a list of which PLLs support this feature.

When enabling SSCG for such a PLL, use the center-spread modulation type. To do this, configure the PLL's PLLFM register fields as follows:

- SSCGBYP = 0b
- SPREADCTL = 0b

In this case, refer to the maximum frequencies in the data sheet labeled "with center-spread SSCG enabled" when configuring the PLL. In all other cases, refer to those labeled "without center-spread SSCG enabled".

23.5.2 Clock-off

23.5.3 PLL turn on sequence

Perform the following PLL turn on sequence for correct chip operation:

1. Turn on the AURORA_PLL.
2. Check the AURORA_PLL lock status.
3. Repeat the previous step if the AURORA_PLL is not locked. Else, go to the next step.
4. Turn on the CORE_PLL.

5. Check the CORE_PLL lock status.
6. Repeat the previous step if the CORE_PLL is not locked. Else, go to the next step.
7. Turn on the PERIPH_PLL.
8. Check the PERIPH_PLL lock status.
9. Repeat the previous step if the PERIPH_PLL is not locked. Else, go to the next step.
10. Turn on the DDR_PLL.
11. Check the DDR_PLL lock status.
12. Repeat the previous set if the DDR_PLL is not locked. Else, go to the next step.
13. Turn on the ACCEL_PLL.
14. Check the ACCEL_PLL lock status.
15. Repeat the previous step if the ACCEL_PLL is not locked. Else, the PLL turn on sequencing is complete.

23.5.4 Turning on the CLKOUT*n* signals

To avoid glitches on the CLKOUT*n* signals when turning on the output clocks, you must observe the following:

1. Select the CLKOUT*n* signal functionality by configuring the SIUL2 (for example, SIUL2_MSCR*n*).
2. Configure and turn on the desired output clock source.
3. Select the desired output clock source in the MC_CGM_0 (as shown in Application clock source options).
4. Configure and enable the corresponding output clock divider in the MC_CGM_0 (for example, writing 1 to MC_CGM_0_MUX_1_DC[DE]).

23.5.5 Turning off the CLKOUT*n* signals

To avoid glitches on the CLKOUT*n* signals when turning off the output clocks, you must observe the following:

1. Disable the corresponding output clock divider in the MC_CGM_0 (for example, writing 0 to MC_CGM_0_MUX_1_DC[DE]).
2. Optionally turn off the previously selected output clock source.
3. Optionally reconfigure the CLKOUT*n* pin via the SIUL2 for an alternate functionality.

IMPORTANT

If there is a reset event, a glitch may occur on the CLKOUT*n* signals. In this case, RESET_B asserts indicating to any peripheral monitoring RESET_B that CLKOUT*n* is no longer valid.

23.6 Clock gating

See the partition mapping tables in section "MC_ME partition mapping" of the "Mode Entry Module (MC_ME)" chapter for module clock gating possibilities.

NOTE

For module behavior when the module clock is gated, see the Software resettable domains section in the Reset overview chapter.

23.7 Module clocking

Beijing CHJ Automotive Technology Co., Ltd. COMPANY PROPRIETARY Provided under NDA only c8c46265482e4a8b9251-3900ab624c1

23.7.1 Safety modules

Figure 57 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 70 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK, uses the same source for REG_INTF_CLK as used by the MODULE_CLK.

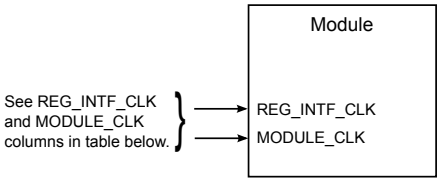


Figure 57. Safety module

Table 70. Safety module clocking

Module	MODULE_CLK	REG_INTF_CLK
CRC	XBAR_DIV3_CLK

COMPANY PROPRIETARY
Beijing Chipsea Automotive Technology Co., Ltd.
c8c462e5-4821-4a8b-9525-590d3ab624c1

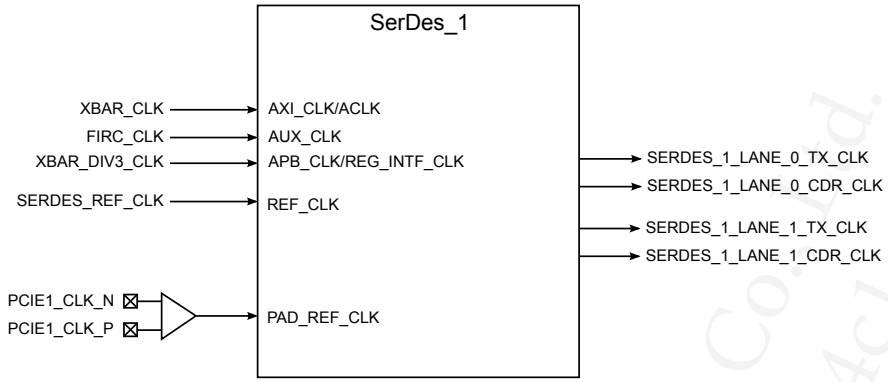

Figure 61. SerDes_1 clocking

NOTE

If using SerDes_*n* output clocks for Ethernet operation, you must configure one of the following inputs:

- PCIE*n*_CLK_N and PCIE*n*_CLK_P
- SERDES_REF_CLK

Table 72. Permissible clock sources for PCIe modes

PCIe mode	Permissible clock source
Gen1	• External clock • Internal PLL
Gen2	
Gen3	Use PCIE*n*_CLK_N and PCIE*n*_CLK_P source only (due to tighter jitter requirements)

NOTE

When you configure SerDes_*n* to use internal clocking, ground PCIE*n*_CLK_N and PCIE*n*_CLK_P to avoid noise on the SerDes_*n* clock inputs.

23.7.2.2 Ethernet (GMAC_0)

23.8 Clock monitoring

23.8.1 Introduction

For all safety critical clocks, the chip must detect a missing clock or incorrect frequency. The use of CMUs achieve this result. The reference clock used depends on the CMU instance (either FIRC_CLK or FXOSC_CLK). For detailed information on CMUs, see the "Clock monitor unit (CMU)" chapter.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
cc462e5-4821-48a8-8251-3a0d3ab624c4

NOTE

If the FIRC is not operating within operating parameters, recovery must be done with a POR. The methods used to trigger the POR are as follows:

- The software executing on the master safety core detects the FIRC that is not operating correctly (based on the CMU_FM metering FIRC_CLK with FXOSC_CLK as reference clock). Then it sends a POR command to the external PMIC via SPI (assuming that the software is able to issue the reset).
- If the software stops functioning correctly because of FIRC failure, or if it stops PMIC servicing, the PMIC watchdog timer expires (within the FTTI) and a POR asserts.

NOTE

Configure peripheral clocks before enabling peripherals. To verify that the peripheral clocks are operating within the expected parameters, check CMUs corresponding to the peripheral clocks. If a CMU shows an incorrect frequency, despite correct configuration, software should issue a destructive reset to correct the problem.

23.8.2 Clock input sources

The table below shows the clocks monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the chip. The second column of the table shows the address offset for the corresponding CMU instance.

NOTE

All "CMU instances" shown in paretheses are for future use and their associated register space is reserved.

Table 105. Clock input sources

CMU instance	Address offset	Reference clock	Monitored clock	Error response
CMU_FC_0	0000h	FIRC_CLK	FXOSC_CLK	FXOSC_FAIL (MC_RGM destructive reset)

23.8.3 Enabling and disabling CMU_FC_0 and CMU_FC_5

CMU_FC_0 and CMU_FC_5 need to be enabled and running in order to properly detect loss of clock events.

- CMU_FC_0:
  - You must enable CMU_FC_0 as soon as the FXOSC has been turned on and is stable.
  - You must disable CMU_FC_0 just prior to turning off the FXOSC.
- CMU_FC_5:
  - You must enable CMU_FC_5 as soon as the XBAR_DIV3_CLK has been configured, that is, after source configuration and selection.
  - You must disable CMU_FC_5 just prior to reconfiguring the XBAR_DIV3_CLK, that is, prior to source reconfiguration or source selection change.

Chapter 24
Clock Generation Module (MC_CGM)

24.1 Chip-specific MC_CGM information

This chip has the following MC_CGM instances:

- MC_CGM_0 generates clocks for the system peripherals.
- MC_CGM_1 generates clocks for the Cortex-A53 cores.
- MC_CGM_2 generates clocks for PFE clocks.
- MC_CGM_5 generates clocks for the DDR peripheral.

Clock source numbers

In this chapter, each numbered clock source represented as clk_src_*n* refers to the clock source with the same index number in the "MC_CGM clock source mapping" table in the "Clock source mapping on MC_CGM clock selectors" section.

24.2 Chip-specific MC_CGM_2 information

24.2.1 MC_CGM feature configuration

MC_CGM instances on this chip do not implement Divider Trigger Control Registers or Divider Trigger Registers. Disregard their references in the MC_CGM_2 register descriptions.

24.3 Introduction

The clock generation module (MC_CGM) is used to set up the configurable clock domains used by various chip blocks as per the application needs. It includes the clock multiplexers that allow software to select the desired clock sources for these domains. This is managed by the MC_CGM to ensure that the changing of the clock selection from one source to another occurs in a glitch-less fashion. In addition, the MC_CGM includes the clock dividers that can be configured by software.

See following figure for the MC_CGM block diagram:

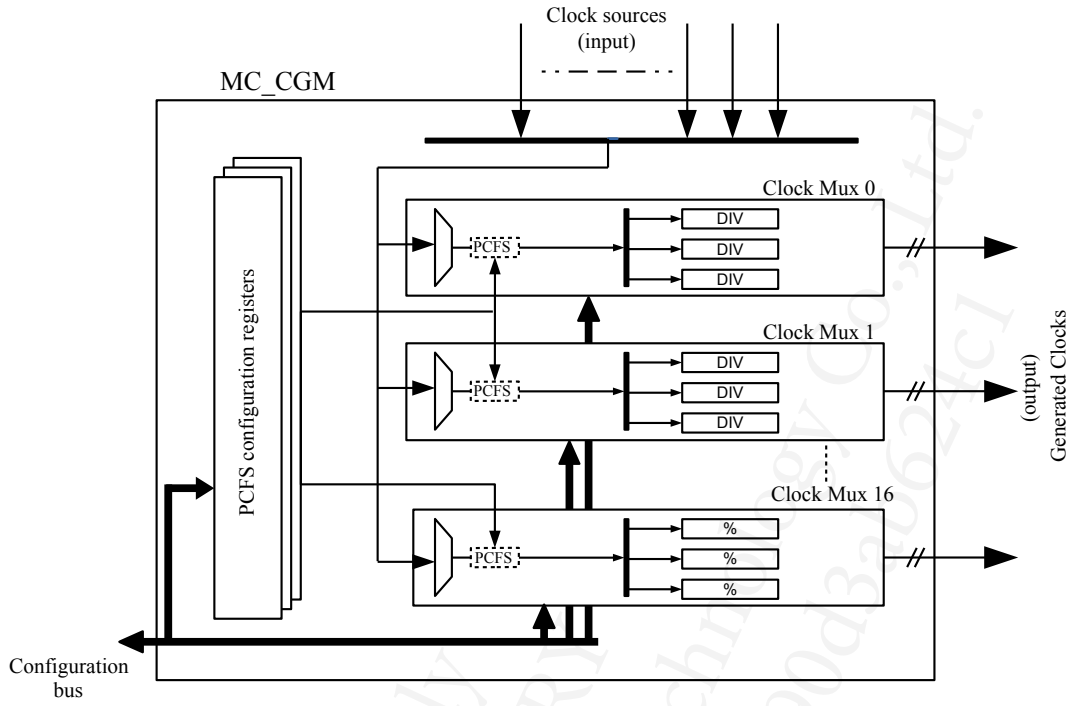

Figure 97. MC_CGM block diagram

NOTE

The block diagram is generic and does not necessarily reflect any specific MC_CGM implementation.

24.4 Features

MC_CGM includes the following features:

- Implements software configurable clock multiplexers for selecting from various clock sources
- Provides hardware-controlled multiplexers that guarantee glitchless transition, while the software-controlled multiplexers need a software sequence to ensure such a transition
- Provides software configurable automatic PCFS on certain clocks to minimize the impact of a sudden power consumption change through a gentle ramp-down and -up of the clock frequency when switching clock sources
- Implements software configurable clock dividers

24.5 MC_CGM_0 register descriptions

MC_CGM implements a set of clock multiplexers that share PCFS configuration registers. MC_CGM registers have the following properties:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits do not terminate with an error, and hardware behavior is unpredictable.
- Writes to read-only register fields in writable registers are ignored and do not provide an error response.
- Writes to read-only registers are aborted with an error response.

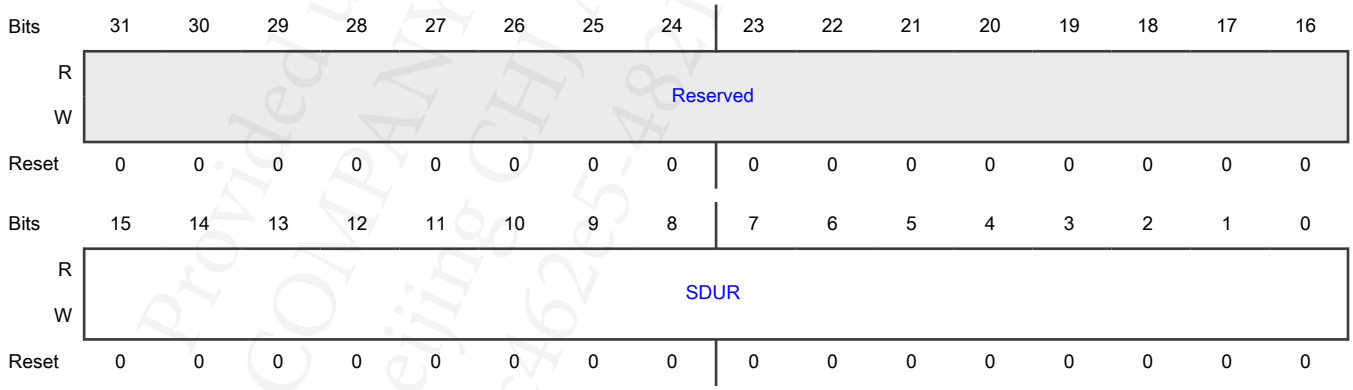
24.5.2 PCFS Step Duration (PCFS_SDUR)

Offset



Register	Offset
PCFS_SDUR	0h

Function

This register specifies the step duration of each PCFS step. The value provided in this register specifies the PCFS step duration in terms of the number of cycles of clk_src_0.

This register is reset only by a destructive reset. For details, see PCFS.

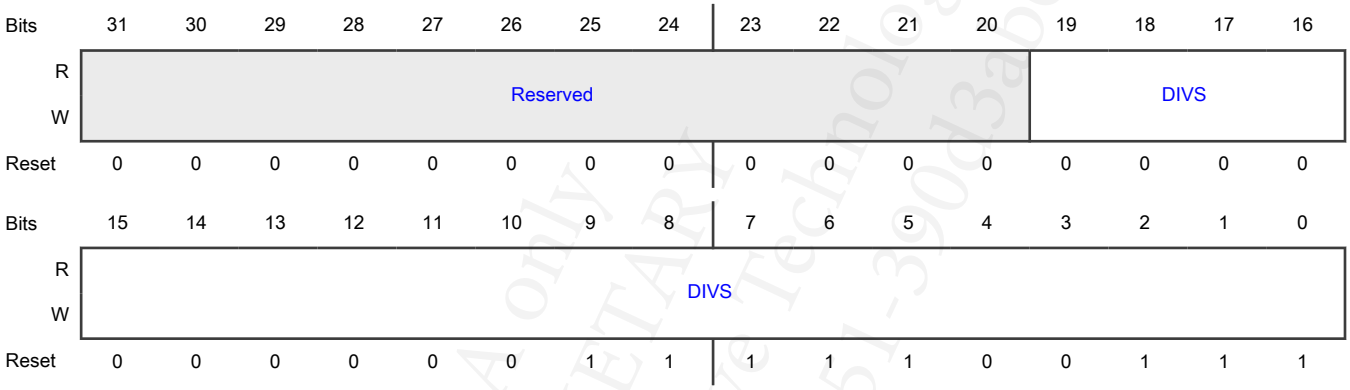
24.5.5 PCFS Divider Start 12 Register (PCFS_DIVS12)

Offset



Register	Offset
PCFS_DIVS12	90h

Function

This register defines the initial division value on frequency ramp-up for the progressive system clock switching of clk_src_12.

This register is reset only on destructive reset.

Diagram

Fields

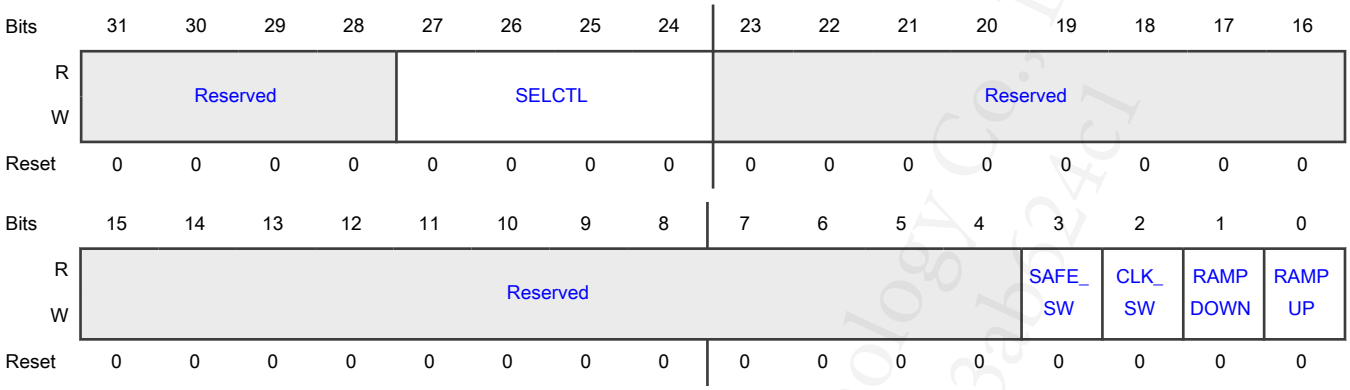
Field	Function
31-20 —	This field is reserved and reads return zeros.
19-0 DIVS	Divider start value This field provides the start value of the clock divider for the clk_src_12 ramp-up phase

24.5.6 Clock Mux 0 Select Control Register (MUX_0_CSC)

Offset

Register	Offset
MUX_0_CSC	300h

Function



This register provides the clock source selection control for clock mux 0. Clock mux 0 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

Provided under NDA only
COMPANY PROPRIETARY

8c462e5-4821-48a8-b251-39043a62401

This register is reset on destructive reset only.

An update to all the PCFS-related fields of this register must be an atomic write, which means a single write must update the CLK_SW, RAMPDOWN, and RAMPUP fields. It is necessary to set both RAMPUP and RAMPDOWN bits together even if you want to trigger either RAMPUP or RAMPDOWN process otherwise the desired PCFS sequence will not be executed.

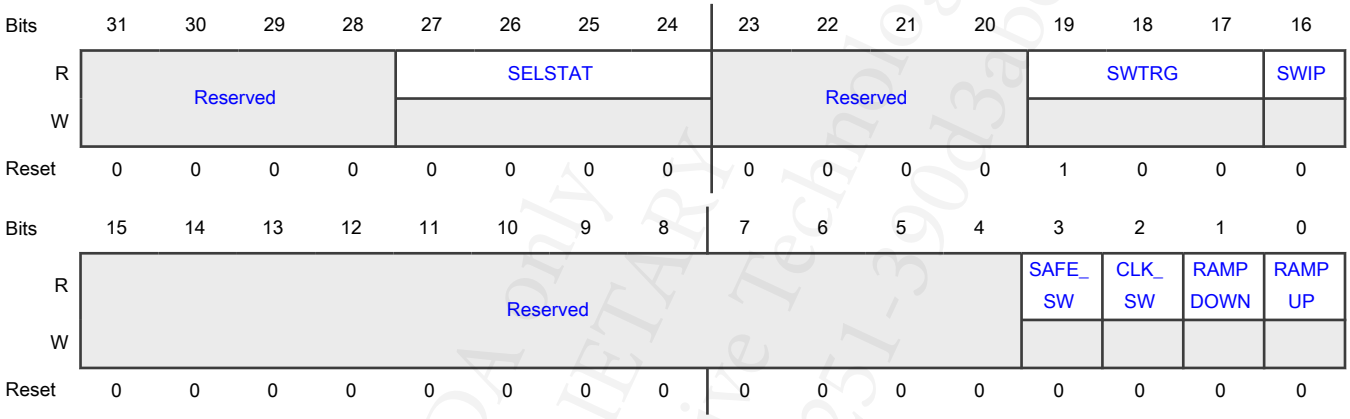
Diagram

Fields

Field	Function
31-28 —	This field is reserved and reads return zeros.
27-24 SELCTL	Clock source selection control Selects the source clock for clock mux 0. The reserved values are not displayed. 0000b - clk_src_0 1100b - clk_src_12
23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request Writing 1 to this bit makes a safe clock switch request to clk_src_0. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 0. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1 RAMPDOWN	PCFS ramp-down Writing 1 to this bit makes a PCFS ramp-down request to clock mux 0. After a PCFS ramp-down operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
0 RAMPUP	PCFS ramp-up Writing 1 to this bit makes a PCFS ramp-up request to clock mux 0. After a PCFS ramp-up operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.

24.5.7 Clock Mux 0 Select Status Register (MUX_0_CSS)

Offset



Register	Offset
MUX_0_CSS	304h

Function

This register provides the current clock source selection status for clock mux 0.

This register is reset on destructive reset only.

Diagram

Fields

Field	Function
31-28 —	This field is reserved and reads return zeros.
27-24 SELSTAT	Clock source selection status This value indicates the current source selected for clock mux 0. The reserved values are not displayed. 0000b - clk_src_0 1100b - clk_src_12
23-20 —	This field is reserved and reads return zeros.
19-17 SWTRG	Switch trigger cause This value indicates the cause for the latest clock source switch.

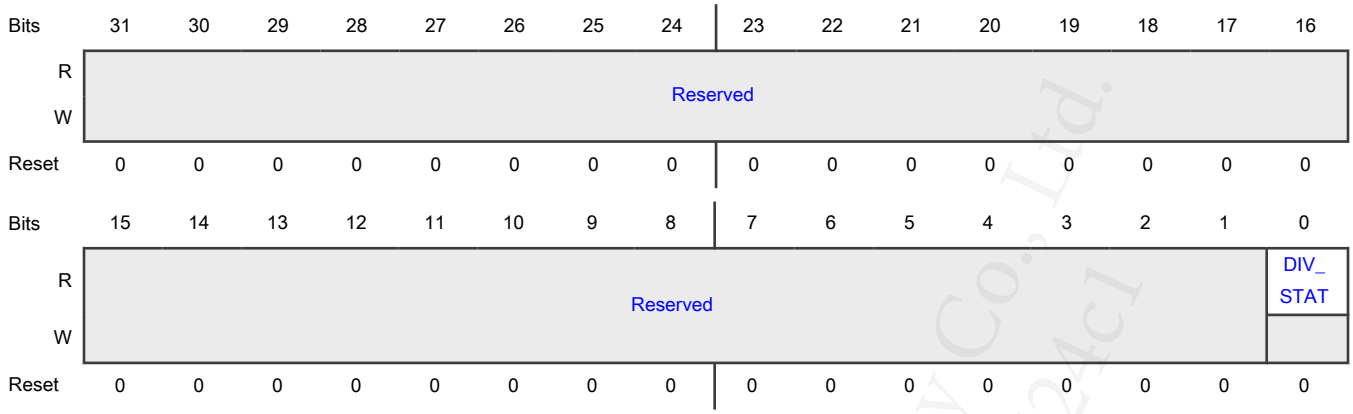
24.5.10 Clock Mux 0 Divider Update Status Register (MUX_0_DIV_UPD_STAT)

Offset



Register	Offset
MUX_0_DIV_UPD_STAT	33Ch

Function

This register provides the update status of the clock dividers corresponding to clock mux 0. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

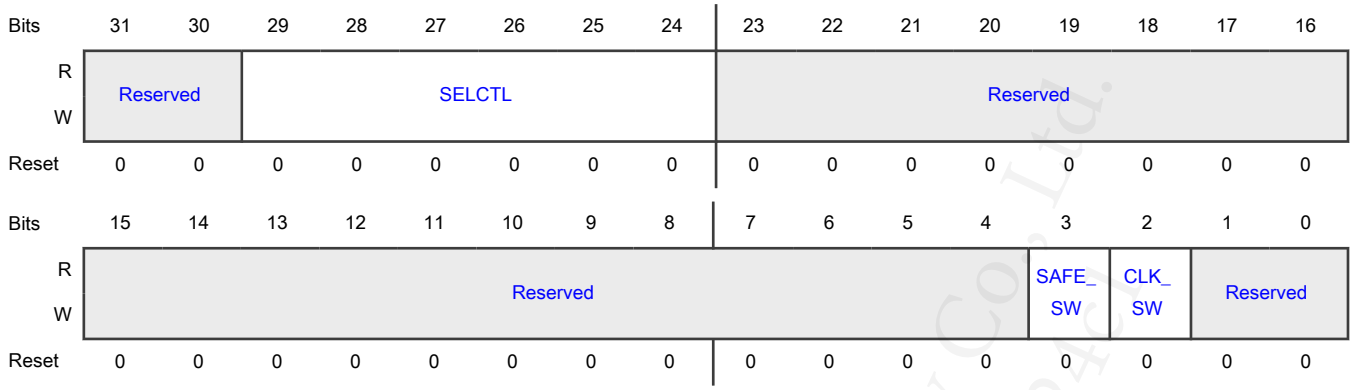
Diagram

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 3 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.23 Clock Mux 4 Select Control Register (MUX_4_CSC)

Offset



Register	Offset
MUX_4_CSC	400h

Function

This register provides the clock source selection control for clock mux 4. Clock mux 4 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request Writing 1 to this bit makes a safe clock switch request to clk_src_0. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 9. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1-0 —	This field is reserved and reads return zeros.

24.5.40 Clock Mux 9 Select Status Register (MUX_9_CSS)

Offset

Register	Offset
MUX_9_CSS	544h

Function

This register provides the current clock source selection status for clock mux 9.

This register is reset on destructive reset only.

31-30 —	This field is reserved and reads return zeros.
29-24 SELSTAT	Clock source selection status This value indicates the current source selected for clock mux 9. The reserved values are not displayed. 000000b - clk_src_0 010110b - clk_src_22 101100b - clk_src_44
23-20 —	This field is reserved and reads return zeros.
19-17 SWTRG	Switch trigger cause This value indicates the cause for the latest clock source switch. **NOTE** If the clock fails, followed by multiple safe clock switch requests for MC_CGM hardware clock mux, the value of the SWTRG field can be either 4 or 5. 000b - Reserved 001b - Switch after request succeeded. 010b - Switch after the request failed because of an inactive target clock and the current clock is clk_src_0. 011b - Switch after the request failed because of an inactive current clock and the current clock is clk_src_0. 100b - Switch to clk_src_0 because of a safe clock request or reset succeeded. 101b - Switch to clk_src_0 because of a safe clock request or reset succeeded, but the previous current clock source was inactive. 110b - Reserved 111b - Reserved
16 SWIP	Switch in progress **NOTE** New clock switch request can only be given three clock cycles after the completion of the previous request. 0b - Clock source switching is complete. 1b - Clock source switching is in progress.
15-4 —	This field is reserved and reads return zeros.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 SAFE_SW	Safe clock request This field provides an indication of whether a switch to safe clock operation was requested during the previous/ongoing request on clock mux 9. 0b - No safe clock switch operation was requested. 1b - Safe clock switch operation was requested.
2 CLK_SW	Clock switch This field provides an indication of whether a clock switch operation was requested during the previous/ ongoing request on clock mux 9. 0b - No clock switch operation was requested. 1b - Clock switch operation was requested.
1-0 —	This field is reserved and reads return zeros.

24.5.41 Clock Mux 9 Divider 0 Control Register (MUX_9_DC_0)

Offset

Register	Offset
MUX_9_DC_0	548h

Function

This register controls the clock divider 0 for clock mux 9.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

Diagram

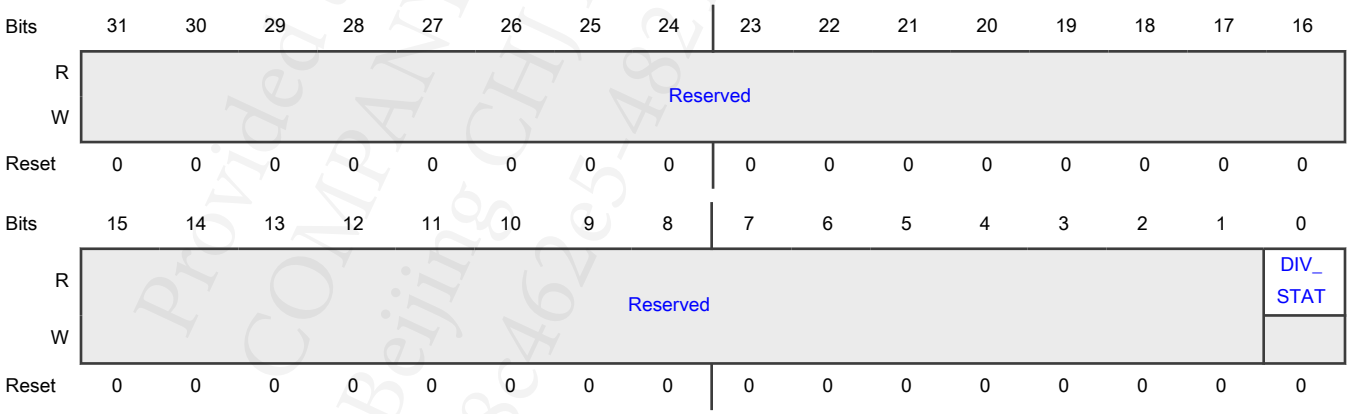
Fields

Field	Function
31 DE	Divider enable 0b - Divider is disabled. 1b - Divider is enabled.
30-24 —	This field is reserved and reads return zeros.
23-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.5.42 Clock Mux 9 Divider Update Status Register (MUX_9_DIV_UPD_STAT)



Offset

Register	Offset
MUX_9_DIV_UPD_STAT	57Ch

Function

This register provides the update status of the clock dividers corresponding to clock mux 9. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

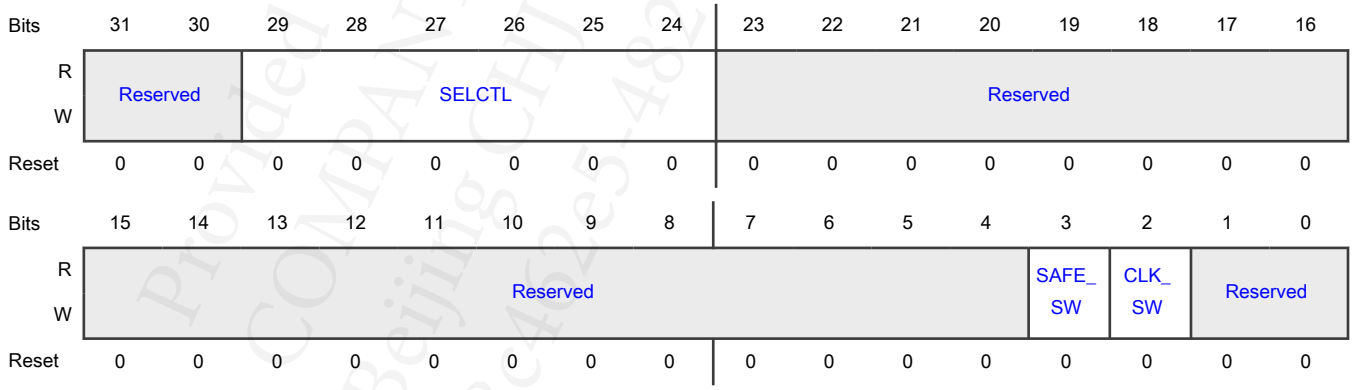
Diagram

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 9 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.43 Clock Mux 10 Select Control Register (MUX_10_CSC)

Offset



Register	Offset
MUX_10_CSC	580h

Function

This register provides the clock source selection control for clock mux 10. Clock mux 10 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Function

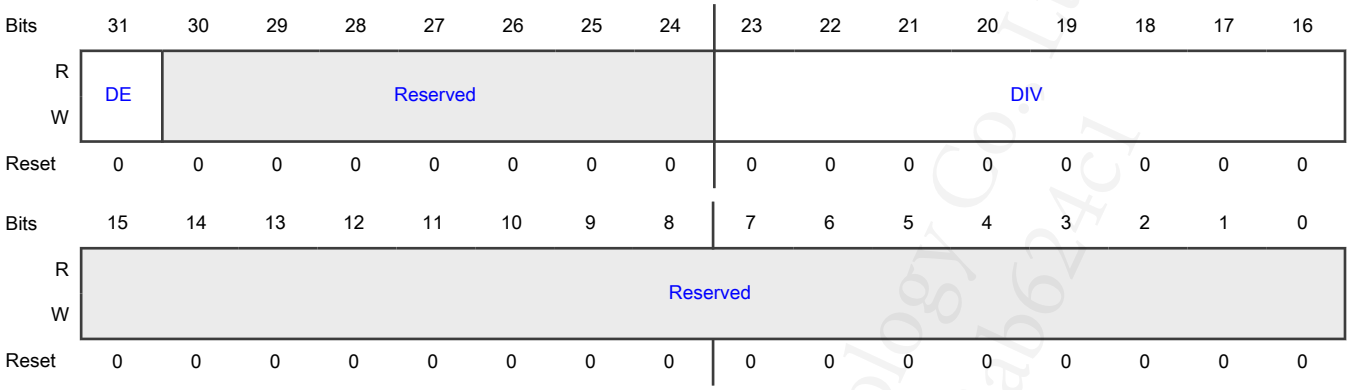
This register controls the clock divider 0 for clock mux 14.



This divider is a 50% duty cycle divider.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.
c8462e5-481-48a8-b251-390d3ab6240

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

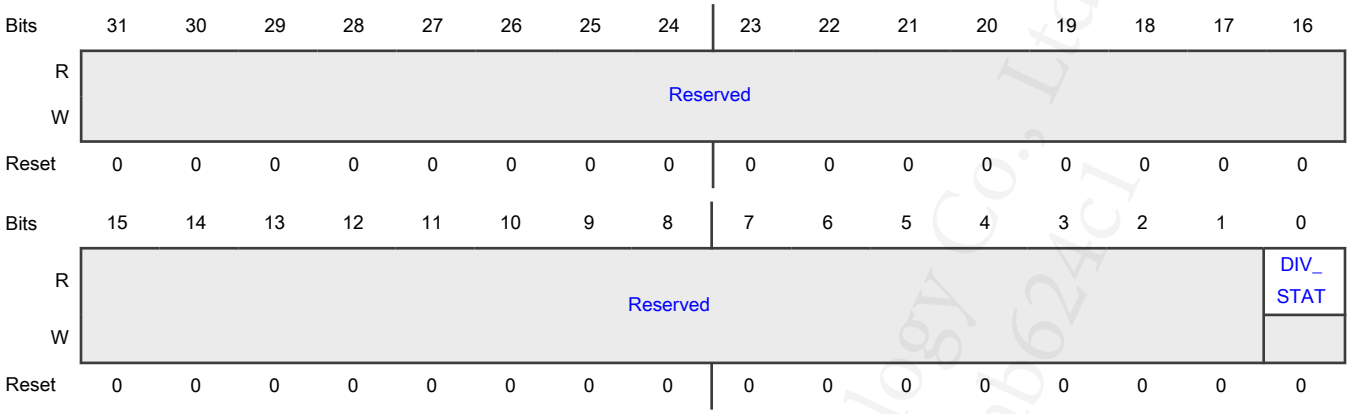
Diagram

Fields

Field	Function
31 DE	Divider enable 0b - Divider is disabled. 1b - Divider is enabled.
30-24 —	This field is reserved and reads return zeros.
23-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.5.56 Clock Mux 14 Divider Update Status Register (MUX_14_DIV_UPD_STAT)

Offset



Register	Offset
MUX_14_DIV_UPD_STAT	6BCh

Function

This register provides the update status of the clock dividers corresponding to clock mux 14. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other

clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

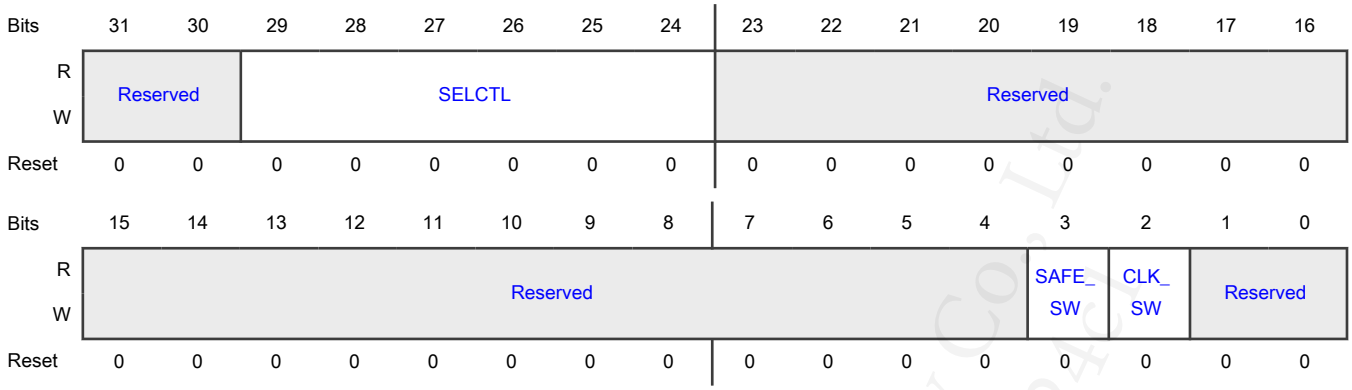
Diagram

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 14 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.57 Clock Mux 15 Select Control Register (MUX_15_CSC)

Offset



Register	Offset
MUX_15_CSC	6C0h

Function

This register provides the clock source selection control for clock mux 15. Clock mux 15 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Diagram

Fields

Field	Function
31-30 —	This field is reserved and reads return zeros.
29-24 SELCTL	Clock source selection control Selects the source clock for clock mux 15. The reserved values are not displayed. 000000b - clk_src_0 100111b - clk_src_39
23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request Writing 1 to this bit makes a safe clock switch request to clk_src_0. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 15. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1-0 —	This field is reserved and reads return zeros.

24.6 MC_CGM_1 register descriptions

MC_CGM implements a set of clock multiplexers that share PCFS configuration registers. MC_CGM registers have the following properties:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits do not terminate with an error, and hardware behavior is unpredictable.
- Writes to read-only register fields in writable registers are ignored and do not provide an error response.
- Writes to read-only registers are aborted with an error response.

24.6.1 MC_CGM_1 memory map

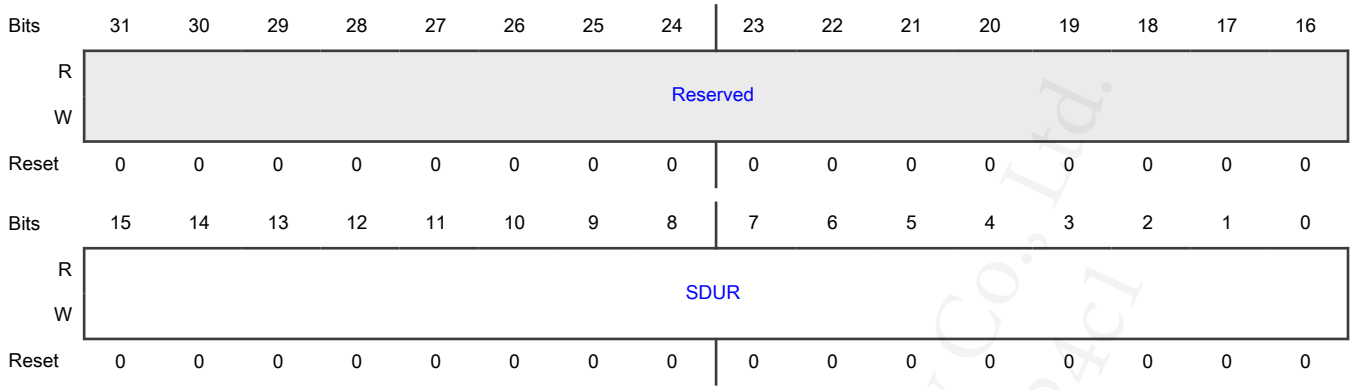
MC_CGM_1 base address: 4003_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	PCFS Step Duration (PCFS_SDUR)	32	RW	0000_0000h
28h	PCFS Divider Change 4 Register (PCFS_DIVC4)	32	RW	0000_0000h
2Ch	PCFS Divider End 4 Register (PCFS_DIVE4)	32	RW	0000_03E7h
30h	PCFS Divider Start 4 Register (PCFS_DIVS4)	32	RW	0000_03E7h
300h	Clock Mux 0 Select Control Register (MUX_0_CSC)	32	RW	0000_0000h
304h	Clock Mux 0 Select Status Register (MUX_0_CSS)	32	RO	0008_0000h

24.6.2 PCFS Step Duration (PCFS_SDUR)

Offset

Register	Offset
PCFS_SDUR	0h



Function

This register specifies the step duration of each PCFS step. The value provided in this register specifies the PCFS step duration in terms of the number of cycles of clk_src_0.

This register is reset only by a destructive reset. For details, see PCFS.

24.6.6 Clock Mux 0 Select Control Register (MUX_0_CSC)

Offset

Register	Offset
MUX_0_CSC	300h

Function

This register provides the clock source selection control for clock mux 0. Clock mux 0 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

An update to all the PCFS-related fields of this register must be an atomic write, which means a single write must update the CLK_SW, RAMPDOWN, and RAMPUP fields. It is necessary to set both RAMPUP and RAMPDOWN bits together even if you want to trigger either RAMPUP or RAMPDOWN process otherwise the desired PCFS sequence will not be executed.

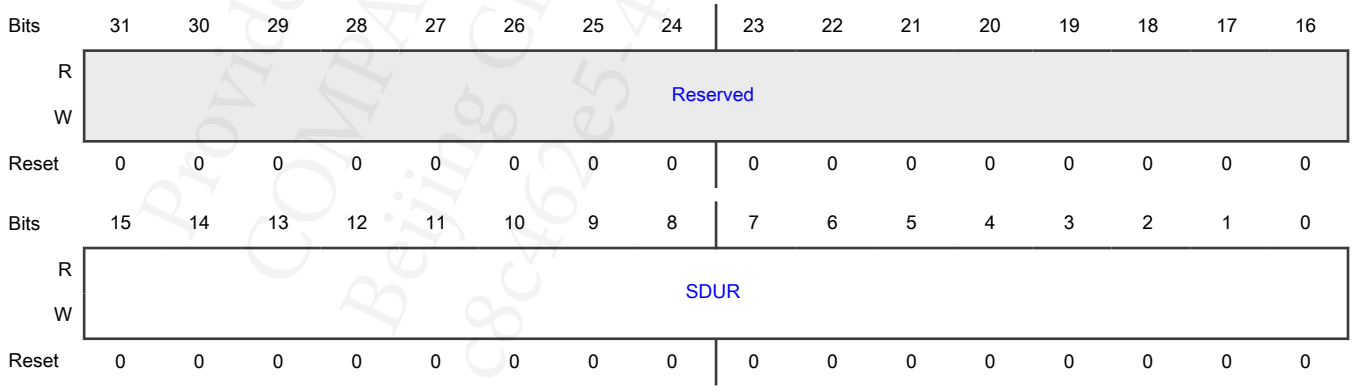
24.7.2 PCFS Step Duration (PCFS_SDUR)

Offset



Register	Offset
PCFS_SDUR	0h

Function

This register specifies the step duration of each PCFS step. The value provided in this register specifies the PCFS step duration in terms of the number of cycles of clk_src_0.

This register is reset only by a destructive reset. For details, see PCFS.

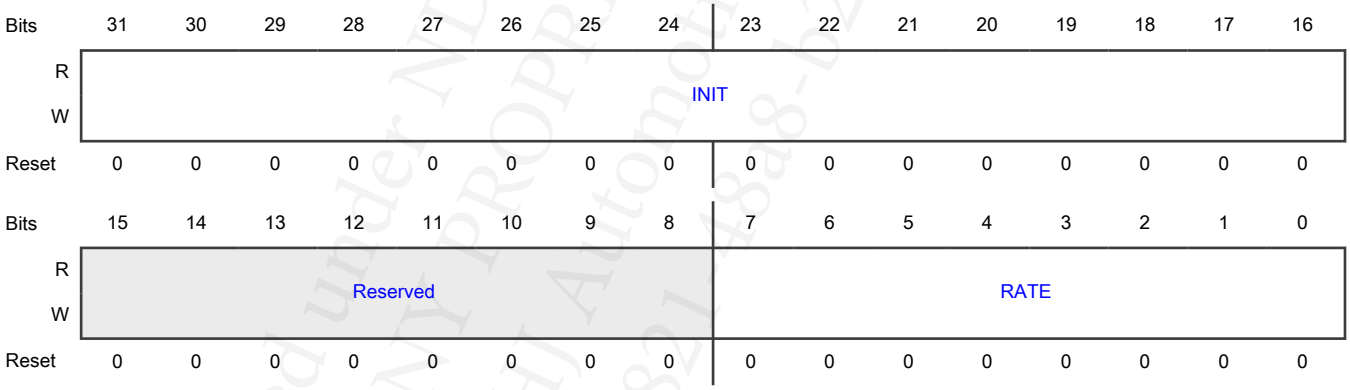
Diagram

Fields

Field	Function
31-16 —	This field is reserved and reads return zeros.
15-0 SDUR	Step duration Count value of the step duration

24.7.3 PCFS Divider Change 33 Register (PCFS_DIVC33)

Offset



Register	Offset
PCFS_DIVC33	184h

Function

This register defines the rate of frequency change and initial change value on frequency ramp-up for the Progressive Clock Frequency switching of clk_src_33.

This register is reset only on destructive reset.

Diagram

Fields

Field	Function
31-16 INIT	Divider change initial value This field provides the initial change value of the clock divider for the clock ramp-up phase of clk_src_33.
15-8 —	This field is reserved and reads return zeros.

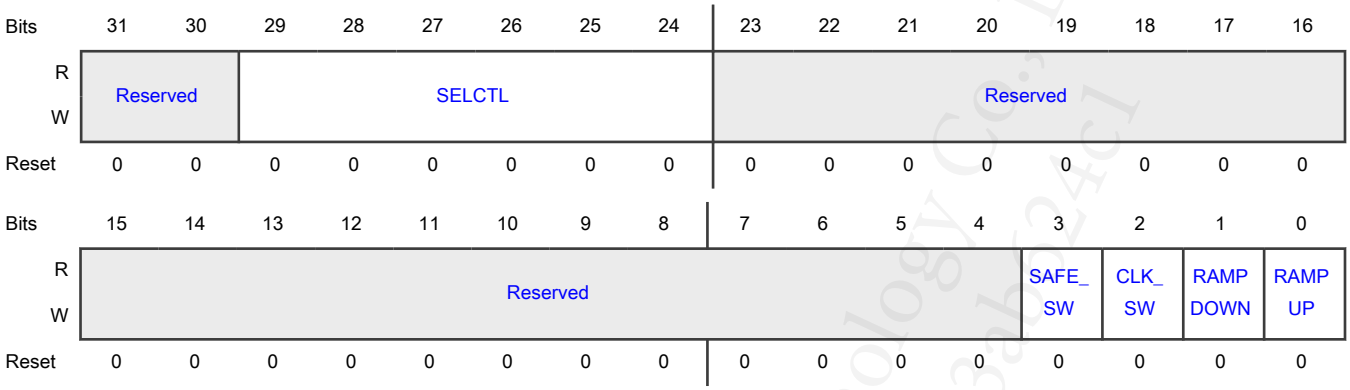
24.7.6 Clock Mux 0 Select Control Register (MUX_0_CSC)

Offset

Register	Offset
MUX_0_CSC	300h

Function



This register provides the clock source selection control for clock mux 0. Clock mux 0 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CTI Automotive Technology Co., Ltd.
8c462e5-4821-48a8-b251-39043a62401

This register is reset on destructive reset only.

An update to all the PCFS-related fields of this register must be an atomic write, which means a single write must update the CLK_SW, RAMPDOWN, and RAMPUP fields. It is necessary to set both RAMPUP and RAMPDOWN bits together even if you want to trigger either RAMPUP or RAMPDOWN process otherwise the desired PCFS sequence will not be executed.

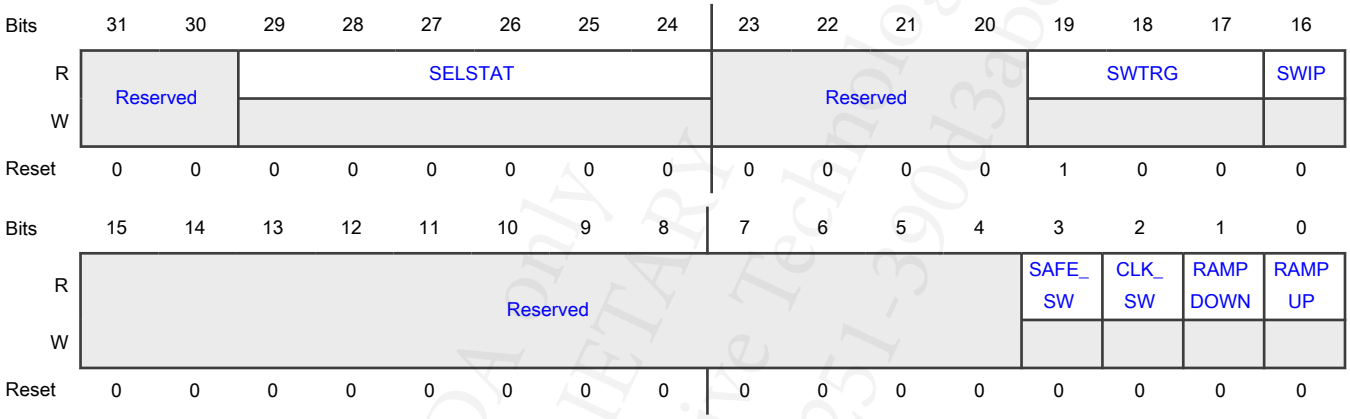
Diagram

Fields

Field	Function
31-30 —	This field is reserved and reads return zeros.
29-24 SELCTL	Clock source selection control Selects the source clock for clock mux 0. The reserved values are not displayed. 000000b - clk_src_0 100001b - clk_src_33
23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request Writing 1 to this bit makes a safe clock switch request to clk_src_0. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 0. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1 RAMPDOWN	PCFS ramp-down Writing 1 to this bit makes a PCFS ramp-down request to clock mux 0. After a PCFS ramp-down operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
0 RAMPUP	PCFS ramp-up Writing 1 to this bit makes a PCFS ramp-up request to clock mux 0. After a PCFS ramp-up operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.

24.7.7 Clock Mux 0 Select Status Register (MUX_0_CSS)

Offset



Register	Offset
MUX_0_CSS	304h

Function

This register provides the current clock source selection status for clock mux 0.

This register is reset on destructive reset only.

Diagram

Fields

Field	Function
31-30 —	This field is reserved and reads return zeros.
29-24 SELSTAT	Clock source selection status This value indicates the current source selected for clock mux 0. The reserved values are not displayed. 000000b - clk_src_0 100001b - clk_src_33
23-20 —	This field is reserved and reads return zeros.
19-17 SWTRG	Switch trigger cause This value indicates the cause for the latest clock source switch.

	NOTE If the clock fails, followed by multiple safe clock switch requests for MC_CGM hardware clock mux, the value of the SWTRG field can be either 4 or 5. 000b - Reserved 001b - Switch after request succeeded. 010b - Switch after the request failed because of an inactive target clock and the current clock is clk_src_0. 011b - Switch after the request failed because of an inactive current clock and the current clock is clk_src_0. 100b - Switch to clk_src_0 because of a safe clock request or reset succeeded. 101b - Switch to clk_src_0 because of a safe clock request or reset succeeded, but the previous current clock source was inactive. 110b - Reserved 111b - Reserved
16 SWIP	Switch in progress **NOTE** New clock switch request can only be given three clock cycles after the completion of the previous request. 0b - Clock source switching is complete. 1b - Clock source switching is in progress.
15-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request This field provides an indication of whether a switch to safe clock operation was requested during the previous/ongoing request on clock mux 0. 0b - No safe clock switch operation was requested. 1b - Safe clock switch operation was requested.
2 CLK_SW	Clock switch This field provides an indication of whether a clock switch operation was requested during the previous/ongoing request on clock mux 0. 0b - No clock switch operation was requested. 1b - Clock switch operation was requested.
1 RAMPDOWN	PCFS ramp-down

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field provides an indication of whether a PCFS ramp-down operation was requested during the previous/ongoing request on clock mux 0. **NOTE** In case of safe clock switching, the ramp-down operation runs internally, but the value of the corresponding status field is not set to 1. 0b - No ramp-down operation was requested. 1b - Ramp-down operation was requested.
0 RAMPUP	PCFS ramp-up This field provides an indication of whether a PCFS ramp-up operation was requested during the previous/ ongoing request on clock mux 0. 0b - No ramp-up operation was requested. 1b - Ramp-up operation was requested.

24.7.8 Clock Mux 0 Divider 0 Control Register (MUX_0_DC_0)

Offset

Register	Offset
MUX_0_DC_0	308h

Function

This register controls the clock divider 0 for clock mux 0.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

Diagram

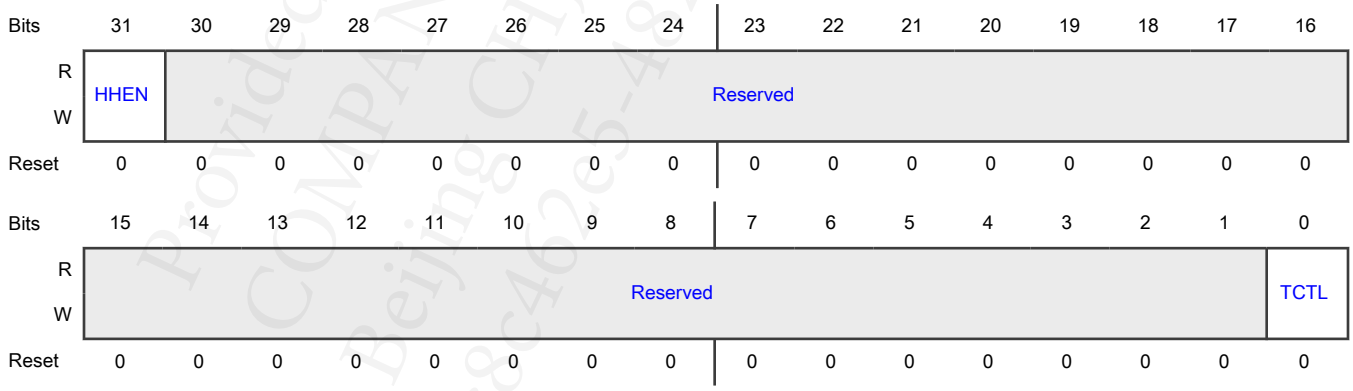
31 DE	Divider enable 0b - Divider is disabled. 1b - Divider is enabled.
30-20 —	This field is reserved and reads return zeros.
19-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.7.9 Clock Mux 0 Divider Trigger Control Register (MUX_0_DIV_TRIG_CTRL)



Offset

Register	Offset
MUX_0_DIV_TRIG_CTRL	334h

Function

This register selects whether the dividers associated with clock mux 0 are updated immediately on writing to the corresponding divider configuration register (referred to as immediate divider update) or only on writing to the MC_CGM_MUX_0_DIV_TRIG register (referred to as common trigger update). When common trigger update is configured, this register also controls initiation of the halt handshake protocol with the on-chip AXBS. Software is required to configure HHEN field for handshaking with on-chip AXBS when the ratio of division value among the clock dividers need to be changed.

Diagram

Provided under NDA only
COMPANY PROPRIETARY

Fields

Field	Function
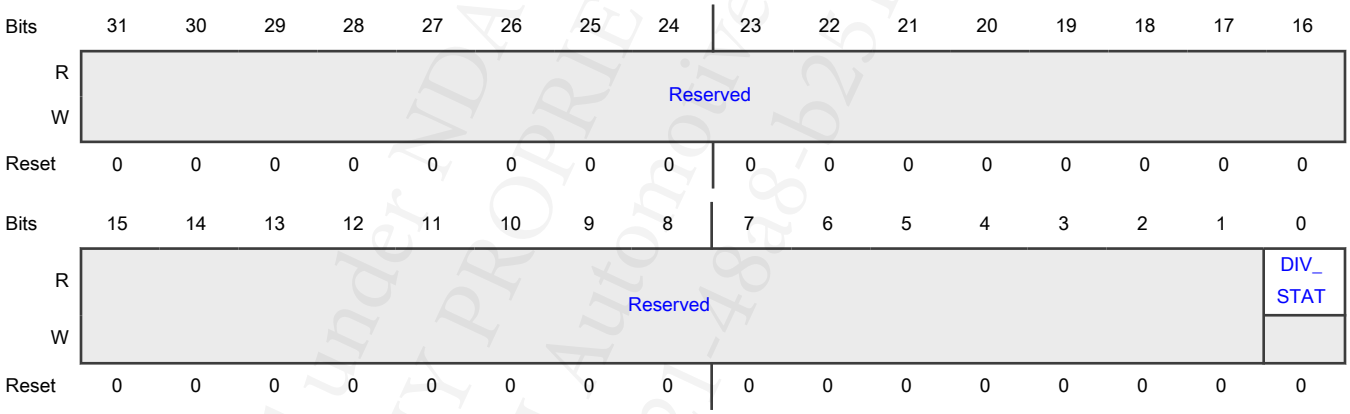
31-0 TRIGGER	Trigger for divider update

24.7.11 Clock Mux 0 Divider Update Status Register (MUX_0_DIV_UPD_STAT)



Offset

Register	Offset
MUX_0_DIV_UPD_STAT	33Ch

Function

This register provides the update status of the clock dividers corresponding to clock mux 0. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

Diagram

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 0 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source:

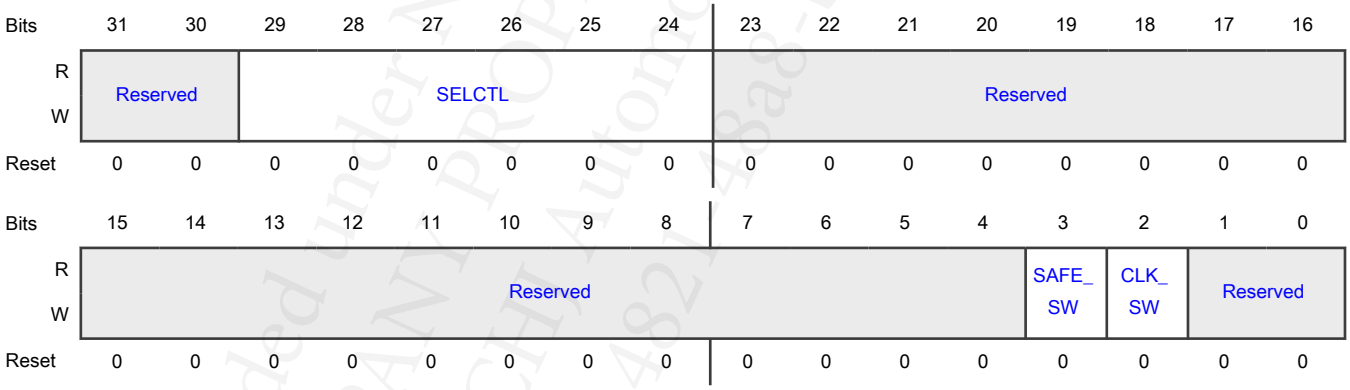
Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.7.12 Clock Mux 1 Select Control Register (MUX_1_CSC)

Offset



Register	Offset
MUX_1_CSC	340h

Function

This register provides the clock source selection control for clock mux 1. Clock mux 1 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Diagram

24.7.21 Clock Mux 2 Divider 0 Control Register (MUX_2_DC_0)

Offset

Register	Offset
MUX_2_DC_0	388h

Function

This register controls the clock divider 0 for clock mux 2.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

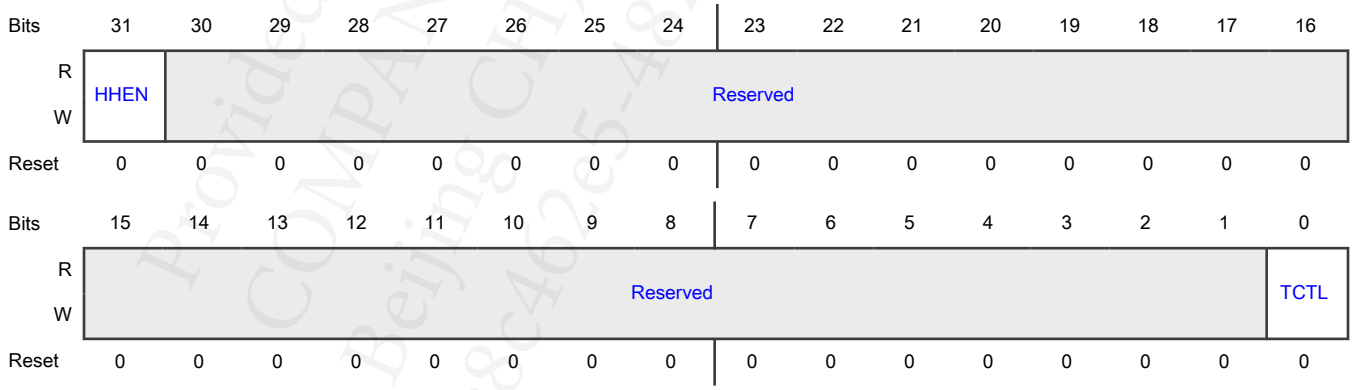
24.7.23 Clock Mux 2 Divider Trigger Control Register (MUX_2_DIV_TRIG_CTRL)



Offset

Register	Offset
MUX_2_DIV_TRIG_CTRL	3B4h

Function

This register selects whether the dividers associated with clock mux 2 are updated immediately on writing to the corresponding divider configuration register (referred to as immediate divider update) or only on writing to the MC_CGM_MUX_2_DIV_TRIG register (referred to as common trigger update). When common trigger update is configured, this register also controls initiation of the halt handshake protocol with the on-chip AXBS. Software is required to configure HHEN field for handshaking with on-chip AXBS when the ratio of division value among the clock dividers need to be changed.

Diagram

30-1 —	This field is reserved and reads return zeros.
0 TCTL	Trigger control This field controls the divider update configuration between immediate and common update. 0b - Immediate divider update 1b - Common trigger divider update

24.7.24 Clock Mux 2 Divider Trigger Register (MUX_2_DIV_TRIG)

Offset

Register	Offset
MUX_2_DIV_TRIG	3B8h

Function

This register provides a common trigger for the clock dividers (only 50% duty cycle dividers) of clock mux 2. Writing any value to this register provides a trigger to the dividers. This register should only be written after appropriately configuring the MC_CGM_MUX_2_DIV_TRIG_CTRL register.

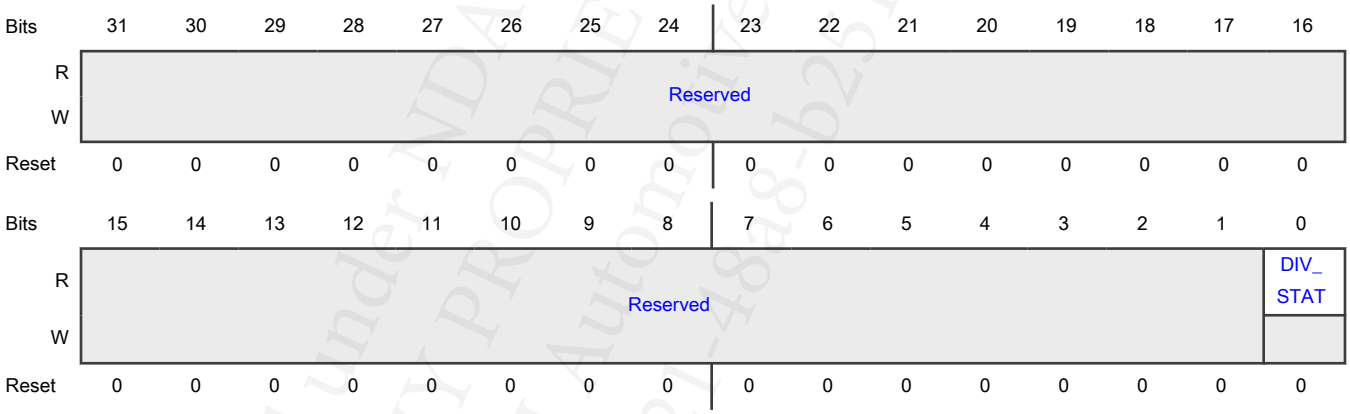
Field	Function
31-0 TRIGGER	Trigger for divider update

24.7.25 Clock Mux 2 Divider Update Status Register (MUX_2_DIV_UPD_STAT)



Offset

Register	Offset
MUX_2_DIV_UPD_STAT	3BCh

Function

This register provides the update status of the clock dividers corresponding to clock mux 2. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

Diagram

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 2 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.7.26 Clock Mux 3 Select Control Register (MUX_3_CSC)

Offset

Register	Offset
MUX_3_CSC	3C0h

Function

This register provides the clock source selection control for clock mux 3. Clock mux 3 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

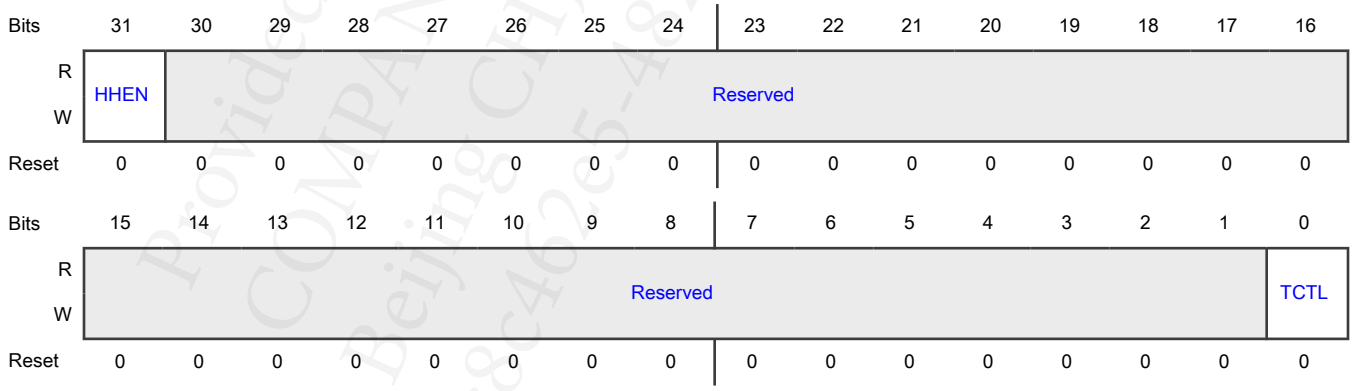
24.7.42 Clock Mux 7 Divider Trigger Control Register (MUX_7_DIV_TRIG_CTRL)



Offset

Register	Offset
MUX_7_DIV_TRIG_CTRL	4F4h

Function

This register selects whether the dividers associated with clock mux 7 are updated immediately on writing to the corresponding divider configuration register (referred to as immediate divider update) or only on writing to the MC_CGM_MUX_7_DIV_TRIG register (referred to as common trigger update). When common trigger update is configured, this register also controls initiation of the halt handshake protocol with the on-chip AXBS. Software is required to configure HHEN field for handshaking with on-chip AXBS when the ratio of division value among the clock dividers need to be changed.

Diagram

Fields

Field	Function
31 HHEN	Halt handshake enable This field controls the initiation of the halt handshake protocol with AXBS when a common trigger divider update is initiated. 0b - No halt handshake protocol is initiated. 1b - Halt handshake protocol is initiated.

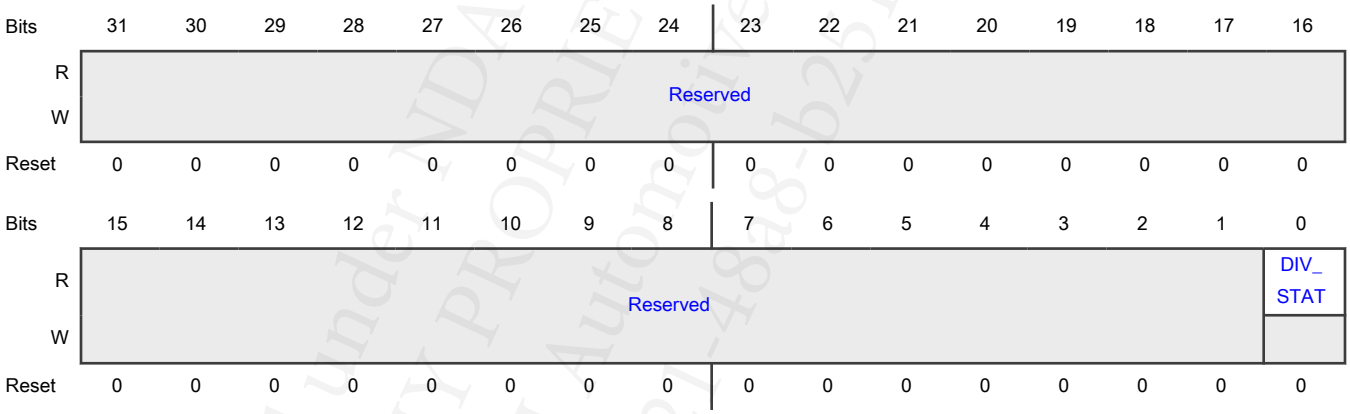
24.7.44 Clock Mux 7 Divider Update Status Register (MUX_7_DIV_UPD_STAT)



Offset

Register	Offset
MUX_7_DIV_UPD_STAT	4FCh

Function

This register provides the update status of the clock dividers corresponding to clock mux 7. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

Diagram

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 7 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source:

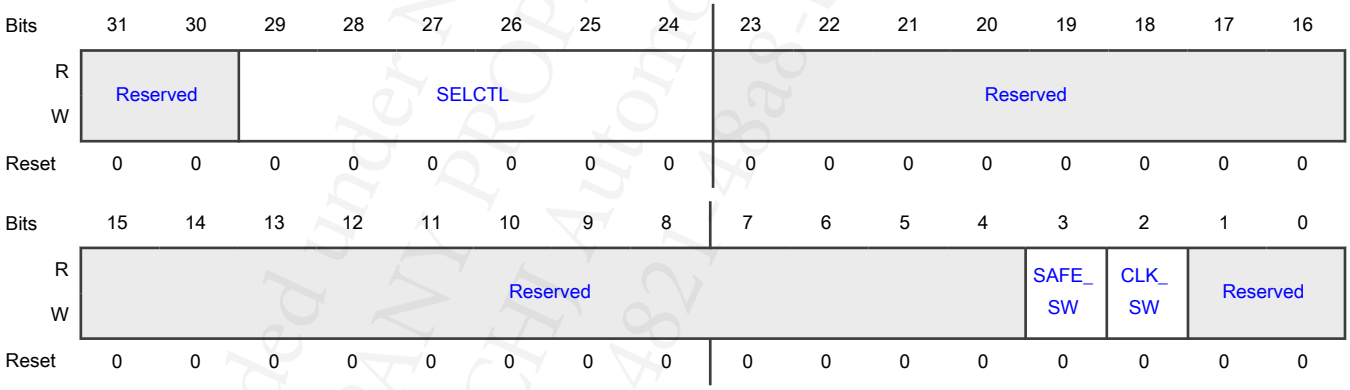
Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.7.45 Clock Mux 8 Select Control Register (MUX_8_CSC)

Offset



Register	Offset
MUX_8_CSC	500h

Function

This register provides the clock source selection control for clock mux 8. Clock mux 8 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

30-1 —	This field is reserved and reads return zeros.
0 TCTL	Trigger control This field controls the divider update configuration between immediate and common update. 0b - Immediate divider update 1b - Common trigger divider update

24.7.55 Clock Mux 9 Divider Trigger Register (MUX_9_DIV_TRIG)

Offset

Register	Offset
MUX_9_DIV_TRIG	578h

Function

This register provides a common trigger for the clock dividers (only 50% duty cycle dividers) of clock mux 9. Writing any value to this register provides a trigger to the dividers. This register should only be written after appropriately configuring the MC_CGM_MUX_9_DIV_TRIG_CTRL register.

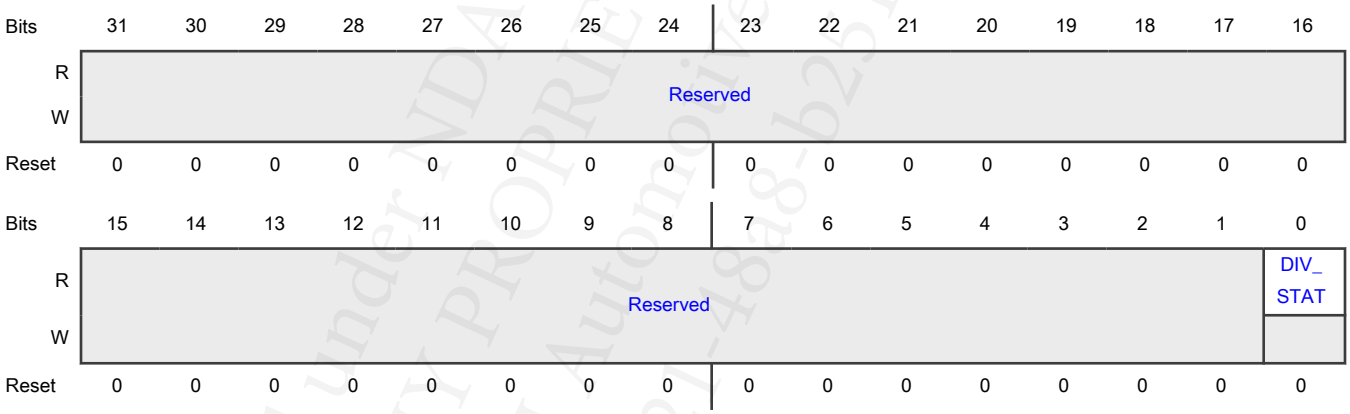
24.7.56 Clock Mux 9 Divider Update Status Register (MUX_9_DIV_UPD_STAT)



Offset

Register	Offset
MUX_9_DIV_UPD_STAT	57Ch

Function

This register provides the update status of the clock dividers corresponding to clock mux 9. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

Diagram

0 DIV_STAT	Divider status for clock mux 9 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.8 MC_CGM_5 register descriptions

MC_CGM implements a set of clock multiplexers that share PCFS configuration registers. MC_CGM registers have the following properties:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits do not terminate with an error, and hardware behavior is unpredictable.
- Writes to read-only register fields in writable registers are ignored and do not provide an error response.
- Writes to read-only registers are aborted with an error response.

1-0 —	This field is reserved and reads return zeros.

24.9 Functional description

24.9.1 Clock selection multiplexer

Each of the clock multiplexers inside the MC_CGM either implements a fully hardware-controlled clock multiplexer or a software-controlled clock multiplexer. The following sections describe the two variants of the clock multiplexer.

24.9.1.1 Hardware-controlled clock multiplexer

In hardware-based clock multiplexing, the underlying assumption is that under some conditions, error or reset states, software may not be active. Therefore, the clock switching is fully hardware based and is glitchless. To facilitate clock switching requests with software, the MUX_n_CSC and MUX_n_CSS registers implement request and status for the clock multiplexer, the rest is managed in hardware. Using these registers, the software can monitor the state of the hardware-based clock multiplexer

and also make clock switching requests. It is recommended that a new clock switch request is given only when there are no pending/ongoing clock switching requests. However, a switch to the safe clock, that is, clk_src_0, can be performed at any instance of time. A switch to the safe clock is always completed. Software should ensure that while making a software-based switch to safe clock, the register configuration clock should be available, at least for completing the write to the MUX_n_CSC register. This means that the clock should be running for the register write to complete. Hardware clock multiplexer also supports hardware-based switch to safe clock, which is requested externally to MC_CGM (for example, by MC_RGM). For a hardware-based switch to safe clock, it is not required to have a register configuration clock for MC_CGM.

NOTE

- "Switch to safe clock" from software is requested by programming the MUX_n_CSC[SAFE_SW] bit field only and not by combining the MUX_n_CSC[CLK_SW] and MUX_n_CSC[SELCTL] bit fields of the MUX_n_CSC register. Writes to other fields are ignored when requesting switch for safe clock.
- After the switch to the safe clock requested by the MC_RGM has completed, the MC_RGM also requests the clock dividers to switch to their default values. This hardware-triggered divider update can be monitored in the same manner as for software-configured updates, and software should use it to ensure that the configuration update has completed before reconfiguring the clocks.
- Write accesses to the MUX_n_CSC register with clock select pointing to the "reserved" input clock source are aborted with bus transfer errors.

See Figure 98 that shows the flowchart representation for the sequence of steps to be followed when making a clock switch request to hardware-controlled clock multiplexer. Switch to safe clock can be requested at any instance of time, and for clarity reasons, it is not shown in Figure 98.

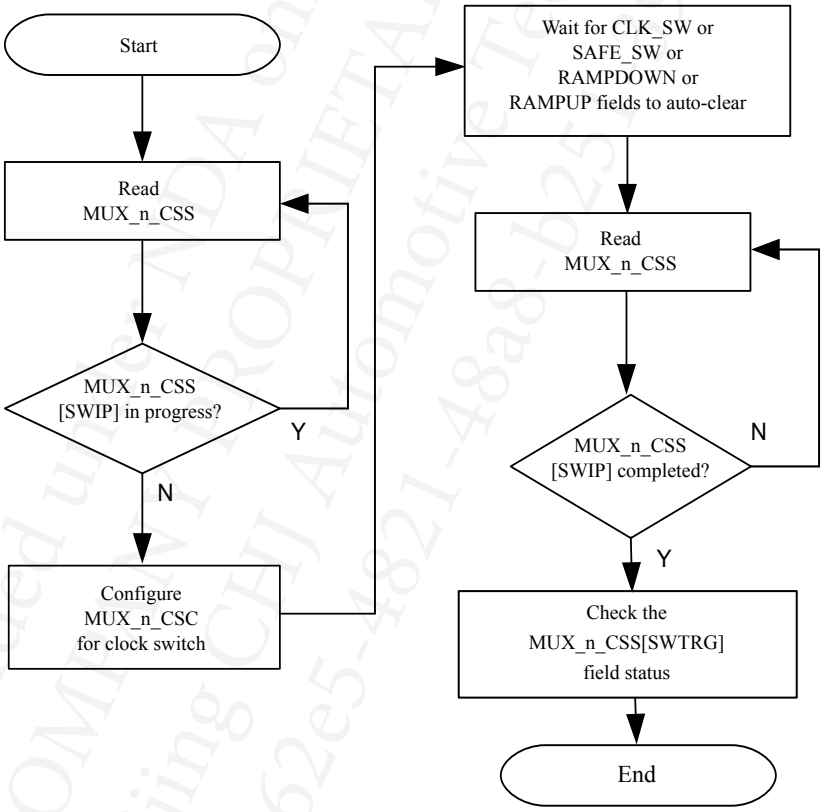

Figure 98. Flow for clock switch request on hardware-controlled clock multiplexer

NOTE

- A switch to the safe clock command always leads to a ramp-down from the currently selected clock and then a switch to "safe clock", except when there is an ongoing clock switch requested by the software without ramp-up and ramp-down. A safe clock switch request when there is an ongoing clock switch without ramp-up or ramp-down results in a switch to the safe clock without performing a ramp-down (either by MC_RGM or provided using the MUX_n_CSC register) does not perform a ramp-down before switching to "safe clock".
- The above flowchart steps can be preceded by points 1 and 3 below:
  1. Disable the divider.
  2. Switch clocks through hardware multiplexer.
  3. Enable and configure the dividers (atomic write instruction).

24.9.1.2 Software-controlled clock multiplexer

In software-based clock multiplexing, the underlying assumption is that the software is always available and there are no error or reset conditions in the chip. This implies that a glitchless switch between input clock sources of MC_CGM MUX can be achieved by following a sequence of steps in software. The software-based clock multiplexer implements a clock gate at the output of the clock mux. The software can gate the selected clock of MC_CGM MUX using a synchronous/graceful clock gate bit (that is, MUX_n_CSC[CG]) or a forced clock gate bit (that is, MUX_n_CSC[FCG]). The hardware does not guarantee that any glitches will escape when using forced clock gating. When a forced clock gate bit is written to 1, the internal clock gate forcefully gates the selected clock to logic-0, therefore, to avoid clock glitches, it should be ensured that the selected clock source is not running. See Figure 99 that shows the flowchart representation for the sequence of steps to be followed when making a clock switch request to software-controlled clock multiplexer. No switch to safe clock is supported in software-controlled clock multiplexer.

Provided under NDA of COMPANY PROPRIETARY Beijing CHJ Automotive Technology Co., Ltd. c8c462e5-4821-48a8-b251-3[illegible]624c1

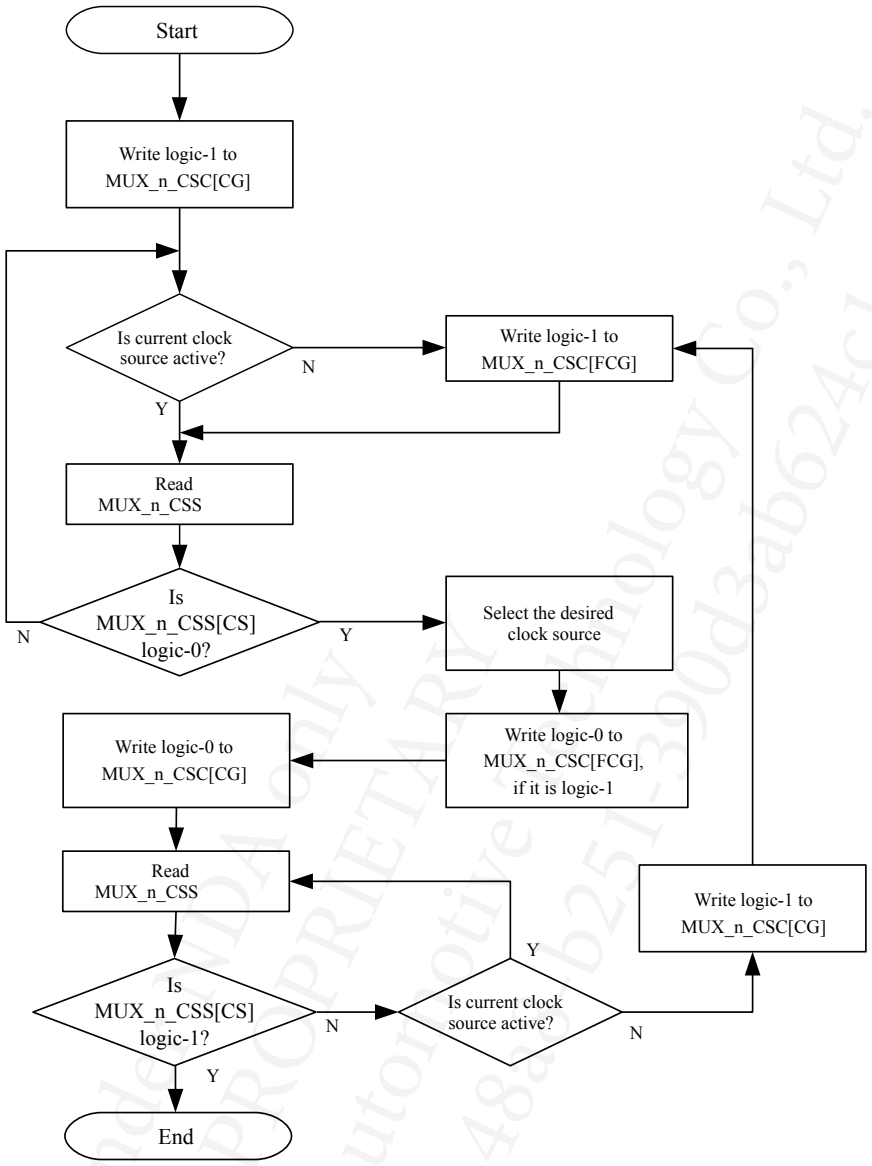

Figure 99. Flow for clock switch request on software controlled clock multiplexer

NOTE

- Ensure that before using the force gate bit, any IP or other logic using the clock of MC_CGM MUX is in the inactive state or a clock glitch resulting from usage of forced gating does not effect the IP (that is, it is clock gated after the MC_CGM).
- In Figure 99, the clock source to be selected should be active at the time of clock switch, else the MUX_n_CSS[CS] field will remain set to logic-0. In case the clock source to be selected becomes inactive (that is, loss of clock, and so on) during the switching operation, the switch to another clock source can be initiated by writing both the MUX_n_CSC[CG] and MUX_n_CSC[FCG] fields to logic-1.
- Writing a 'reserved' value for the MUX_n_CSC[SELCTL] field may result in an unpredictable clock at the output of the clock multiplexer.

NOTE

The above flowchart steps can be preceded by points 1 and 3 below:

1. Disable the divider.
2. Switch clocks through software multiplexer.
3. Enable and configure the dividers (atomic write instruction).

24.9.2 PCFS

MC_CGM implements PCFS when changing clock source at an MC_CGM clock mux. The PCFS is only implemented in a hardware-controlled clock multiplexer and not in a software-controlled clock multiplexer. It allows a gradual load change for a power/voltage supply unit by employing a gradual frequency changeover from one to another. The frequency changeover is achieved by clock division of input clock source with a sequence of division values, where frequency ramp down and ramp up is achieved when the sequence of division values are ascending and descending in nature, respectively. As the clock division (fractional) is implemented in digital logic, therefore, it is a coarse-level clock division rather than being an accurate-level division, implying that the duty cycle of the progressively divided clock can vary with time.

The PCFS feature is utilized when a drain current to frequency relationship is known, that is, for a given drain current what is the maximum allowed change in frequency (f_{chg}). The f_{chg} is the first input parameter for PCFS and other parameters for PCFS are specified or calculated in relation to clk_src_0.

The PCFS hardware generates the clock division factors based on certain values that are programmed into the PCFS configuration register. The following pseudo codes represent the generation of clock division value sequence (d_i).

```
/* ramp down division values (d_n) with k steps*/
      delta_1 = RATE/1000;
      delta_2 = RATE/1000;
      d_0     = 1.0;
      for i=1 to k-1 do
        d_i = d_i-1 + delta_1;
        delta_1 = delta_1 + delta_2;
      endfor
```

```
/* ramp up division values (d_n) with k steps*/
      delta_1 = RATE*k/1000;
      delta_2 = RATE/1000;
      d_0     = 1.0 + RATE*k*(k+1)/2;
      for i=1 to k-1 do
        d_i = d_i-1 - delta_1;
        delta_1 = delta_1 - delta_2;
    endfor
```

As the generation of clock division values is not a closed-bounded function, calculating RATE for a given f_{chg} is an iterative process. Find a value of RATE that produces a clock division sequence, which when used does not lead to a frequency change greater than f_{chg}. See Table 106 that tabulates some of the RATE values against a_{max}, where

$$a_{max}=f_{chg}/F_i$$

where, F_i is the frequency of i^{th} input clock source of the clock mux.

Table 106. PCFS RATE values

a_{max}	PCFS rate
0.005	12
0.01	48

Table continues on the next page...

Table 106. PCFS RATE values (continued)

a_{max}	PCFS rate
0.15	112
0.20	184

The last clock division factor in case of ramp-down or the first clock in case of ramp-up (following a ramp-down procedure), should be such that clock switch from any input clock source to another should be termed as safe, indicating that load changes have sustainable power effects. This frequency level is referred to as "safe frequency", equivalent to frequency of clk_src_0 referred to as "safe clock" with frequency "safe clock frequency" (f_{safe}). The last clock division factor in the sequence of clock division factors happens after "k" steps. The factor k (=steps) is calculated by using the following formula:

$$k = ceil(0.5 + sqrt(0.25 - (2000 * (1 - (F_i/f_{safe})) / RATE)))$$

Using the above formula, all the PCFS register configuration values can be calculated for a given frequency of a clock source:

$$PCFS\_DIVEi.DIV = (F_i/f_{safe})*1000-1;$$

```
        PCFS_DIVCi.INIT = RATE * k;
        PCFS_DIVCi.RATE = RATE;
        PCFS_DIVSi.DIV  = 999 + (RATE * k * (k+1)/2);
```

See Figure 100 that shows a graphical representation of the change in frequency, which happens during PCFS ramp-down and ramp-up.

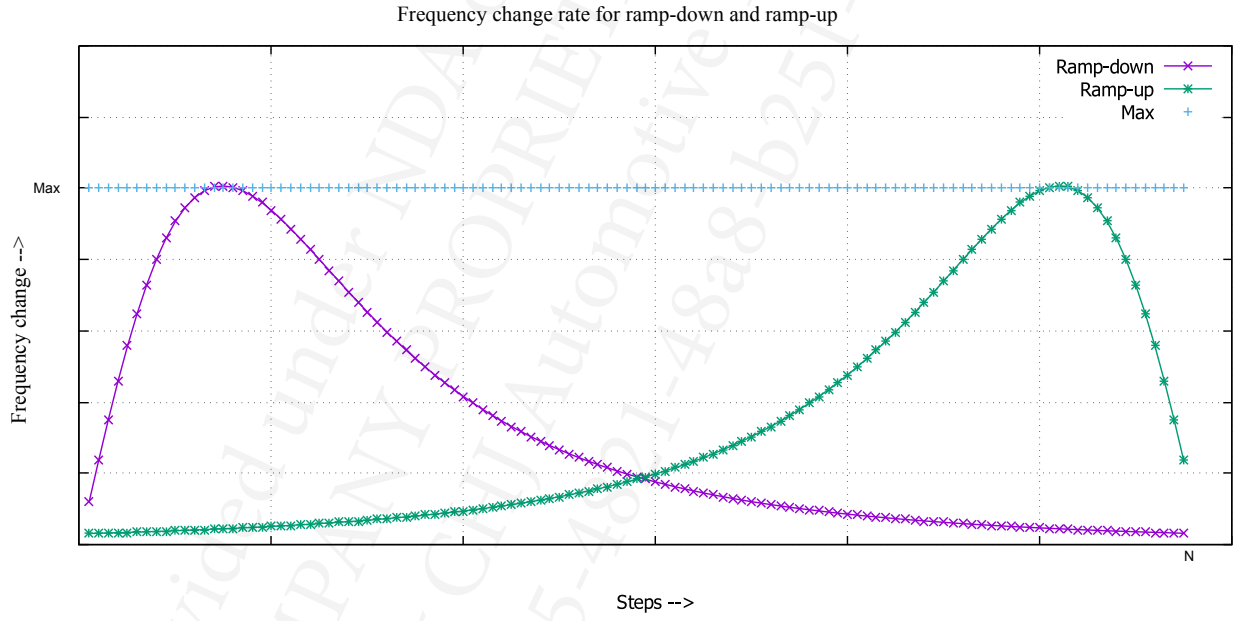

Figure 100. PCFS steps vs frequency changes

For any given clock source, if its frequency is less than that of clk_src_0, then its corresponding registers should be programmed to default values, where the default values are such that PCFS divider start and PCFS divider end values are same and equal to divide-by-1. The default values ensure that no progressive clock division is done when a clock switch request is given to switch from or to that source.

NOTE

Calculate the minimum frequency during the PCFS RAMPDOWN and RAMPUP operations by using the formula:

```
(clk_src_0/((PCFS_DIVE+1)/1000)) MHz
```

24.9.2.1 PCFS control

The PCFS operation is configured by a set of configuration registers. One set pertains to the calculation of the clock division factors, which are PCFS_DIVC, PCFS_DIVE, PCFS_DIVS, and PCFS_SDUR, while the registers MUX_n_CSC and MUX_n_CSS implement trigger and status of the PCFS operation. The clock division factors are expected to be programmed before any other MC_CGM operation is initiated and remain unchanged. All the registers corresponding to the clock division factors should be programmed with clk_src_0 as the configuration clock and before doing any clock switch or PCFS operation on any of the MC_CGM mux. It should be noted that the default values of the register corresponding to clock division factors are such that only the clock division factor is calculated by hardware that is divide-by-1. The PCFS operation is always triggered when the safe clock request is generated except when there is an on-going clock switch without ramp-up or ramp-down. Therefore, the software needs to ensure that the PCFS configuration is complete and correct.

While configuring MUX_n_CSC, only valid PCFS and clock switch requests should be provided. PCFS or clock switch requests should only be provided if the PCFS operation is in the idle state. If there is an ongoing PCFS operation, it is recommended not to provide any new PCFS triggers (except switch to safe clock) until the ongoing operation is completed. Switch to safe clock via hardware or by register configuration can be provided at any instance of time and is always completed. Valid combinations of PCFS and clock switches triggers are listed in Table 107. All the PCFS commands should be atomic in nature, which means a single register write should provide complete PCFS sequence to be executed that is ramp-down, clock switch, and ramp-up.

Table 107. Valid PCFS and clock switch requests

PCFS operation state	Command
Idle	Ramp-down, clock switch, and ramp-up
Idle	Clock switch only (without ramp-up or ramp-down)

When a switch to safe clock is provided by writing to MUX_n_CSC, then writes to other register fields are ignored.

24.9.2.2 Clock source powerup and selection

This section provides guidelines for powering up a given clock source and selecting it at the MC_CGM clock multiplexer.

Following is the powerup procedure for a clock source:

1. Configure the parameter, if any.
2. Configure the powerup (or powerdown) control field.
3. Wait for the powerup status indication.

After a powerup indication, the clock source can be selected to provide output clock at an MC_CGM clock multiplexer. A clock-monitoring setup can also be activated on the powered-up clock source.

See Figure 101 that shows a flow chart representation of this sequence.

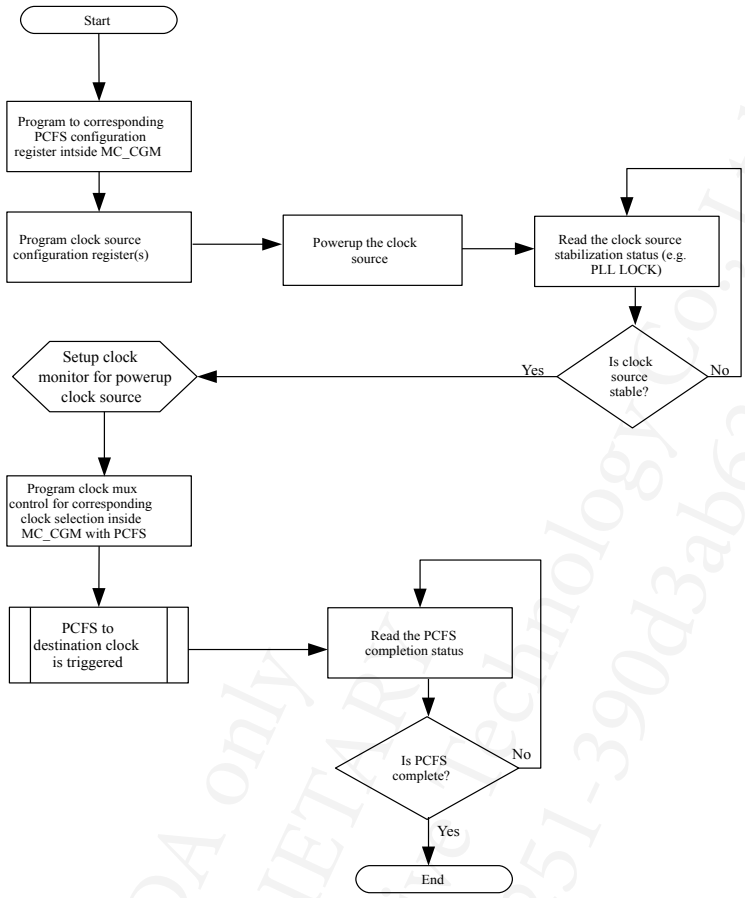

Figure 101. Clock source powerup and selection procedure

24.9.2.3 Clock source powerdown and deselection

This section provides guidelines for powering down a given clock source and deselecting it at MC_CGM clock multiplexer.

Following is the powerdown procedure for a clock source:

1. Deselect the clock source at all MC_CGM clock multiplexers.
2. Configure the powerup (or powerdown) control field.
3. Wait for the powerdown status indication.

See Figure 102 that shows a flow chart representation of this sequence.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-4888-b251-390d3ab624c1

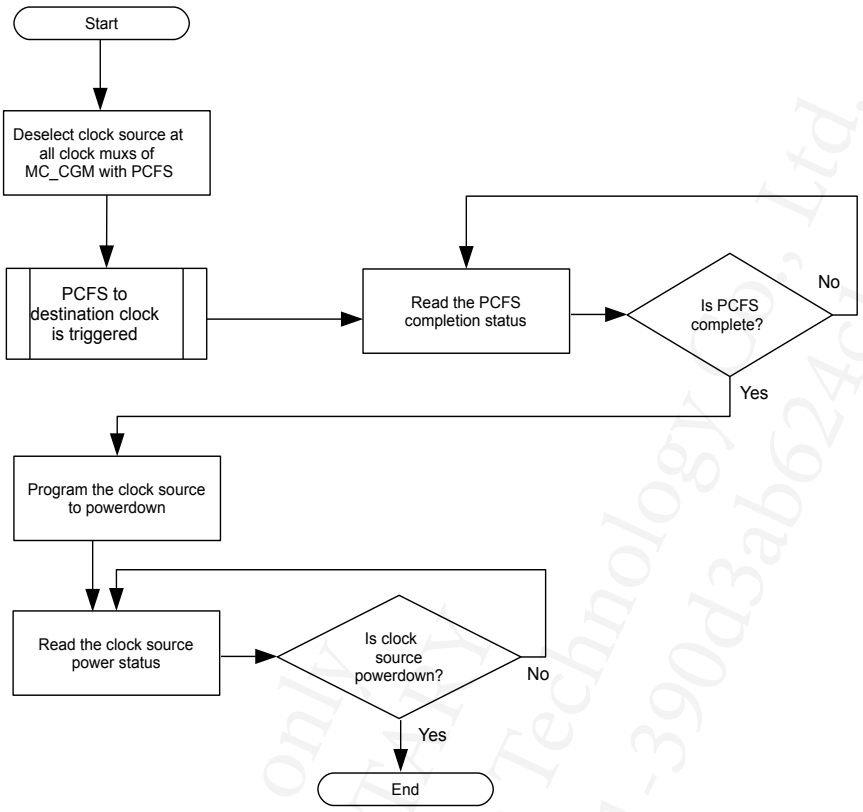

Figure 102. Clock source powerdown and clock source deselection procedure

24.9.2.4 Clock switch with load change

This section provides guidelines to switch between two high-frequency clock sources along with load changes in the system. Load change is referred to switching ON or OFF of logic/peripherals in the system, which has an effect of significant capacitance changes on the chip. This triggers the voltage regulation for the chip.

When a large number of peripherals or digital logic is enabled or disabled, it is recommended that this step should be performed at a low frequency. Independent of whether a clock switch is required, this criteria needs to be met. When a clock switch is required at two high frequencies, the recommended sequence is as follows:

1. Intermediately switch to clk_src_0.
2. Change load (that is, enable/disable peripherals).
3. Switch to the target clock.

See the following figure that shows a flow chart representation of this sequence.

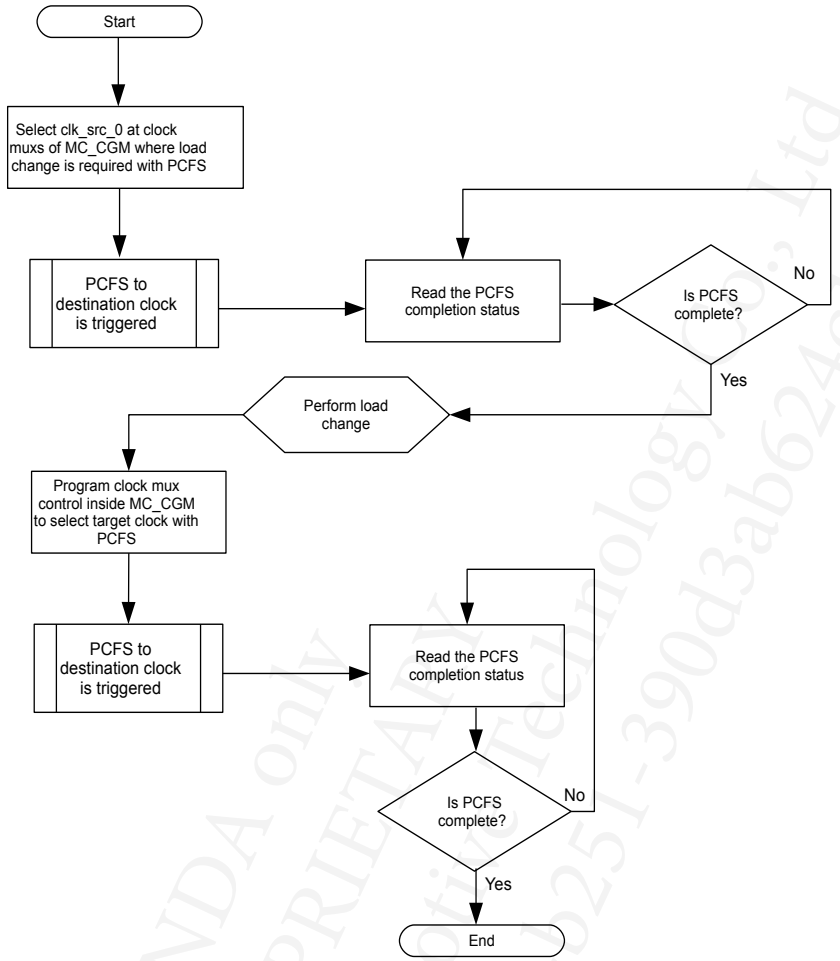

Figure 103. Clock switch with load change procedure

24.9.3 Clock dividers

Clock dividers are used for the generation of a divided clock that is used for running IPs or peripherals. The MC_CGM provides the following built-in dividers at each clock mux:

- 50% clock dividers

Each divider can be controlled by the Divider Enable (DE) bit and the Division Value (DIV) field. If a divider has its DE bit set to logic-0 in the respective configuration register, then that divider is disabled and the output divided clock is held to logic-0. If the DE bit is logic-1, the divider is enabled and provides a divided clock according to the value set in the DIV field.

24.9.3.1 50% clock divider

50% duty cycle dividers generate a real divided clock. The division factor is always an integer but is not restricted to even numbers. The rising edge of the divided clock is always synchronous to the rising edge of the divider source clock, but the falling edge is synchronous to the rising edge or the falling edge depending on whether the division factor is even or odd, respectively. If the input clock has a duty cycle of 50%, the divided output clock maintains the same 50% duty cycle. See Figure 104 that shows the 50% clock divider operation and its associated signals.

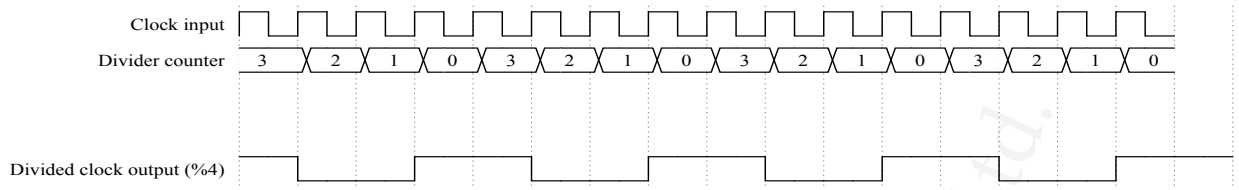

Figure 104. 50% clock divider programmed for divide by 4 (DIV=3)

A 50% divided clock can be considered asynchronous (not edge aligned) to other divided clocks from dividers at the same clock mux. 50% clock dividers are implemented without an active closed loop, and are expected not to get stuck if the input clock glitches for a single cycle.

24.9.3.2 Clock dividers update

To update the division value or the divider enable, the software should follow the procedure as shown in Figure 105. These updates happen only after the current division cycle has elapsed. However, if the phase of the clock divider is updated, the update happens independently from the state of the division cycle. Any update to the clock divider fields does not result in clock glitch either at the divided clock output or the phase-divided clock output.

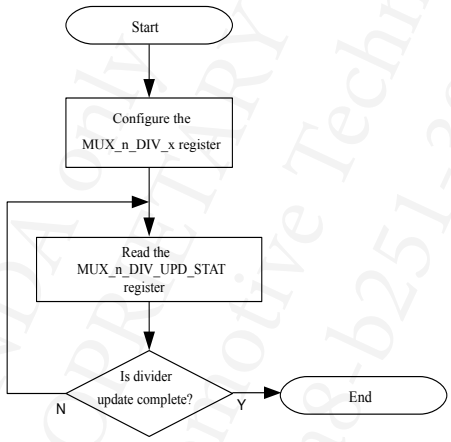

Figure 105. Flow for clock divider programming update

Recommended software sequence for ensuring no undivided output at MC_CGM:

1. Reset is de-asserted
2. MC_RGM goes to IDLE
3. Enable the clock dividers of MC_CGM to provide FIRC clock so that reset of fixed dividers can be lifted.
4. Program the MC_CGM as per use case division values.
5. Switch the clock of MC_CGM Mux to desired one, and run the system.

PCFS	Progressive clock frequency switching
LCM	Least common multiple

Chapter 25
Digital Frequency Synthesizer (DFS)

25.1 Introduction

This block generates different clock outputs of programmable frequency from an input clock source provided by a corresponding PLL. The DFS block provides clock signals as outputs on its ports as per the respective configuration of the ports. Also, the block provides an indication of lock for each output port.

25.1.1 Block diagram

Here is the DFS block diagram:

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

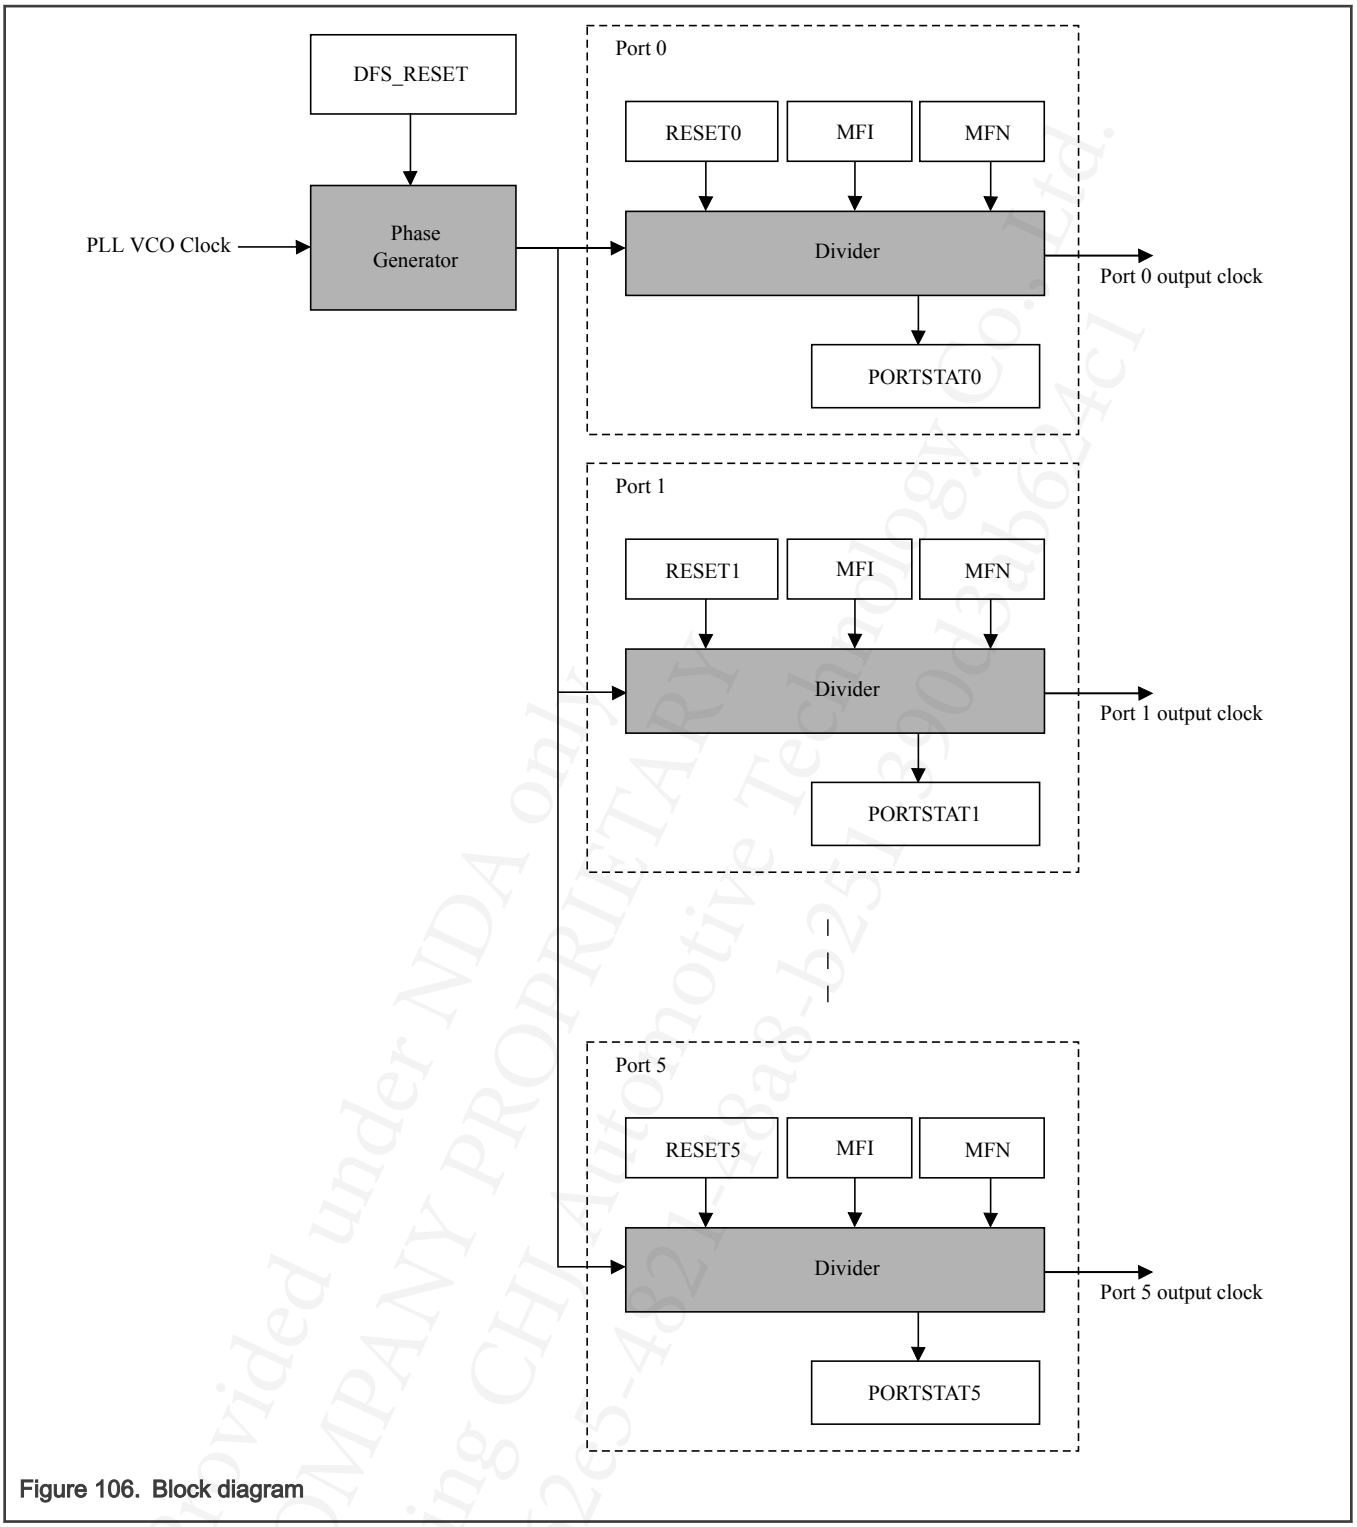

Figure 106. Block diagram

25.1.2 Features

DFS includes the following features:

- Six fractional clock dividers, with
  - individually configurable division factors.

  - individual enable/disable control.
  - individual lock status reporting.
- software controllable master DFS reset.

25.1.3 Modes of operation

The following lists the various supported DFS modes of operation.

Table 108. Modes of operation

Mode	CTL[RESET]	PORTRESET[RESET*n*]	Description
Non-functional	1	x	The DFS phase generator is in reset.
Functional	0	0	DFS port *n* is enabled.
	0	1	DFS port *n* is disabled.

Any combination of enabled and disabled ports is supported when the DFS is in functional mode.

25.2 Initialization information

Initialization

The following steps describe the procedure for DFS initialization:

1. Place the master DFS and output ports of analog DFS in reset by:
   - Writing 3Fh to PORTRESET[RESET*n*]
   - Check that PORTSR is 0.
   - Writing 1 to CTL[DFS_RESET]
2. Set the PLL clock output for the analog DFS to stabilize and lock the PLL.
3. Configure each DFS port with the desired division factor via the DVPORT*n* registers.
4. Write a 0 to CTL[DFS_RESET] to deassert the reset to master RESET of the analog DFS block.
5. Write a 0 to PORTRESET[RESET*n*] to deassert the reset to the output ports of the analog DFS block.
6. Poll PORTSR until all configured analog DFS output ports are locked.

Re-programing a DFS port without disabling the main DFS reset

The following steps describe the procedure for re-programing a DFS port without disabling the main DFS reset (when DFS ports have already been locked):

1. Program DFS using the procedure mentioned in the aforementioned initialization sequence.
2. Assert port reset of output port whose programming you want to change by configuring the corresponding field in PORTRESET.
3. Wait for the corresponding field in PORTSR to become 0.
4. Change configuration of MFI and MFN in the corresponding divide register (DVPORT0).
5. Deassert port reset of output port whose programming you want to change by configuring the corresponding field in PORTRESET.
6. Poll PORTSR to check if the corresponding DFS output port is locked.

Initialization after DFS LOL:

The following steps describe the procedure for initialization after DFS LOL:

1. Clear DFS LOL by writting 1 to PORTLOLSR[LOLF*n*]
2. Place the master DFS and output ports of analog DFS in reset by:
    a. Writing 3Fh to PORTRESET[RESET*n*].
    b. Writing 1 to CTL[DFS_RESET].
3. Set the PLL clock output for the analog DFS to stabilize and lock the PLL.
4. Configure each DFS port with the desired division factor via the DVPORT*n* registers.
5. Write 0 to CTL[DFS_RESET] to deassert the reset to master RESET of the analog DFS block.
6. Wait for 200 ns.
7. Write 0 to PORTRESET[RESET*n*] to deassert the reset to the output ports of the analog DFS block.
8. Poll PORTSR until all configured analog DFS output ports are locked.

Disabling DFS

The following steps describe the procedure to disable DFS:

1. Write 3Fh to PORTRESET[RESET*n*].
2. Wait for PORTSR to be 0.
3. Write 1 to CTL[DFS_RESET].

25.3 DFS register descriptions

This section provides the memory map and the detailed description of all the DFS registers.

The memory map shows address offsets from the module base address.

25.3.1 DFS memory map

PORTSR	Ch

Function

This register reflects the lock status of DFS output ports.

Diagram

Fields

Field	Function
31-6 —	Reserved
5-0 PORTSTATn	Lock status for port n This field reflects the lock status of the DFS output ports of the DFS analog block. Each bit represents a port from the analog block. For example, PORTSR[PORTSTAT[0]] represents port 0. 0b - Port *n* is not locked. 1b - Port *n* is locked.

25.3.3 Port Loss of Lock Status (PORTLOLSR)

Offset

Register	Offset
PORTLOLSR	10h

Function

This register contains the loss-of-lock status flags for the DFS output ports.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

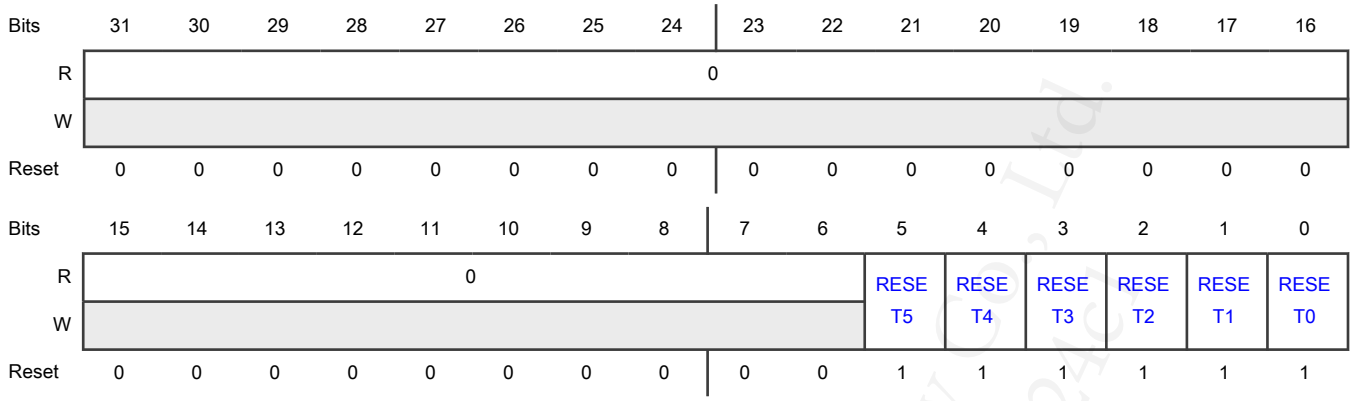
Fields

Field	Function
31-6 —	Reserved
5-0 LOLFn	Loss of lock flag DFS IP does not have real time clock monitor to declare lock or loss of lock. If PLL IP is disabled before DFS then loss of lock will be generated. This field is sticky. This means that if lock is re-acquired, the field remains 1 until you clear it by writing 1 to it or by asserting reset. 0b - The DFS detects no loss of lock for channel port *n* output. 1b - The DFS detected a loss of lock for channel port *n* output.

25.3.4 Port Reset (PORTRESET)

Offset



Register	Offset
PORTRESET	14h

Function

This register controls the enabling and disabling of the DFS output ports.

Fields

Field	Function
31-16 —	Reserved
15-8 MFI	This field provides the integer part of division factor for port *n*.
7-6 —	Reserved
5-0 MFN	This field provides the numerator of fractional part of division factor for port *n*.

25.4 Functional description

25.4.1 Port divider configuration

DFS IP takes input clock from PLL and generates multiple phases of clock. Six independent phase dividers then use these phases. You control the division factor of each port's divider by programming the DVPORT*n*[MFI] and DVPORT*n*[MFN] fields. The following equation describes the relationship between the input and output clock of each phase divider:

$$f_{\text{dfsclkout}}n = \frac{f_{\text{dfsclkin}}n}{2\times\left(\text{DVPORTn[MFI]}+\frac{\text{DVPORTn[MFN]}}{36}\right)}$$

Figure 107. Equation for input and output clocks of each port divider

In this equation:

- *n* is the DFS output port number.
- DVPORT*n*[MFI] is the integer part of the division value, and can range from 1d to 255d.
- DVPORT*n*[MFN] is the numerator of the fractional part of the division value, and can range from 0d to 35d.

Chapter 26
PLL Digital Interface (PLLDIG)

26.1 Introduction

The PLL can multiply or divide the frequency of a given clock input.

26.1.1 Features

PLL includes the following features:

- Provision for selecting multiple clock sources as the reference clock
- Programmable frequency modulation
- Multiple integer dividers on PLL outputs
- Lock detection circuitry reports when the PLL achieves frequency lock
- Continuous monitoring of lock status to report Loss of Lock (LOL) condition
- Powering down the module for low-power operation (Power-down mode)

26.1.2 Block diagram

The following figure shows the block diagram for PLL.

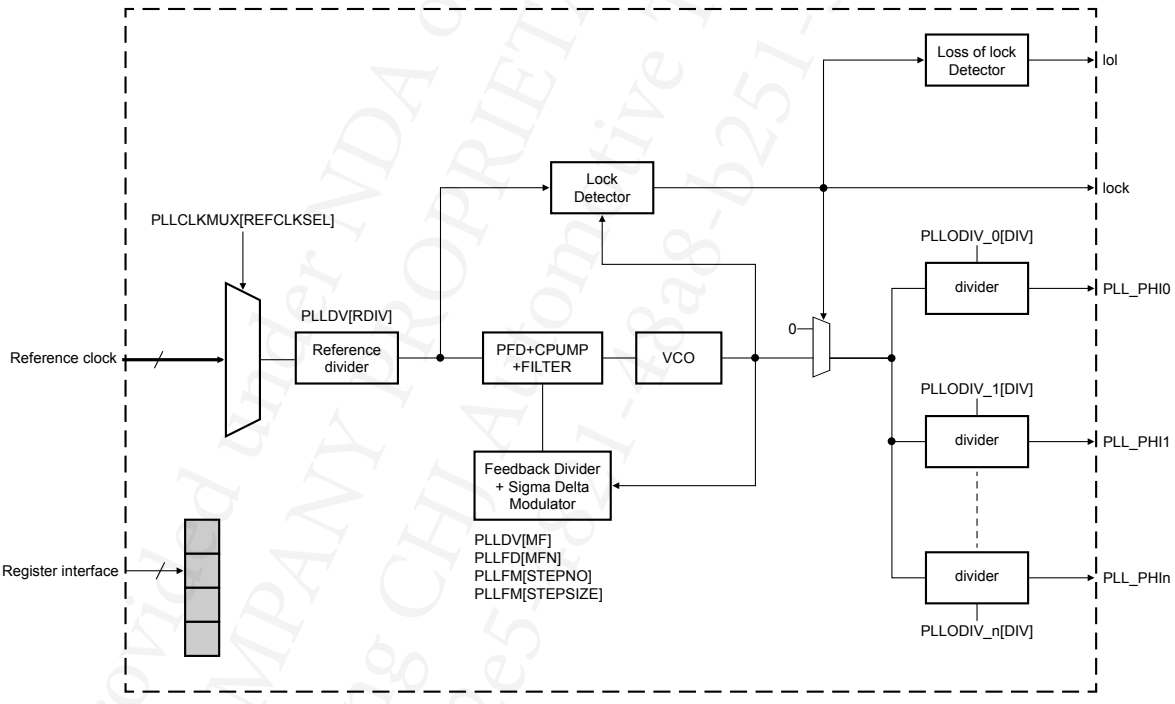

Figure 108. Block diagram

Number of output dividers can vary with the module instance. Refer to the Clocking chapter to confirm the number of PLL output dividers.

26.2 Modes of operation

Table 109. Modes of operation

PLLCR[PLLPD]	PLLFD[SDMEN]	PLLFM[SSCGBYP]	Description
1	x	x	PLL is disabled.
0	0	1	Functional mode – PLL operates in integer-only mode. See Clock configuration.
0	1	1	Functional mode – PLL operates in Fractional mode (non-Frequency modulation). See Clock configuration.
0	1	0	Functional mode – PLL operates in Frequency Modulation mode. See Frequency modulation.

26.3 ACCEL_PLL register descriptions

This section provides the memory map and detailed descriptions of registers used for configuring the PLL. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers are accessed using 8-bit, 16-bit, or 32-bit addressing.

26.3.1 ACCEL_PLL memory map

ACCEL_PLL base address: 4004_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	PLL Control Register (PLLCR)	32	RW	8000_0000h
4h	PLL Status Register (PLLSR)	32	W1C	0000_0300h
8h	PLL Divider (PLLDV)	32	RW	0C3F_1032h
Ch	PLL Frequency Modulation (PLLFM)	32	RW	4000_0000h

26.7 Functional description

This section explains the operation and configuration of the PLL module.

26.7.1 Input clock frequency

The PLL is designed to operate over a specified input clock frequency range. PLL source frequency limits are discussed in this chip's data sheet.

26.7.2 Clock configuration

See the equations below and the corresponding register configuration that determine the relationship between VCO frequency (f_{VCO}) and PLL reference frequency.

- Integer-only mode:

— When PLLDV[RDIV] is 0:

$$f_{pll\_VCO} = f pll\_ref \times PLLDV[MFI]$$

Figure 109. PLL VCO frequency in integer-only mode when PLLDV[RDIV] is 0

— When PLLDV[RDIV] is not 0:

$$f_{pll\_VCO} = \frac{f_{pll\_ref}}{PLLDV[RDIV]} \times PLLDV[MFI]$$

Figure 110. PLL VCO frequency in integer-only mode when PLLDV[RDIV] is not 0

- Fractional mode:

— When PLLDV[RDIV] is 0:

$$f_{pll\_VCO} = f_{pll\_ref} \times \left(PLLDV[MFI] + \frac{PLLFD[MFN]}{18432}\right)$$

Figure 111. PLL VCO frequency in Fractional mode when PLLDV[RDIV] is 0

— When PLLDV[RDIV] is not 0:

$$f_{pll\_VCO} = \frac{f_{pll\_ref}}{PLLDV[RDIV]} \times \left(PLLDV[MFI] + \frac{PLLFD[MFN]}{18432}\right)$$

Figure 112. PLL VCO frequency in Fractional mode when PLLDV[RDIV] is not 0

See the equation below and the corresponding register configuration that determine the relationship between reference and PLL_PHI*n* output frequencies.

$$f_{pll\_phi} = \frac{f_{pll\_VCO}}{PLLODV\_n[DIV+1]}$$

Figure 113. PLL PHI output frequency

When configuring the PLL, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of the PLL (see this chip's data sheet for frequency limits).

NOTE

The PLL must be disabled by writing PLLCR[PLLPD] = 1 before any PLL configuration or input clock are modified.

NOTE

The PLL must be disabled by writing PLLCR[PLLPD] = 1 for at least 5 µs before enabling the PLL (writing PLLCR[PLLPD] = 0).

The recommended procedure to program the PLL and engage normal mode is shown in Initialization information.

26.7.3 LOL

PLL provides LOL indication. The LOL indication can only be generated when the PLL is in functional mode (see Modes of operation). When the PLL detects a LOL, it asserts its LOL event output.

Provided under NDA
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c62e3-42f4-48a8-25...

NOTE

- The PLL does not detect loss of reference clock. If the reference clock stops after the PLL achieves lock, PLL continues to indicate lock. It is assumed that monitoring of the PLL's reference clock that is done outside the PLL is enabled while the PLL is in operation.
- PLL LOL is intended for detection of gross failures. Use CMUs for accurate frequency monitoring.

26.7.4 Frequency modulation

In Frequency Modulation mode, the PLL generates a frequency-modulated clock. The modulation depth and modulation frequency are calculated using the equations shown in Frequency modulation programming.

The field PLLFM[SPREADCTL] must set to 0b to select center-spread modulation. See Figure 114 that shows an example of center-spread modulation.

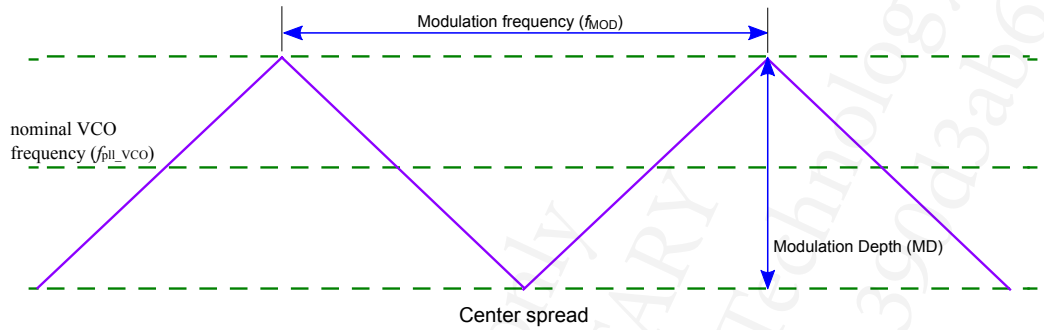

Figure 114. Frequency modulation

26.7.4.1 Frequency modulation programming

Modulation depth and modulation frequency programming uses step number (PLLFM[STEPNO]) and step size (PLLFM[STEPSIZE]). The table below shows variables used during calculations when programming the PLL for frequency modulation.

Table 110. Variables for configuring modulation depth and frequency

Variable	Description
f_{REF}	Input clock frequency
f_{MOD}	Expected modulation frequency
MD	Expected modulation depth in percentage
LDF	Loop division factor

Use the following equations to configure the PLL for frequency modulation.

$$LDF = PLLDV[MFI] + \frac{PLLFD[MFN]}{18432}$$

Figure 115. LDF

$$\text{PLLFM[STEPNO]} = \frac{f_{\text{REF}}}{\left(2 \times f_{\text{MOD}} \times \text{PLLDV[RDIV]}\right)}$$

Figure 116. Step number

$$\text{PLLFM[STEPSIZE]} = \frac{\text{MD} \times \text{LDF}}{100 \times \text{PLLFM[STEPNO]}} \times 18432$$

Figure 117. Step size

Frequency Modulation is only possible if the condition shown in Figure 118 is met.

$$(\text{PLLFM[STEPSIZE]} \times \text{PLLFM[STEPNO]}) < 18432$$

Figure 118. Requirement to achieve FM

NOTE

PLLFM[SSCGBYP] must be cleared and PLLFD[SDMEN] must be set for frequency modulation to be enabled.

CAUTION

The effective modulation depth may differ from the intended modulation depth because of rounding operations applied to PLLFM[STEPSIZE] and PLLFM[STEPNO].

26.8 Initialization information

Perform the following steps to complete the PLL initialization:

1. Confirm that PLLODIV_*n*[DE] = 0 for all dividers.
2. Confirm that PLLCR[PLLPD] = 1.
3. Program PLLCLKMUX to select appropriate PLL reference clock.
4. Program the following as needed:
   - PLLDV
   - PLLFD
   - PLLFM to the desired value.
5. Program field PLLODIV_*n*[DIV] to the desired value.
6. Wait for the PLL reference clock to be stable.
7. Write PLLCR[PLLPD] = 0.
8. Wait for field PLLSR[LOCK] = 1.
9. Write PLLODIV_*n*[DE] = 1.

Perform the following steps to complete the PLL shut-down:

1. Write PLLODIV_n[DE] = 0 for all dividers.
2. Write PLLCR[PLLPD] = 1.

Chapter 27
Fast Crystal Oscillator Digital Controller (FXOSC)

27.1 Introduction

27.1.1 Overview

This module provides the fast crystal oscillator to the chip.

27.1.2 Features

FXOSC features are as follows:

- Status register shows current module state.
- Control register can:
  - Select a mode of operation:
    - Crystal mode
    - Single-Input Bypass mode using EXTAL clock input
    - Differential Input Bypass mode using EXTAL and XTAL inputs
  - Disable the module (Power-Down mode)

27.2 FXOSC register descriptions

This section provides the descriptions of all registers used for configuring the FXOSC.

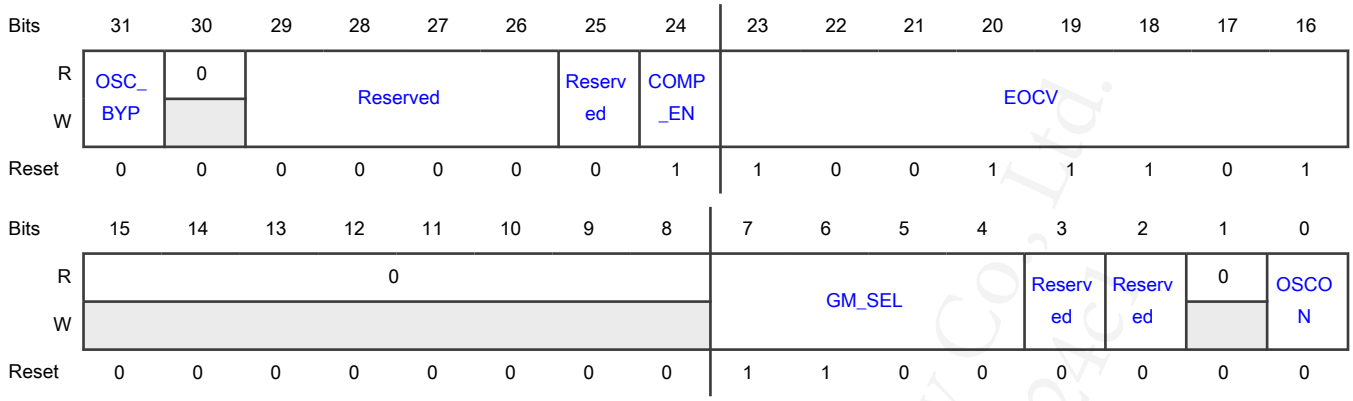
27.2.1 FXOSC memory map

Use 8-bit, 16-bit, or 32-bit addressing to access registers.

FXOSC base address: 4005_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	FXOSC Control Register (CTRL)	32	RW	019D_00C0h
4h	Oscillator Status Register (STAT)	32	RO	0000_0000h

27.2.2 FXOSC Control Register (CTRL)



Offset

Register	Offset
CTRL	0h

Function
Configures FXOSC operation.

Table continued from the previous page...

Field	Function
	The oscillator counter runs on the crystal clock divided by 4 and counts up to EOCV × 128. This counting period ensures that the external oscillator clock signal is stable before the system selects FXOSC as a source. **NOTE** • You must set EOCV to the appropriate value to allow clock and duty cycle to stabilize and guarantee that OSC_STAT becomes set within the crystal startup time. — In Crystal mode, EOCV value must to be calculated to appropriate value based on the crystal specification using the equation in Initializing FXOSC. — In Differential Bypass mode, EOCV value must be configured corresponding to at least 1 ms. — In Single-Input Bypass mode, EOCV value is irrelevant. FXOSC holds the counter in reset. • Before modifying EOCV, FXOSC must be disabled.
15-8 —	Reserved
7-4 GM_SEL	Crystal overdrive protection Selects the transconductance applied by the FXOSC amplifier. This setting depends on crystal specification. **NOTE** • In Crystal mode and Differential Bypass mode FXOSC will not function with zero transconductance (GM_SEL = 0000b). • For details on how to set this field, see Initializing FXOSC. 0000b - 0× 0001b - 0.145× 0010b - 0.223× 0011b - 0.368× 0100b - 0.291× 0101b - 0.436× 0110b - 0.514× 0111b - 0.660× 1000b - 0.339× 1001b - 0.485× 1010b - 0.563× 1011b - 0.708×

Field	Function
31 OSC_STAT	Crystal oscillator status Indicates the crystal oscillator status. **NOTE** OSC_STAT value is is not valid if transconductance is set to 0. 0b - Crystal oscillator is off or on but not stable. 1b - Crystal oscillator is on and providing a stable clock.
30-0 —	Reserved

27.3 Functional description

The table below shows configuration settings for the different FXOSC modes set by the CTRL register:

Table 111. FXOSC operation mode settings

Mode	CTRL[OSCON]	CTRL[OSC_BYP]	CTRL[COMP_EN]	FXOSC_CLK
Power-Down mode	0	X	X	0
Crystal mode	1	0	1	Crystal clock
Single-Input Bypass mode	1	1	0	EXTAL
Differential Bypass mode	1	0	1	EXTAL and XTAL

Power-Down mode is the FXOSC default condition after any reset: POR, Destructive, or Functional.

27.3.1 Clock generation in Crystal mode

Counter logic and FXOSC_CLK start when counter value reaches EOCV × 128.

27.3.2 Clock generation in Single-Input Bypass mode

This mode bypasses the oscillator and uses a single-input external clock (EXTAL input) for FXOSC_CLK.

27.3.3 Clock generation in Differential Input Bypass mode

This mode bypasses the oscillator and uses differential-input external clocks (EXTAL and XTAL inputs) for FXOSC_CLK.

27.4 Initialization information

Initializing FXOSC

Initialize FXOSC as follows:

1. Write the desired value to CTRL[OSC_BYP] and CTRL[COMP_EN] to select an operation mode as shown in Table 111.

NOTE

FXOSC must be disabled when the operation mode is modified.

2. Configure CTRL[GM_SEL].
   - In Crystal mode configure the transconductance based on the module specification in the chip data sheet.
   - In Single-Input Bypass mode write 0000b to this field.
   - In Differential Bypass mode write 0001b to this field.

   NOTE

   In Crystal mode and Differential Bypass mode FXOSC will not function with zero transconductance (GM_SEL = 0000b).
3. Set CRTL[EOCV] calculating the value as follows:
   - EOCV (in decimal) = (stabilization time in ns) ÷ (4 × 128 × (period of clock in ns))
4. Write 1 to CRTL[OSCON] to enable FXOSC.
5. Confirm the clock is stable (STAT[OSC_STAT] = 1) before using it.

Disabling FXOSC

Write 0 to CRTL[OSCON] to disable FXOSC when FXOSC_CLK is running and stable.

FXOSC enters Power-down mode after at least four crystal clocks. No glitches occur during the transition to Power-Down mode because synchronizers are used.

NOTE

After disabling FXOSC:

- Wait for at least 2 µs before enabling FXOSC again.
- You must not change other values in FXOSC registers for at least 16 FXOSC_CLK cycles.

Chapter 28
Reset

28.1 Introduction

This chapter describes the reset sequence and behavior of the chip.

The reset sequence consists of defined entry points with a fixed sequence that leads to a known and deterministic state of the chip after completion. One or more modules on the chip triggers a reset event, and these reset events determine the entry points to a reset sequence.

This chapter discusses the following details:

- Global reset behavior of the chip
- Various reset sources
- Possible reset sequences and their stages
- Software resettable domains that can be reset independently without affecting the functionality of other modules
- Status of modules during the reset process
- Reset behavior of the chip during low-power (Standby) mode entry and exit

The figure below illustrates the high-level reset architecture that involves various module interactions with the Reset Generation Module (MC_RGM) during different stages of the reset sequence.

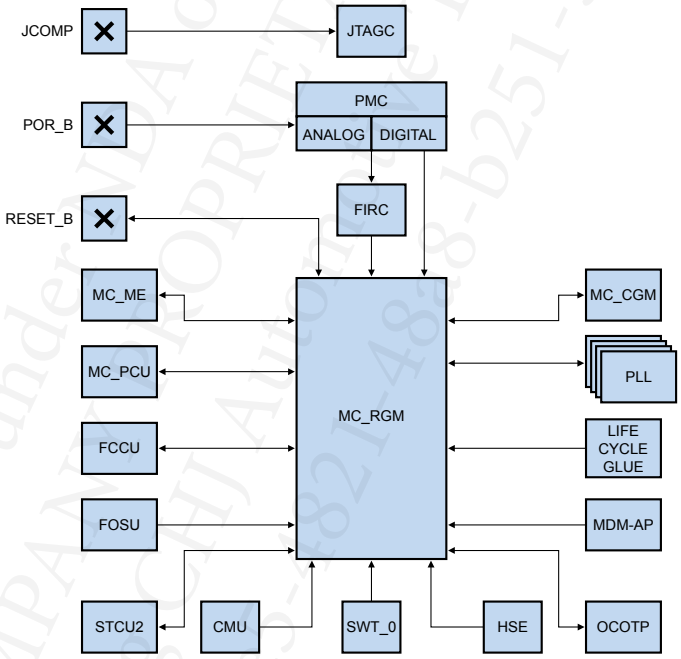

Figure 119. Reset top-level diagram

NOTE

- Bidirectional arrow: The RGM handshakes with these modules during the reset sequence.
- Unidirectional arrow: These modules are sources of reset.

The following table shows the types of reset events that can lead to their respective reset sequences.

Table 112. Description of reset events

Reset event	Description
Functional reset	Chip operation is still reliable and SRAM memory content can be preserved. Leads to a reset of modules for which functionality is not guaranteed.
Destructive reset	Resets most of the chip except for a few selected modules. Memory content is considered to be lost after this reset event.
Power-on reset (POR)	The entire chip is reset.

28.2 Reset features

The reset architecture of this chip provides the following features:

- Reset sequence controls with three entry points:
  - POR
  - Destructive reset
  - Functional reset
- Status reporting of destructive and functional reset events
- Functional reset escalation to destructive reset
- Destructive reset escalation to stay in reset until next POR
- SRAM content protection against corruption on any functional reset event
- Software resettable domains management
- Reset management after chip exits Standby mode
- Chip configuration through fuses

28.3 High-level reset sequence

The following diagram shows the high-level reset sequence overview for POR, destructive, and functional reset events. When the reset process has reached the 'Out of Reset' state, the chip is operational.

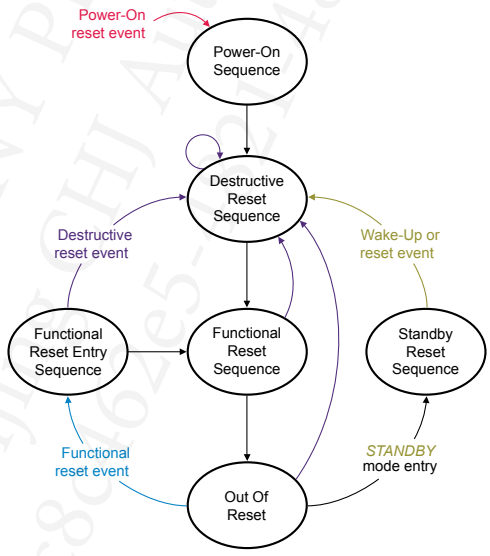

Figure 120. High-level reset sequence flow

A POR event causes an immediate entry into the beginning of the Power-On Sequence state regardless of whether the chip is in one of the reset sequences or the Out Of Reset state. A single red arrow represents this in order to simplify the above diagram.

The following table shows the entry points into the high-level reset sequence for each type of reset event.

Table 113. Reset event reactions in reset sequence

Reset event type	From	Reaction
POR	Anywhere	Move to beginning of power-on sequence
Destructive	Power-on sequence	No reset sequence change
Destructive	Anywhere else	Move to beginning of destructive reset sequence
Functional	Out of reset	Move to beginning of functional reset entry sequence
Functional	Standby reset sequence before VDD_CORE_OK is asserted or FIRC is stable	Move to beginning of destructive reset sequence
	Anywhere else	No reset sequence change

The chip does the following for each reset event captured by MC_RGM:

- Writes a 1 to the corresponding reset event status field in MC_RGM_DES and MC_RGM_FES registers.
- Places its pins into their default states.
- Enters the reset sequence as described in the table above.

28.4 Reset sources

All POR sources always assert RESET_B when active. The POR cannot be demoted to an IRQ. No escalation is needed.

All destructive reset sources always assert RESET_B when active.

If fields in the MC_RGM_DES and MC_RGM_FES registers are both 1 after a reset sequence, it means that the chip experienced a destructive reset when the functional reset source was active. In this case, ignore F_DR_8, F_DR_13, and F_DR_18 in the MC_RGM_DES register, because these are spuriously set.

Table 114. Reset sources

Name	Description	Source module	Index	RESET_B assertion	Can be demoted to IRQ	Escalation
POR reset sources						
POR	Core supply	PMC	D[0]	Always	No	No

1. This reset source is intended to be used for DEBUG purpose only.

28.5 Reset sources descriptions

28.5.1 POR sources

28.5.1.1 On-chip POR

During chip power-up, the chip asserts its internal POR signal as soon as the on-chip POR detection circuitry is functional (see the "Power management" chapter for supplies monitored during POR).

During normal chip operation, the internal power-on reset signal asserts when any of the chip voltages monitored by the on-chip POR detection circuitry fall below their specified minimum thresholds. When the chip asserts the internal POR signal, the signal remains asserted until all the chip voltages monitored by the on-chip POR detection circuitry rise above their minimum functional thresholds.

The on-chip POR circuitry exists in the CSPDs attached to the following power rails (see the chapter "Power Management Controller (PMC)" for details):

- Logic required for the reset sequence and initial boot
- Analog portion of the FIRC
- Critical pins (for example, RESET_B)

28.5.1.2 Critical LVDs

During chip power-up, the chip asserts each critical LVD reset signal as soon as the signal's corresponding on-chip LVD detection circuits are functional.

During normal chip operation, the chip asserts each critical LVD reset signal as soon as the corresponding monitored voltage falls below its corresponding specified threshold.

When the chip asserts a critical LVD reset signal, the chip continues to assert the signal until the corresponding chip voltage rises above its threshold.

The monitored LVD chip voltages that cause reset assertion when they fall below their specified voltages are listed in the Power Management chapter, in the "Minimum off-chip LVDs and HVDs" table.

The critical on-chip LVD circuitry exists in CSPDs. They are connected to the power rails which are required to be at specified levels for the boot process to execute properly.

28.5.1.3 External POR_B pin

The active-low POR_B pin uses a weak pull-down on its input.

During chip power-up, off-chip power management circuitry asserts the POR_B pin as soon as it becomes functional. The off-chip power management circuit may consist of a single Power Management IC (PMIC) or a combination of chips.

During normal operation, the off-chip power management circuit asserts the POR_B pin when any of voltages monitored by this circuitry falls below its corresponding threshold.

When off-chip power management circuitry asserts the POR_B pin, this circuitry continues to assert POR_B until all of its monitored voltages rise above their corresponding thresholds.

Off-chip power management circuitry monitors all off-chip-supplied voltages.

28.5.1.4 POR watchdog timer

The chip asserts POR_WDG reset immediately when the POR watchdog timer expires.

The chip clears the POR watchdog timer and deasserts POR_WDG reset immediately after the chip enters a POR sequence.

The following reset events initiate the POR watchdog timer count:

1. All POR events (after completion of the power-on sequence)
2. All destructive reset events (immediately after event detection)
3. All functional reset events (immediately after event detection)

The default timeout value of POR_WDOG is 960 SIRC clock cycles (30 ms).

The following conditions mentioned must be true for the POR watchdog to function:

- Fuses do not disable the POR watchdog.
- Nothing triggers a destructive reset escalation threshold.

28.5.2 Destructive reset sources

28.5.2.1 SPD fail

SPDs detect disturbances in the connections between the associated regulator and the monitored power. Such a disturbance may be:

- A broken wire between the PMIC and the chip
- An intermittent connection
- A high-resistance connection

During chip operation, the chip asserts each SPD fail signal as soon as the corresponding chip voltage monitored by the SPD circuitry falls to a level below the precision LVD minimum voltage, but still above the level at which the logic needed to process the ensuing reset can function.

When the chip asserts an SPD fail signal, it continues to assert that signal until the monitored voltage rises above its threshold.

The reaction of NCSPDs is disabled on

- Power-on reset
- Destructive sequence entry
- Functional reset

The NCSPD_CTL register inside the PMC is reset upon functional reset. The default configuration of this register is such that reactions of all NCSPDs are disabled.

You can enable NCSPDs via software.

Software can determine which NCSPD has caused a destructive reset by reading a write-1-clear status register in the PMC.

You cannot disable CSPDs.

Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-482-48a8-b251-390d3ab624c1

28.5.2.2 FCCU failure to react

The FOSU module monitors the FCCU and asserts the FCCU failure-to-react reset if the FCCU fails to react to a fault within the specified amount of time.

The FCCU failure-to-react reset is deasserted immediately on destructive reset and POR sequence entries.

28.5.2.3 STCU2 unrecoverable fault

The STCU2 asserts an unrecoverable fault based on the STCU2's configuration of multiple possible error conditions.

The STCU2 unrecoverable fault reset is deasserted immediately on destructive reset and POR sequence entries.

28.5.2.4 Functional reset escalation to destructive reset

Functional reset escalation reset is asserted by MC_RGM immediately upon the functional reset event that causes the escalation counter to increment and reach the threshold value in the MC_RGM_FRET[FRET] register field.

The functional reset escalation counter is cleared and functional reset escalation reset is deasserted immediately on destructive reset and POR sequence entries.

The functional reset escalation feature can be enabled and disabled via software.

The functional reset escalation threshold value can be set via software.

The default configuration of the functional reset escalation feature immediately after destructive reset and POR sequence exit is enabled with the FRET value set to 15.

If enabled, the functional reset escalation counter increments by one with each functional reset event that occurs when the chip is out of reset.

The functional reset escalation counter can be cleared by software.

28.5.2.5 FXOSC failure

FXOSC failure reset is asserted by the clock monitor that is monitoring the FXOSC output clock as soon as the monitor detects that the FXOSC output clock's frequency has gone out of the specified minimum/maximum frequency threshold range.

FXOSC failure reset is deasserted immediately on destructive reset and POR sequence entries.

28.5.2.6 CORE_PLL loss of lock

CORE_PLL loss of lock is asserted by the CORE_PLL as soon as it loses its lock after having previously acquired it.

CORE_PLL loss of lock is deasserted immediately on any reset sequence entry.

28.5.2.7 PERIPH_PLL loss of lock

PERIPH_PLL loss of lock is asserted by the PERIPH_PLL as soon as it loses its lock after having previously acquired it.

PERIPH_PLL loss of lock is deasserted immediately on any reset sequence entry.

PERIPH_PLL is reset on functional reset. The PERIPH_PLL loss of lock generates destructive reset and therefore is reset on destructive reset sequence entry.

28.5.2.8 DDR_PLL loss of lock

DDR_PLL loss of lock is asserted by the DDR_PLL as soon as it loses its lock after having previously acquired it.

DDR_PLL loss of lock is deasserted immediately on any reset sequence entry.

DDR_PLL is reset on functional reset. The DDR_PLL loss of lock generates destructive reset and therefore is reset on destructive reset sequence entry.

28.5.2.9 ACCEL_PLL loss of lock

The ACCEL_PLL loss of lock is asserted by the ACCEL_PLL as soon as it loses its lock after having previously acquired it.

The ACCEL_PLL loss of lock is deasserted immediately on any reset sequence entry.

ACCEL_PLL gets reset on functional reset. The ACCEL_PLL loss of lock will generate the destructive reset and hence will get reset on destructive reset sequence entry.

28.5.2.10 XBAR_DIV3 clock failure

The minimum frequency threshold for the XBAR_DIV3_CLK failure monitor is typically set lower than for the precision monitoring done by the CMU that provides an FCCU reaction. This is because this monitor is checking primarily for a loss of clock in this clock domain.

XBAR_DIV3_CLK failure reset is deasserted immediately on destructive reset and POR sequence entries.

28.5.2.11 Life-cycle error

The security Life-cycle fault reset is asserted by the Life-cycle block immediately on the detection of an error in the Life-cycle value because of, for example:

- A failure during the reading of the Life-cycle value
- Reading an invalid Life-cycle value
- A corruption of the stored Life-cycle value

The security Life-cycle fault reset is deasserted immediately on destructive reset and POR sequence entries.

28.5.2.12 Software destructive reset

Software destructive reset is asserted immediately upon a mode change request to a destructive reset via the MC_ME.

Software destructive reset is cleared immediately on destructive reset and POR sequence entries.

28.5.2.13 Debug destructive reset

Debug destructive reset is asserted immediately when the debugger sets the destructive reset field in the DAP's MDM_AP register to 1.

Debug destructive reset is deasserted immediately when the debugger sets the destructive reset field in the DAP's MDM_AP register to 0 (the field is automatically set to 0 because the debugger logic is working on the destructive reset itself).

28.5.2.14 HSE_H SWT timeout

The HSE_H SWT timeout signal is asserted as soon as the HSE_H SWT has not been serviced by the software running on the HSE_H core before the SWT's reset timer has expired.

HSE_H SWT is reset on functional reset. The HSE_H SWT timeout signal is deasserted immediately on any reset.

28.5.2.15 HSE SNVS tamper detected

The HSE tamper-detected signal is asserted as soon as the SNVS has detected tampering that potentially jeopardizes the security of the chip.

The HSE SNVS tamper-detected signal is deasserted automatically by the SNVS after assertion and immediately on destructive reset and POR sequence entries.

The HSE software can determine which tamper was detected by reading a status register in the SNVS.

28.5.3 Functional reset sources

28.5.3.1 FCCU reset reaction

The FCCU reset reaction reset is asserted by the FCCU when a fault is detected by the FCCU and the fault is configured to generate a soft reaction.

The FCCU reset reaction reset is deasserted automatically by the FCCU after assertion and immediately on destructive reset and POR sequence entries.

Software can determine which fault caused the FCCU reset reaction by reading a status register in the FCCU.

28.5.3.2 Self-test done

The self-test done reset is asserted by the STCU2 after the execution of the BIST (LBIST/MBIST) has completed on the main reset domain.

The self-test done reset is deasserted automatically by the STCU2 after assertion and immediately on destructive and POR sequence entry.

28.5.3.3 SWT0 timeout

The SWT0 timeout reset request is asserted as soon as SWT0 has not been serviced by the software running on "Cortex-M7 cluster0" before the SWT's reset timer has expired. The SWT0 timeout signal is deasserted immediately on any reset sequence entry.

28.5.3.4 HSE memory ECC error

The HSE memory ECC error signal is asserted when the security subsystem's ECC circuitry detects an ECC error in any of the HSE's memories.

The HSE memory ECC error signal is deasserted immediately on any reset sequence entry.

28.5.3.5 HSE boot error

The HSE boot error signal is asserted when the security subsystem detects an error during boot code execution. The HSE boot error signal is deasserted immediately on any reset sequence entry.

28.5.3.6 HSE core lock

The HSE core lock signal is asserted when the security subsystem detects a lock condition on its Cortex-M7 core. The HSE core lock signal is deasserted immediately on any reset sequence entry.

28.5.3.7 Software functional reset

Software functional reset is asserted immediately upon a mode change request to a functional reset via the MC_ME.

Software functional reset is cleared immediately on functional reset, destructive reset, and POR sequence entries.

28.5.3.8 Debug functional reset

Debug functional reset is asserted immediately upon the setting of the functional reset field in the DAP's MDM_AP register by the debugger.

Debug functional reset is deasserted immediately upon the clearing of the functional reset field in the DAP's MDM_AP register by the debugger.

c8c62e5482148adb25139003ab624c1

28.5.4 Non-MC_RGM and indirect reset sources

28.5.4.1 JCOMP pin

The active-high JCOMP pin is input-only with a weak pulldown.

The JCOMP pin is asserted whenever JTAG operation is needed (for example, during debug) and is continuously deasserted when JTAG operation is not needed.

The JCOMP reset is asserted when the JCOMP pin is deasserted.

The JCOMP reset is deasserted when the JCOMP pin is asserted.

28.5.5 Destructive reset escalation to stay in reset

The destructive reset escalation reset is asserted by the MC_RGM immediately upon the destructive reset event that causes the escalation counter to increment and reach the threshold value in MC_RGM_DRET[DRET].

When the destructive reset escalation reset is asserted, the reset sequence immediately enters DEST0 state and remains there until a POR event starts a POR sequence.

The destructive reset escalation feature can be enabled and disabled via software.

The destructive reset escalation threshold value can be set via software.

The default configuration of the destructive reset escalation feature immediately after power-on sequence exit is disabled.

If enabled, the destructive reset escalation counter increments by one with each destructive reset event.

The destructive reset escalation counter can be cleared by software.

28.5.6 RESET_B

The active-low RESET_B pin is open-drain bidirectional with a weak pullup.

The input value of the RESET_B pin is ignored when the chip is asserting the RESET_B pin.

MC_RGM always asserts the RESET_B pin on destructive reset and POR sequence entry.

The default configuration, which is set immediately on destructive and power-on reset sequence entries, is that all functional reset events cause RESET_B to be asserted.

After MC_RGM has asserted the RESET_B pin, it continues to assert it until all the conditions for reset sequence exit have been met except for the check that RESET_B has been deasserted.

For all reset sequences, the reset sequence exit cannot occur until the RESET_B pin has reached its deassertion state; in other words, not until the RESET_B pin is not being asserted by MC_RGM nor by the external system.

The external reset event is asserted when an assertion edge is detected on the RESET_B pin when the RESET_B pin is not being asserted by MC_RGM.

The RESET_B pin input signal is filtered against high and low glitches with the following characteristics:

- Maximum pulse rejected: 20 ns
- Minimum pulse passed: 400 ns

The RESET_B pin is asserted by the off-chip power management circuitry starting before the device supplies begin ramping up and at least until the POR_B pin is deasserted. This prevents the RESET_B pin from behaving erratically when its supply is ramping up.

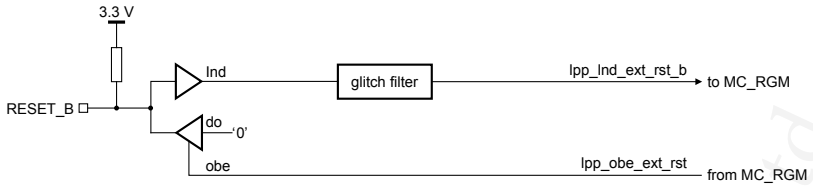

Figure 121. RESET_B overview

28.6 Reset process

28.6.1 Overview

The reset process is a sequence of several reset stages based on the reset event that has occurred. All reset events follow the same chip reset sequence with only the entry points varying depending on the reset event type. These stages are sequential in terms of execution. Each stage is triggered by the MC_RGM on completion of the previous stage. These stages are executed in a specific order to ensure a deterministic state of the system on exit from any reset event.

28.6.2 Reset process sequence

28.6.2.1 POR sequence

This stage is entered when a POR event occurs (for example, any of the POR sources are asserted). In this stage, the chip waits for the power-up sequence to complete. This stage is exited when all the POR sources clear.

The following modules are involved in POR reset sequence:

- PMC
- FIRC
- POR_B
- JTAGC/JCOMP

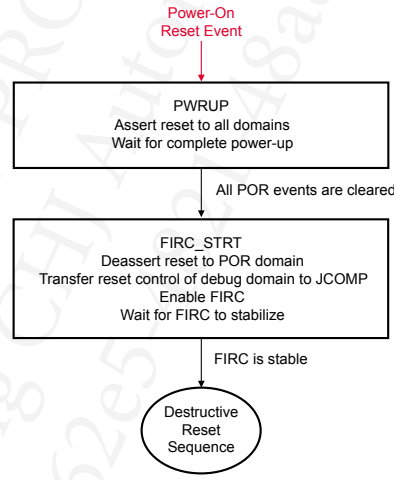

Figure 122. POR sequence flow diagram

28.6.2.2 Destructive reset sequence

The following modules are involved in the destructive reset sequence:

- OCOTP

- PMC
- FIRC
- SIRC
- Life-cycle logic

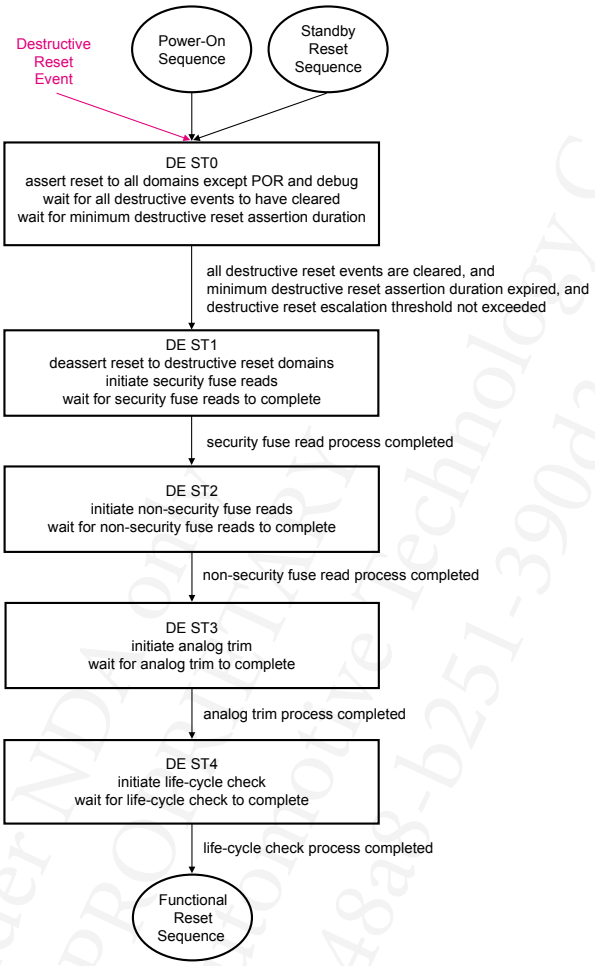

Figure 123. Destructive sequence flow diagram

NOTE

Since FIRC is the only clock source available during the reset sequence, and non-FIRC clock domains may glitch on destructive reset sequence entry, all IP in the POR domain run on the FIRC clock or TCK. One small exception to this is the POR_WDOG, which has an additional internally generated and independent clock that it uses for its watchdog timer.

28.6.2.3 Functional reset sequence

FUNC0 to FUNC7 in the flow diagram below represents the functional reset entry sequence. The following modules are involved in the functional reset entry sequence:

- STCU2
- FCCU/FOSU
- CMU

- SWT
- Debug/ETR/MDM-AP
- HSE
- NoC
- CGM
- DFS
- PLL
- FXOSC

FUNC8 to FUNC10 in the flow diagram below represent the functional reset exit sequence. The following modules are involved in the functional reset exit sequence:

- MTR/Memory repair
- RESET_B
- Boot configuration pins (Refer to the 'Boot modes' section of the 'Boot' chapter for details on the pins which are sampled during the reset sequence for boot mode selection and configuration)

NOTE

To allow the boot configuration pins to be properly sampled, you must ensure that the corresponding I/O power supplies are within their specified ranges. If this is not the case, the reset sequence is not prevented from completing, but could lead to an incorrect boot.

See the chip's IOMUX sheet.

28.12 Software resettable domains

28.12.1 Introduction

The chip is subdivided into several reset domains.

After POR, destructive, or functional reset, only the Main Reset Domain is released from reset. All other reset domains stay in reset until software writes the register field in MC_RGM that releases a given reset domain from reset.

Software can also write a register field in MC_RGM, and selectively put a reset domain back into reset, after ensuring a certain configuration. This configuration is controlled by MC_CGM, MC_ME, and RDC modules. These reset domains are referred to as software-resettable domains/partitions.

This reset structure results in better device availability. If a fault is detected in a software reset domain, that domain can be reset separately without impacting the operation of the rest of the chip.

MC_RGM provides 64 bits per reset domain/partition including the main reset domain. These bits are used for resetting the software-resettable domain/partition itself or cores.

- 32-bit register RGM_PRSTn_0[PERIPH_(64*n+31)_RST : PERIPH_(64*n)_RST]
- 32-bit register RGM_PRSTn_1[PERIPH_(64*n+63)_RST : PERIPH_(64*n+32)_RST]

The RGM_PRST0_0/1 registers correspond to the main reset partition, the RGM_PRST1_0/1 registers correspond to the first software resettable partition, the RGM_PRST2_0/1 registers (if present) correspond to the second software resettable partition, and so on.

RGM_PRSTn_0[PERIPH_(64*n)_RST] corresponds to partition reset.

Table 121. PRST fields for individual partitions and cores

PRST field	Partition reset	Core/Peripheral reset	Reset partition name	Core/Peripheral name
RGM_PRST0_0				
PERIPH_0_RST	No	Yes	Main	Cortex-M7 cluster0
PERIPH_1_RST	No	Yes	Main	Cortex-M7 cluster1

28.12.2 List of software reset domains/partitions on the chip

The following table lists software resettable domains/partitions on the chip.

Table 122. Software-resettable domains/partitions list

Software-resettable domain	Modules	Reset control field in MC_RGM
RD1	Cortex-A53 Cluster	RGM_PRST1_0[PERIPH_64_RST]
RD2	PFE	RGM_PRST2_0[PERIPH_128_RST]
RD3	LLCE	RGM_PRST3_0[PERIPH_192_RST]

All other modules in the chip are part of the main reset domain (RD0).

NOTE

A module is disabled when the module clock is gated or reset is not de-asserted. Attempting to access a module that is disabled by such causes will result in invalid behavior with no error response, a transfer error, or a hang.

28.12.2.1 Cortex-A53 software-resettable domain/partition

This reset domain consists of:

- Two Cortex-A53 clusters
- One GIC 500 pair in lockstep for handling interrupts
- The coherency fabric (Ncore) including directory cache

- Delay and comparison units to support lockstep operation

Each cluster consists of two Cortex-A53 cores. Both clusters can be either in delayed lockstep to each other, or can be run independently, depending on the prior configuration before removing them from reset.

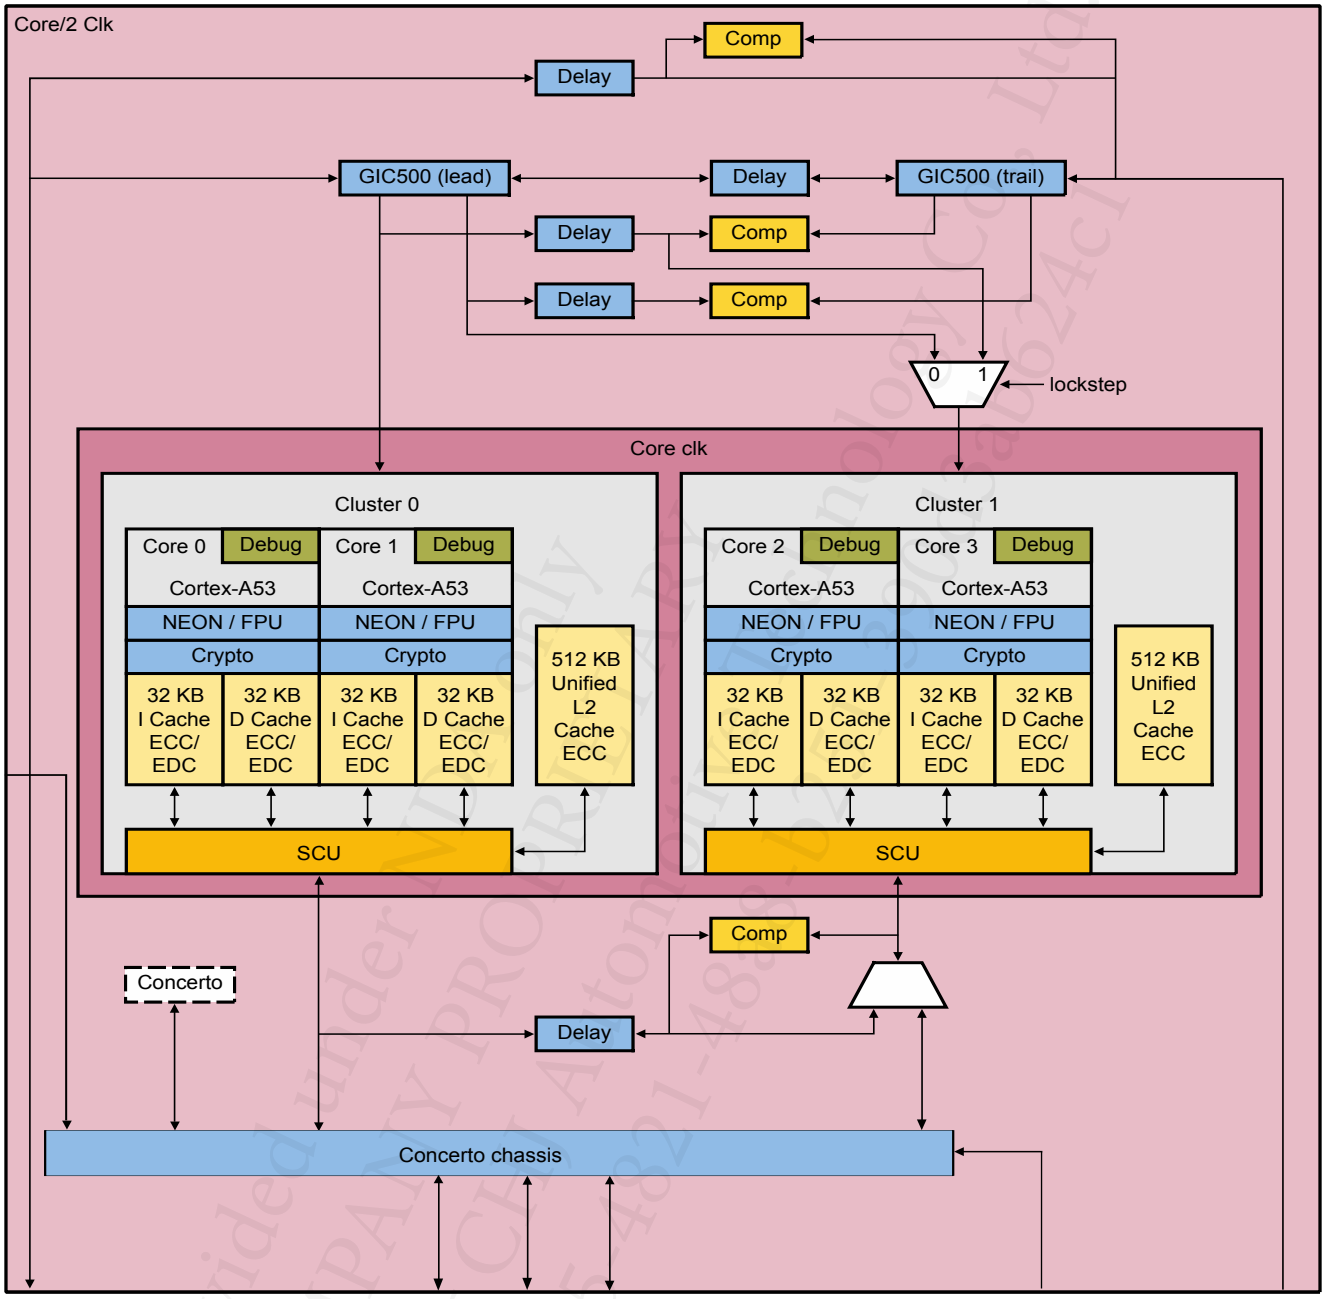

Figure 127. Software reset domain/partition

28.12.3 State of the software reset domains/partitions after power-up/destructive/functional reset sequence

All of the software resettable domains/partitions are in reset state. Clocks to the reset domains/partitions are gated. Outputs of the reset domains/partitions are safe-stated, that is, output isolation is asserted. The NoC/crossbar interface of bus masters in the software-resettable domain/partition is safe-stated with the NoC/crossbar.

28.12.4 Software reset partition turn-on flowchart

For the Cortex-A53 reset domain, clocks for the initial frequencies can be set up by configuring MC_CGM_1 to the FIRC clock. See the clocking chapter for details.

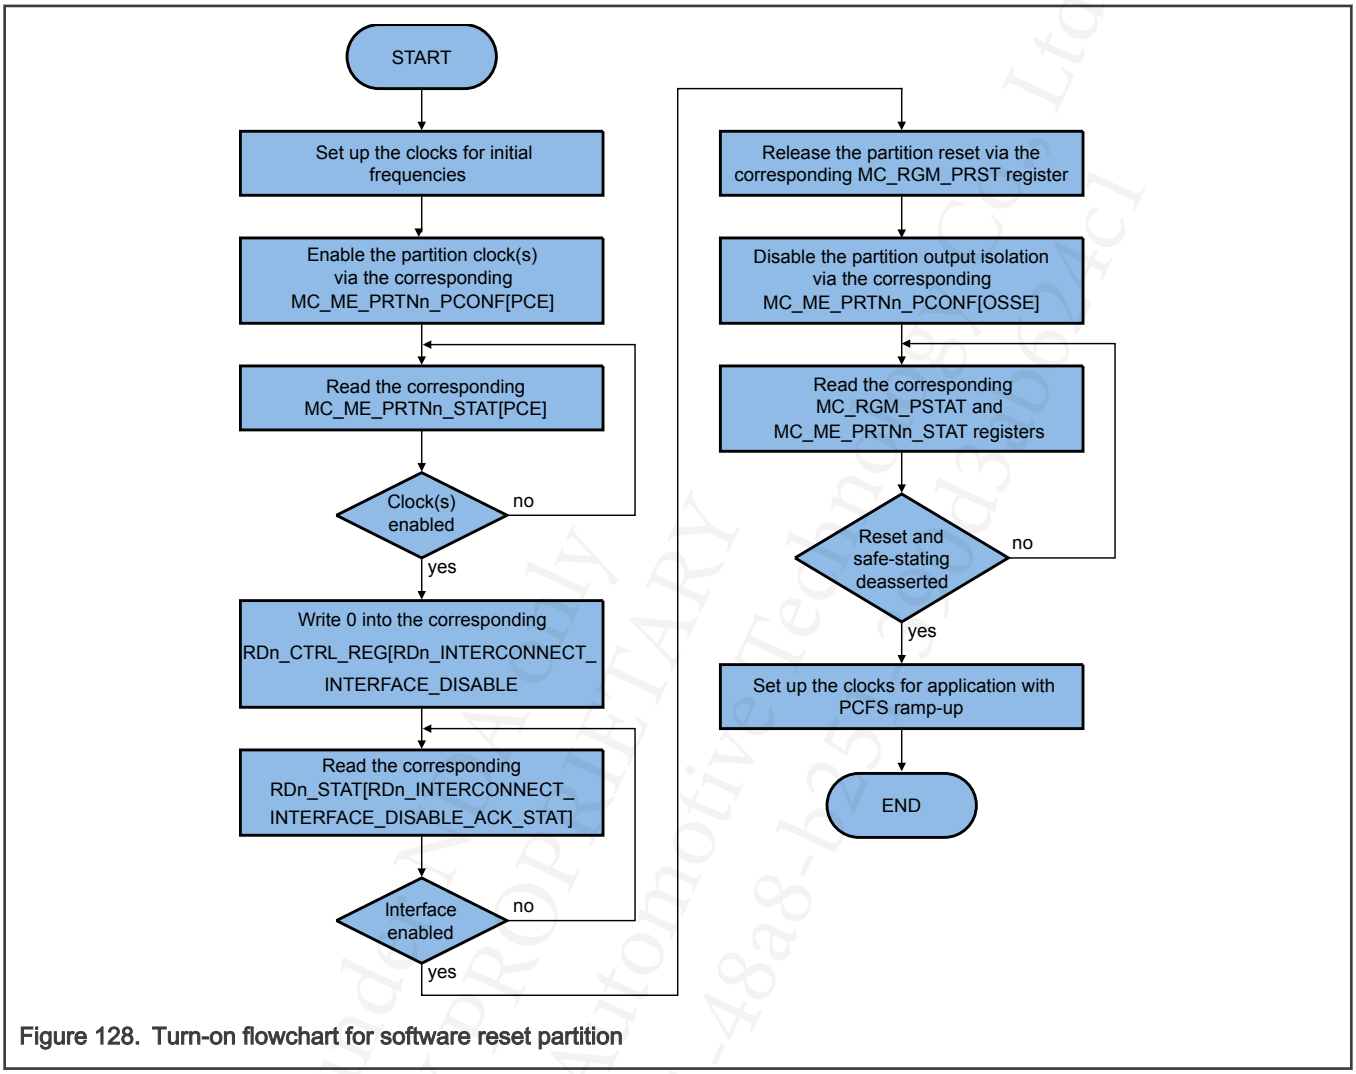

Figure 128. Turn-on flowchart for software reset partition

28.12.5 Software reset partition turn-off flowchart

For the Cortex-A53 reset domain, clocks for the initial frequencies can be set up by configuring MC_CGM_1 to the FIRC clock. See the clocking chapter for details.

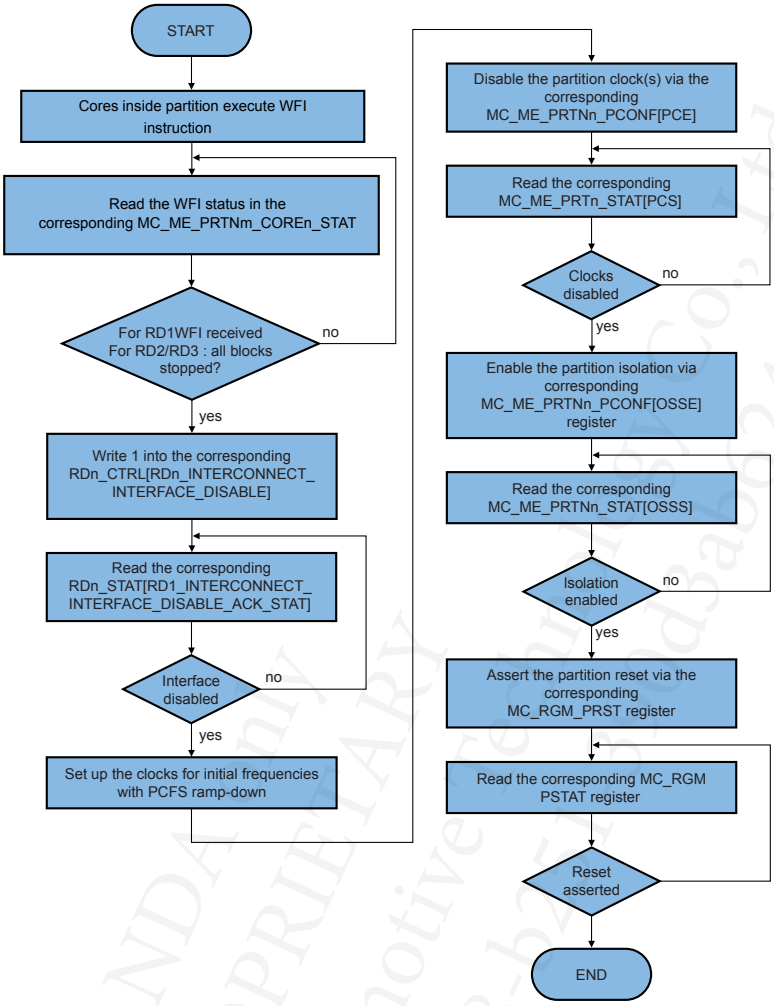

Figure 129. Turn-off flowchart for software reset partition

NOTE

The software must ensure that NoC masters inside a software reset domain remain in Idle state before executing the turn off sequence.

28.12.6 PFE software reset partition turn-off flowchart

For the PFE reset domain, clocks for the initial frequencies can be set up by configuring MC_CGM_1 to the FIRC clock. See the clocking chapter for details.

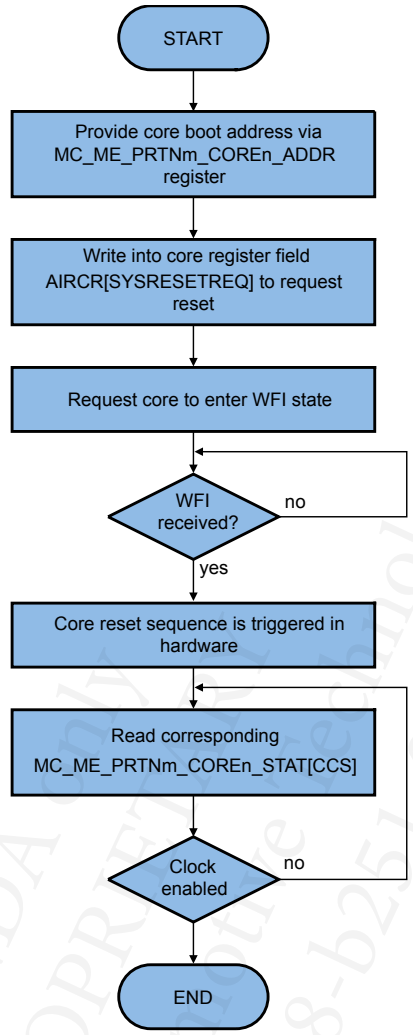

Figure 133. Self-triggered sequence

28.12.10 Cortex-A53 core warm reset sequence

You must follow these steps for the Cortex-A53 warm reset sequence.

1. Write RM[RR] to issue WARMRESETREQ.
2. Write 0 to SCTLR[C] to prevent further data cache allocation.
3. Clean and invalidate all data from the L1 data cache.
4. Disable data coherency with other cores in the cluster by clearing CPUECTLR[SMPEN].
5. Execute an ISB instruction to ensure that all register changes from the previous steps have been completed.
6. Execute a DSB SY instruction to ensure that all cache, TLB, and branch predictor maintenance operations issued by any core in the cluster device before the SMPEN field was cleared have completed.
7. Execute a WFI instruction and wait until the STANDBYWFI output is asserted.

Warm reset is issued to the core (that is, nCORERESET is asserted) when the WARMRESETREQ and STANDBYWFI signals are asserted and the SMPEN signal is deasserted. The duration of warm reset is 256 cycles of Cortex-A53_CORE_CLK.

For more information see Cortex-A53 documentation: Arm Cortex-A53 MPCore Processor Technical Reference Manual, Revision r0p4 at www.arm.com.

28.12.11 Software peripheral resets

Some peripherals (or logic on them) must exit reset only after software implements a particular configuration. In these cases, dedicated software fields ensure the peripherals exit reset.

Table 124. Fields for peripheral reset

Peripheral	Reset control field in MC_RGM	Description
DDR	RGM_PRST0_0[PERIPH_3_RST]	Reset for AXI interface and DDR controller
PCIe_0	RGM_PRST0_0[PERIPH_4_RST]	Reset control of PCIe_0
PCIe_0	RGM_PRST0_0[PERIPH_5_RST]	Power-on reset of SerDes subsystem
PCIe_1	RGM_PRST0_0[PERIPH_16_RST]	Reset control of PCIe_1
PCIe_1	RGM_PRST0_0[PERIPH_17_RST	Power-on reset of SerDes subsystem

NOTE

The peripheral resets, after deassertion, should not be asserted again using these register fields. They are asserted on the next functional, destructive, or POR reset.

NOTE

For a description of any soft reset feature supported by a peripheral, see the peripheral's dedicated chapter.

NOTE

The PRST0_0[PERIPH_3_RST] reset must deassert when DDR_CLK is selected as FIRC. DDR_CLK can be switched to functional frequency after the reset deasserts.

28.13 Reset Domain Controller (RDC) register descriptions

This section provides the memory map and descriptions of registers for configuring the system reset. All registers can be accessed using 8-bit, 16-bit, or 32-bit addressing.

Chapter 29
Reset Generation Module (MC_RGM)

29.1 Chip-specific MC_RGM information

29.1.1 Reset sources

The MC_RGM module centralizes the various reset sources of the chip. For information on reset sources, see the "Reset sources" table in the "Reset sources" section of Reset chapter.

29.1.1.1 Destructive reset sources

In this chapter, each numbered destructive reset source, such as in the F_DR_*n* fields of the RGM_DES register, refers to the reset source with the same D[*n*] index number in the "Reset sources" table in the Reset chapter.

29.1.1.2 Functional reset sources

In this chapter, each numbered functional reset source, such as in the F_FR_*n* fields of the RGM_FES register, refers to the reset source with the same F[*n*] index number in the "Reset sources" table in the Reset chapter.

29.1.2 Peripheral numbers

For information on peripheral-number mapping, see the "PRST bits for individual partitions and cores" table in the "Software resettable domains" section of the Reset chapter.

29.1.3 Clear functional reset counter during initial application sequence

Boot ROM reads the RGM_FREC register to determine the number of functional resets. If the number of functional resets issued during Boot ROM is greater than eight, the boot process enters Fail-Safe, which is serial boot. To avoid having the Boot ROM enter Fail-Safe because of repeated functional resets from the application, clear RGM_FREC when you pass control to it.

29.1.4 Limitations on individual peripheral resets

This device supports individual peripheral resets in a limited manner. For details, see the "Software resettable domains" section of the Reset chapter.

29.2 Introduction

The Reset Generation Module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. There are various registers available in this module to monitor and control the chip reset sequence.

The following figure shows the block diagram of MC_RGM.

Provided under NXP Only

Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-4888-b5e5-390a3ab624c1

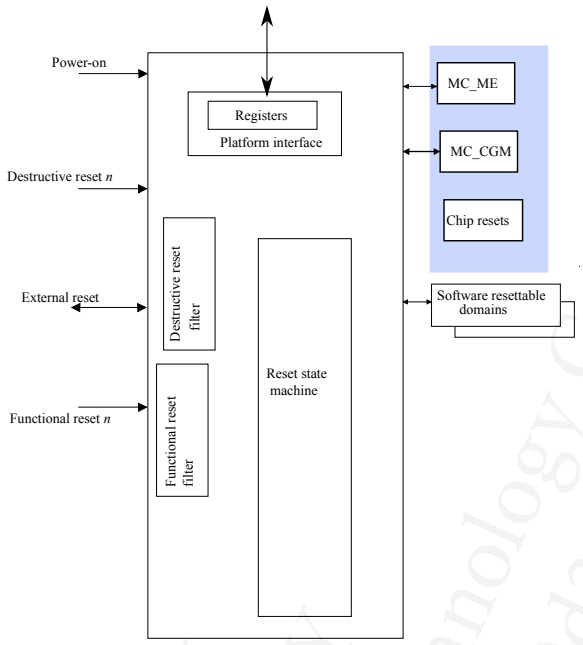

Figure 134. MC_RGM block diagram

29.3 Features

Here are the key features of MC_RGM:

- Support for destructive reset management
- Support for functional reset management
- Signaling of reset events after each reset sequence (reset status flags)
- Configurable escalation of recurring 'functional' resets to 'destructive' reset
- Configurable escalation of recurring 'destructive' resets to keep the chip in the reset state until the next power-on reset
- Support for resetting peripherals individually. For any limitations on this feature, see the chip-specific MC_RGM information
- Software controllable reset assertion
- Pad safe state control generation

29.4 Reset sources

The different reset sources are organized in three categories: power-on, destructive, and functional.

A power-on reset source is associated with an event typically related to power-up or low-voltage scenarios. When a power-on reset occurs, the full reset sequence is applied to the chip. This resets the full chip, including the MC_RGM, and the memory content must be considered to be unknown.

A destructive reset source is associated with an event related to a critical, usually hardware, error or dysfunction. When a destructive reset event occurs, the full reset sequence is applied to the chip. This resets the full chip (except for a small portion, for example FIRC, JTAG interface, and the MC_RGM itself) ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown.

A functional reset source is associated with an event related to a less-critical, usually non-hardware, error or dysfunction. When a functional reset event occurs, a partial reset sequence is applied to the chip. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (for example, debug modules, flash modules) as well as the system memory content is preserved.

29.5 External signal description

The MC_RGM interfaces with the RESET_B pin.

The following table describes the signals that are connected to the I/O pad ring.

Table 125. MC_RGM external signals

Signal name	Reset value	Description
RESET_B	0	Active low external reset

29.6 RESET_B pin assertion and pin safe state control

The MC_RGM asserts the RESET_B pin when the device is in a reset sequence, and it remains asserted until the end of the reset sequence. During this reset sequence, most of the chip's pins are safe-stated according to the values shown in the IOMUX table. Note that the safe state values may vary according to the reset sequence type.

In addition, the MC_RGM has a feature to assert the RESET_B pin through software, without initiating a reset sequence. This is achieved by writing 1b to the ERCTRL[ERASSERT]. When this occurs, most of the chip's pins are safe-stated according to the values shown in the IOMUX table. The RESET_B assertion and pin safe-stating remain active until the end of the next reset sequence.

This feature is intended for use only in conjunction with self-test of the main reset domain. See STCU2 chapter for more details on its usage.

29.7 MC_RGM register descriptions

29.7.3 Functional /External Reset Status Register (FES)

Offset

Register	Offset
FES	8h

Function

This register contains the status of the 'functional' and external reset sources. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source.This register is reset only on power-on reset.

NOTE

The status of this register must be ignored if the fields of Destructive Event Status Register (DES) other than DES[F_POR] are set. In this case, a destructive reset had occurred while functional reset source was active.

29.7.4 Functional Event Reset Disable Register (FERD)

Offset

Register	Offset
FERD	Ch

Function

This register provides dedicated fields to disable functional reset sources. When any of these reset sources are disabled, the associated functional event is demoted to trigger an interrupt request. The register can be read and written to in Supervisor mode and only read in User mode. Each byte can be written to only once after a destructive or power-on reset and this register is reset only on power-on and any destructive reset.

NOTE

It is important to clear the Functional /External Reset Status Register (FES) before writing 1 to any of the fields in this register. Otherwise a interrupt request may occur.

29.7.5 Functional Reset Escalation Counter Register (FREC)

Offset

Register	Offset
FREC	14h

Function

This register provides the current count of functional reset escalation counter. It can be accessed in read/write, either in supervisor mode. It can be accessed in read in the user mode. This register is reset only on power-on reset or destructive reset. This register is also reset when you reconfigure the FREC field to Fh.

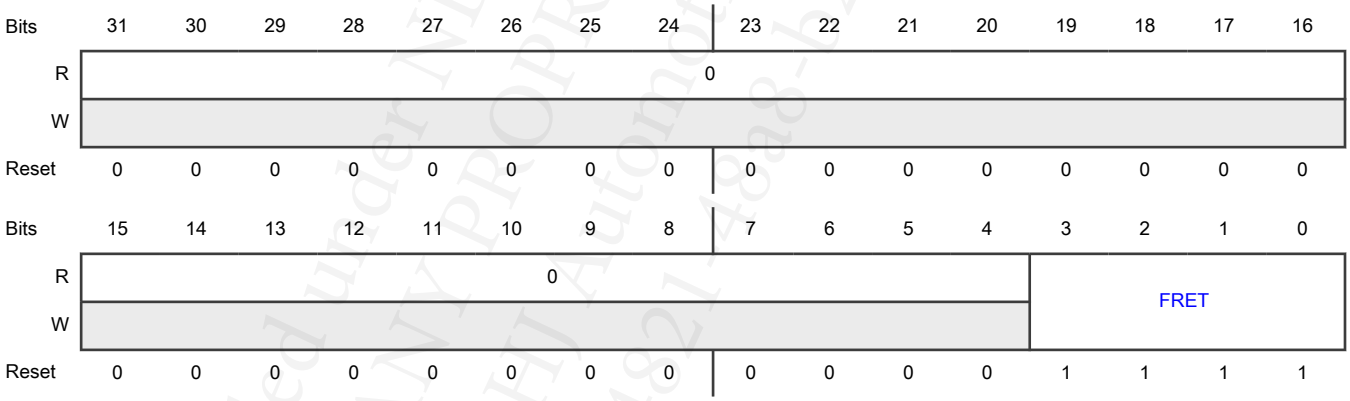
3-0 FREC	Functional' Reset Escalation Counter This bit field provides the value of functional reset escalation counter.

29.7.6 Functional Reset Escalation Threshold Register (FRET)



Offset

Register	Offset
FRET	18h

Function

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Writing a non-zero value to the FRET field enables the 'functional' reset escalation function. Writing any value to this register resets the 'functional' reset counter. See Functional reset escalation for details on the 'functional' reset escalation function. This register is reset only on power-on and any 'destructive' reset.

Diagram

Fields

Field	Function
31-4 —	Reserved
3-0 FRET	'Functional' Reset Escalation Threshold

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets that causes a 'destructive' reset if the FRET register isn't written to beforehand.

29.7.7 Destructive Reset Escalation Threshold Register (DRET)

Offset

Register	Offset
DRET	1Ch

Function

This register sets the threshold for 'destructive' reset escalation to keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Writing a non-zero value to the DRET field enables the 'destructive' reset escalation function. Writing any value to this register resets the 'destructive' reset counter. See Destructive reset escalation for details on the 'destructive' reset escalation function. This register is reset only on power-on reset.

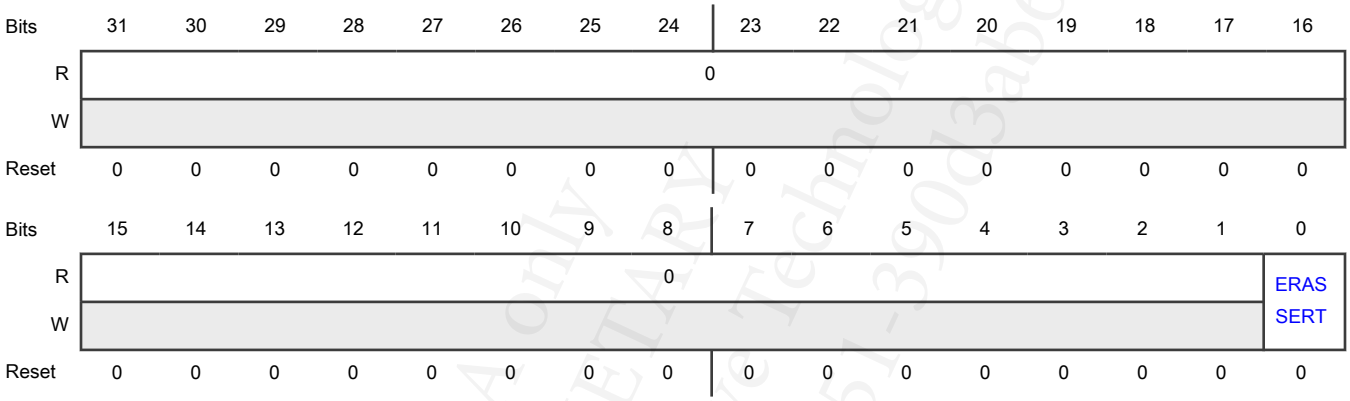
Any other value is the number of 'destructive' resets which keeps the chip in the reset state until the next power-on reset triggers a new reset sequence if the DRET register isn't written to beforehand.

29.7.8 External Reset Control Register (ERCTRL)



Offset

Register	Offset
ERCTRL	20h

Function

This register allows software to control the assertion of External reset pin. It can be accessed in read/write, in supervisor mode. It can be accessed in read-only in the user mode. This register is reset on all resets.

Diagram

Fields

Field	Function
31-1 —	Reserved
0 ERASSERT	ERASSERT **NOTE** Setting ERASSERT to 1b also safe states most of the chip's pins. See the IOMUX table for each pin's safe state value. Software must use the ERASSERT bit for this purpose only as part of the main reset domain self-test entry procedure. Using it at any other time may result in unpredictable system behavior. 0b - No change 1b - External reset is asserted

29.7.9 Reset During Standby Status Register (RDSS)

Offset

Register	Offset
RDSS	24h

Function

This register provides status of whether a reset event occurred during standby mode. Register bits are cleared on write '1'. This register is reset only on power-on reset.

NOTE

On exiting a reset sequence after standby exit, the software must perform a read operation on MC_ME[PREV_MODE] and RDSS register. If any bit of the RDSS register is set, the software must ignore the status reported by MC_ME[PREV_MODE] register otherwise the status of MC_ME[PREV_MODE] register reports the device status.

If MC_ME indicates last mode as RESET, then perform a reset exit in software else a standby exit.

29.8 Functional description

29.8.1 Reset state machine

The main role of MC_RGM is the generation of the reset sequence that ensures that the correct parts of the chip are reset based on the reset source event.

For each reset event, immediately after it is captured by the MC_RGM, the following takes place:

1. The corresponding reset event status bit is set in the MC_RGM_DES and MC_RGM_FES registers.
2. The pins are put into their default states
3. The RESET_B pin is asserted.

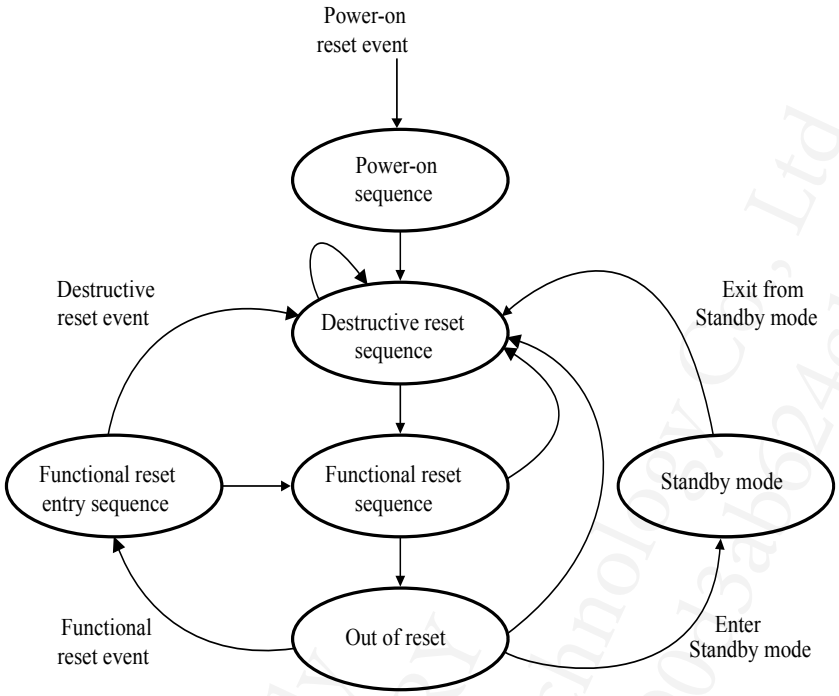

Figure 135. Reset sequence

29.8.1.1 Power-on reset sequence

A reset is always generated when the power-on reset source is asserted, and it has priority over all other reset sources. Such a power-on reset forces the reset state machine to enter the power-on sequence resulting in the assertion of all reset signals. The reset state machine starts progressing when the following two conditions are verified:

1. All the power-on reset events are cleared
2. The MC_RGM's clock source (the FIRC) has started up and stabilized

If a power-on reset event has occurred, the DES[F_POR] bit is set.

The power-on reset cannot be demoted by the software.

29.8.1.2 Destructive reset sequence

The 'Destructive reset sequence' is comprised of a number of phases, where DEST0 is the first phase and is followed by DEST1 and so forth.

This phase is entered immediately from any phase on a power-on, standby reset sequence, or enabled destructive reset event . A destructive reset counter starts immediately on entry in the DEST0 phase . The DEST0 state is exited to the DEST1 state on the rising edge of ipg_clk immediately after all of the following conditions have been established:

- the DEST0 duration time has expired
- all dest_rst inputs are deasserted

The DEST0 state is immediately exited to the power-on state after if a power-on reset event occurrs

The reset state machine exits the destructive reset sequence and enters the functional reset sequence when:

- All the destructive reset events are cleared.
- All the processes that take place during the destructive reset sequence have completed. For details on completed destructive reset sequence, see "Reset process sequence" section in the Reset chapter.

- The 'destructive' reset escalator counter has not reached the value in the DRET field of the RGM_DRET resister.

29.8.1.3 Functional reset sequence

There are two categories of functional reset sequence, the functional reset entry sequence and the functional reset exit sequence.

29.8.1.3.1 Functional reset entry sequence

The functional reset entry sequence is only entered when a functional reset event occurs during the idle phase.

If a functional reset event occurs during an ongoing reset sequence, the corresponding event status flag is set, and the RESET_B pin is asserted per the reset event's configuration. However, the reset sequence is not influenced, and it continues to progress without interruption.

No reset is asserted during the functional reset entry sequence.

The functional reset entry sequence is exited to the DEST0 on the next clock rising edge if a destructive reset event has occurred. The sequence enters the power up sequence if a POR event occurs

In all other cases, the sequence exits to the first stage of functional reset exit sequence.

29.8.1.3.2 Functional reset exit sequence

The functional reset exit sequence is entered either on exit from the destructive reset sequence or on completion of the functional reset entry sequence. The reset state machine exits this sequence and enters the idle phase on verification of the following:

- All the functional reset events are cleared.
- All the processes that take place during the destructive reset sequence have completed. For details on completed destructive reset sequence, see "Reset process sequence" section in the Reset chapter.

If a functional reset event occurs during an ongoing reset sequence, the corresponding event status flag is set, and the RESET_B pin is asserted per the reset event's configuration. However, the reset sequence is not influenced, and it continues to progress without interruption.

29.8.1.4 Idle phase

This is the final phase and is entered on exit from the functional reset exit sequence . When this phase is reached, MC_RGM releases control of the system to the platform and waits for the new reset events that can trigger a reset sequence.

29.8.2 Destructive resets

A destructive reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given destructive reset event (Destructive Event Status Register (DES)) is set when the destructive reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously and the software determines which reset source is the most critical for the application.

The low-voltage detector threshold ensures that when the reset corresponding to the core supply low-voltage detect is enabled, the supply is sufficient to have the destructive event correctly propagated through the digital logic. Therefore, if a given destructive reset is enabled, MC_RGM ensures that the associated reset event is correctly triggered to the full system.

An enabled destructive reset triggers a reset sequence starting from the beginning of DEST0.

29.8.3 External reset

MC_RGM manages the external reset coming from RESET_B. The detection of a falling edge on RESET_B starts the reset sequence from the beginning of the functional reset entry sequence.

The status flag associated with the external reset falling edge event (the RGM_FES[F_EXR] bit) is set when the external reset is asserted and the power-on reset is not asserted.

MC_RGM asserts the external reset if the reset sequence is triggered by one of the following:

- A power-on reset
- A destructive reset event
- A functional reset event

In this case, external reset is asserted until all conditions for the exiting functional reset sequence have been met, with the exception of the RESET_B assertion check

29.8.4 Functional resets

A functional reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given functional reset event (Functional /External Reset Status Register (FES)) is set when the functional reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously and the software determines which reset source is the most critical for the application.

An enabled functional reset triggers a reset sequence starting from the beginning of the functional reset entry sequence.

29.8.5 External reset assertion control

The software indicates to the MC_RGM that the RESET_B is to be asserted by writing to the **ERASSERT** bit in the RGM_ERCTRL register. When this bit is set by the software, RESET_B gets asserted. Setting of this field does not impact the reset sequence in any way.

An example where the **ERASSERT** bit could be set by the software is when entering the self test sequence, during which RESET_B is to be asserted. This indicates the chip is not available in the functional mode although a reset sequence is not in progress. The deassertion of RESET_B is not controlled by the software. Instead, the RESET_B pin remains asserted until the next time the chip exits a reset sequence.

ERASSERT bit is also cleared during the reset sequence.

29.8.6 Functional reset escalation

Functional reset escalation can be used to generate a destructive reset if a number of functional resets is occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

After the functional reset escalation is enabled, MC_RGM increases a counter on each functional reset that causes a reset sequence to be initiated (which means, entrance into FUNC0 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or destructive reset. If the counter reaches the value in the FRET field of the RGM_FRET register, MC_RGM asserts a destructive reset.

The following figure shows the functional reset escalation counter.

Provided by IHS Markit
COMPANY CONFIDENTIAL
Beijing CIIC Automotive Technology Co., Ltd.
c8c462e5-4821-4fa8-b21c-30d8ab024c1

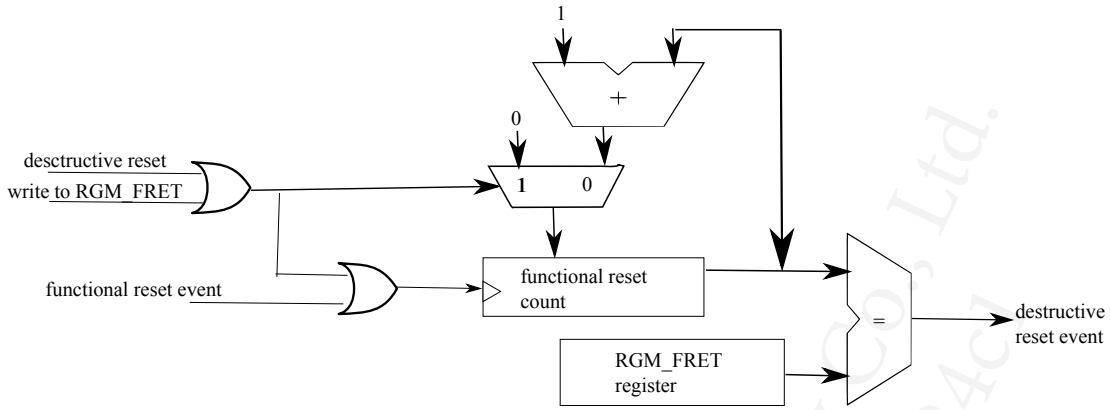

Figure 136. Functional reset escalation counter

29.8.7 Destructive reset escalation

Destructive reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of destructive resets are occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

After destructive reset escalation is enabled, MC_RGM increases a counter on each destructive reset that is enabled to increment the escalator. . This causes a reset sequence to be initiated (that is, entrance into DEST0 from the idle phase) or an ongoing reset sequence to restart (that is, entrance into DEST0 from any other reset phase). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the DRET field of the RGM_DRET register, MC_RGM enters reset DEST0 and stays there until the next power-on reset occurs .

The following figure shows the destructive reset escalation counter.

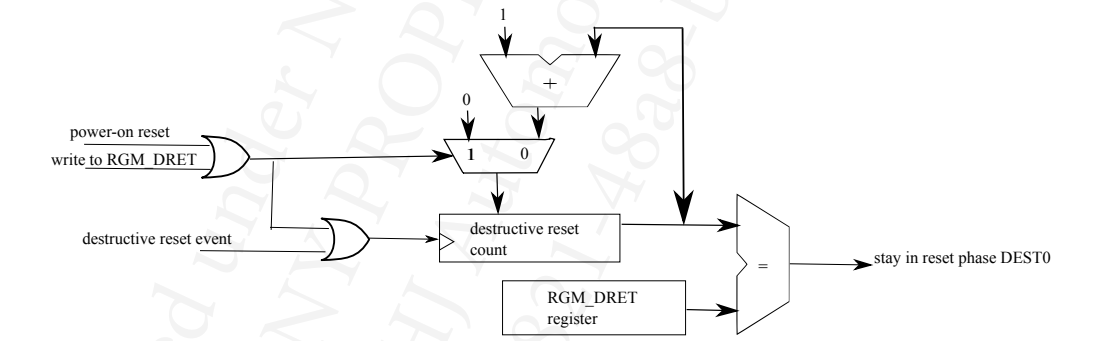

Figure 137. Destructive reset escalation counter

29.8.8 Individual peripheral resets

A peripheral can be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRSTn registers. However, to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset through MC_ME (see the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRSTn registers.
4. Wait until the bit corresponding to the peripheral in the RGM_PSTATn registers isset.
5. Clear the bit corresponding to the peripheral in the RGM_PRSTn registers.

6. Wait until the bit corresponding to the peripheral in the RGM_PSTATn registers is cleared.

The peripheral can be kept in reset indefinitely by not executing steps 5 and 6. After the completion of step 6, the peripheral can be enabled again through MC_ME.

NOTE

For any limitations on this feature, see the chip-specific MC_RGM information.

Chapter 30
Boot

30.1 Introduction

This chapter describes the system boot sequence and provides details about boot options.

When the hardware reset sequence completes, the only processor core available is the Cortex-M7 core in the HSE_H subsystem, referred to as the HSE_H core. The HSE_H core begins executing firmware from the HSE_H ROM module that contains the BootROM firmware. The BootROM firmware manages the boot sequence until it passes control to other code, based on the type of boot:

- In a *non-secure boot*, firmware passes control to customer software that runs on a processor core that is outside the HSE_H subsystem.
- In a *secure boot*, firmware passes control to the HSE_H firmware running on the HSE_H core.

30.2 Features

BootROM boots both customer applications and HSE_H firmware. For a secure boot, it creates the Root of Chain of Trust. BootROM supports the following features:

- Boot from external flash memory
- Secure and Non-Secure boot modes
- Selection of boot core for customer applications
- Serial download
- Execution of Device Configuration Data (DCD)
- Configuration and start of customer-provided self-test data
- Advance of chip life cycle state
- Debug challenge/response authentication
- Boot from Standby/Low Power mode
- Boot from a backup program image

30.3 Boot modes

This chip supports two boot modes:

- Serial Boot mode (from UART, CAN, or Ethernet) is typically used for development and factory line programming. You can disable serial boot mode by blowing the DIS_SER_BOOT fuse.
- Boot from external flash memory (from QuadSPI flash, SD, or MMC) is typically used in production devices.

At reset, BootROM code for the HSE_H core configures the boot mode, including memory type, speed, and so on. It does this from either RCON pins or fuses, based on the FUSE_SEL fuse status.

Combinations of the following inputs control the boot mode:

- Boot mode pins (BMODE1 and BMODE2)
- FUSE_SEL fuse (inhibits the use of RCON and forces fuse-based boot)
- Life cycle state (blocks some boot modes that are valid only for specific life cycle states)

The boot mode pin values are latched before deassertion of the RESET_B signal, enabling selection of the required boot mode externally from the chip.

8216e621-21-48a8-b251-390a8ab624c

The following table shows the supported boot modes for various combinations of inputs.

Table 126. Supported boot modes

Life cycle state	FUSE_SEL	BMODE1	BMODE2	Mode	Use case
MCU_PROD or CUST_DEL or OEM_PROD or IN_FIELD	0	0	0	Serial boot + XOSC in Differential mode	Production configuration for an unprogrammed chip
	0	0	1	Serial boot + XOSC in Crystal mode or Bypass mode	Production configuration for an unprogrammed chip
	0	1	0	Boot from RCON	Development configuration
	1	0	0	Boot from fuses	Production configuration for a programmed chip
	1	0	1	Boot from fuses	Production configuration for a programmed chip
	1	1	0	Serial boot	Debug of a programmed chip
	X	1	1	Reserved	Reserved

NOTE

- The XOSC Crystal mode and XOSC Bypass mode configurations are valid only if the XOSC_VALID fuse bit is not blown. See the attached fuse map spreadsheet.
- Boot from RCON and boot from fuses correspond to boot from external flash memory. BOOT_CFG1[7:5]/ RCON[7:5] values determine the source for external flash memory.

30.3.1 Serial Boot mode

Serial Boot mode enables application code to be downloaded to SRAM. There are many possible uses for serial boot, but the two primary use cases are:

- End-of-line flash memory and fuse programming
- Recovery of chips that fail to boot correctly (nonresponsive modules)

NOTE

You can disable serial boot by blowing the DIS_SER_BOOT (BOOT_CFG2[3]) fuse.

30.3.1.1 End-of-line programming

In a new chip on the production line, the flash memory is not programmed and all fuses are not blown. To make the device usable, the flash memory must be programmed and the fuses blown with the desired configuration. Serial Boot mode enables download of the initial customer application and data to an unprogrammed device.

30.3.1.2 Non-responsive modules

Modules that fail to boot—due to software programming errors, flash memory failure, or PCB failure during production, for example—indicate that a chip is not responsive. Serial Boot mode provides a mechanism to download executable recovery software to SRAM. For example, the downloaded executable may reprogram the flash memory or may execute diagnostic code to determine the fault cause.

30.3.2 Boot from fuses and RCON

BootROM supports booting from multiple interfaces. To configure the interfaces to meet application requirements, BootROM requires a mechanism through which information can be passed to BootROM. BootROM supports two such mechanisms:

- Fuses
- RCONs

The following sections provide details of these mechanisms.

30.3.2.1 Boot from fuses

Boot from fuses is the primary method of configuring the boot process for production devices. In this method, boot code fetches boot configuration data from three fuse words. The following table lists the fuse words associated with boot from fuses.

Fuse word	Offset
BOOT_CFG1	234h
BOOT_CFG2	238h
BOOT_CFG3	23Ch

See the attached fuse map spreadsheet for fuse details. The Boot ROM Fuse Description tab in the spreadsheet provides a detailed view of the BOOT_CFG*n* fuses. The boot fuse words are described under BOOT_CFG_LOCK and must be programmed by the application. Select the boot from fuses mechanism by blowing the FUSE_SEL fuse and by pulling the BMODE1 and BMODE2 pins to the required state during reset.

NOTE

After you have finalized the correct fuse values for each fuse word associated with boot from fuses, block further changes by enabling the fuse lock for BOOT_CFG.

30.3.2.2 Boot from RCON

During application development, you may change a boot configuration multiple times before reaching the final version. After you blow the boot configuration fuses, you cannot change the configuration. If the configuration contains errors, the device may fail to boot. BootROM supports a mechanism for passing configuration parameters. The mechanism is referred to as *Boot from RCON*.

Boot from RCON enables you to change boot configurations during development without blowing fuses, because the RCON boot configuration data resides outside the chip. This boot mechanism is useful primarily during development to enable testing various boot configurations before blowing fuses, which finalizes the configuration.

BootROM supports booting from parallel RCON and serial RCON, as explained in the following sections.

30.3.2.2.1 Boot from parallel RCON

RCON uses up to 32 general-purpose I/O pins—RCON[0] to RCON[31]—that are latched on functional reset deassertion. RCON[31:0] corresponds bit by bit to values in the fuse word BOOT_CFG1[31:0]. On every reset, the chip reads the 32 I/O pads and loads their values into the SRC module's BOTT_GPR_BMR1 register for later use by BootROM.

RCON[31:0] contains configuration parameters that may change multiple times during development. The BOOT_CFG2 and BOOT_CFG3 fuse words contain configuration parameters that do not require testing of multiple configurations.

On development boards, each of the 32 I/Os requires a DIP switch and an analog isolation gate to allow normal operation after reset.

30.3.2.2.2 Boot from serial RCON

An RCON over serial EEPROM scheme, referred to as serial RCON, is available. Unlike parallel RCON, serial RCON does not require DIP switches for 32 I/O PADs and analog gates, saving significant board area.

Serial RCON requires an external serial EEPROM that communicates with the chip via I^2C. The 32 reset configuration bits are fetched from the external EEPROM (first 4 bytes, starting from offset 0h) as part of the boot process. I^2C transmits one byte of data per read and BootROM reads the first 4 bytes. BootROM expects RCON[7:0] on first read, RCON[15: 8] on second, RCON[23:16] in third, and RCON[31:24] on the fourth read. Because I^2C transmits the most significant bit first, keep the values in little-endian format.

The chip operates in master mode and the external serial EEPROM must be in slave mode. The SCL and SDA lines are configured in open-drain mode.

In master mode, I^2C drives the SCL clock from XBAR_DIV3_CLK. I^2C is initialized before the system clock is switched to PLL. The Inter Bus Clock rate (IBFD[IBC]) is programmed as 0Fh, and the effective SCL frequency is 8 MHz/68 = 117.67 kHz. See the I^2C divider and hold tables in the Inter-Integrated Circuit (I^2C) chapter for the corresponding I^2C timing definitions.

Serial EEPROM devices currently supported include:

- Atmel AT24C01C
- ON Semiconductor CAT24C01

Address pins A2 through A0 of the external serial EEPROM should be set to 0 to make the device address A0h.

30.3.2.3 RCON mode selection

The RCON[8] value determines which RCON mode is enabled:

- RCON[8] = 1 indicates that an I^2C EEPROM is connected to RCON[7:8], and 32 bits of configuration data must be read from the EEPROM (see Boot from serial RCON).
- RCON[8] = 0 indicates that all 32 parallel RCON pins are used for the boot configuration (see Boot from parallel RCON).

Serial RCON uses two pins for configuration:

- RCON[7] is the I^2C SDA signal.
- RCON[8] is the I^2C SCL signal. It also indicates to BootROM whether RCON is going to use 32 parallel I/Os or a serial I^2C device.

30.3.2.4 Selection of boot from fuses or boot from RCON

Boot from RCON is a development feature that is enabled on unprogrammed devices, so you do not need to do anything to select it. When you decide to use boot from RCON during application development, you need only choose between parallel RCON and serial RCON. See RCON mode selection for details.

After development is complete, the recommendation is to force the chip to always boot from fuses by performing the following steps:

1. Blow the BOOT_CFG*n* fuses with the proper values.
2. Blow the FUSE_SEL fuse to permanently disable boot from RCON. During end-of-line programming on the production line, you can perform this step via serial boot.
3. Pull the BMODE pins to the required state during reset. See Table 126 for BMODE pin states.

The following diagram shows the logical view of selecting the source of boot configuration information from fuses, parallel RCON, or serial RCON.

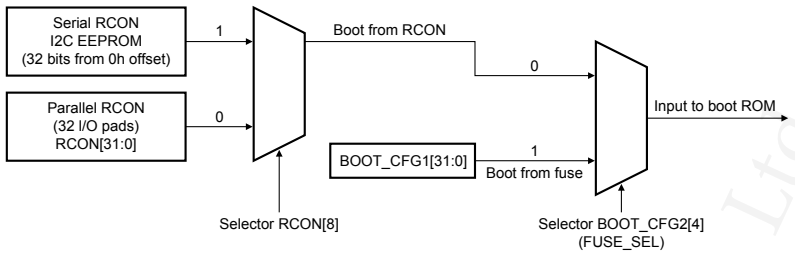

Figure 138. Source selection of boot configuration data

30.4 Program image

This section describes the set of images that you must include in a chip program image. A program image consists of:

- Image Vector Table (IVT) (see Image Vector Table (IVT))
- Device Configuration Data (DCD) (see Device Configuration Data (DCD))
- Self-Test DCD (see Self-Test)
- Application boot image (see Application boot)
- Serial boot image (see Serial boot)

30.4.1 Image Vector Table (IVT)

The IVT is the first image that BootROM reads from the boot device. The IVT contains the required data components: image entry point, pointer to Device Configuration Data (DCD), and other pointers used by BootROM during the boot process. The location of the IVT is the only fixed requirement by BootROM. The remainder of the image memory map is flexible and is traceable by the contents of the IVT. The IVT offset from the device base address and initial load region size for each boot device is defined in the tables below.

Table 127. IVT offset

Boot device type	IVT offset
SD/MMC/eMMC	1000h
QuadSPI serial flash memory	0h

BootROM expects pointers to DCD, Self-Test DCD, the application image, and the HSE_H firmware image to be 8-byte aligned for QuadSPI boot and 512-byte block aligned for µSDHC boot.

Table 128. IVT image structure

Address	Size (bytes)	Name	Comments
0h	4	IVT header	Header showing the start of the IVT

30.4.2 Device Configuration Data (DCD)

On reset, all module registers have default values. These settings are typically not ideal for achieving optimal system performance. Also, some peripherals must be configured before they can be used. DCD is the configuration information contained in the DCD image that BootROM uses to configure peripherals on the device. BootROM determines the location of the DCD table from the pointer in the IVT (see Table 128). Table 134 shows the DCD image structure—a big-endian byte array of allowed DCD commands. The maximum size of the DCD image is 8192 bytes.

Table 134. DCD image structure

Address offset	Size (bytes)	Name	Comments
0h	4	DCD header	Header to signify start of DCD data
4h	DCD_Length	DCD data	DCD commands
DCD_Length + 4	16	GMAC	Cryptographic hash for DCD header and complete DCD data using IVTDCD key

Table 135. DCD header format

Byte 0	Byte 1	Byte 2	Byte 3
TAG = D2h	Length[1] (2 bytes)		Version = 60h

1. Size of the DCD data plus the size of the DCD header

30.4.2.1 DCD commands

The DCD data is comprised of three commands:

- Write Data
- Check Data
- NOP

30.4.2.1.1 Write Data command

Use the Write Data command to write a list of 1-byte, 2-byte, or 4-byte values (or bit masks) to a corresponding list of target addresses. The Write Data command structure is a big-endian byte array as shown in the table below.

Table 136. Write Data command format

Command type	Byte 0	Byte 1	Byte 2	Byte 3
Header	TAG = CCh	Length		Parameters
CMD	Address			
	Value/Mask			
CMD	Address			
	Value/Mask			
...	...			
CMD	Address			
	Value/Mask

Beijing CHJ Automotive Technology Co., Ltd.
c8462e5-4821-488-b251-390d3ab624c1

Table 137. Write Data command byte descriptions

Command byte(s)	Description
Length	Size of entire Write Data command structure including header.
Parameters	A single byte divided into fields as shown in Table 138.
Address	Target address where data will be written. As shown in Table 136, you can specify one or more Address and Value/Mask pairs. The same bytes and flag parameters apply to all locations in the command.
Value/Mask	Data value or bit mask to be written to Address. As shown in Table 136, you can specify one or more Address and Value/Mask pairs. The same bytes and flag parameters apply to all locations in the command.

Table 138. Write Data command Parameters byte

7	6	5	4	3	2	1	0
			Data Set	Data Mask	Bytes		

Table 139. Write Data command Parameters byte field descriptions

Field	Description
7:5 —	Reserved
4 Data Set	Status bit showing whether bits at target were successfully overwritten. 0 - Bits at target address not overwritten 1 - Bits at the target address overwritten
3 Data Mask	Enables overwriting of bits at target address. 0 - All bits may be overwritten 1 - Only specific bits may be overwritten
2:0 Bytes	Width of target location(s) in bytes. 001 - 1 byte 010 - 2 bytes 100 - 4 bytes

When successful, this command writes to each target address in accordance with the Data Mask and Data Set values as indicated in the following table.

Table 140. Effect of Write Data command Data Mask and Data Set values

Data Mask	Data Set	Action	Interpretation
0	X	*address = val_mask	Write value
1	0	*address &= ~val_mask	Clear bit mask
1	1	*address |= val_mask	Set bit mask

BootROM performs the following checks when processing the list of write Address/Value pairs:

1. If any of the target addresses does not have the same alignment as the data width specified in the Bytes field of the Parameters byte, none of the values are written.
2. If any of the values is larger, or any of the bit masks is wider, than permitted by the data width specified in the Bytes field of the Parameters byte, none of the values are written.
3. If any of the target addresses do not lie within an allowed region, none of the values are written. For allowed target address ranges, see the notes below.

NOTE

- You cannot use the Write Data command to write SRAM before SRAM initialization, because this will cause an ECC error due to the 64-bit ECC protection.
- BootROM does not allow HSE_H address space or HSE_H Cortex-M7 system control register space to be modified via DCD commands.

30.4.2.1.2 Check Data command

Use the Check Data command to test for a specific 1-, 2-, or 4-byte bit mask from a source address. The Check Data command structure is a big-endian byte array as shown in the following table.

Table 141. Check Data command structure

Command type	Byte 0	Byte 1	Byte 2	Byte 3
Header	TAG = CFh (1 byte)	Length (2 bytes)		Parameters (1 byte)
CMD	Address (4 bytes)			
	Mask (4 bytes)			
	Count (4 bytes)			

Table 142. Check Data command byte descriptions

Command byte(s)	Description
Length	Size of the entire Check Data command structure, including the header. Used to determine the optional Count.
Parameters	A single byte divided into fields as shown in Table 143.
Address	Source address to test. The values in the same Parameters byte apply to all the Address/ Mask pairs in the command structure.
Mask	Bit mask to test. The values in the same Parameters byte apply to all the Address/Mask pairs in the command structure.
Count	Optional poll count. If no value is specified this command polls indefinitely until the exit condition is met. For a finite value, this command polls Count times. If Count = 0, this command behaves as a NOP command.

Table 143. Check Data command Parameters byte

7	6	5	4	3	2	1	0
			Data Set	Data Mask	Bytes		

Table 144. Check Data command Parameters byte field descriptions

Field	Description
7:5 —	Reserved
4 Data Set	Enables bit checking at target address. 0 - Bits at target address are ignored 1 - Bits at target address are checked
3 Data Mask	Enables partial/complete checking of bits when the Data Set field is set to 1. 0 - All bits in mask are checked 1 - Any bit in mask may be checked at target address
2:0 Bytes	Size of target locations in bytes. 001 - 1 byte 010 - 2 bytes 100 - 4 bytes

The Check Data command polls until either the exit condition is satisfied, or the poll count is reached. If the exit condition is not satisfied until the poll count is reached, it is simply skipped. The exit condition is determined by the Data Mask and Data Set values as shown in the following table.

Table 145. Effect of Check Data command Data Mask and Data Set values

Data Mask	Data Set	Action	Interpretation
0	0	*address & mask == 0	All bits in mask clear.
0	1	*address & mask == mask	All bits in mask set.
1	0	*address & mask != mask	At least one bit in mask clear.
1	1	*address & mask != 0	At least one bit in mask set.

Reasons Check Data command fields are not read:

- If the Address does not have the same alignment as the data width specified in the Bytes field of the Parameters byte, the value is not read.
- If the Mask is wider than permitted by the data width specified in the Bytes field of the Parameters byte, the value is not read.

30.4.2.1.3 NOP command

This command has no effect. The NOP command structure is a big-endian 4-byte array as shown in the table below.

Table 146. NOP command structure

Byte 0	Byte 1	Byte 2	Byte 3
TAG = C0h	Length = 04h		Reserved

Provided under NDA only

Table 147. NOP command byte descriptions

Command byte(s)	Description
Length	Size of the NOP command in bytes, fixed to 4. Any value in this field is ignored.
Reserved	This byte is ignored.

30.4.3 Self-Test

BootROM provides the capability to optionally execute self-test on reset.

Self-test is executed when all of the following conditions are true:

- Device is coming out of POR and self-test completion status is not set.
- Self-Test Image Vector is programmed in IVT.

30.4.3.1 Self-Test boot operation

BootROM executes self-test only when booting from POR and self-test completion status (ST_DONE) is not set in MC_RGM. The following sequence shows how the BootROM executes the self-test.

1. Verify the Self-Test DCD Image header.
2. Copy the Self-Test DCD Image to internal memory.
3. Authenticate image if (LC==(OEM_PROD|IN_FIELD) && IVT_AUTH==1) && EXPORT CONTROL NOT ENABLED.
4. Execute self-test commands.

NOTE

The last self-test command must be to start self-test by setting RUNSW[RUNSW] = 1 in STCU2.

30.4.3.2 Self-Test DCD image structure

The Self-Test DCD image structure has the same format as the DCD image structure (see Device Configuration Data (DCD)). BootROM determines the location of the Self-Test DCD image via the Self-Test DCD pointer in the IVT. The maximum size of the image is 8192 bytes (see Device Configuration Data (DCD) for details on available commands).

Table 148. Self-Test header

Byte 0	Byte 1	Byte 2	Byte 3
TAG = D3h	Length[1]		Version = 60h

1. Size of the entire Self-Test DCD Image structure, that is, the size of the Self-Test DCD data and the DCD header.

30.4.4 Application boot

The Application Boot Code image must comply with the structure shown in the following table for non-secure boot (BOOT_SEQ == 0).

Table 149. Non-secure Application Boot Code image structure (BOOT_SEQ == 0)

Address offset	Size (bytes)	Name	Comments
0h	4	Image header	Marks start of application image.
4h	4	RAM start pointer	Pointer to the first RAM address to which BootROM

Table continues on the next page...

Table 149. Non-secure Application Boot Code image structure (BOOT_SEQ == 0) (continued)

Address offset	Size (bytes)	Name	Comments
			must load application boot code.
8h	4	RAM entry pointer	Pointer to out of RESET start of boot target core. For Cortex-M7, it corresponds to VTOR. For A53, it corresponds to start of code execution. This pointer should be within the section of SRAM where the application image is downloaded.
Ch	4	Code length	Length of code section of the image.
10h	48	Reserved	Reserved
40h	Code_len	Code	Code can be any size up to the maximum size of system SRAM.

The header used by the Application Boot Code image is shown below.

Table 150. Application boot image header

Byte 0	Byte 1	Byte 2	Byte 3
TAG = D5h	Reserved[1]		Version = 60h

1. The Reserved field has no effect. It is set to all zeroes.

NOTE

For application boot via the µSDHC interface, when BOOT_SEQ == 0, the RAM start pointer for the application should not point between 34008000h to 34078000h. This address range is used by BootROM for internal operation during boot via the µSDHC interface. BootROM also uses 4 KB of SRAM memory starting at 343FF000h for ADMA descriptors in case of µSDHC boot. The Application boot image header should not point to this location in case of µSDHC boot.

30.4.5 Serial boot

The image structure for non-secure serial boot is shown below.

Table 151. Image structure for non-secure serial boot

Address offset	Bytes	Name	Comments
0h	4	Image header	Marks start of serial boot code image (see Table 153).
4h	4	RAM start pointer	Pointer to first RAM address to which BootROM must load serial boot code.

Table continues on the next page...

Table 151. Image structure for non-secure serial boot (continued)

Address offset	Bytes	Name	Comments
8h	4	RAM Entry pointer	Pointer to out of RESET start of boot target core. For CCortex-M7, it corresponds to VTOR, and for Cortex-A53 to start of code execution.
Ch	4	Code length word	Length of code section of the image (see Table 154).
10h	48	Reserved	Reserved
40h	Code_len	Code	Code can be any size up to the maximum size of SRAM.

The image structure for secure serial boot is shown below.

Table 152. Image structure secure serial boot

Address offset	Bytes	Name	Comments
0h	4	Image header	Marks start of serial boot code image (see Table 153).
4h	4	RAM start pointer	Pointer to first RAM address to which BootROM must load serial boot code.
8h	4	RAM Entry pointer	Pointer to out of RESET start of boot target core. For Cortex-M7, it corresponds to VTOR, and for Cortex-A53 to start of code execution.
Ch	4	Code length word	Length of code section of the image (see Table 154).
10h	4	Auth mode	Authentication mode. Reserved for non-secure boot.
14h	4	NSKPUB Key Selector	NSK public key selector
18h	40	Reserved	Reserved
40h	4096	NSKPUB	NXP Public keys (16) for RSA authentication.
1040h	256	CSKPUB	Customer Public key for RSA authentication.
1140h	256	CSK Signature	RSA signature for CSKPUB authentication.
1240h	Code length	Code	Code can be any size up to the maximum size of SRAM.
1240h + Code length	256	Public key Signature	Public key signature for image authentication.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.
c8c462e5-4821-48a8-b231-390d3ab6a4

NOTE

CSKPUB and CSK Signature fields are reserved if the serial boot application is signed by NXP.

The image header shown below is common to both the non-secure and secure serial boot image structures.

Table 153. Non-secure and secure boot image header

Byte 3	Byte 2	Byte 1	Byte 0
Version = 60h	Reserved	Reserved	TAG = D8h

The Code length word is described in the table below.

Table 154. Code length word

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NO_ECHO	CODE_SIZE														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CODE_SIZE															

Table 155. Code length word field description

Field	Description
31 NO_ECHO	Do not echo incoming serial data from next serial phase onward.
30:0 CODE_SIZE	Size of the serial boot code to be downloaded.

30.5 Boot register descriptions

During execution, Boot ROM accesses memory-mapped registers to:

- Retrieve configuration details
- Maintain execution details required for proper execution

Some of the registers are read-only and provide input to Boot ROM. Other registers are read/write and contain status information required for proper functioning. The following sections contain the register memory map and detailed register descriptions that include reset phase and field descriptions.

30.5.1 Boot memory map

Boot_CC base address: 4007_C900h

Offset	Register	Width (In bits)	Access	Reset value
0h	Boot Configuration 1 (BOOT_GPR_BMR1)	32	RO	0000_0000h
4h	Boot Configuration 2 (BOOT_GPR_BMR2)	32	RO	0000_0000h
38h	SRC POR Control (SRC_POR_CTRL_REG)	32	RW	0000_0000h

30.5.2 Boot Configuration 1 (BOOT_GPR_BMR1)

Offset

Register	Offset
BOOT_GPR_BMR1	0h

Function

Contains boot configuration data latched from fuses or GPIOs based on RCON/FUSE_SEL fuse setting. The data is latched at PHASE3 deassertion in the chip. The reset value for a chip that is not configured is 0000_0000h. Otherwise, the reset value is dependent on the values latched.

RCON uses 32 IO signals labelled RCON[0] to RCON[31]. See the attached IOMUX spreadsheet for details.

NOTE

RCON pads should be supplied with a pull on the board.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

COMPANY PROPRIETARY
Beijing ESHJ Automotive Technology Co., Ltd.
8c462e54-821-48a8-b251-390d3ab624c1

Diagram

Fields

Field	Function
31-16 HSE_FW_ROLLBACK_MARKER	HSE_H Firmware Rollback Marker HSE_H firmware writes the HSE_H rollback marker. boot ROM defines only BADAh as a valid marker.
15-8 HSE_FW_ROLLBACK_COUNT_B	HSE Firmware Rollback Count – Backup Image Represents the number of times that boot ROM passed control to the HSE_H firmware backup image, and the HSE_H firmware failed to write a valid HSE_FW_ROLLBACK_MARKER value.
7-0 HSE_FW_ROLLBACK_COUNT_A	HSE Firmware Rollback Count – Primary Image Represents the number of times that boot ROM passed control to the HSE_H firmware primary image, and HSE_H firmware failed to write a valid HSE_FW_ROLLBACK_MARKER value.

30.6 Boot flow

HSE_H BootROM boots HSE_H firmware and/or application code based on the BOOT_SEQ value. Following are basic details about boot flow.

1. Depending on self-test pointers and other BootROM checks on the Self-Test DCD, boot flow can complete in either three phases or one phase. See Boot flow phases for more detail.
2. BootROM supports booting of application code and and HSE_H firmware images, depending upon the BOOT_SEQ value and whether the image pointers in the IVT are valid.
3. BootROM supports the concept of backup images for:
   - Self-Test DCD
   - DCD
   - Application code
   - HSE_H firmware

Beijing CTI Automotive Technology Co., Ltd.
c8c4623-42-48a-b23-390d3ab624c4

For each type of program image, BootROM first tries to execute the primary image if the IVT points to a valid location. Only 0h is considered an invalid location. If any of the following are encountered, BootROM tries to execute the backup image pointed to by the IVT, wherever applicable:

- Primary image points to 0h.
- Primary image header does not conform to the required image header format.
- Authentication fails.

4. BootROM allows rollback of the HSE_H firmware from the backup image when a failed update of HSE_H firmware occurs in its primary slot. The failure scenario is as follows:
   a. The updated primary HSE_H firmware image passes all header checks.
   b. The updated image successfully completes the BootROM authentication process.
   c. After getting control, the updated firmware issues a RESET or generates a SWT RESET due to a hang scenario before reaching the point of execution where it can boot application code and provide services.

   BootROM can identify these scenarios.

   a. After a sequence of 8 failed attempts for the primary HSE_H firmware image, BootROM tries booting from the HSE_H firmware backup image.
   b. When a sequence of 8 failures of the backup image occurs, BootROM enters Serial Boot.

   BootROM uses an SRC GPR register (POR_CTRL_REG1) to keep track of the number of trials for the primary image and the backup image. A marker, HSE_FW_ROLLBACK_MARKER (BADAh), must be written by HSE_H firmware at the point of its execution where it has passed control to application code and is ready to provide services. BootROM looks for this marker to determine whether booting from the HSE_H firmware primary image or the backup was successful.

See Boot register descriptions for more details about the POR_CTRL_REG1 register.

30.6.1 Boot flow phases

When booting from external flash memory, BootROM execution occurs in three phases.

Table 156. Boot flow phases when booting from external flash memory

Step	Phase	Description
1	Initialize 1	BootROM execution on HSE_H core.
2	Self-Test	LBIST/MBIST execution by STCU2 (if configured).
3	Initialize 2	BootROM execution on HSE_H core after STCU2-induced reset.

The Initialize 2 phase initializes the device after reset when self-test completes, and continues the boot process. If the Self-Test DCD vector is not programmed in the IVT, the boot flow skips step 1 and step 2, and starts from step 3, the Initialize 2 phase.

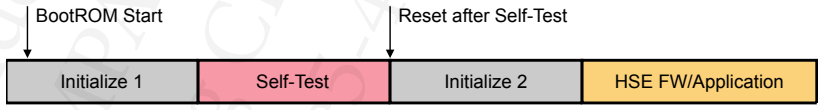

Figure 139. Boot flow phases

30.6.1.1 Initialize 1 boot flow phase

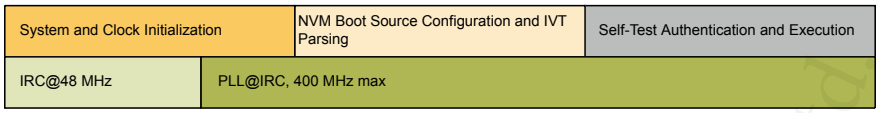

Figure 140. Initialize 1 boot flow phase

The steps below define the Initialize 1 boot flow phase:

1. Initialize the stack pointer to memory pointed to by the stack area as described in the memory map.
2. If coming out of Standby mode, enter boot from Standby mode (see Standby boot).
3. If OCOTP detects a double-bit ECC (DED) error for HSE_H or the SYS fuse box, or the MTR status is failure, issue a destructive reset.
4. Identify the boot interface.
5. Enable PLL@FIRC and reconfigure the clock to run at 400 MHz.
6. Initialize CAAM and PKC.
7. If the number of functional resets ≥ 8, enter Serial Boot mode.
8. Configure QuadSPI/SD/MMC/eMMC based on fuse information.
    a. If interface is QuadSPI:
        - Read customer-provided flash memory reconfiguration parameters.
        - Reconfigure QuadSPI to run at the required speed, pads, and other configuration.
9. Copy the IVT from QuadSPI/SD/MMC/eMMC.
10. Authenticate the IVT, if (LC==OEM_PROD OR IN_FIELD) AND (IVT_AUTH==1) AND (EXPORT CONTROL NOT ENABLED).
11. Check the IVT and issue a functional reset if any of these conditions apply:
    - Header is invalid.
    - Boot target is incorrect.
    - Both the primary and backup pointers for application code and HSE_H firmware are NULL.
12. If self-test has not been executed, copy and authenticate (depending on step 10) the Self-Test DCD data pointed to by the primary pointer if the pointer is not NULL. If any failure occurs—authentication, invalid header, or wrong DCD, for example—do not execute the remaining Self-Test DCDs under the primary pointer and instead begin self-test configuration operations from the Self-Test DCD under the backup pointer.

    If authentication fails for the Self-Test DCD data pointed to by the backup pointer, issue a functional reset.

    In case of other failures—invalid header or wrong DCD, for example—skip DCD execution for subsequent DCDs from backup and allow BootROM to proceed to subsequent application boot steps.

NOTE

It is recommended that a Write Data DCD command be added just before the DCD command to trigger STCU2. The Write Data DCD command can write a Self-Test DCD configuration completion signature marker. Application code can later read this location and verify whether the Self-Test DCD configuration completion signature marker is available. Application code can use the ST_DONE status along with the signature marker to determine the outcome of the Self-Test phase.

30.6.1.2 Self-Test

Self-test can execute Memory BIST (MBIST) and/or Logic BIST (LBIST). The tests to be performed are defined in the Self-Test DCD image.

- Self-test is run only after POR, and if the Self-Test Completion status flag is not set to 1 in MC_RGM.
- Self-test is optional and cannot be executed if the primary and back up pointers are NULL.
- Self-test execution begins after the Self-Test DCD triggers STCU2.
- STCU2 performs a reset at the end of self-test.

30.6.1.3 Initialize 2 boot flow phase

The following figure illustrates the Initialize 2 boot flow phase.

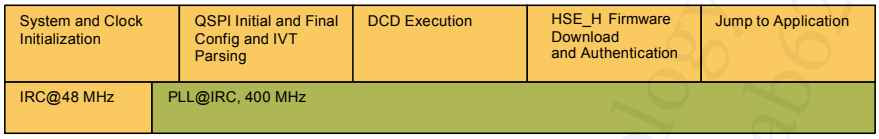

Figure 141. Initialize 2 boot flow phase

The steps below define the Initialize 2 boot flow phase:

1. Initialize the stack pointer to the memory pointed to by the stack area as described in the memory map.
2. If coming out of Standby mode, enter boot from Standby mode. (See Standby boot).
3. If an OCOTP double-bit ECC (DED) error is latched for HSE_H or the SYS fuse box, or the MTR status is failure, issue a destructive reset.
4. Identify the boot interface.
5. Enable PLL@FIRC and reconfigure the clock to run at 400 MHz.
6. Initialize CAAM and PKC.
7. If the number of functional resets ≥ 8, enter Serial Boot mode.
8. Configure QuadSPI/SD/MMC/eMMC based on fuse information.
    a. If interface is QuadSPI:
        i. Read customer-provided flash memory reconfiguration parameters.
        ii. Reconfigure QuadSPI to run at required speed, pads, and other configuration.
9. Copy the IVT from QuadSPI/SD/MMC/eMMC.
10. Authenticate the IVT, if (LC==OEM_PROD OR IN_FIELD) AND (IVT_AUTH==1) AND (EXPORT CONTROL NOT ENABLED).
11. Check the IVT and issue a functional reset if any of these conditions apply:
    - Header is invalid.
    - Boot target is incorrect.
    - Both the primary and backup pointers for application code and HSE_H firmware are NULL.
12. Copy and authenticate (depending on the above step) the DCD data if the DCD pointer is not NULL. In case of any failure—authentication, invalid header, or wrong DCD, for example—do not execute the remaining DCDs under the primary pointer and instead begin DCD operations for the DCD data under the backup pointer.

    If authentication fails for the DCD data pointed to by the DCD backup pointer, issue a reset.

In case of other failures—invalid header or wrong DCD, for example—skip DCD execution for subsequent DCDs from backup and allow BootROM to proceed to subsequent application boot steps.

13. Set up the Debug challenge/response.
14. If the IVT Boot Configuration Word [BOOT_SEQ] == 0, parse the IVT and locate the Primary Application Boot Code Structure.
    a. If the Primary Application header is valid, download the application to target memory.
    b. If the Primary Application header is invalid, verify that the backup application header is valid. If it is, download the backup application to target memory.
    c. If both the Primary Application header and the backup application header are invalid, skip downloading the application.
15. Parse the IVT and locate the Primary HSE_H Firmware Structure.
16. If the value of HSE_ROLLBACK_COUNT_A in the SRC module's POR_CTRL_REG1[7:0] ≤ 8:
    a. If the value of HSE_ROLLBACK_MARKER in the SRC module's POR_CTRL_REG1[31:16] == BADAh:
        i. Clear HSE_ROLLBACK_COUNT_A in the SRC module's POR_CTRL_REG1[7:0] to 0.
        ii. Clear HSE_ROLLBACK_MARKER in the SRC module's POR_CTRL_REG1[7:0] to 0.
    b. If the Primary HSE_H Firmware header is valid:
        i. Decrypt the HSE_H firmware, authenticate, and copy to target memory.
        ii. If authentication is successful:
            i. If (BOOT_SEQ == 0) AND (Application downloaded successfully in step 14), enable the Application core.
            ii. Enable the HSE_H firmware.
            iii. Increment the value of HSE_ROLLBACK_COUNT_A in SRC module's POR_CTRL_REG1[7:0] by 1.
        iii. Else, jump to step 17.
    c. Else, jump to step 17.
17. If the value of HSE_ROLLBACK_COUNT_B in the SRC module's POR_CTRL_REG1[15:8] ≤ 8:
    a. If the value of HSE_ROLLBACK_MARKER in the SRC module's POR_CTRL_REG1[31:16] == BADAh:
        i. Clear the HSE_ROLLBACK_COUNT_B value in the SRC module's POR_CTRL_REG1[15:8] to 0.
        ii. Clear the HSE_ROLLBACK_MARKER value in the SRC module's POR_CTRL_REG1[31:16] to 0.
    b. If the HSE_H firmware backup image header is valid:
        i. Decrypt the HSE_H firmware, authenticate, and copy to target memory.
            i. If authentication is successful:
                i. If (BOOT_SEQ == 0) AND (Application downloaded successfully in step 14), enable the Application target core.
                ii. Enable HSE_H firmware.
                iii. Increment the value of HSE_ROLLBACK_COUNT_B in the SRC module's POR_CTRL_REG1[15:8] by 1.
            ii. Else:
                i. If (BOOTSEQ == 0) and (Application downloaded successfully in step 14):
                    i. Enable the Application target core.

ii. Put the HSE_H Cortex-M7 core into an infinite wait loop.

ii. Else, issue a functional reset.

c. Else:

i. If (BOOTSEQ == 0) AND (Application downloaded successfully in step 14):

i. Enable the Application target core.

ii. Put the HSE_H Cortex-M7 core into an infinite wait loop.

ii. Else, issue a functional reset.

NOTE

When BOOT_SEQ == 0, BootROM downloads application code to SRAM as described in Phase 2 of the boot flow. Although BootROM expects the length of all program images to be 8-byte aligned, for the application download, it initializes an additional 8 bytes of memory just after the last location of the copied image. This is to avoid pre-fetch errors when the application executes.

30.6.2 Boot flow diagram

The following figure shows the high level boot flow of BootROM firmware.

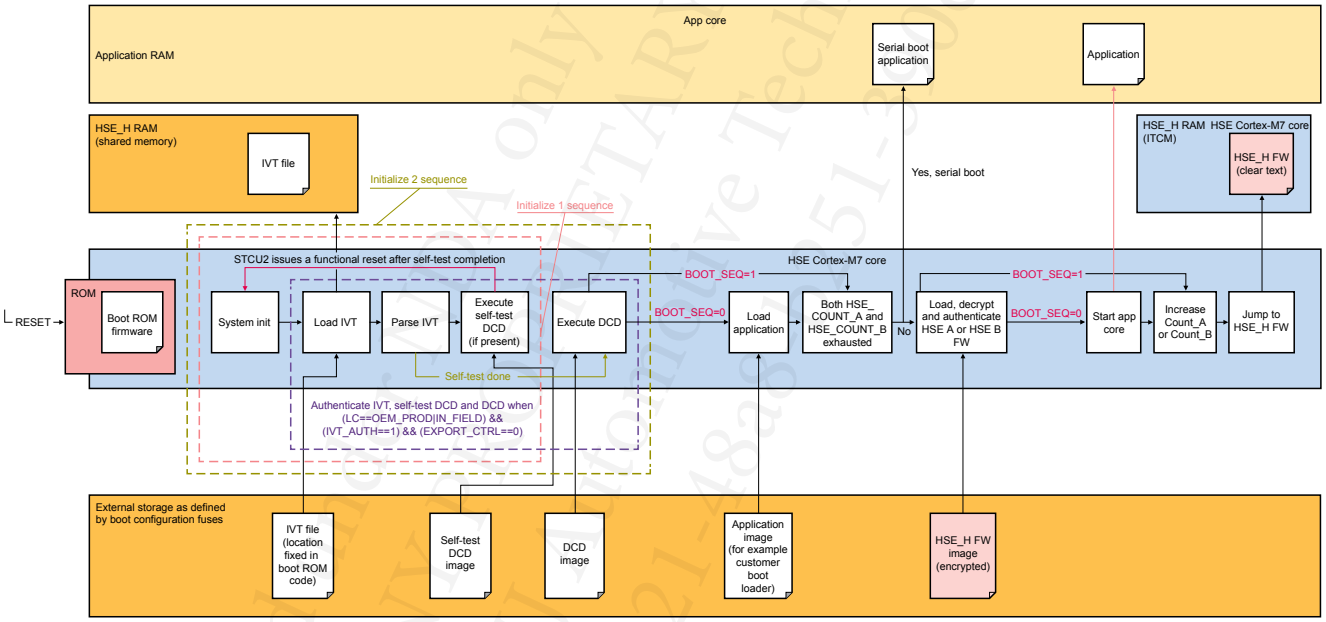

Figure 142. High level boot flow

30.7 Boot settings and fuse map

For additional details about boot settings and the fuse map, see the Boot Settings and Fuse Map spreadsheets.

30.8 BootROM impact on module registers' reset values

BootROM execution might change the reset values of some modules' registers when control passes to the application. For list of these modules, their affected registers, and the registers' values, see the Boot Settings attachment.

NOTE

- BootROM supports many configuration options and permissible combinations. Interfaces used by BootROM, e.g., QSPI or other boot sources, may not be in outright operational state on entry into the booted application. Such interfaces needs to be reconfigured properly before application use.
- If application needs to modify the clock configuration or change interface settings at the start of execution, it should first disable the interface. If application intended to keep using any interface after clock change then it should ensure that interface is reconfigured properly before further use.

30.9 BootROM clock configuration

BootROM begins execution with FIRC as the default system clock source. For better performance, BootROM tries to configure CORE PLL-DFS over FIRC. After CORE PLL-DFS is sucessfully locked, BootROM switches the XBAR clock (source to booting core) to CORE_DFS1_CLOCK, which is targeted to be 400 MHz. In case of failure to lock PLL-DFS, BootROM continues booting with FIRC as the system clock.

BootROM also has a provision to boot without locking the core PLL. This feature is controlled by BOOT_CFG1[31]/RCON[31]. A value of 1b forces BootROM to skip PLL-DFS programming when booting from QuadSPI or µSDHC. BOOT_CFG1[31]/RCON[31] does not have any impact on PLL-DFS programming when booting from any serial interface—for example, BootROM always configures the core PLL when performing a serial download.

When BOOT_SEQ == 0, before BootROM passes control to application code, the system clock is switched back to FIRC and CORE PLL-DFS is switched off.

When BOOT_SEQ == 1, BootROM passes control to the HSE_H firmware with the system clock as CORE PLL-DFS.

See the respective interface sections for the clocking scheme of boot interfaces.

30.10 Image authentication and decryption

BootROM can load multiple images from non-volatile storage space (QuadSPI or SD/MMC/eMMC) to boot on:

- HSE_H Cortex-M7 core (for HSE_H firmware)
- Cortex-M7/Cortex-A53 core (for application boot code)

Application boot can be either non-secure or secure, depending on the life cycle state and the BOOT_SEQ field value in the IVT Boot Configuration word. The following images are authenticated by BootROM when performing a secure boot:

- IVT
- DCD
- Self-Test DCD
- Serial application image
- HSE_H firmware image

30.11 Serial boot

Serial Boot mode is entered via the BMODE input pins. Serial download can also be initiated if the Functional Reset Counter (FREC register in the MC_RGM module) reaches a value ≥8. This mode is available in all life cycle states except:

- OUT_OF_FAB
- FA

In Serial Boot mode, BootROM programs the HSE_H SWT for a 60-second timeout, then continuously polls for activity on any of the available interfaces:

- Ethernet
- CAN

- UART

If no activity is detected, the timer expires and the core is reset. BootROM sequentially checks for activity on all available interfaces and selects the first serial interface that it identifies as active as the download interface. The following figure describes the selection process.

NOTE

In Serial Download mode, BootROM disables HSE_H SWT if the life cycle state is:

- MCU_PROD
- CUST_DEL

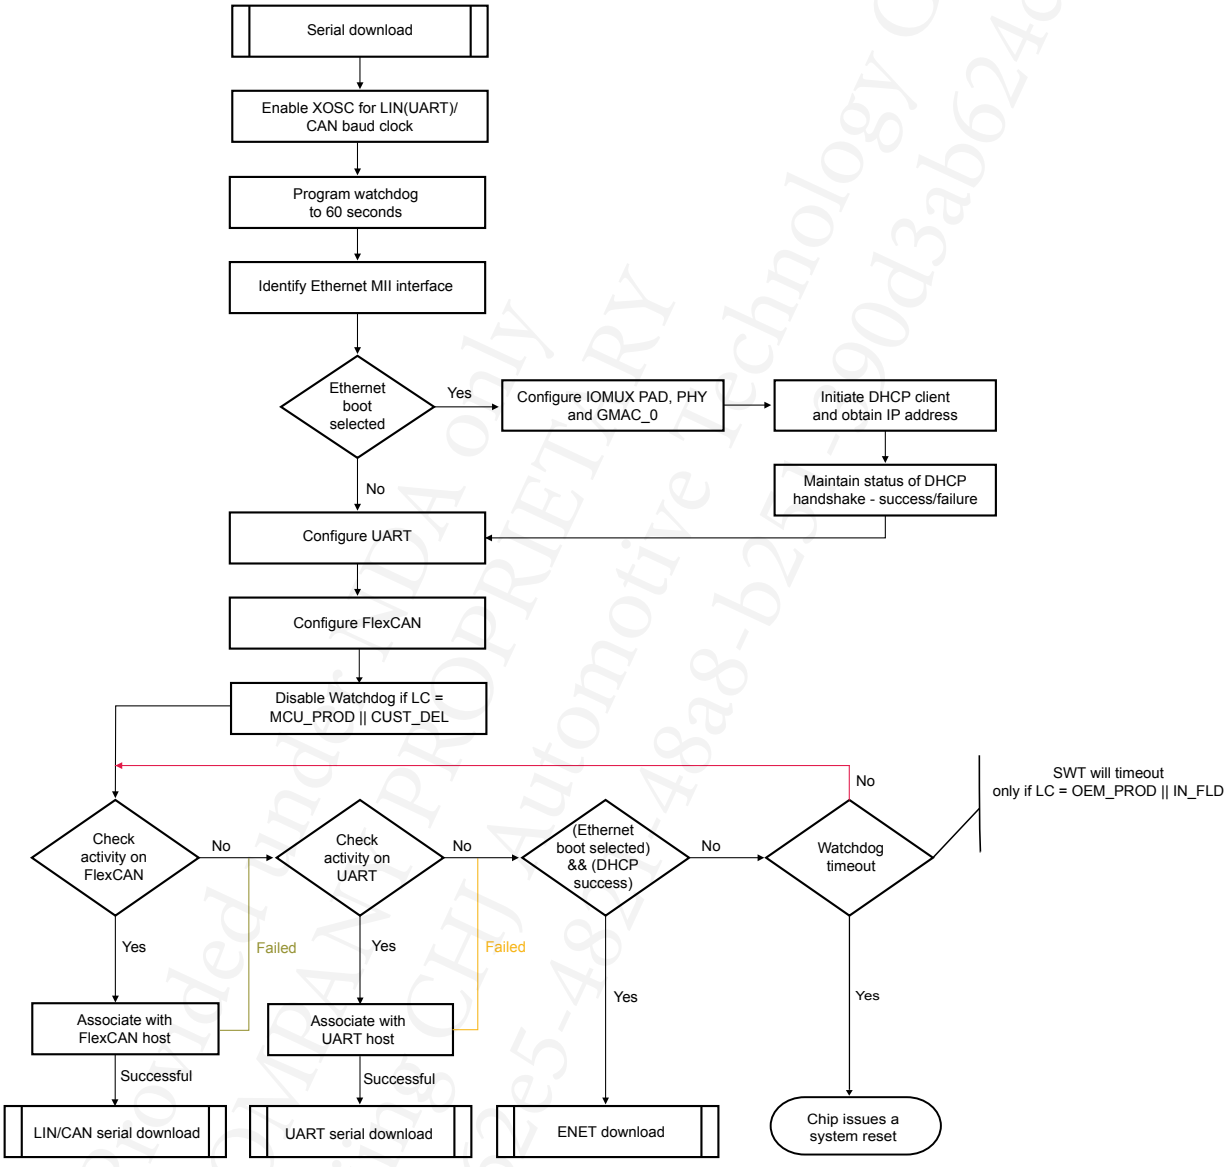

Figure 143. BootROM serial download sequence

30.11.1 XOSC configuration

During serial boot, BootROM uses XOSC as the clock source for serial interfaces.

- LIN_CLK and CAN_CLK are derived from an external clock source connected over XOSC.

- The GMAC_0 clock is derived from the Peripheral PLL (PERIPH_PLL) locked over XOSC.

The XOSC interface supports multiple operating modes and requires specific configuration for providing a stable clock in these modes. BootROM must be provided with the configuration details for enabling correct configuration, as per clock source connected on ECU, over the XOSC interface.

30.11.2 Serial download protocol

30.11.2.1 Serial download protocol – UART and CAN

The following figure shows the download protocol followed by BootROM during serial download over FlexCAN and UART.

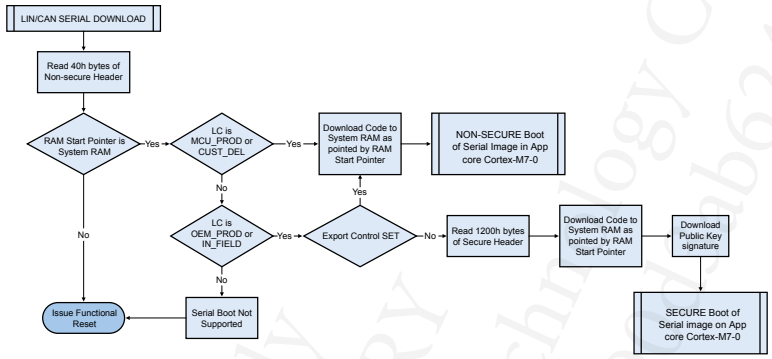

Figure 144. FlexCAN and UART download protocol

The serial download protocol is divided into various phases as described below. The phases marked "Secure boot", are skipped during a non-secure boot.

Table 157. Serial download protocol phases

No.	Phase	Description	Size (bytes)	Entry
1	Initialization	BootROM prepares the device to perform a serial download by performing the following steps: 1. Configure clock. 2. Configure the module. 3. Configure watchdog to 60 seconds. 4. Disable SWT if the life cycle state is MCU_PROD or CUST_DEL.	—	—
2	Association	BootROM polls sequentially for activity on the transmission channel until the marker FEED_FACE_CAFE_BEEFh is received. Any incorrect data received is discarded.	8h	Always
3	Non-secure header	BootROM reads the first 40h bytes over the channel and extracts the RAM start pointer, entry pointer, and the code size from the image.	40h	Always

Table continues on the next page...

Table 157. Serial download protocol phases (continued)

No.	Phase	Description	Size (bytes)	Entry
		BootROM also extracts the NO_ECHO field from the most significant bit of the Code length word. **NOTE** • BootROM allows serial download of data only to system RAM. The maximum size of the serial image is limited to the size of the system RAM on the chip. • The image download address must be 64-bit aligned.		
4	Secure header	BootROM reads the next 1200h bytes of the image containing the NSK Public keys, CSK Public key, and the CSK signature.	1200h	Secure boot
5	Code download	BootROM downloads the serial code of specified length over the channel and stores it at the specified location.	Code length	Always
6	Public signature	BootROM reads the Public key signature of the image used for authentication of the image.	100h	Secure boot
7	Execution	After successful download of entire image, the Cortex-M7_0 core is enabled with the reset vector pointing to the Entry pointer. Before enabling the core, the watchdog SWT_0 is enabled with its default configuration. **NOTE** It is the application's responsibility to service the watchdog appropriately.	—	—

When performing a secure boot, after the image is downloaded, BootROM first performs authentication of the image per the Authentication mode selected.

Received packets can be either echoed or not. The NO_ECHO field in the Code length word determines the configuration. By default, all packets are echoed. If the NO_ECHO field is set to 1:

- For a secure boot, starting from the Secure header phase, CAN packets are not echoed.
- For a non-secure boot, starting from the Code download phase, CAN packets are not echoed.

30.11.2.2 Serial download protocol – Ethernet

The serial download protocol over GMAC interface performs the following steps:

1. Identifies MII Interface connected over GMAC_0.
2. Configures PHY and GMAC_0 for Ethernet packet exchange.
3. DHCP client launch:
    a. Chip performs a DHCP request to get an IP address (IPV4).

b. DHCP exchange also retrieves the address of a TFTP server. BootROM expects the TFTP server address to be the same as the DHCP server address.

4. If the DHCP operation was successful, perform a TFTP data exchange:
   a. Fetch SerHeader.img using TFTP protocol from the TFTP Server.
   b. Fetch SerApp.img using TFTP protocol from the TFTP Server.
   c. Fetch SerSign.img using TFTP protocol from the TFTP Server.
5. The image is loaded into SRAM and executed. If the chip is configured for Secure mode, the downloaded image is authenticated before it is executed.

30.11.3 FlexCAN

BootROM supports serial download from the FlexCAN_0 module. Communication between the chip and the host (transmitting utility) is done by exchange of data through CAN packets. BootROM supports transfer of data only in non-FD mode.

30.11.3.1 FlexCAN I/O multiplexer configuration

The I/O pads for FlexCAN communication are configured as shown in the following table.

Table 158. FlexCAN I/O

Signal	Pad name
CAN RX	PAD[43]
CAN TX	PAD[44]

30.11.3.2 Clock configuration

The baud clock for the FlexCAN module is derived from the MC_CGM_0 clock Mux 7 selector, as shown below. BootROM uses XOSC as the clock source for CAN_PE_CLK during boot. If XOSC fails to initialize, FIRC is selected as the MUX source.

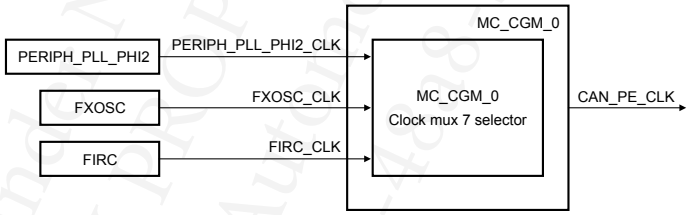

Figure 145. FlexCAN clock configuration

30.11.3.3 Baud rates

The baud rate is determined by two factors: the timing parameters programmed for the module and the baud clock.

The FlexCAN baud clock is derived from XOSC as mentioned in Clock configuration. The timing parameters are programmed to achieve a common bit rate for both clock sources.

For XOSC, for varying frequencies of the crystal, the bit rate achieved is directly proportional to the baud clock.

Table 159. FlexCAN baud rates

Baud clock frequency	Bit rate
20 MHz (XOSC)	0.5 MBd
40 MHz (XOSC)	1 MBd

30.11.3.4 FlexCAN boot operation

The host transfers the application image as per the serial download protocol (see Serial download protocol). The message IDs used by the chip (MCU) for transfer of frames over the FlexCAN interface are defined in the following table. The message IDs are segregated based on the phase of communication.

Table 160. FlexCAN mailbox IDs

Serial download phase	Rx MB ID	Tx MB ID
Association phase	11h	01h
Non-secure header phase	12h	02h
Secure header phase	13h	03h
Code download phase	14h	04h
Public signature phase	15h	05h

NOTE

The payload size of the message transmitted is restricted to 8 bytes.

30.11.4 UART

BootROM supports boot from the LINFlexD_0 module, configured in UART mode. The communication between the MCU and the host (transmitting utility) is done by exchange of data through UART packets. LINFlexD_0 is configured to communicate in 8E1 configuration.

30.11.4.1 UART IOMUX configuration

The IOMUX pads for UART communication are configured as shown in the following table.

Table 161. UART external I/O

Signal	PAD name
RX	PAD[42]
TX	PAD[41]

30.11.4.2 Clock configuration

The clock for the LINFlexD module is derived from the MC_CGM_0 clock Mux 8 selector. BootROM uses XOSC as a clock source for LIN_BAUD_CLK during boot. If XOSC fails to initialize, FIRC is selected as the MUX source.

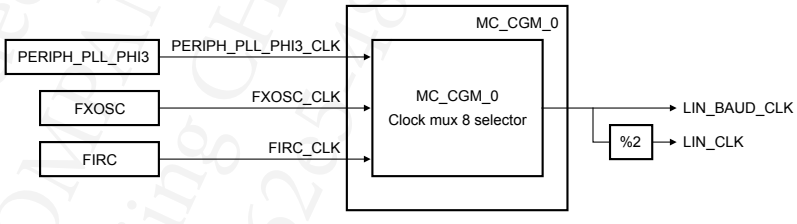

Figure 146. UART clock configuration

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e82-1682-48a8-b251-30d3ab624c

30.11.4.3 UART baud rates

The baud rate is determined by two factors: the timing parameters programmed for the module and the baud clock. The LINFlexD baud clock is derived from either XOSC or FIRC, as shown in Clock configuration. The timing parameters are programmed to achieve a common bit rate for both clock sources.

For XOSC, for varying frequencies of the crystal, the bit rate achieved is directly proportional to the baud clock.

Table 162. LINFlexD baud rates

Baud clock frequency	LINFlexD baud rate
20 MHz (XOSC)	24 kBd
40 MHz (XOSC)	48 kBd
48 MHz (FIRC)	48 kBd

30.11.5 Ethernet boot

BootROM supports serial download over an Ethernet interface. Ethernet boot currently supports RGMII interface.

30.11.5.1 IOMUX configuration

For details on the IOMUX configuration for Ethernet boot, see the BootROM_IOMUX_Settings tab in Boot_Settings_Sheet attached to this document.

30.11.5.2 Functional description

At a high level, Ethernet serial download follows the steps shown below:

1. Ethernet MII interface detection and configuration.
2. PHY identification and configuration.
3. GMAC_0 speed and clock configuration.
4. GMAC_0 controller configuration.
5. MAC address configuration.
6. DHCP client launch.
7. The chip performs a DHCP request to get an IP address (IPV4).
8. The DHCP exchange also retrieves the address of a TFTP server. BootROM expects the TFTP server address to be the same as the DHCP server address.
9. The file is then fetched using TFTP protocol from the TFTP server.
10. The file is loaded into SRAM and executed. If the chip is configured for Secure mode, the code is authenticated before it is executed.

30.11.5.2.1 MII interface detection

For an unprogrammed device, MMI Interface selection is made by a second configuration applied to the BMODE1 and BMODE2 pins.

1. The first configuration is applied before deassertion of the RESET_B signal. It selects the boot mode.
2. The second configuration is applied after RESET_B is deasserted. It selects the PHY according to the table below.

The first configuration is sampled by chip hardware. The second configuration is sampled by BootROM in Serial Boot mode (BMODE combination of 00 and 01) only.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CIT Automotive Technology Co., Ltd.

Table 163. MII interface detection via BMODE

Before reset		After reset		Mode	Recommended hardware configuration	
BMODE1	BMODE2	BMODE1	BMODE2		BMODE1	BMODE2
0	0	0	0	Serial boot with XOSC in Differential mode No Ethernet PHY	Tie to GND (0 V)	Tie to GND (0 V)
0	0	0	1	Serial boot with XOSC in Differential mode SGMII Ethernet PHY	Tie to GND (0 V)	Tie to RESET_B
0	0	1	0	Serial boot with XOSC in Differential mode RGMII Ethernet PHY	Tie to RESET_B	Tie to GND (0 V)
0	0	1	1	Serial boot with XOSC in Differential mode RMII Ethernet PHY	Tie to RESET_B	Tie to RESET_B
0	1	0	0	Serial boot with XOSC in Crystal mode or Bypass mode No Ethernet PHY	Tie to GND (0 V)	Tie to invert of RESET_B
0	1	0	1	Serial boot with XOSC in Crystal mode or Bypass mode SGMII Ethernet PHY	Tie to GND (0 V)	Tie to HIGH (3.3 V)
0	1	1	0	Serial boot with XOSC in Crystal mode or Bypass mode RGMII Ethernet PHY	Tie to RESET_B	Tie to invert of RESET_B
0	1	1	1	Serial boot with XOSC in Crystal mode or Bypass mode RMII Ethernet PHY	Tie to RESET_B	Tie to HIGH (3.3 V)

For serial boot via fail-safe path, selection of PHY is made via the HSE_GPR_BMR1[1:0] field according to the table below. HSE_GPR_BMR1[1:0] is loaded either via BOOT_CFG[1:0] or RCON[1:0], based upon the FUSE_SEL fuse value.

Table 164. MII interface detection through BOOT_CFG1/RCON

BOOT_CFG[0]	BOOT_CFG[1]	Ethernet PHY
0	0	RMII
0	1	SGMII

Table continues on the next page...

Table 164. MII interface detection through BOOT_CFG1/RCON (continued)

BOOT_CFG[0]	BOOT_CFG[1]	Ethernet PHY
1	0	RGMII
1	1	No PHY

30.11.5.2.2 PHY identification and configuration

BootROM reads the PHYID1 and PHYID2 PHY registers via the MDIO interface to identify the connected PHY. BootROM maintains a list of RGMII PHYs against which these PHYIDn registers are compared. BootROM expects PHYs to start Autonegotiation after every reset and wait for autonegotiation to complete within 5 seconds.

After autonegotiation completes, BootROM reads the link status, negotiated speed, and duplex mode. It then configures GMAC_0 accordingly.

BootROM forces PHY configurations for 1000 Mbps and full duplex mode operation if one of these events occurs:

- Autonegotiation fails within 5 seconds.
- The connected PHY is not in the list of supported PHYs.
- The link status is not OK.

GMAC_0 is also configured for 1000 Mbps and Full Duplex mode. You must ensure there is a stable connection.

BootROM communicates via the MDIO interface for configuring the PHY and uses 1 as the PHY address. It is recommended that the default address of PHY, connected to GMAC_0, be 1.

Currently, BootROM supports identification of the PHYs listed below for status reads after autonegotiation completes:

Table 165. Supported PHYs

PHY	PHYID1	PHYID2
RTL8211F	001Ch	C916h

30.11.5.2.3 GMAC_0 speed and clock configuration

BootROM supports GMAC_0 speeds of 1000 Mbit/s, 100 Mbit/s, and 10 Mbit/s.

BootROM locks the PLL over XOSC for generating the GMAC_0 TX clock. PERIPH_PLL is locked for generating 125 MHz at the PHI5 output. BootROM selects CLK_PERIPH_PLL_PHI5 as the source for MC_CGM_0_MUX_10, which controls the GMAC_0 TX clock.

Depending on the negotiated or configured GMAC_0 speed of 1000 Mbit/s, 100 Mbit/s, or 10 Mbit/s, MC_CGM_0_MUX_10_DIV_0 is programmed for generating the relevant clock of 125 MHz, 25 MHz, or 2.5 MHz. The GMAC_0 RX clock is controlled via MC_CGM_0_MUX_11. It is sourced from GMAC_0_EXT_RX_CLK. For more details, see Boot_Settings_Sheet attached to this document.

30.11.5.2.4 GMAC_0 controller configuration

BootROM configures the GMAC_0 controller for transmission and reception of data with PHY, connected via MII interface. GMAC_0 uses internal DMA channels for transferring data between MAC and application (system RAM). BootROM uses DMA channel 0 for this purpose and uses the first 256 bytes of system RAM (beginning at 34000000h) for preparing the DMA descriptor. Application code must not target this memory location as the download address for Ethernet boot.

30.11.5.2.5 MAC address configuration

This chip provides six bytes of fuse area for programming the device MAC address for GMAC_0 (see MAC0_ADDR[47:0] in the attached fuse map sheet). BootROM reads the MAC address from fuses and uses it as the GMAC_0 source address for packet exchange. In unprogrammed devices, where the MAC address is not programmed and fuses for the MAC Address read 0h,

BootROM creates a MAC Address using the device unique id, which is programmed in fuses. For the first three bytes of the MAC address, the designated OUI number 00:04:9F is used.

Table 166. Unprogrammed device MAC Address 1

MAC[0]	00h
MAC[1]	04h
MAC[2]	9Fh

The next three bytes are prepared with the scheme shown below.

Table 167. Unprogrammed device MAC Address 2

	7	6	5	4	3	2	1	0
MAC[3]	UNIQUE_ID[47:43]					Reserved	UNIQUE_ID[1:0]	
MAC[4]	UNIQUE_ID[55:48]							
MAC[5]	UNIQUE_ID[63:56]							

MAC[0] is sent as the first byte of the MAC address and MAC[5] is sent as the last.

30.11.5.2.6 DHCP handshake

The basic steps that occur when a DHCP client requests an IP address from a DHCP server are shown in the following figure.

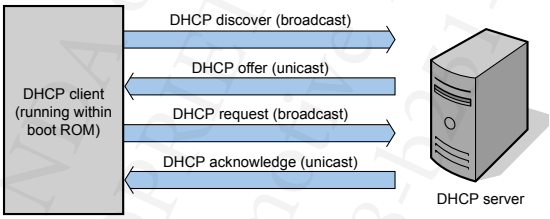

Figure 147. DHCP handshake

1. The client sends a DHCP DISCOVER broadcast message to locate a DHCP server.
2. A DHCP server offers configuration parameters (such as an IP address and a TFTP server IP address).
3. The client returns a formal request for the first offered IP address to the DHCP server in a DHCPREQUEST broadcast message.
4. The DHCP server confirms that the IP address has been allocated to the client by returning a DHCPACK unicast message to the client.
5. The MAC address can be set during the boot after reading from the MAC_ADDR eFuses (if present). Otherwise boot firmware creates a unique MAC address using the NXP OUI and part of the device unique ID stored in fuses.

30.11.5.2.7 TFTP data transfer flow

BootROM implements a TFTP client that supports three types of TFTP messages:

- RRQ (Read request)
- DATA (Data)
- ACK (Acknowledgment)

The following figure illustrates the TFTP handshake process.

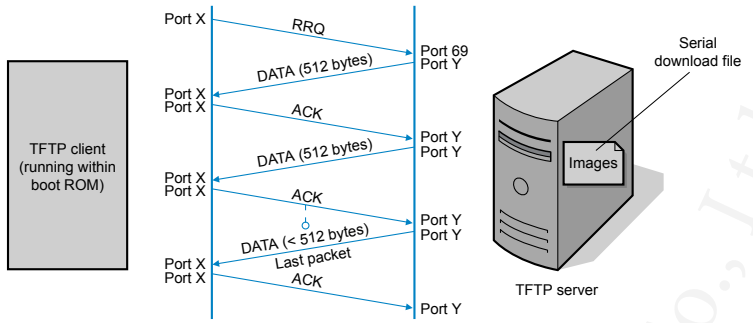

Figure 148. TFTP data transfer flow

The service uses the UDP port 69. Because TFTP uses UDP, it must supply its own session support. Each file transferred via TFTP constitutes an independent exchange.

1. The initiating client (BootROM in this case) sends an RRQ packet, containing the filename and the transfer mode.
2. The TFTP server responds with a DATA packet if it received an RRQ message (this also indicates to the client the ports being used).
3. The sending host then sends numbered DATA packets to the destination host after receiving each ACK message. All but the last message contains a full-sized block of data. The destination host replies with numbered ACK packets for each received DATA packet. This forms a simple ARQ protocol, providing retransmission when a packet is lost.
4. The final DATA packet must contain less than a full-sized block of data (including possibly zero bytes) to indicate that it is the last block of the transfer.

NOTE

- TFTP has no authentication or encryption mechanisms.
- If the chip is configured for Secure mode, the image fetched via TFTP is authenticated before it is executed on the application core.

The following table lists the files downloaded by BootROM from the TFTP server:

Table 168. Files downloaded from TFTP server by BootROM

Name	Description
SerHeader.img	• When doing non-secure serial boot, this file contains the first 64 bytes of the serial image structure. See Serial boot for details. • When doing secure serial boot, this file contains the first 1240h bytes of the serial image structure. See Serial boot for details. **NOTE** BootROM uses the first 8 KB of SRAM memory for its internal operation during serial boot over Ethernet. Care must be taken to ensure that the first 8 KB of SRAM is not used for the serial application.
SerApp.img	Contains the serial boot code.
SerSign.img	BootROM downloads this file only for secure serial boot. This file contains the public key signature. See Serial boot for details.

30.11.5.3 Flow diagram

The following diagram illustrates the Ethernet serial download boot flow.

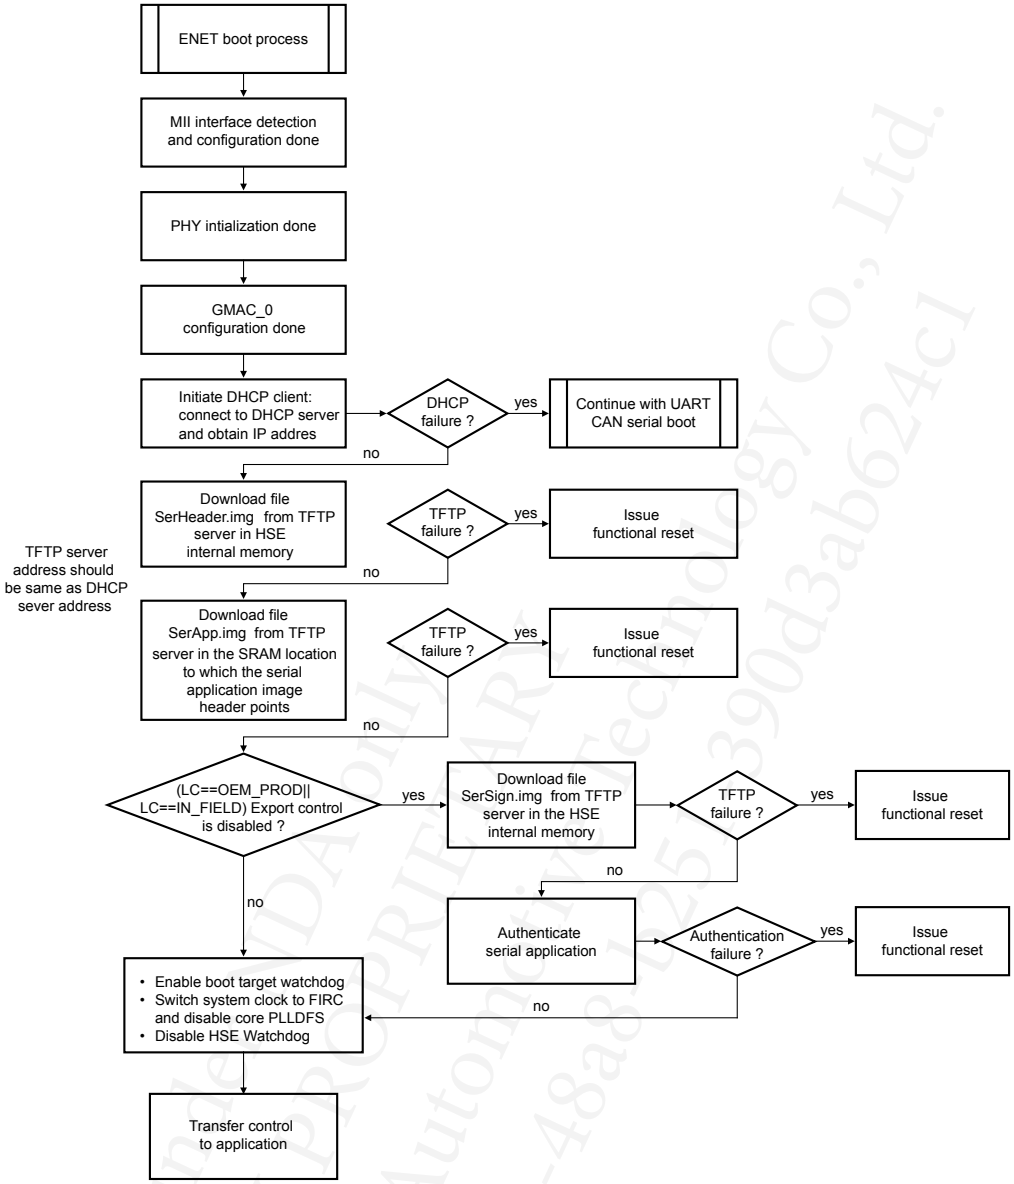

Figure 149. Ethernet serial download boot flow

30.12 Boot from external flash memory

BootROM supports boot from external flash memory devices over the following interfaces:

- QuadSPI
- SD/MMC/eMMC via µSDHC interface

Boot device selection is controlled by Boot_CFG1[7:5] eFuses as shown in the following table.

Table 169. Boot device selection

BOOT_CFG[7:5]	Boot device
000	QuadSPI flash memory

Table continues on the next page...

Table 169. Boot device selection (continued)

BOOT_CFG[7:5]	Boot device
001	Reserved
010	SD
011	MMC/eMMC

30.12.1 QuadSPI boot

BootROM supports booting from the QuadSPI_0 interface:

- Quad and Octal flash memories in 1-bit SDR mode
- HyperFlash flash memories in 8-bit mode

This configuration is only required for initial reads to identify the flash memory. You can reconfigure the interface for optimal performance, based on flash memory configuration parameters provided by customers.

30.12.1.1 Functional description

Boot ROM supports boot from a variety of flash memories, providing flexibility for choosing the configuration parameters for which the controller must be programmed during boot. The configuration parameters can be based on product requirements. For better performance, the QuadSPI controller supports high-speed operations in DDR and SDR modes, which requires specific configurations to achieve correct data sampling at such a high rate. The QuadSPI controller supports reading data over an AHB interface or an IP interface—however, boot ROM supports only read via an AHB interface. Boot ROM does not support any write operations to QuadSPI flash memory.

Boot ROM performs QuadSPI controller configuration in two phases, as described in the following table.

Table 170. QuadSPI controller configuration phases

No.	Name	Description
1	QuadSPI initial configuration	Configure the QuadSPI controller at a frequency of 40 MHz in 1-bit mode for Quad and Octal flash memories, and 8-bit mode for HyperFlash flash memories. BootROM uses BOOT_CFG/RCON based values, table 170, for configuring QSPI controller for applying successful initial configuration.Read the flash memory reconfiguration data as shown in Table 173 located at offset 200h of the flash memory.
2	QuadSPI final configuration	Prepare the clock source per required frequency in reconfiguration data. Reconfigure the QuadSPI controller based on details provided in the QuadSPI reconfiguration data.

You must prepare the QuadSPI reconfiguration data per the flash memory requirement, which is finalized during development. Details of these configurations can be passed either via RCON, during development, or via fuses for the projected use case, when the FUSE_SEL fuse is blown (production use case). For a detailed description, see the boot ROM Fuse description tab in the attached Fuse map spreadsheet. When QuadSPI reconfiguration data is not provided, the QuadSPI final configuration phase is skipped.

Table 171. QuadSPI fuse description

No.	Fuse word offset	Fuse bit position	Fuse name	Settings	Description
1	234h	RCON/ BOOT_CFG1[7:5]	Boot interface	000	Selects QuadSPI as the boot interface.

Table continues on the next page...

Table 171. QuadSPI fuse description (continued)

No.	Fuse word offset	Fuse bit position	Fuse name	Settings	Description
2	234h	RCON/ BOOT_CFG1[4:2]	QuadSPI mode	000: Quad flash memory 001: HyperFlash flash memory 011: Octal flash memory	Selects type of flash memory.
3	234h	RCON/ BOOT_CFG1[9]	QuadSPI port selection	0: Port A 1: Port B	Selects the QuadSPI port on which external flash memory is connected.
4	234h	RCON/ BOOT_CFG1[18:16]	QuadSPI POR delay	000: 300 µsec 001: 600 µsec 010: 1000 µsec 011: 2000 µsec 100: 5000 µsec 101: 50000 µsec 110: 100000 µsec 111: 300000 µsec	A delay is required before the first access is issued to flash memory after flash memory reset.
5	234h	RCON/ BOOT_CFG1[14:11]	QuadSPI CAS	0000-1111: QuadSPI_SFACR[CAS] value	Column address space. Only valid for HyperFlash mode. See the SFACR[CAS] register field description in the QuadSPI chapter.
6	234h	RCON/ BOOT_CFG1[30:29]	DQS selection	00: Reserved 01: Pad loopback 10: Reserved 11: External DQS	Selects DQS clock for sampling read data. • For Quad and Octal flash memories, a setting of 10b is recommended. • For HyperFlash memory a setting of 11b is recommended. See the MCR[DQS_FB_SEL] register field description in the QuadSPI chapter.
7	234h	RCON/ BOOT_CFG1[23:22]	TDH: Time Hold Delay	00: Data aligned at PosEdge of	Serial flash memory data in hold time.

Table continues on the next page...

Table 171. QuadSPI fuse description (continued)

No.	Fuse word offset	Fuse bit position	Fuse name	Settings	Description
				internal reference clock 01: Data aligned with 2X serial flash memory	See the FLSHCR[TDH] register field description in the QuadSPI chapter.
8	234h	RCON/ BOOT_CFG1[25]	FSDLY: Full Speed Delay	0: Same DQS 1: Half cycle early DQS	Full speed delay selection. See the SMPR[FSDLY] register field description in the QuadSPI chapter.
9	234h	RCON/ BOOT_CFG1[24]	FSPHS: Full Speed Phase	0: Select sampling at non-inverted clock 1: Select sampling at inverted clock	Full speed phase selection. See the SMPR[FSPHS] register field description in the QuadSPI chapter.
10	234h	RCON/ BOOT_CFG1[28:26]	DLLFSMPF	N can vary from '0' – '7'	Selects the nth tap provided by the slave delay-chain. See the SMPR[DLLFSMPFB] register field description in the QuadSPI chapter.
11	234h	RCON/ BOOT_CFG1[19]	CKN: Differential clock selector	0: Differential clock not required 1: Differential clock required	Enables clock on differential pad.
12	234h	RCON/ BOOT_CFG1[10]	CK2: CK2 clock selector	0: CK2 clock not required 1: CK2 clock required	Enables 90-degree phase-shifted clock.
13	238h	BOOT_CFG2[12]	SLAVE DELAY EN	1: SLV_DLY_OFFSET and SLV_DLY_COARSE fuses configure slave delay 0: Boot ROM configured value	Enables DLLCRA[SLV_DLY_COARSE] and DLLCRA[SLV_DLY_OFFSET].

Table continues on the next page...

Table 171. QuadSPI fuse description (continued)

No.	Fuse word offset	Fuse bit position	Fuse name	Settings	Description
				configures slave delay	
14	238h	BOOT_CFG2[16:13]	SLV_DLY_COARSE	10000b – 1111b	Sets number of delay elements in each delay tap. See the DLLCRA[SLV_DLY_COARSE] or DLLCRB[SLV_DLY_COARSE] descriptions in the QuadSPI chapter.
15	238h	BOOT_CFG2[20:17]	SLV_DLY_OFFSET	10000b – 1111b	Selects the number of T/16th offset delay elements, tap, in incoming DQS. See the DLLCRA[SLV_DLY_OFFSET] or DLLCRB[SLV_DLY_OFFSET] descriptions in the QuadSPI Chapter.

NOTE

Because information in BOOT_CFG1, at 234h offset, has bit-by-bit correspondence to RCON[31:0], the FUSE_BIT_POSITION column in the table also corresponds to the RCON description.

30.12.1.2 QuadSPI IOMUX configuration

Table 172 shows the QuadSPI IOMUX pin configuration used in BootROM.

BootROM provides an option of overriding some default QuadSPI IOMUX configuration settings implemented in BootROM firmware, and contained in the attached BootROM Settings Sheet, via a pad override scheme. If BOOT_CFG3[9] is enabled, BootROM applies the following IOMUX configuration based on fuse values in BOOT_CFG3. This feature is applicable for both PORT A and PORT B.

Table 172. QuadSPI IOMUX pin configuration

No.	OCOTP fuse word offset	Fuse bit position	Definition	Description
1	23Ch	BOOT_CFG3[9]	PAD_OVERRIDE_EN	Enable pad override for QuadSPI. 0: Disabled 1: Enabled
2	23Ch	BOOT_CFG3[7:5]	QSPI_SRE	Pad slew rate value applies to all QuadSPI pads.

Table continues on the next page...

Table 172. QuadSPI IOMUX pin configuration (continued)

No.	OCOTP fuse word offset	Fuse bit position	Definition	Description
3	23Ch	BOOT_CFG3[4]	QSPI_PUS_CS	Pullup select for all CS pads for chosen QuadSPI interface. 0: Pulldown 1: Pullup
4	23Ch	BOOT_CFG3[3]	QSPI_PUS_DATA[7:0]	Pullup select for all DATA pads for chosen QuadSPI interface. 0: Pulldown 1: Pullup
5	23Ch	BOOT_CFG3[2]	QSPI_PUS_DQS	Pullup select for DQS pad for chosen QuadSPI. 0: Pulldown 1: Pullup
6	23Ch	BOOT_CFG3[1]	RCVR	Value applies to all QuadSPI pads.
7	23Ch	BOOT_CFG3[0]	QSPI_PUS_CK_CK2	Pullup select for all clock pads for chosen QuadSPI. 0: Pulldown 1: Pullup

30.12.1.3 QuadSPI clock configuration

QuadSPI drives the clock from CLK_MUX_12 selector in MC_CGM_0. CLK_MUX_12 selectors can select QSPI_CLK from either IRC or PERIPH_PLL_DFS1, as shown in the following figure.

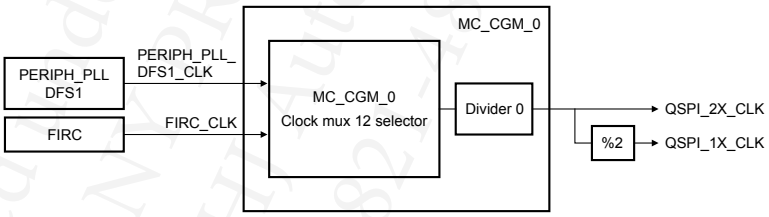

Figure 150. QuadSPI clock selector

In the initial configuration phase, the BootROM clocking scheme for QuadSPI operations depends on the PLL lock status. BootROM tries to lock the PERIPH PLL and PERIPH DFS1 for generating QSPI_1X_CLK at 40 MHz. If PLL-DFS is locked successfully at 40 MHz, then the clock is switched to PLL. Otherwise, the QuadSPI clock is derived from FIRC, resulting in QSPI_1X_CLK being at FIRC/2.

In the final configuration phase, QuadSPI read operation clock requirements are derived by the clock that you provide in the QuadSPI reconfiguration data. In case of failure to generate the required clock, BootROM skips the configuration provided and continues read operations with the default configuration and the QuadSPI clock derived from FIRC.

30.12.1.4 QuadSPI configuration parameters

The following table lists QuadSPI configuration parameters in order, and the required details to be programmed in flash memory at offset 200h.

Table 173. QuadSPI configuration parameters

Name	Offset	Size in bytes	Description
Header	0h	4	Should be 5A5A5A5Ah.
MCR	4h	4	MCR values for targeted operation.
FLSHCR	8h	4	FLSHCR values for targeted operation.
BFGENCR	Ch	4	BFGENCR values for targeted operation.
DLLCR	10h	4	Configuration to be programmed in DLLCRA or DLLCRB register depending on whether flash memory is connected to Port A or B. Only the DLLCR[30:4] bits are used—bit 31 and bits 0–3 are masked out.
PARITYCR	14h	4	Values to be programmed in case flash memory is enabled for parity.
SFACR	18h	4	Holds value to be configured in SFACR register.
SMPR	1Ch	4	Holds value to be configured in SMPR register for Phase 2 configurations.
DLCR	20h	4	Data Learning Control Register configuration required as per desired Phase 2 configurations.
SFLASH_1_SIZE	24h	4	Flash 1 top address, applicable to either Port A or B. Only one port is supported during boot. Port selection depends on the value in BOOT_CFG[9].
SFLASH_2_SIZE	28h	4	Flash 2 top address, applicable to either Port A or B. Only one port is supported during boot. Port selection depends on the value in BOOT_CFG[9].
DLPR	2Ch	4	Data Learning Pattern Register, as applicable for required Phase 2 configurations by user.
SFAR	30h	4	Serial flash memory address to be configured in Phase 2 configuration.
IPCR	34h	4	Content to be programmed in IP Configuration register.
TBDR	38h	4	Data to be written in TBDR register.
DLL_BYPASS_EN	3Ch	1	Based upon DLL_BYPASS_EN configuration, BootROM configures DLL in bypass mode for Phase 2 configurations. You should choose only one DLL configuration, out of the total three, at a time unless stated otherwise. 0: Disable 1: Enable
Reserved	3Dh	1	Reserved

Table continues on the next page...

Table 173. QuadSPI configuration parameters (continued)

Name	Offset	Size in bytes	Description
DLL_AUTO_UPD_EN	3Eh	1	Based upon DLL_AUTO_UPD_EN configuration, BootROM configures DLL in auto update mode for Phase 2 configurations. User should choose only one DLL configuration, out of total three, at a time unless stated otherwise. 0: Disable 1: Enable **NOTE** When this mode is selected, the value of DLL_BYPASS_EN must be 1.
IPCR_TRIGGER_EN	3Fh	1	Writes IPCR field to IPCR register only if IPCR_TRIGGER_EN is 1.
SFLASH_CLK_FREQ	40h	1	User-provided frequency (in MHz) for Phase 2 QuadSPI configuration. This frequency corresponds to the QSPI_1X_CLK clock.
Reserved	41h	1	Reserved
Reserved	42h	1	Reserved
Reserved	43h	1	Reserved
COMMAND_SEQ	44h	320	User-provided LUT configuration to be used for read operations over the AHB interface. The LUT should be programmed as per requirements of the flash memory connected and the mode of operation selected, including clock, DDR, SDR, 1-bit, 4-bit, or 8-bit operation. The LUT sequence to be invoked during a read is controlled by the configuration provided in BFGENCR.
FLASH_WRITE_DATA	184h	120	An array of 10 structures. Each structure contains details of a command and related parameters to be sent to flash memory after Phase 1 and before Phase 2.

For better performance, you may need to reconfigure flash memory using default settings, after the initial configuration phase is over. To do this, boot ROM supports a list of 10 commands (CMDs). Each of these commands and associated data are encoded in 12 bytes. See Table 174 and Table 175 that provide details related to:

- FLASH_WRITE_DATA structure
- Data to be configured
- Status register address for external flash memory configuration

Using the command configuration structure in Table 174:

- You can pass CMD-related information to boot ROM that is used for configuration.
- BootROM parses the FLASH_WRITE_DATA structure array until the CMD field becomes 0.

This structure is only meant to write to flash memory configuration registers, and not perform operations in the flash memory array. Also, you must perform all flash memory configurations through FLASH_WRITE_DATA commands and in 1-bit SPI mode.

Table 174. Word 0 (Bytes 0-3): Command Configuration

31	30–24	23–18	17–16	15–8	7–0
Address valid	Configuration data size	Valid address bits	Pad	Reserved	Command Opcode (from Flash Datasheet)
0 – Do not send address bytes 1 – send address bytes	00 – 0 byte 01 – 1 byte 02 – 2 byte 03 – 3 byte 04 – 4 byte Others values for this field are reserved and must not be used	Number of address bits to be sent (for ex., 6'd24 => 24 address bits required)	00 – 1 bit (SPI) 01 – 2 bit (DUAL) 10 – 4 bit (QUAD) 11 – 8 bit (OCTAL)		
e.g. for Macronix Flash, WREN command doesn't need any address to be sent, but WRCR2 needs 4 bytes of address			As only 1-bit SPI commands are supported, set this to 00	Set this field to 0x00	e.g. for Macronix Flash, WREN command has opcode 0x06, so set this field to 0x06

Table 175. Word 1 (Byte 7-4): External Flash Configuration/Status Register Address

31 - 20	19-0
Reserved, set them to 0x000	Set to the address of the register as per Flash datasheet
	e.g. for Macronix Flash, address of Configuration Register 2 (to set DOPI bit) is 0x00000000, hence set this field to 0x00000

Word 2(Byte 11-8): Data to be sent to Flash along with the command

- 0 to 4 bytes of data
- Store it in Little Endian form in the image

After every reset, BootROM requires connected flash memory to be in a configuration mode in which the flash memory is able to respond to a SPI read command.

- If the application alters the flash memory configuration such that the flash memory requires a reset for it to switch to its default SPI mode, then the application must ensure that flash memory is reset on device reset.
- If the application alters the flash memory configuration such that flash memory does not revert to SPI mode even after a reset, then the application must either ensure that flash memory enters SPI mode before every reset, or must use CMDs that do not require such a mode change.

30.12.1.5 QuadSPI boot flow diagram

The following figure illustrates the QuadSPI boot flow.

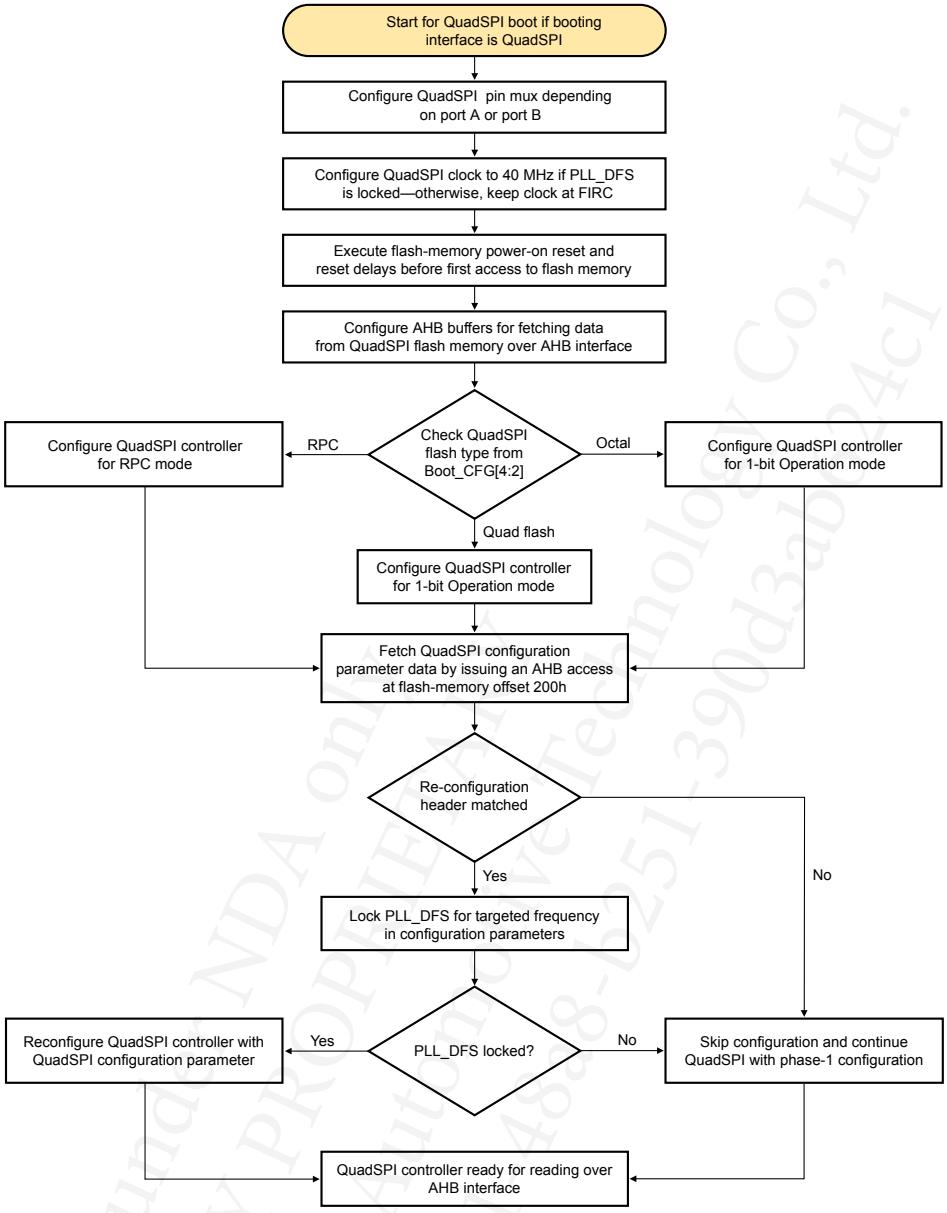

Figure 151. QuadSPI boot flow

30.12.2 µSDHC boot

BootROM supports booting from the SDHC interface. The SDHC controller initial configuration is based on information provided via eFuse or RCON GPIO pins. BootROM supports boot from SD, MMC, and eMMC cards in different data rate modes. BOOT_CFG1[7:5] controls the selection of SD card for boot over the µSDHC interface. For eFuse information on SD/MMC card support, see the Fuse Map in the attached spreadsheet.

30.12.2.1 µSDHC IOMUX configuration

BootROM provides an option of overriding some of the default µSDHC IOMUX configuration settings in BootROM firmware, shown in the attached BootROM settings spreadsheet, via a pad override scheme. If BOOT_CFG3[9] is enabled, BootROM applies the following IOMUX configuration, based on fuse values in BOOT_CFG3.

Table 176. µSDHC IOMUX configuration

No.	OCOTP FUSE word offset	Fuse bit position	Definition	Description
1	23Ch	BOOT_CFG3[9]	PAD_OVERRIDE_EN	Enable pad override for SDHC. 0: Disabled 1: Enabled
2	23Ch	BOOT_CFG3[8]	SDHC_PUS_CMD	Pull up select for CMD I/O PAD. 0: Pull down 1: Pull up
3	23Ch	BOOT_CFG3[7:5]	SDHC_SRE	Pad slew rate value applies to all SDHC pads.
4	23Ch	BOOT_CFG3[4]	SDHC_PUS_RST	Pullup select for all RST pads 0: Pulldown 1: Pullup
5	23Ch	BOOT_CFG3[3]	SDHC_PUS_DATA[7:0]	Pullup select for all SDHC DATA pads interface. 0: Pulldown 1: Pullup
6	23Ch	BOOT_CFG3[2]	SDHC_PUS_DQS	Pullup select for SDHC DQS pad. 0: Pulldown 1: Pullup
7	23Ch	BOOT_CFG3[1]	RCVR	Value applies to all SDHC pads.
8	23Ch	BOOT_CFG3[0]	SDHC_PUS_CLK	Pullup select for clock pad. 0: Pulldown 1: Pullup

30.12.2.2 µSDHC clock configuration

SDHC_CLK is derived from clock MUX 14 in CGM_0. SDHC_CLK can be derived from either FIRC or PERIPHRAL_PLL_DFS3. As per the clocking scheme, BootROM tries to lock the Peripheral PLL-DFS and, in case of success, switches the SDHC_CLK from FIRC to PLL.

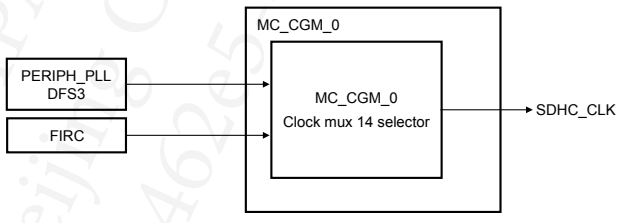

Figure 152. µSDHC clock configuration

30.12.2.3 µSDHC supported data rates

Only 3.3 V high speed and default speed data rate operations are supported when booting from SD cards. BootROM does not support switching to 1.8 V for SDR modes. During Card Identification mode, the clock is kept below 400 KHz. All SDSC, SDHC, and SDXC cards support these data rates. The application can switch to SDR modes after control is passed to it.

Table 177. SD supported boot data rates

Speed modes	Maximum baud rate	Clock speed	Signal voltage
Identification mode	No data transfer	~380 kHz	3.3 V
Default speed	12.5 MB/s	25 MHz	3.3 V
High speed	25 MB/s	50 MHz	3.3 V

BOOT_CFG1[19] controls the selection of Default Speed or High Speed mode when the SD card is used over the µSDHC interface.

For MMC/eMMC cards, BootROM supports the speed modes listed in the following table.

Table 178. Data rates supported for MMC card boot

Speed modes	Maximum baud rate	Clock speed	Bus width
High speed	25 MB/s	25 MHz	1, 4, or 8 bits
Normal speed	50 MB/s	50 MHz	1, 4, or 8 bits
Normal DDR	100 MB/s	50 MHz	4 or 8 bits

BOOT_CFG1[22:19] controls the selection of speed modes when an MMC/eMMC card is used over the µSDHC interface

30.13 Fail-Safe

Errors may be encountered during BootROM execution—software programming errors during development, flash memory failure, PCB failure during production, timeout due to failure of hardware modules, authentication failure during secure boot, exceptions during BootROM execution, and so on. BootROM issues a functional reset in all error conditions.

When BootROM issues repeated functional resets due to a persistent error condition, it is unable to pass control to the application. To manage this scenario, BootROM checks the number of functional resets issued. If ≥ 8, BootROM enters Serial Boot mode to download application code via supported serial interfaces. This mechanism is called Fail-Safe. See Figure 142 for condition RESETs >= 8.

NOTE

The application should check for reset sources and the number of functional resets in the starting instructions and make a local copy for further reference. It should then clear these registers in MC_RGM. Otherwise, persistent resets caused by the application (not from BootROM), will force the BootROM firmware to enter Fail-Safe even though the application can be successfully booted.

30.14 Boot target

The *boot target* is the core responsible for running application code. You can choose to start execution of your application on either the Cortex-M7_0 or Cortex-A53_0 core. For safety applications, the boot target must be Cortex-M7_0. The boot target is enabled only in the default configuration. For lockstep Cortex-A53 configuration, the boot target must be Cortex-M7_0, and the application can then start the Cortex-A53_0 in lockstep mode. Application code running on the boot target can start on any other core(s) in any sequence. To set the target application core, provide the settings in the IVT Boot configuration word (see IVT boot configuration word). An invalid value triggers a functional reset.

30.15 Boot target watchdog

The *Boot target watchdog*, SWT_0, is the watchdog instance responsible for the application code running on the boot target. You can enable the watchdog via setting a field in the IVT Boot configuration word (see IVT boot configuration word for details). When BOOT_SEQ = 0 (in the Boot configuration word) and the watchdog is configured to be enabled in the IVT Boot configuration word, BootROM enables the boot target watchdog before enabling the boot target, with its reset configuration of FIRC at 7601632 cycles. When BOOT_SEQ = 1, HSE_H firmware configures the boot target watchdog. When the watchdog is enabled, the customer application must service it in a timely manner. Otherwise a functional reset occurs.

30.16 Standby boot

Exit from Standby mode triggers execution of BootROM. Depending on the wakeup source, BootROM boots from either the Standby IVT or performs a full boot, as after any reset.

The Standby IVT has the same format as the normal IVT (see Image Vector Table (IVT)), but its location is fixed at start of standby RAM (24000000h). When booting via the Standby IVT, BootROM only supports:

- DCD operations (from primary and backup)
- Application boot (from primary and backup)

The Standby IVT does not support Self-Test or HSE_H firmware. It only supports (IVT boot configuration word field) BOOT_SEQ = 0, which indicates a non-secure boot is to be performed. If BOOT_SEQ = 1, BootROM issues a reset.

When booting from the Standby IVT, BootROM does not support fetching of data from either QuadSPI or an SD/MMC/eMMC card.

Before entering Standby mode, the application should program:

- The IVT (at 24000000h)
- DCD (if required)
- Application on standby RAM, whose contents remain valid during Standby mode

All pointers in the IVT must point to addresses within standby RAM. BootROM does not perform any authentication on the Standby IVT, DCD, or application when booting via the Standby IVT.

When a full boot is requested, BootROM performs normal boot operation, as after any reset, as detailed in this chapter. BootROM does not check the Standby IVT at the start of standby RAM. For more details on wakeup sources,see the Wakeup Unit (WKPU) chapter.

The decision to perform a full boot or boot from the Standby IVT, is based on the wakeup source that triggers the wakeup from standby. If the wakeup source is configured to perform a full boot, BootROM performs a full boot. Otherwise, it boots from the Standby IVT.

If more than one wakeup source is latched in wakeup status, and one of the wakeup sources is configured for full boot, then a full boot is performed.

Chapter 31
Power Management

31.1 Introduction

This chapter describes the power management architecture. It also provides details for the necessary chip voltages and how to control them.

31.1.1 Power management functional blocks

Table 179. Power management functional blocks

Module	Description
MC_ME	Mode Entry module Manages: • On/off control of blocks and subsystems • Standby mode entry requests • Software reset requests.
MC_PCU	Power Control Unit Manages: • Standby mode entry after MC_ME request • Standby mode exit.
MC_RGM	Reset Generation Module Manages full-chip and post-wake-up reset sequences.
PMC	On-Chip Power Management Controller • Controls Non-Critical Supply Presence Detectors (NCSPDs). • Manages power-on reset mechanism.
PMIC	Off-Chip Power Management IC The off-chip power management circuit may be a single IC or a combination of components, and may contain associated safety and low-power mode infrastructure.
WKPU	Wakeup Unit Manages external NMIs and Standby mode wake-up sources.

31.2 Power management features

The power management provides the following features:

- Interfaces to an external SBC (PMIC), providing all chip voltages
- Provides hardware-controlled entry into Run mode
- Enables software-controlled entry into Standby mode
- Enables software-controlled disabling of partitions to reduce power consumption during Run mode
- Provides wake-up event management for exit from Standby mode

31.3 Power-related I/Os

Table 180. Power-related I/O

Name	I/O type	Logic (0.8 V) pullup/pulldown	Muxable	Description
PMIC_STBY_MODE_B	Output	—	No	Active-low Standby mode indicator, causes PMIC to disable all switchable power supplies except the Standby mode core supply and 3.3 V required to power the POR and standby pads. The selection of which supply remains ON in standby mode depends on the programming done to the PMIC registers.
PMIC_VDD_OK	Input	—	No	Output from PMIC indicating the core supply voltage is in the specified operating range, to enable Standby mode exit process to proceed.
PMIC_SENSE	Output	—	No	Sense for core supply (0.8 V)
NMI	Input	—	No	External non-maskable interrupts
WKUP*n*	Input	—	Yes	External wake-ups that can cause an exit from Standby mode (where '*n*' = 0 to 22)
POR_B	Input	Pulldown	No	Startup reset pin indicating supplies are within their specified operating range

NOTE

See the attached IOMUX spreadsheet for details on power-related I/Os and supply pins.

The package pins/balls and corresponding chip pads that supply each analog block in the list below are independent (for example, they are not shared and not adjacent to each other):

- PMC
- FIRC
- FXOSC

This does not preclude that the supplies may be shared at the board and/or PMIC level.

31.4 Operating modes

The power management architecture supports three modes of operation:

- Reset mode
  - Entire chip is powered.
  - Reset mode is the initial mode of the chip. Run mode is entered after Reset mode.
- Run mode
  - Entire chip is powered.
  - Power consumption is managed by clock gating unused processing blocks and peripherals.
  - This mode is always entered on exit from reset and wake-up from Standby mode.
- Standby mode
  - Only a portion of the chip is powered.

— This mode is supported in chips requiring ultra-low power. This mode is required when the chip enters a very low-power state caused by PMIC programming that shuts off supplies. It also enters the mode by following the protocol for Standby entry and exit scenarios.

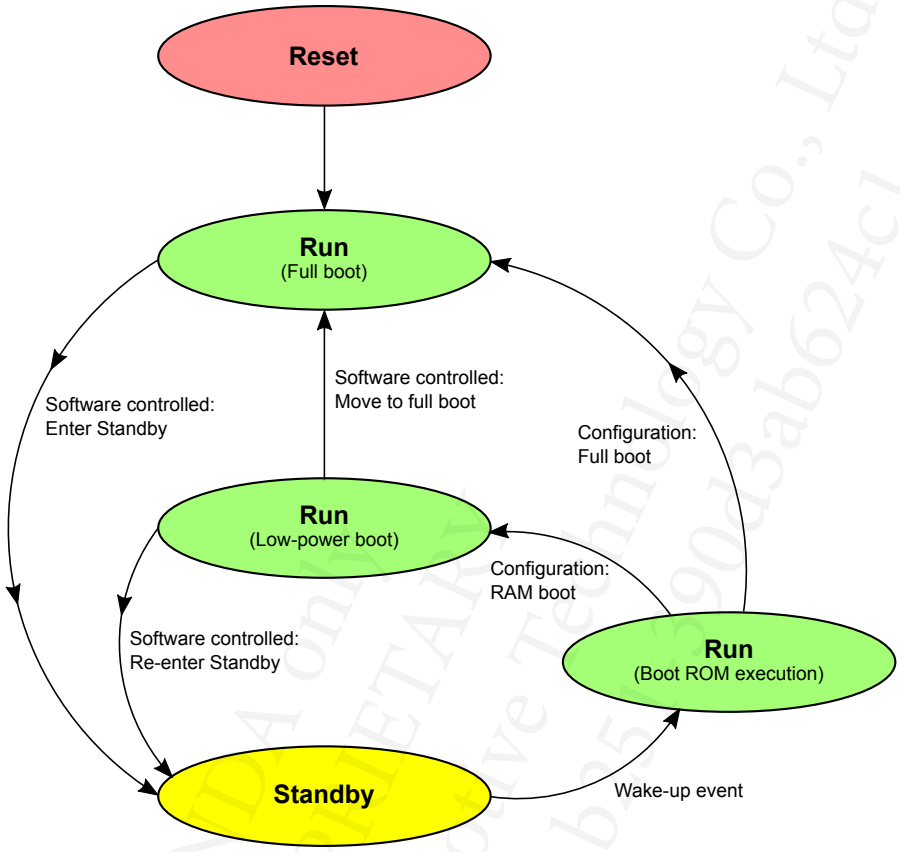

Figure 160. MC_ME supported modes

31.4.1 Reset mode

Reset mode has the following attributes:

- The chip is in a safe state.
- All pins are in their default safe states.
- All computing and communication processes are terminated.
- The chip is fully powered, if not previously fully turned on, on Reset mode entry.
- The chip transitions to its default state prior to enabling Reset mode exit.

The chip always enters Run mode after Reset mode exit (see the "Reset" chapter for related details).

31.4.2 Run mode

Run mode has the following attributes:

- Run mode is the only mode during which the chip executes computational and communications functions.
- The chip is fully powered.
- The boot core is the only core enabled on Run mode entry.

- Software can enable/disable cores and subsystems as needed by the application, based on functional and power requirements.
- Software can configure the device pins needed by the application.
- Software can set up and trigger BIST execution as needed by the application:
  - Main Reset domain:
    - Device pins are placed in a safe state.
    - No computational or communication activities are possible.
    - After BIST completes, Reset mode is entered automatically.
  - Software Reset domain: Some computational and communication activities can run when BIST is running.

31.4.3 Standby mode

Standby mode is the lowest power consumption mode of the chip. Only a minimal portion of chip logic is powered during Standby mode.

Operations permitted during Standby mode are:

- Execution shutdown sequence
- Storage of data needed after Standby mode and store data during standby mode
- Generation of wake-up events
- Detection and response to reset and wake-up events
- Execution of the startup sequence.

31.4.3.1 Standby mode modules

Table 181. Standby mode modules

Module	Description
MC_PCU	Manages power-up/power-down sequencing.
MC_RGM	Manages resets occurring during Standby mode and the reset sequences associated with Standby mode entry/exit.
PMC	Generates a POR on any of the following during Standby mode: • POR_B assertion • CSPD_STANDBY_0P8 indicates loss of voltage on VDD_STBY
RTC	Optionally generates a periodic wake-up event.
SIRC	Provides the clock used by the RTC.
OCOTP	Retains the fuse values (avoids the need to read fuses after each Standby mode exit).
LC_CHECK	Detects any corruption of life cycle information provided by OCOTP.
STDBY_RAM	Stores data that must be intact after Standby mode exit.

NOTE

All supplies switched off in Standby mode must have low impedance to ground. The supplies must discharge to less than 100 mV before making the PMIC_VDD_OK pin low. The requirement is to keep impedance less than 50 Ω.

All wake-up sources, including wake-up pins, are functional and powered during Standby mode.

31.4.3.2 High-level Standby mode power-down/power-up flow diagram

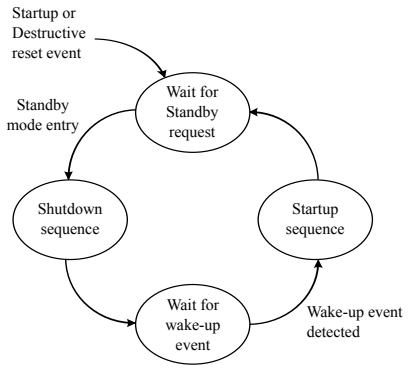

Figure 161. High level Standby mode power up/down sequence flow diagram

31.5 Operating mode transitions

31.5.1 Reset mode to Run mode

The transition from Reset mode to Run mode occurs automatically on any reset sequence exit.

See the "Reset" chapter for details on the reset sequence portion of this mode transition.

31.5.2 Configuring clocks

See the "Clocking" chapter for clock configuration details.

31.5.3 Turning on cores and partitions

See the "Mode Entry Module (MC_ME)" and "Reset" chapters for details.

31.5.4 Run mode to Reset mode

Numerous sources can trigger a transition to Reset mode.

See the "Reset" chapter for details on the reset sequence portion of this mode transition, and for a list of sources that can trigger a reset.

31.5.5 Run mode to Standby mode

During the transition from Run mode to Standby mode, software uses the I^2C or SPI module to communicate that the transition of the chip to Standby mode is in progress. Communicating the transition ensures that the PMIC is aware that the chip is entering Standby mode and prevents undesired Standby mode entry sequence triggers.

31.5.5.1 Standby mode entry flow

After the chip notifies the PMIC that Standby mode entry is pending by writing to the Standby Time Window register in the PMIC, the PMIC ignores all further communication bus activity until one of the following events occurs:

- The Standby entry sequence has completed, followed by the Standby exit sequence having completed.
- The PMIC's Standby mode watchdog timer has timed out.
- The reset sequence completes successfully after a reset event is indicated by deassertion of the RESET_B pin.

Processed by IDA on NXP COMPANY PROPRIETARY Beijing CU Automotive Technology Co., Ltd. ca46e521-21a8-4a8-b251-390d3ab624c1

31.5.5.1.1 Standby mode entry flow diagram

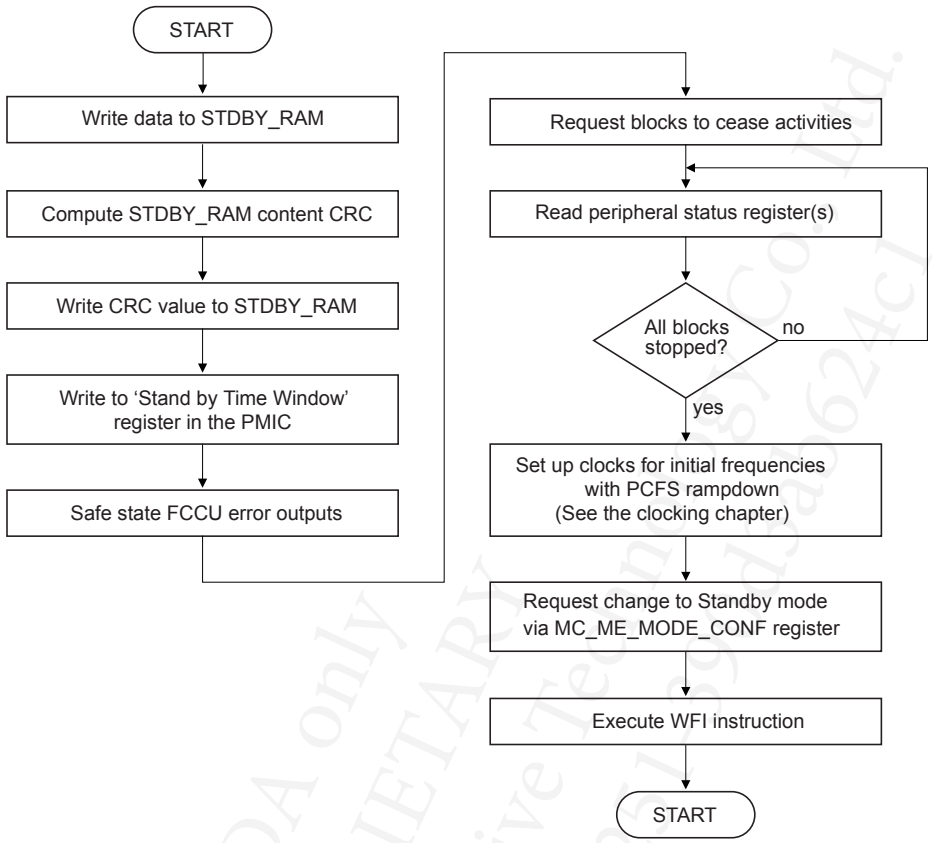

Figure 162. Standby mode entry flow diagram

See Standby mode to Run mode for Standby mode exit flow.

31.5.6 Standby mode to Run mode

Only a wake-up event triggers a transition from Standby mode to Run mode. WKPU manages all wake-up events.

If a wake-up event occurs while a transition from Run mode to Standby mode is in progress, the current transition completes. Only after the transition has completed does the wake-up event trigger a transition back to Run mode.

31.5.6.1 Standby mode exit flow

MC_PCU ignores wake-up and functional reset events that occur during shutdown sequencing. The chip retains the events, then MC_PCU evaluates them. This evaluation occurs one SIRC clock cycle after PMIC confirmation that the run power domain has successfully shut down.

31.5.6.1.1 Standby mode exit flow diagram

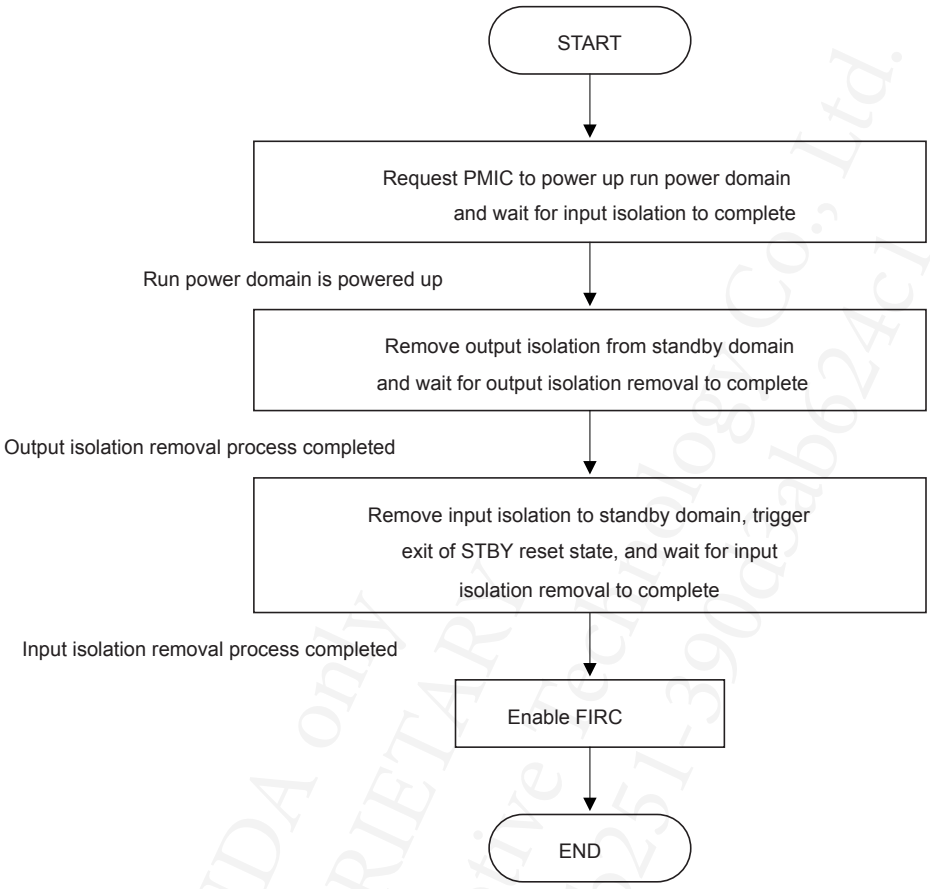

Figure 163. Standby mode exit flow diagram

See the "Reset" chapter for details on the reset sequence portion of this mode transition.

31.5.7 Standby to Reset mode

There are numerous reset sources that can trigger a transition to Reset mode.

A reset source available in Standby mode can trigger a transition to Reset mode.

The actions listed below occur automatically when a power-on reset event occurs at any time during Standby mode or during the transition to/from Standby mode:

- Immediate abort of any ongoing Standby mode transition step
- Deassertion of the STANDBY_MODE_B signal to the PMIC
- Transition to the startup sequence by MC_RGM.

See the "Reset" chapter for a list of reset sources and related details.

31.5.8 Wake-up pin pullup/pulldown control during Run and Standby modes

SIUL2, WKPU, and S32G_STBY_GPR modules manage the pull control of the WKUP*n* pins.

To configure pullup/pulldown of WKUP*n* pins:

1. Write zero to WKUP_PUS[WKUP_PU_OVERRIDE] of S32G_STBY_GPR during Run mode, so that SIUL2 has full control over the pad pullup/pulldown for each WKUP*n* pad (see Table 182).

2. Write one to WKUP_PUS[WKUP_PU_OVERRIDE] of S32G_STBY_GPR before entering Standby mode, to give WKPU control. It can remain one if the application is only spending a short time in Run mode between Standby mode periods (for example, short wake-up events) (see Table 183).

Table 182. Wake-up pin pullup/pulldown during Run mode (WKUP_PUS[WKUP_PU_OVERRIDE] = 0)

Desired pull	SIUL2_MSCR*n*[PUE]	WKPU_WIPUER[IPUE[*p*]]	SIUL2_MSCR*m*[PUS]	S32G_STBY_GPR WKUP_PUS[WKUP_PUS]
None	0	x	x	x
Pullup	1	x	1	x
Pulldown	1	x	0	x

Table 183. Wake-up pin pullup/pulldown during Standby mode[1] (WKUP_PUS[WKUP_PU_OVERRIDE] = 1)

Desired pull	SIUL2 MSCR*n*[PUE]	WKPU WIPUER[IPUE[*p*]]	SIUL2 MSCR*m*[PUS]	S32G_STBY_GPR WKUP_PUS[WKUP_PUS]
None	x	0	x	x
Pullup	x	1	x	1
Pulldown	x	1	x	0

1. Configure before entering Standby mode.

NOTE

Enabling pullups on the wake-up pins during Standby mode increases overall Standby mode power consumption.

NOTE

It is not valid to configure the wake-up pad from SIUL2 and write zero to WKUP_PUS[WKUP_PU_OVERRIDE] of the S32G_STBY_GPR before entering the Standby mode.

Provided under NDA only

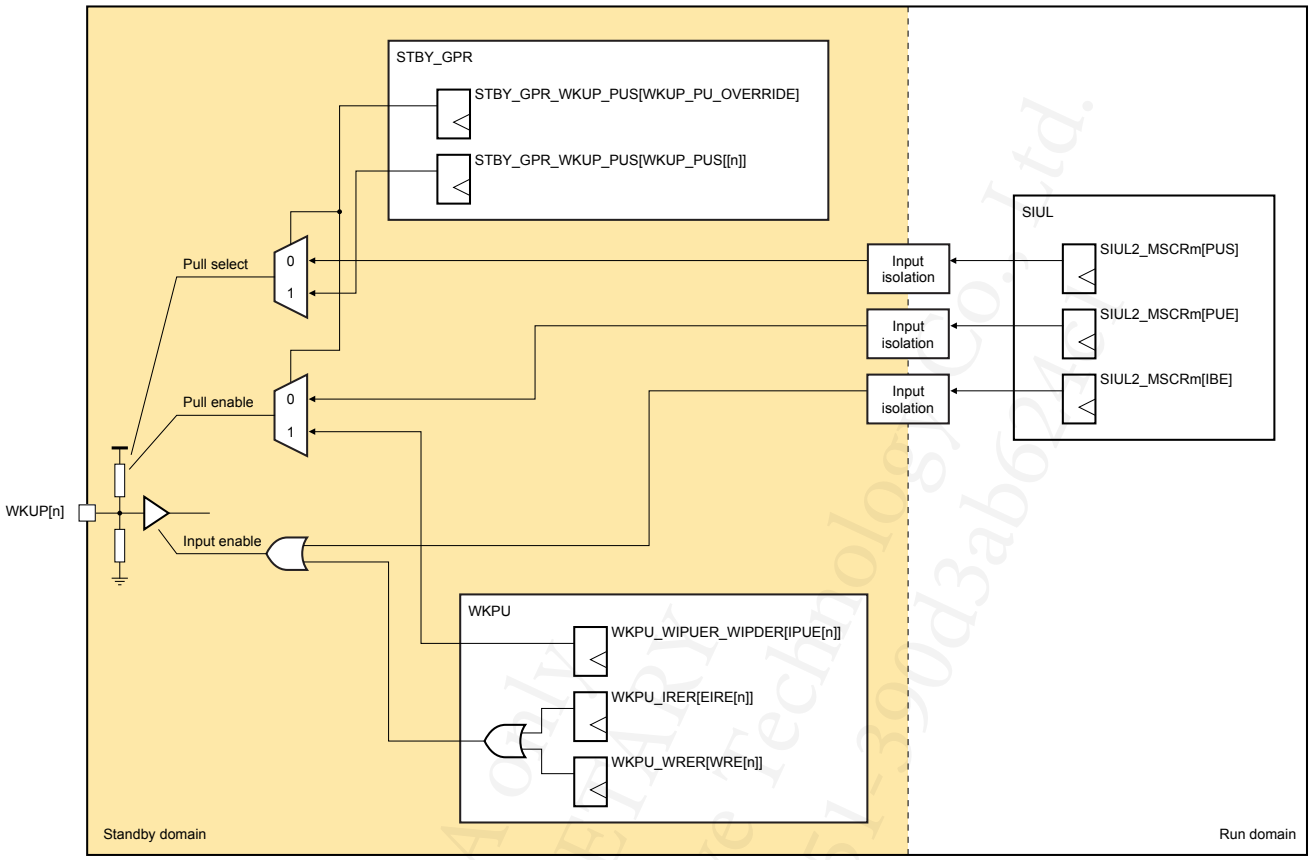

Figure 164. Wake-up pin pullup/pulldown control

31.6 Operating mode control blocks

31.6.1 MC_ME

MC_ME manages the hardware-driven portions of the mode transition processes as follows (see the "Mode Entry Module (MC_ME)" chapter details):

- Provides control and status registers to manage enabling/disabling of partition and core clocks.
- Provides control and status registers to manage enabling/disabling of partition output isolation.
- Provides a set of core address registers providing cores with the jump addresses to application code.
- Provides a mechanism for changing the chip mode from Run mode to Standby mode or Reset mode via software triggering.

MC_ME signals MC_RGM to enter the start of its Standby mode reset sequence. This signal is asserted immediately after software successfully requests a mode change to Standby mode.

31.6.2 MC_PCU

MC_PCU manages shutdown sequencing on entry to Standby mode and startup sequencing on exit from Standby mode (see the "Power Control Unit (MC_PCU)" chapter for details).

31.6.3 MC_RGM

MC_RGM manages power domain resets during Run mode, of both the shutdown sequence and startup sequence (see the "Reset Generation Module (MC_RGM)" chapter).

After entering Standby mode reset sequence, MC_RGM provides a signal to MC_PCU that triggers MC_PCU to start the shutdown sequence.

MC_RGM provides a signal to MC_PCU that triggers MC_PCU to begin startup sequencing. This signal is asserted immediately after MC_RGM detects any functional reset event.

31.6.4 RTC

RTC is a real-time counter that runs on the SIRC clock. You can configure it to generate a periodic interrupt or Standby mode wake-up event (see the "Real Time Clock (RTC)" chapter for details).

31.6.5 WKPU

WKPU provides a mechanism for managing the Standby mode wake-up sources:

- Up to 31 external wake-up pins (WKUP*n* signals in IOMUX spreadsheet)
- A single wake-up from RTC

You can also configure the wake-up sources to trigger an interrupt during Run mode.

WKPU also manages NMI pins. NMI pins do not function as a Standby mode wake-up source.

When an NMI event occurs, software determines the NMI pin that caused the event, then whether an NMI event overflow has occurred on that pin, by reading WKPU_NSR. Software clears each status flag by writing 1 to the corresponding field.

The wake-up outputs of the WKPU connect to the wake-up input of the MC_PCU.

After exiting the Standby mode wake-up sequence, software determines what caused the wake-up by reading WKPU_WISR. Similarly, after a WKPU interrupt event, software determines what caused the interrupt by reading the same register.

Software can clear each individual status flag by writing 1 to the corresponding field. Reading the fields in WKPU_WISR determines the cause of the wake-up:

- Flag 31 equals one indicates an RTC counter rollover.
- If any of the other flags equal one, the cause was an external wake-up event on the corresponding wake-up pin.

After exiting the Standby mode wake-up sequence, software can determine whether to load the low-power boot image or the full boot image by reading WKPU_WBMSR.

Figure 165 shows the wake-up and interrupt mapping of WKPU. The blocks labeled "glitch filter" represent fields in WKPU_WIFER or WKPU_NCR. The blocks labeled "edge det" represent a field in WKPU_WIFEER (riding edge), WKPU_WIFEEF (falling edge), or WKPU_NCR.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-482f-48a8-b241-90d3ab624c1

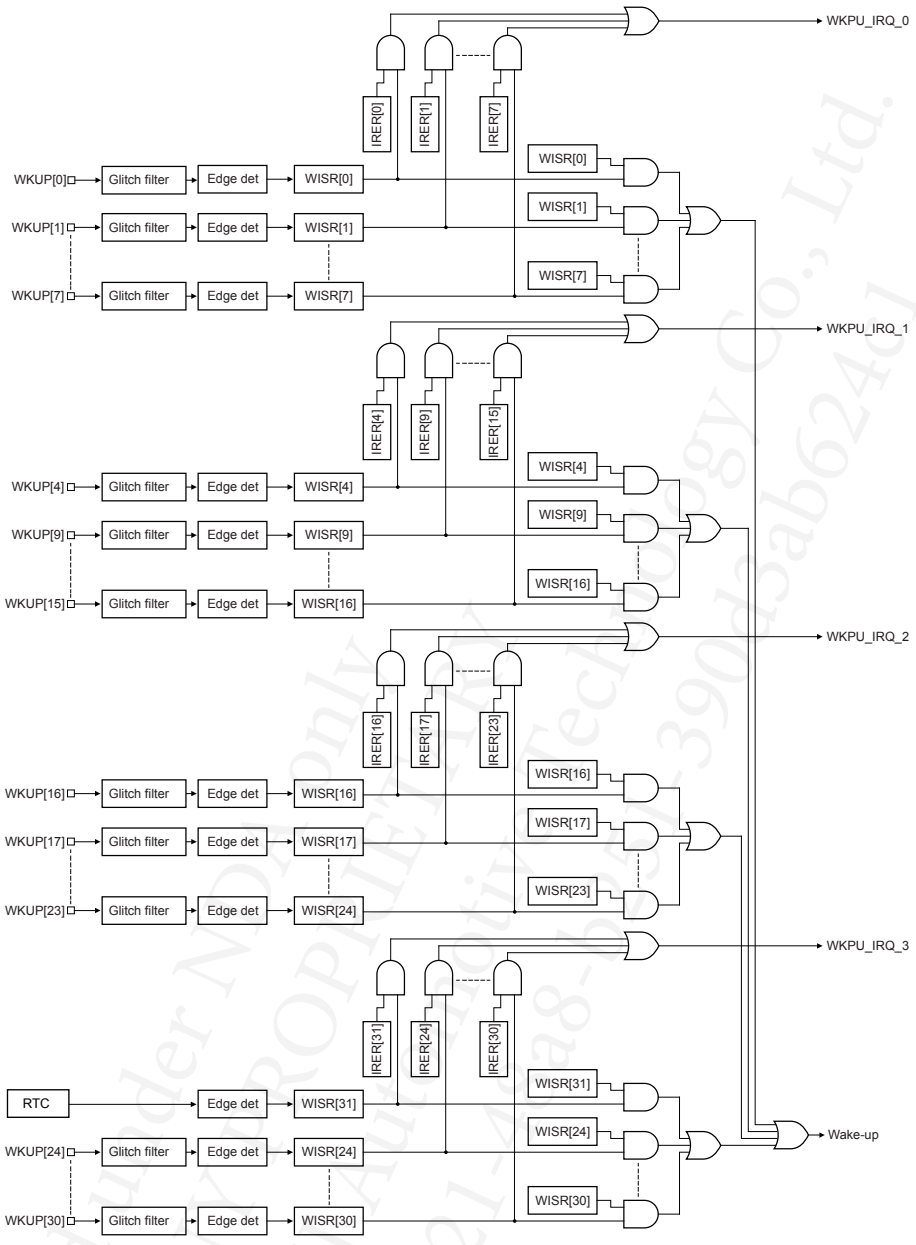

Figure 165. WKPU wake-up and interrupt mapping overview

31.6.5.1 NMI pins

Each NMI pin (NMI[*n*]) maps to NMI *n* in the NMI status and configuration registers in WKPU.

You can configure each NMI input via the corresponding WKPU_NCR[NREE] and WKPU_NCR[NFEE] to trigger an NMI on:

- Any rising edge, but not any falling edge
- Any falling edge, but not any rising edge
- Any edge
- No edge (for example, NMI pin disabled)

The default after a full chip reset is no edge.

You cannot configure NMI inputs to cause a wake-up from Standby mode.

There is a glitch filter between each NMI pad input buffer and its corresponding WKPU input. You can enable and disable the filter via the corresponding WKPU_NCR[NFE] field. The default condition of the filter is disabled after a full chip reset.

See the "Interrupts" section of the WKPU chapter for further details of the processor assignment of each NMI input.

31.6.5.2 Wake-up pins

Each wake-up pin (WKUP[*n*]) maps to wake-up *n* in the WKPU's status and configuration registers.

Each wake-up input is configurable via the corresponding WKPU_WRER, WKPU_WIREER, and WKPU_WIFEER register fields to trigger a wake-up from Standby mode on:

- Any rising edge but not any falling edge
- Any falling edge but not any rising edge
- Any edge
- No edge (for example, wake-up input is disabled)

The default after a full chip reset is no edge.

There is a glitch filter between each wake-up pad input buffer and its corresponding WKPU input. You can enable or disable the filter via the corresponding WKPU_WIFER field. A full chip reset sets the filter to its default condition with the filter disabled.

31.6.5.3 Wake from RTC

RTC wake-up maps to wake-up 31 in the WKPU's wake-up status and configuration registers.

RTC wake-up must be enabled in both WKPU and RTC. You can disable it in either WKPU or RTC.

The RTC wake-up event is triggered on assertion of RTC wake-up output.

31.6.6 Wake-up pin glitch filter

The wake-up input glitch filter filters glitches on the wake-up pins without the need of any clock.

The characteristics of the wake-up pin glitch filter are:

- Maximum pulse width rejected = 20 ns
- Minimum pulse width passed = 400 ns

31.7 Power management and power domains

The power management architecture supports two types of chips:

- Single-core logic power domain
- Two-core power domains (Run mode and Standby mode)

In both cases, there are multiple non-core power domains to support pads and analog modules.

See the IOMUX spreadsheet attached to this reference manual for a list of power domains.

31.7.1 Precision voltage monitoring

The purpose of the precision voltage detectors (LVDs and HVDs) is to ensure that each supply voltage remains within its minimum and maximum operating voltage levels. If any supply voltage level is outside this range, the corresponding precision voltage detector indicates a failure. The consequence of the failure is a power-on reset sequence executed on the chip.

There are no on-chip precision voltage monitors. All required precision voltage monitoring is done off-chip. Each precision voltage monitor should be on the same sense point as the regulator for the corresponding power supply.

There is a dedicated PMIC_SENSE analog output pad for providing the internal cold-point voltage level of the VDD power domain.

The PMIC protects against VDD overvoltage in the case of a broken connection between the VDD sense point and the PMIC (for example, the PMIC_SENSE ball disconnects from the board). The PMIC then indicates the detected failure via POR_B assertion or other error indication.

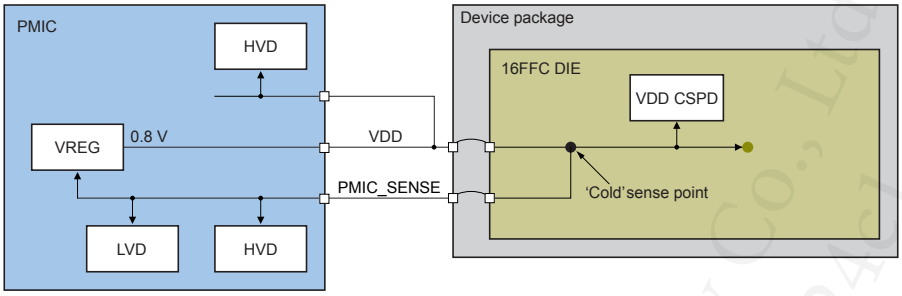

Figure 166. Example of protection against broken PMIC_SENSE connection

NOTE

The additional sense point at the VDD pin on the board is monitored in case PMIC_SENSE connection is broken.

Any extended overvoltage condition detected by PMIC causes PMIC to shut down the corresponding regulator.

Table 184. Minimum off-chip LVDs and HVDs

Supply	Type	Sense
0.8 V	HVD	PMIC_SENSE
	LVD	
1.8 V	HVD	Output of 1.8 V regulator
	LVD	
3.3 V	HVD	Output of 3.3 V regulator
	LVD	
1.1 V to 1.5 V	LVD	Output of 1.1 V to 1.5 V regulator
1.2 V	LVD	Output of 1.2 V regulator

NOTE

There is no need to monitor supplies that are not required for a chip.

When one of the off-chip precision voltage monitors detects an overvoltage or undervoltage condition, the POR_B input asserts.

The VDD_STBY domain may not be monitored by the PMIC when supplied by its low-power regulator. This minimizes overall power consumption during Standby mode.

31.7.2 Supply Presence Detectors (SPD)

SPDs ensure that all the physical connection paths from the voltage regulators to the on-chip voltage supply rails (for example, board connection from PMIC outputs to chip pins, or package connections from pins to the die power supply pads, including substrate and bond wires) are intact.

Depending on the type of SPD (NCSPD or CSPD), if a power rail connection to the supply is broken, the corresponding SPD indicates a failure. The consequences of the failure are:

- An on-chip power-on reset sequence executes for CSPDs.
- If enabled in the PMC NCSPD_CTL register, an on-chip destructive reset sequence executes for NCSPDs.

Each SPD signals a disconnect event based on its detection of an extremely low voltage on a particular power domain. Such an event automatically triggers when the supply of this target power domain is disconnected, or when it falls below a voltage level that is significantly lower than the precision LVD level of the PMIC. When any of the CSPDs/NCSPDs detect a disconnected core supply, the corresponding CSPD/NCSPD input of the PMC asserts. See the "Reset" chapter for further details.

The figure below shows the basic SPD operation.

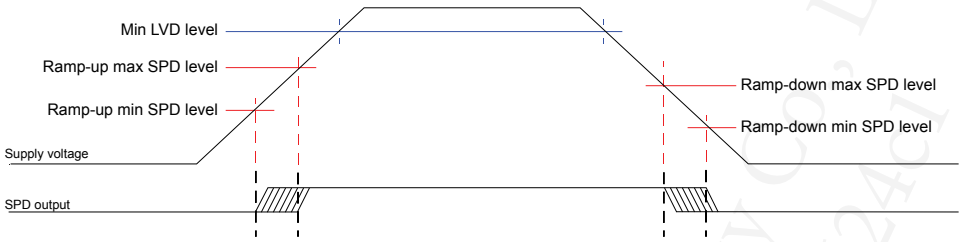

Figure 167. Basic SPD operation

31.7.2.1 NCSPD configuration

The following table shows the NCSPD mapping in the NCSPD_CTL, NCSPD_STAT, and NCSPDEF registers of the PMC.

NOTE

See the chip's data sheet for voltage supply descriptions.

Table 185. PMC NCSPD mapping

PMC NCSPD register fields	NCSPD index	Module	Supply
NCSPDEF[NCSPD_EVENT_CAPTURE0] NCSPD_CTL[NCSPD_CTL0] NCSPD_STAT[NCSPD_STAT0]	NCSPD0	FXOSC	VDD_FXOSC
NCSPDEF[NCSPD_EVENT_CAPTURE1] NCSPD_CTL[NCSPD_CTL1] NCSPD_STAT[NCSPD_STAT1]	NCSPD1	ADC0	VDD_ADC
NCSPDEF[NCSPD_EVENT_CAPTURE2] NCSPD_CTL[NCSPD_CTL2] NCSPD_STAT[NCSPD_STAT2]	NCSPD2	ADC1	VDD_ADC

—	NCSPD19 – NCSPD20	—	Not mapped to any monitor for this chip. Reserved for future expansion.

Table continues on the next page...

Table 185. PMC NCSPD mapping (continued)

PMC NCSPD register fields	NCSPD index	Module	Supply
NCSPDEF[NCSPD_EVENT_CAPTURE21] NCSPD_CTL[NCSPD_CTL21] NCSPD_STAT[NCSPD_STAT21]	NCSPD21	USB	VDD_IO_USB
NCSPDEF[NCSPD_EVENT_CAPTURE22] NCSPD_CTL[NCSPD_CTL22] NCSPD_STAT[NCSPD_STAT22]	NCSPD22	uSDHC	VDD_IO_SDHC
NCSPDEF[NCSPD_EVENT_CAPTURE23] NCSPD_CTL[NCSPD_CTL23] NCSPD_STAT[NCSPD_STAT23]	NCSPD23	QuadSPI	VDD_IO_QSPI
—	NCSPD24 – NCSPD27	—	Not mapped to any monitor for this chip. Reserved for future expansion.
—	NCSPD28	—	VDD_IO_CLKOUT
—	NCSPD29 – NCSPD31	—	Not mapped to any monitor for this chip. Reserved for future expansion.

1. NCSPD on the corresponding HV supply may also trigger when the LV supply drops significantly.
2. When VDD_IO_STBY drops below the NCSPD threshold, it may generate a POR. In this case, the hardware writes 1 to PMC_SSR[POR_SUP].

NOTE

- If the core supply is not active, incorrect results may occur in these CSPD/NCSPD registers:
  - CSPD_EVENT_CAPTURE
  - NCSPD_STAT
  - SSR
- NCSPD11 monitors the 3.3 V supply (VDD_IO_STBY) of the POR_B pad segment to ensure that the chip can enter the destructive reset sequence even if the connection to VDD_IO_STBY is broken and the POR_B signal cannot be properly asserted. For this, the software must enable NCSPD11 in PMC.

  In some cases, the connection to VDD_IO_STBY may be broken but the POR_B signal is still asserted enough to be interpreted as a power-on reset. This results in the PMC_SSR[POR_SUP] written with 1, but the NCSPD11 event capture flag not being set, even if NCSPD11 is enabled.

31.7.2.2 CSPD configuration

The following table shows the field mapping in the PMC_CSPDEF register. See the chip *Data Sheet* for descriptions of all supplies.

Table 186. PMC CSPD mapping

PMC_CSPDEF field	CSPD index	Module	Supply
HVCPOREF	HVCPOREF	PMC	VDD_VREF

Table continues on the next page...

Table 186. PMC CSPD mapping (continued)

PMC_CSPDEF field	CSPD index	Module	Supply
CSPD_EVENT_CAPTURE1	CSPD1	FIRC	VDD_FIRC
CSPD_EVENT_CAPTURE2	CSPD2	FIRC	VDD
3–31	CSPD3 – CSPD31	—	Unused

NOTE

If the core supply is not active, incorrect results may occur in these CSPD/NCSPD registers:

- CSPD_EVENT_CAPTURE
- NCSPD_STAT
- SSR

31.7.3 Voltage overshoot and undershoot protection

PCFS features are provided to ensure smooth clock frequency transitions:

- Ramp-up to protect against an LVD event occurring due to a sudden increase in current consumption when turning on a portion of the chip during Run mode.
- Ramp-down to protect against an HVD event occurring due to a sudden decrease in current consumption due to a functional reset.

There is no on-chip protection against an HVD event occurring due to a sudden decrease in the current consumption of the chip due to a destructive reset.

The off-chip power supply can react quickly enough to a sudden decrease in chip current consumption in the case of a destructive reset.

31.7.4 External PMIC interface

The external PMIC contains safety-critical functionalities:

- Voltage supervision
- Watchdog operation (POR_WDOG)
- Error monitoring
- Analog BIST to check safety functions,

If any failure occurs, the external PMIC asserts POR_B.

31.7.4.1 Use case: Interfacing to external PMIC

For interfacing to the PMIC, see the chip Hardware Design Guidelines.

31.7.4.2 Debug use case: Interfacing to external PMIC

In the debug use case, RESET_B is bidirectional.

The external debugger must clear the watchdog in the external PMIC after RESET_B asserts. Otherwise, the PMIC can assert POR_B after a defined number of RESET_B assertions. Figure 168 shows the debug use case.

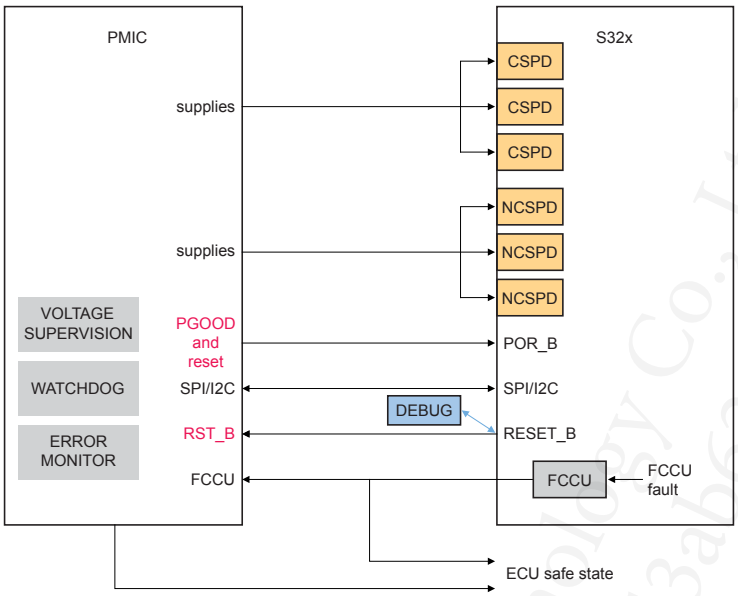

Figure 168. Debug use case: Interfacing to external PMIC

31.7.4.3 Standby mode use case: Interfacing to external PMIC

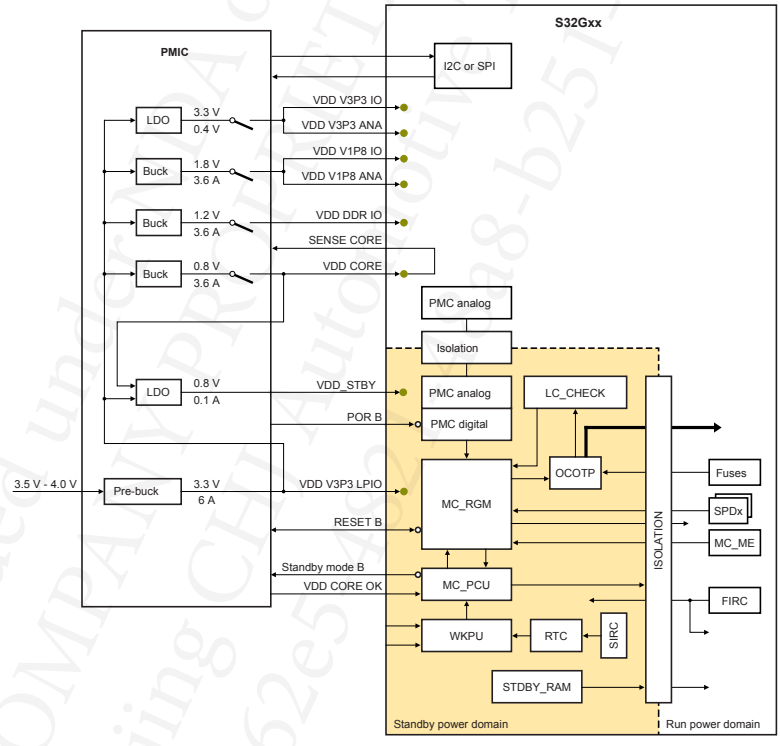

Figure 169. Standby mode use case interfacing external PMIC

31.7.4.4 Safety context for PMIC WDOG

The PMIC WDOG must be available at the system level immediately when safety outputs release. Before that, RSTB (reset output from PMIC) or POR_B (power good output from PMIC) are high so the chip can start its own initialization and WDOG has a timeout of 256 ms for the first time if the chip is stuck.

Sequence of steps:

1. PMIC powers up.
2. The power-up sequence configuration in the PMIC determines chip and peripheral supplies.
3. After power supplies reach correct normal operation, the PMIC POR_B and RSTB pins are automatically deasserted. Upon this deassertion, the PMIC starts an internal counter with a period of 256 ms. During this 256 ms window, the chip starts execution of its own initialization procedure. You must configure the PMIC before the lapse of the window resets the first watchdog.
4. At this point WDOG is working in normal mode. The watchdog refreshes every *x* ms based on the watchdog window period configured during the initialization phase (for example, 10 ms).
5. The chip can now request the PMIC to release the safety output. The chip is now able to start the application.

When the chip is unable to program the PMIC (for example, it is stuck in reset), PMIC detects this case even with an unconfigured watchdog timer. If the chip is pulling reset low continuously, and the PMIC has an internal counter (8 s), the PMIC automatically transitions to Deep Fail-Safe mode.

In Deep Fail-Safe mode:

1. All regulators in the PMIC switch off.
2. The chip enters Reset mode.
3. The PMIC FS0B (fail-safe output 0) and POR_B pins are asserted (driven low).
4. If configured on the chip, the automatic restart function executes.

The automatic restart option, if configured at the factory via fuses, operates according to one of the following options:

- No automatic restart
- Automatic restart (executes a maximum of 15 times)
- Automatic restart (no limit to the number of times it can execute)

31.8 Power mode control blocks

31.8.1 PMIC control

Software controls the PMIC during Run mode via the I^2C communication interface.

Additionally, PMIC control during Standby mode is via a signal from the chip indicating whether VDD can be turned off, or must be turned on. The PMIC uses a hardware signal to indicate to the chip whether the VDD voltage is within its operating range, separate from the POR_B input.

31.8.1.1 Static Voltage Scaling (SVS)

SVS is a method in which the voltage of a power domain can be adjusted up or down to optimize power consumption at operational frequencies used in that domain. The decision of whether the voltage should be adjusted, and by how much, is based on process data for the particular chip.

Beijing CU Automotive Technology Co., Ltd.
COMPANY PROPRIETARY
Limited under NDA only
c8c46225-4241-48a8-b251-390a0ab624f1

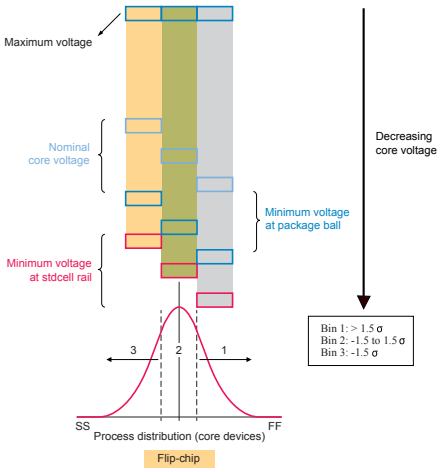

Figure 170. SVS example

NOTE

Voltage levels shown in Figure 170 are examples. See the chip data sheet for actual operating levels.

The process data for each die is stored in the DIE_PROCESS[1:0] fuses according to the following coding:

- DIE_PROCESS[1:0] = 00b, SVS is disabled
- DIE_PROCESS[1:0] = 01b, SVS mode 1
- DIE_PROCESS[1:0] = 10b, SVS mode 2
- DIE_PROCESS[1:0] = 11b, SVS mode 3

For more information on power domain SVS voltage levels, see the “Operating Conditions" section of the chip data sheet.

For more information on power domain SVS voltage levels, see the “DC Electricals" section in the chip data sheet.

An overview of the SVS execution flow is shown in the following diagram.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-9251-3903ab624c1

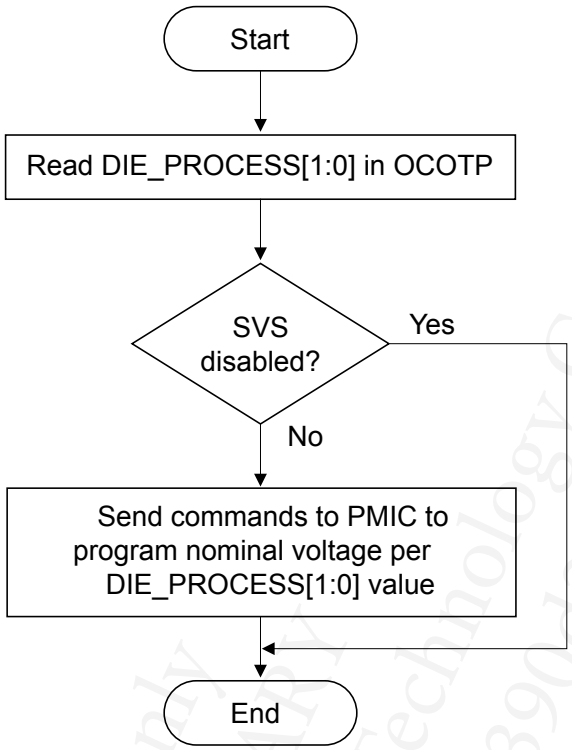

Figure 171. SVS execution steps

The above SVS execution steps are performed by the application software.

Note that PMIC voltage monitoring of the core supply may be disabled while SVS voltage trimming is occurring, which would impact the functional safety viability during this time. Therefore, we recommend that you apply SVS prior to starting the safety application.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b51-390d3ab624c1

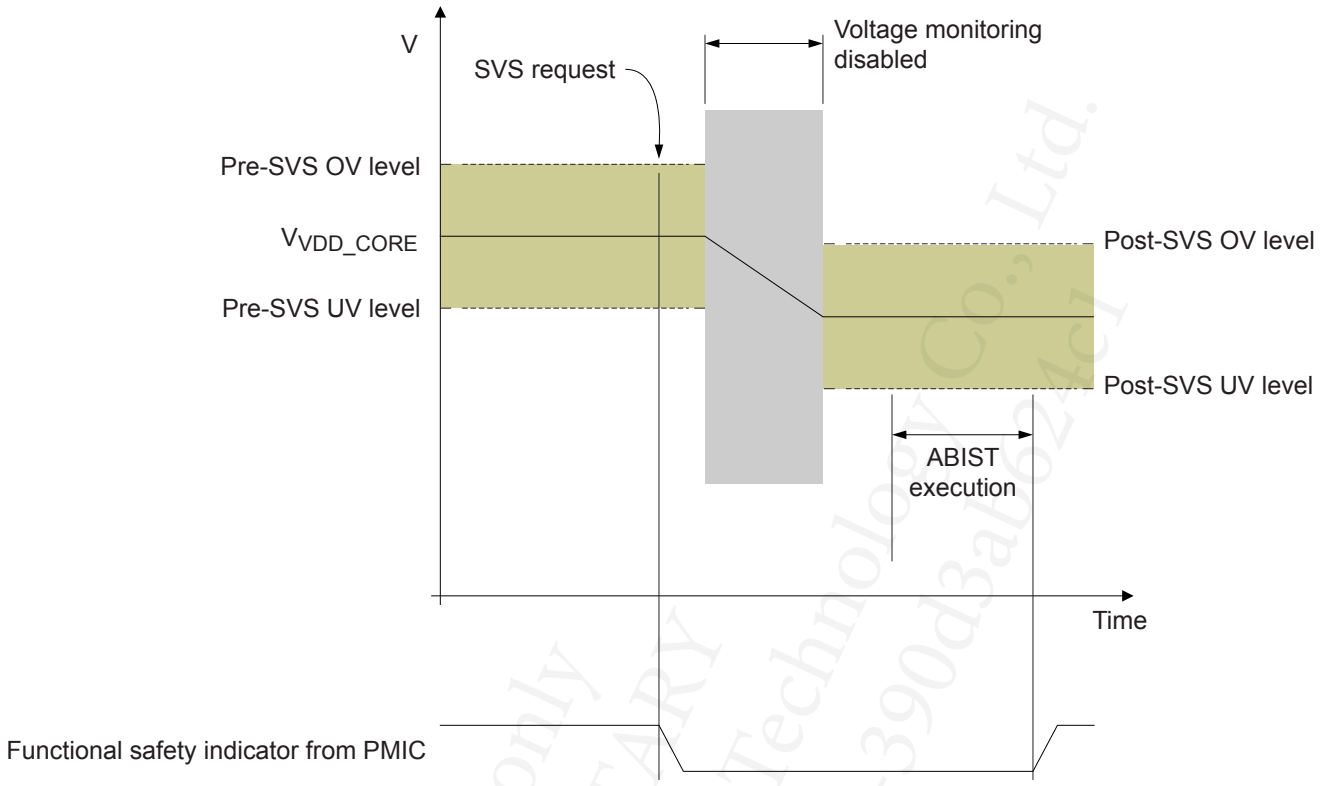

Figure 172. Possible voltage monitor disabling during SVS

Disabling of voltage monitors by the PMIC during SVS is indicated by the PMIC to the chip (for example, via the FSOB output on NXP Semiconductor PMICs).

VDD_STBY is typically trimmed per the SVS setting during Run mode, but at the nominal voltage during Standby mode. In addition, core supply and VDD_STBY may still be at nominal voltage after Standby mode exit and require software to execute SVS again.

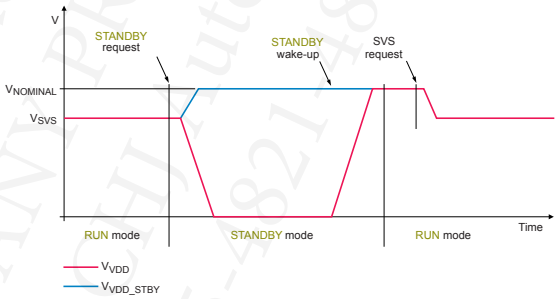

Figure 173. Core supply and VDD_STBY voltages before, during, and after Standby mode

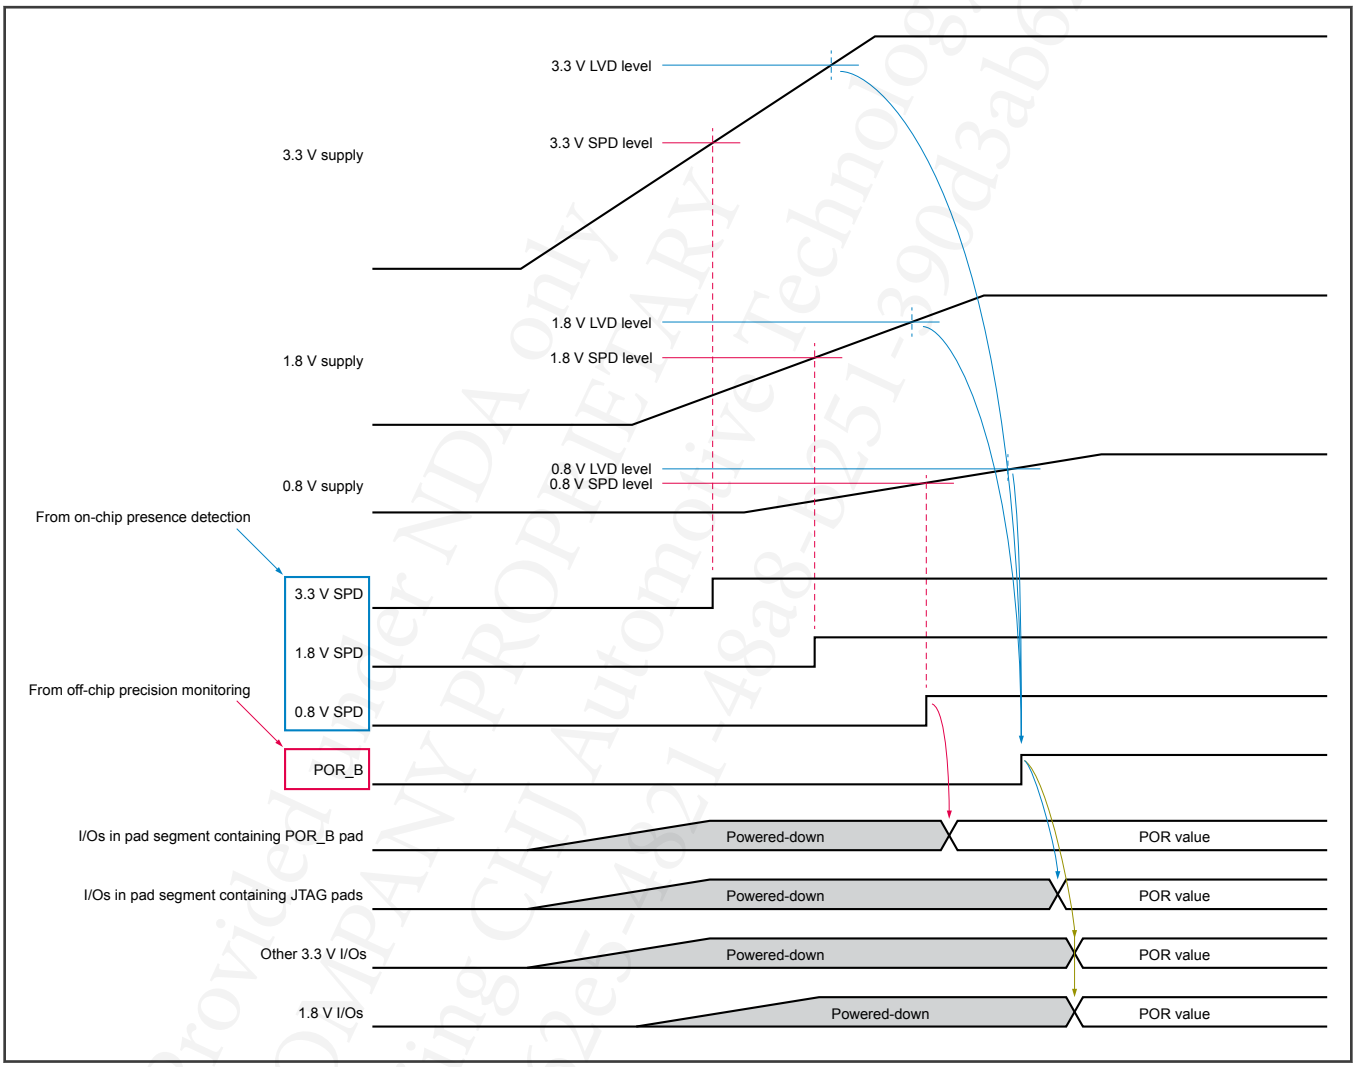
31.8.2 PMC

The analog portion of PMC:

- Ensures that if any of the signals that can assert the raw POR signal in the chip are asserted, the raw POR signal is asserted for a minimum of 1 µs.
- Provides a band gap voltage.

- Contains CSPDs to monitor the following power rails:
  - Core supply - supplies power to the POR signal generation logic.
  - PMC supply - supplies the band gap.

PMC also contains a watchdog to recover from undesired stuck-in-reset conditions.



The digital portion of the PMC contains logic for generating a POR used to reset MC_RGM and the POR signal.

The digital portion of the PMC contains logic and registers required to manage the CSPD and NCSPD signals.

31.9 Powerup/powerdown ramp rates and sequences

See the chip's data sheet for supply ramp rate and sequence specifications.

31.9.1 Pin behavior during powerup

31.9.2 Chip startup and shutdown

When the core supply is turned on during startup, VDD_STBY is also turned on, and the other way around. However, the actual turn-on times and/or ramp rates may differ.

When the core supply is turned off during shutdown, VDD_STBY is also turned off, and the other way around. However, the actual turn-off times and/or ramp rates may differ.

When VDD_IO_A and VDD_IO_B are turned on during startup, VDD_IO_STBY is also turned on, and the other way around. However, the actual turn-on times and/or ramp rates may differ.

When VDD_IO_A and VDD_IO_B are turned off during shutdown, VDD_IO_STBY is also turned off, and the other way around. However, the actual turn-off times and/or ramp rates may differ.

31.9.3 Standby mode entry

Switchable power supplies are not turned off during Standby mode entry until the PMIC_STBY_MODE_B output pin asserts.

Turning off switchable power supplies during Standby mode entry does not cause the supplies still on to have voltage over/undershoots.

Switchable power supplies may be turned off together with no requirement for a specific shutdown sequence.

31.9.4 Standby mode exit

For more information on Standby mode exit sequence, refer to the chip data sheet.

31.10 Low power modes

31.10.1 Wake-up sources

The device supports 23 wake-up pads in Standby mode (WKUP0 – WKUP22). These pads are identified in the IOMUX spreadsheet as being in the VDD_IO_STBY power domain.

To determine the mapping of WKUP*n* pins with I/O Power Domain, see the IO Signal tab in the attached IOMUX spreadsheet.

To reduce standby current, wake-up pins are input-only.

An internal interrupt, API wake-up signal from RTC, is also supported.

A typical use case for the API is to trigger a periodic wake-up for the S32G to feed an external watchdog before returning to Standby mode. Typically the WDOG is in the PMIC.

The power profile for this sequence should be kept to a minimum (for example, the power consumption during the wake-up transition, the feed watchdog code and the Standby mode entry transition should be kept as low as possible).

The watchdog timeout can be as low as 1 s, requiring one API wake-up event per second.

The data sheet provides a typical and maximum spec for the transition time into and out of Standby mode. The entry time is the time from software triggering a transition until Standby mode entry. Exit time is the time from a wake-up event until customer software execution.

31.11 Power management and power domains

31.11.1 I/O power domains

Each general-purpose I/O segment has an independent package supply pin, named VDD_IO_x (see the Supply Pins tab in the attached IOMUX spreadsheet).

The I/O segments are shown in following table.

Table 187. I/O power segments

I/O segment	Voltage	Description
VDD_IO_GMAC0	1.8 V / 3.3 V	Ethernet
VDD_IO_GMAC1	1.8 V / 3.3 V	Ethernet
VDD_IO_SDHC	1.8 V / 3.3 V	SDHC smart card

Table continues on the next page...

Table 187. I/O power segments (continued)

I/O segment	Voltage	Description
VDD_IO_QSPI	1.8 V	Quad SPI
VDD_IO_USB	1.8 V / 3.3 V	USB
VDD_IO_B	3.3 V	General purpose 3.3 V
VDD_IO_STBY	3.3 V	Standby 3.3 V
VDD_IO_A	3.3 V	General purpose 3.3 V
VDD_IO_CLKOUT	1.8 V	1.8 V Clkout (GPIO + LVDS)
VDD_IO_DDR0	1.1 V / 1.2 V / 1.35 V	DDR I/O
VDD_IO_PCIE0	1.8 V	PCIe I/O
VDD_IO_PCIE1	1.8 V	PCIe I/O
VDD_IO_AUR	1.8 V	1.8 V Aurora I/O
VDD_ADC	1.8 V	ADC 1.8 V supply

31.11.2 Standby pads

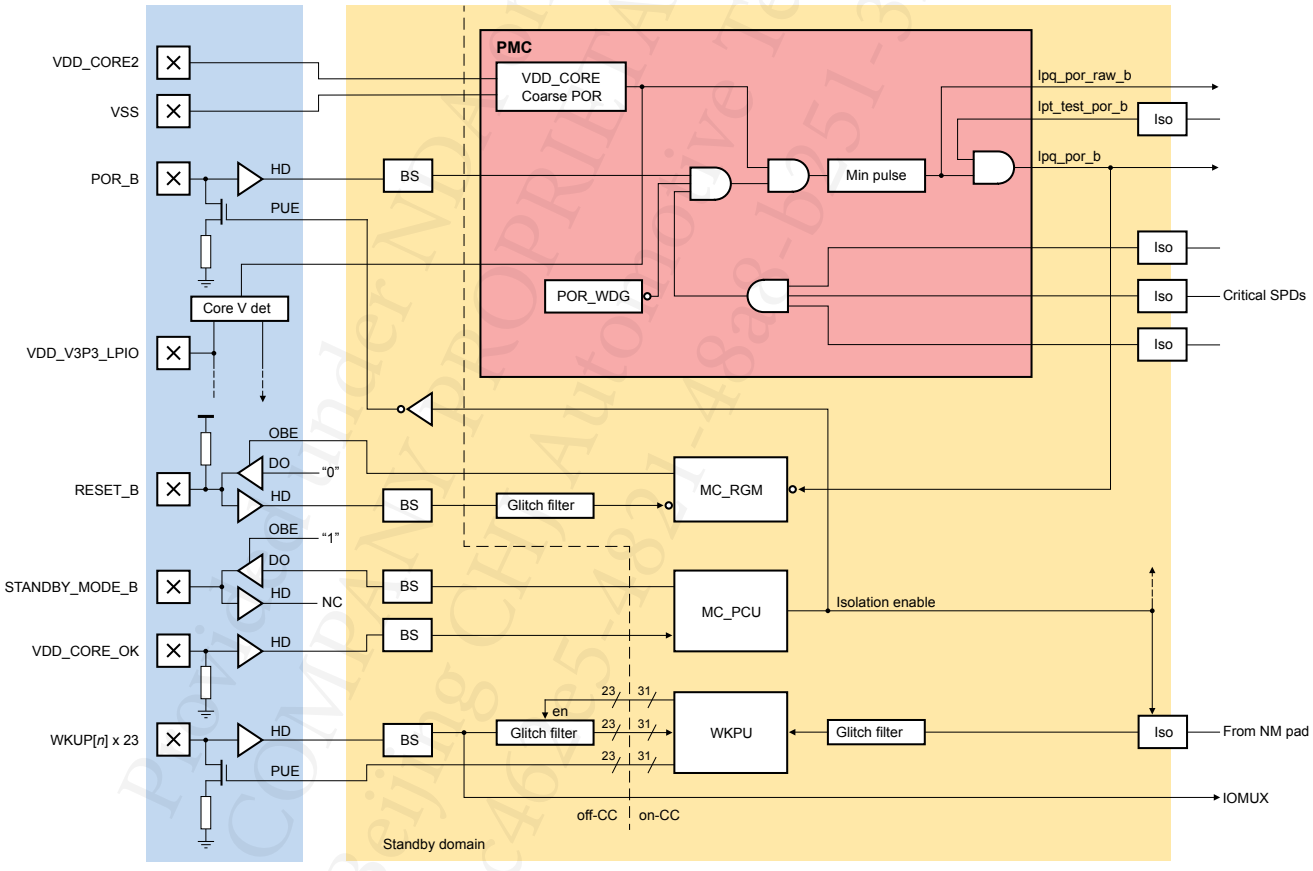


Figure 174. Standby pads overview

Table 188. Standby pad types

Pad name	Pad type	Pull type	Comment
POR_B	3.3 V GPI	Down	Pulldown is disabled when isolation is enabled by MC_PCU; otherwise it is enabled.
RESET_B	3.3 V GPIO	Up	Pullup is always enabled; DO pin is tied to 0.
STANDBY_MODE_B	3.3 V GPIO	None	OBE pin is tied to 1; IND pin remains unconnected.
VDD_CORE_OK	3.3 V GPI	Down	Pulldown is always enabled.
WKUP[*]	3.3 V GPI	Up/Down	PUE and PUS pins are controlled via SIUL and WKPU.

31.12 Glossary

CSPD Critical Supply Presence Detector. See Supply Presence Detectors (SPD) for details.

HVD High Voltage Detector

LVD Low Voltage Detector

NCSPD Noncritical Supply Presence Detector. See Supply Presence Detectors (SPD) for details.

PCFS Progressive Clock Frequency Switching. See the "Clock Generation Module (MC_CGM)" chapter for details.

PMIC_SENSE VDD sense point output to PMIC for low and high-voltage detection

SBC System Basis Chip (for example, PMIC)

VDD_IO_DDR0 DDR I/O power supply

VDD_STBY 0.8 V standby core logic power supply

Chapter 32
Mode Entry Module (MC_ME)

32.1 Chip-specific MC_ME information

32.1.1 MC_ME modes

This chip implements these modes:

- Reset
- Run
- Standby

The chip always enters Run mode on exit from Reset mode.

Run mode is the only mode during which the chip can operate its computational and communications functions.

The chip remains fully powered. The boot core is the only core enabled on Run entry.

Software can enable and disable cores and reset partitions as needed by the application, based on functional and power requirements.

Software can configure the pins as needed by the application. Software can set up and trigger BIST sequence execution off-line as needed by the application:

- Pins are safe-stated.
- No computational or communication activities are possible.

Reset mode is automatically entered after BIST has completed on-line on complete chip or reset partition 0. Some computational and communication activities can run while a BIST sequence runs on one or more reset partitions.

32.1.2 MC_ME partition mapping

32.1.2.1 MC_ME partition 0 mapping

The following table shows partition 0 and its register mapping.

Table 189. MC_ME partition 0 mapping

Register	Register field	Description	Used for
MC_ME_PRTN0_PCONF	PCE	Partition clock enable	Read only (for more information on this field, see the PRTN0_PCONF[PCE] description of MC_ME.)
MC_ME_PRTN0_STAT	PCS	Partition clock status	Read only
MC_ME_PRTN0_COFB0_STAT	BLOCK0	IP block status	uSDHC
	BLOCK1	IP block status	DDR_0
	BLOCK2–4	IP block status	Reserved
	BLOCK5–31	IP block status	Reserved (Off-CC)
MC_ME_PRTN0_COFB0_CLKEN	REQ0	Clock enable	uSDHC
	REQ1	Clock enable	DDR_0

Table continues on the next page...

Table 189. MC_ME partition 0 mapping (continued)

Register	Register field	Description	Used for
	REQ2–4	Clock enable	Reserved
	REQ5–31	Clock enable	Reserved (Off-CC)
MC_ME_PRTN0_CORE0_PCONF	CCE	Core 0 clock enable	CM7_0
MC_ME_PRTN0_CORE0_PUPD	CCUPD	Core 0 clock update	
MC_ME_PRTN0_CORE0_STAT	CCS	Core 0 clock process status	
	WFI	Core 0 wait for interrupt status	
MC_ME_PRTN0_CORE0_ADDR	ADDR	Core 0 address

Register	Register field	Description	Used for
MC_ME_PRTN1_CORE2_ADDR	ADDR	Core 2 address	Performance mode - CA53 cluster1 core0 Lockstep mode - Reserved
MC_ME_PRTN1_CORE3_PCONF	CCE	Core 3 clock enable	Reserved
MC_ME_PRTN1_CORE3_PUPD	CCUPD	Core 3 clock update	Reserved
MC_ME_PRTN1_CORE3_STAT	CCS	Core 3 clock process status	Reserved
	WFI	Core 3 wait for interrupt status	CA53 cluster1 core1
MC_ME_PRTN1_CORE3_ADDR	ADDR	Core 3 address	Performance mode - CA53 cluster1 core1 Lockstep mode - Reserved

32.1.2.3 MC_ME partition 2 mapping

The following table shows partition 2 and its register mapping.

Table 191. MC_ME partition 2 mapping

Register	Register field	Description	Used for
MC_ME_PRTN2_PCONF	PCE	Partition clock enable	Reset domain 2
MC_ME_PRTN2_PCONF	OSSE	Output safe stating enable	Reset domain 2
MC_ME_PRTN2_PUPD	PCUD	Partition clock update	Reset domain 2
MC_ME_PRTN2_PUPD	OSSUD	Output safe stating update	Reset domain 2
MC_ME_PRTN2_STAT	PCS	Partition clock status	Reset domain 2
MC_ME_PRTN2_STAT	OSSS	Output safe stating status	Reset domain 2
MC_ME_PRTN2_COFB0_STAT	BLOCK0–31	IP block status	Reserved
MC_ME_PRTN2_COFB0_CLKEN	REQ0	Clock enable	PFE-MAC0
	REQ1	Clock enable	PFE-MAC1
	REQ2	Clock enable	PFE-MAC2
	REQ3	Clock enable	PFE-TS_CLK
	REQ4–31	Clock enable	Reserved

32.1.2.4 MC_ME partition 3 mapping

The following table shows partition 3 and its register mapping.

Table 192. MC_ME partition 3 mapping

Register	Register field	Description	Used for
MC_ME_PRTN3_PCONF	PCE	Partition clock enable	Reset domain 3
MC_ME_PRTN3_PCONF	OSSE	Output safe stating enable	Reset domain 3
MC_ME_PRTN3_PUPD	PCUD	Partition clock update	Reset domain 3
MC_ME_PRTN3_PUPD	OSSUD	Output safe stating update	Reset domain 3
MC_ME_PRTN3_STAT	PCS	Partition clock status	Reset domain 3
MC_ME_PRTN3_STAT	OSSS	Output safe stating status	Reset domain 3
MC_ME_PRTN3_COFB0_STAT	BLOCK0–31	IP block status	Reserved
MC_ME_PRTN3_COFB0_CLKEN	REQ0–31	Clock enable	Reserved

32.1.3 Core controls

The MC_ME provides the core boot addresses via the MC_ME_PRTNm_COREn_ADDR registers.

For CA53_x, ADDR[39:32] bits come from A53 GPR registers, and ADDR[31:0] bits come from the MC_ME_PRTNm_COREn_ADDR register.

Each core determines its boot address one of two possible ways:

- After core reset deassertion, the core jumps to the location specified in MC_ME_PRTNm_COREn_ADDR and starts executing from there.
- The core obtains the boot address specified in the corresponding MC_ME_PRTNm_COREn_ADDR register via signals from the MC_ME and then boots from that address on reset exit.

32.1.4 Turning off cores and partitions

There is no hardware handshake to ensure a module (core, peripheral, or subsystem) has been shut down before disabling its clock. Software must disable the clock, and when software submits a request to disable a module's clock, the clock is disabled regardless of the module state.

NOTE

For details about turning cores and partitions on or off, see these sections of the Reset chapter:

- Software reset partition turn-on flow chart
- Software reset partition turn-off flowchart
- Core turn-on sequence
- Core turn-off sequence

The subsections below provide the details of procedures related to MC_ME that are referred in the above mentioned sub-sections of the Reset chapter of this document.

32.1.4.1 Enable output isolation

1. Indicate that you want to enable output safe stating for the partition (MC_ME_PRTNm_PCONF[OSSE]).
2. Enable the partition clock hardware-update process (MC_ME_PRTNm_COREn_PUPD[CCUPD]).
3. Start the enabled hardware-update process (MC_ME_CTL_KEY[KEY]).

   MC_ME requests the partition's output isolation cells to switch to isolation mode.
4. Make sure the hardware process has completed (MC_ME_PRTNm_PUPD[PCUD]).

5. Make sure the partition's output isolation cells are transitioned to isolation mode (MC_ME_PRTNm_STAT[OSSS]).

32.1.4.2 Disable core clocks

1. Indicate that you want to disable the core clock (MC_ME_PRTNm_COREn_PCONF[CCE]).
2. Enable the clock hardware-update processes (MC_ME_PRTNm_COREn_PUPD[CCUPD]).
3. Start the enabled hardware-update processes (MC_ME_CTL_KEY[KEY]).

   MC_ME requests closing of the clock gates for the specified core.
4. Make sure the clock hardware process has completed (MC_ME_PRTNm_PUPD[PCUD]).
5. Make sure the core clock gates are closed (MC_ME_PRTNm_COREn_STAT[CCS]).

32.1.4.3 Disable partition clocks

The MC_ME manages the disabling of a partition's clocks by the following steps:

1. Software writes 0 to a partition's MC_ME_PRTNm_PCONF[PCE] and then executes a partition clock hardware-update-process sequence by:
   - Setting MC_ME_PRTNm_PUPD to 1
   - Writing the valid KEY combinations to the MC_ME_CTL_KEY register
2. The MC_ME requests the clock gating logic to close the clock gates corresponding to that partition.
3. When the hardware process is completed, MC_ME_PRTNm_PUPD[PCUD] is reset.
4. When the clock gating logic completes closing the partition's clock gates, the partition's MC_ME_PRTNm_STAT[PCS] is cleared to 0.

32.1.4.4 Disable COFB clocks

To disable COFB clocks using MC_ME, follow the steps mentioned below:

1. Indicate that you want to disable the COFB clock using MC_ME_PRTNm_COFBn_CLKEN[REQ] fields followed by writing 1 into the partition's MC_ME_PRTNm_PCONF[PCE] register field
2. Initiate the clock hardware process by writing “1” to MC_ME_PRNTm_PUPD[PCUD]
3. Write the valid key combinations into the MC_ME_CTRL_KEY register
4. Make sure the COFB clock is gated by reading MC_ME_PRTNm_COFBn_STAT[BLOCK]

32.1.4.5 Assert partition reset signals

1. Request assertion of the partition's reset signals (MC_RGM_PRSTn_0).
2. Make sure the partition reset signals are asserted (MC_RGM_PSTATn_0).

32.2 Introduction

The MC_ME module generates control signals for a set of modules of the SoC. The set of signals are defined in corresponding 'Partition Configuration Registers'. It also implements a software-based mechanism for initiating a functional and destructive reset sequence and standby entry handshake with power management of SoC. See Figure 175 for the MC_ME block diagram.

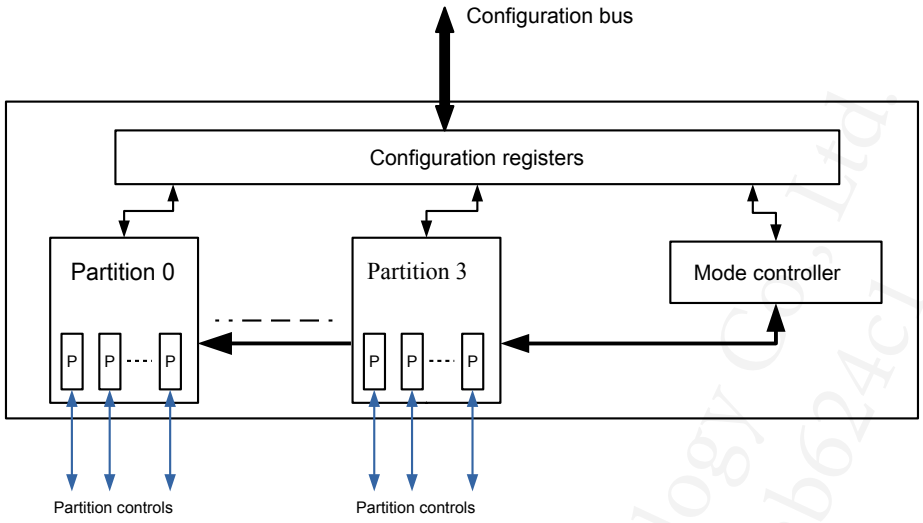

Figure 175. MC_ME block diagram

32.3 Features

MC_ME includes the following features:

- 4 logic partitions implementation and their controls
- Core clock controls
- Partition clock control
- Partition output safe stating control
- Control mechanism for initiating a destructive or functional reset sequence to MC_RGM
- Control mechanism for initiating standby mode entry for SoC

The logic partition inside MC_ME refers to a certain group of on-chip resources (or IP blocks) that are clubbed together to represent a single 'Partition' inside MC_ME. The MC_ME partition can be the same or different than an LBIST partition. Each of the MC_ME partitions implements a certain number of hardware processes. These hardware processes provide a mechanism to regulate various control signals provided to or received from the IP blocks. The corresponding status signals can also be monitored from MC_ME register(s). Each of the hardware processes is bound to finish in 256 cycles of the MC_ME register configuration clocks. Therefore, the hardware processes are non blocking in nature. Mismatch in the expected versus actual status of any hardware process is controlled by a pre-defined software.

32.4 MC_ME register descriptions

MC_ME implements set hardware processes that can be used by the software for changing the mode of operation for a partition. Following are the features of MC_ME registers:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits do not terminate with an error, and hardware behavior is unpredictable.
- Writes to read-only register fields in writable registers are ignored and do not provide an error message.
- Writes to read-only registers are aborted with an error message.

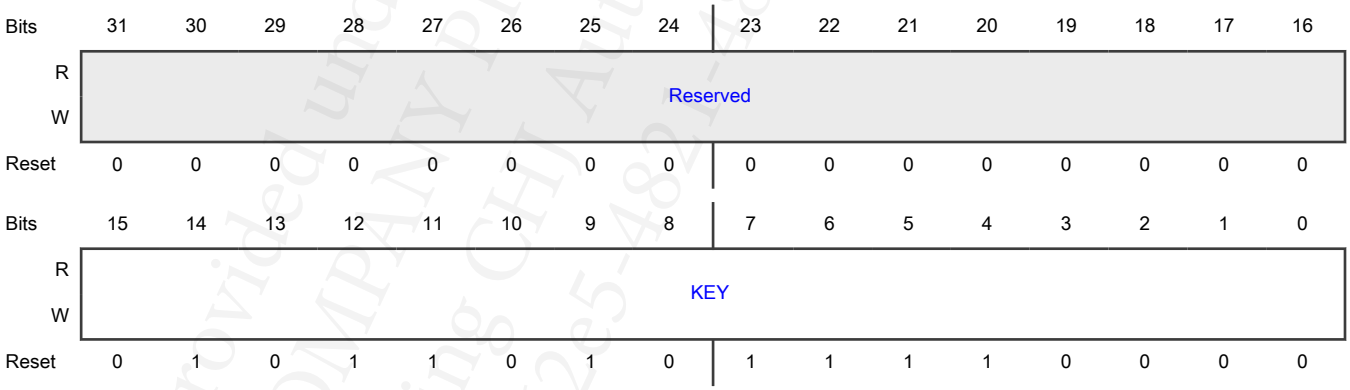
32.4.2 Control Key Register (CTL_KEY)

Offset

Register	Offset
CTL_KEY	0h

Function



This register provides the mechanism to MC_ME for starting the hardware processes for the partition(s) and standby entry sequence. The hardware processes for partitions are triggered through the corresponding PRTNn_PCONF register. The mechanism to trigger the hardware processes of the respective partitions require two write operations: first time with key and second time with inverted key. The hexadecimal value of key is 0x5AF0 whereas for inverted key is 0xA50F.

For initiating a standby entry sequence, the MODE_CONF register is used for providing a standby entry request along with a valid key combination.

NOTE

Reads from this register return a valid key value to be written next.

Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15-0 KEY	Control key Key for starting the hardware processes. Writes with a value other than key or inverted key are ignored. Reads return bit inverted value corresponding to last write.

32.4.3 Mode Configuration Register (MODE_CONF)

Offset

Register	Offset
MODE_CONF	4h

Function

This register is used for initiating a standby request or a reset event (destructive or functional) for the chip. The functional or destructive events are signaled to MC_RGM for further handling.

NOTE

Software must not enable mode entry if the value of multiple fields is 1 in the MODE_CONF register.

Diagram

Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 STANDBY	Standby request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a standby entry sequence request to MC_ME.
14-2 —	Reserved This field is reserved and read returns zeros.
1 FUNC_RST	Functional reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a functional reset event signaling to MC_RGM.
0 DEST_RST	Destructive reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a destructive reset event signaling to MC_RGM.

32.4.4 Mode Update Register (MODE_UPD)

Offset

Register	Offset
MODE_UPD	8h

Function

This register is used for initiating a mode change. Mode change refers to initiating a standby request, or generating a destructive or functional reset event to MC_RGM. Setting mode update field to logic-1, along with programming MODE_CONF registers and then followed by a valid key combination will generate a mode transition request.

NOTE

The MODE_UPD register is implemented to make mode transition programming model the same as partition programming model. This is for future expansion inside MC_ME.

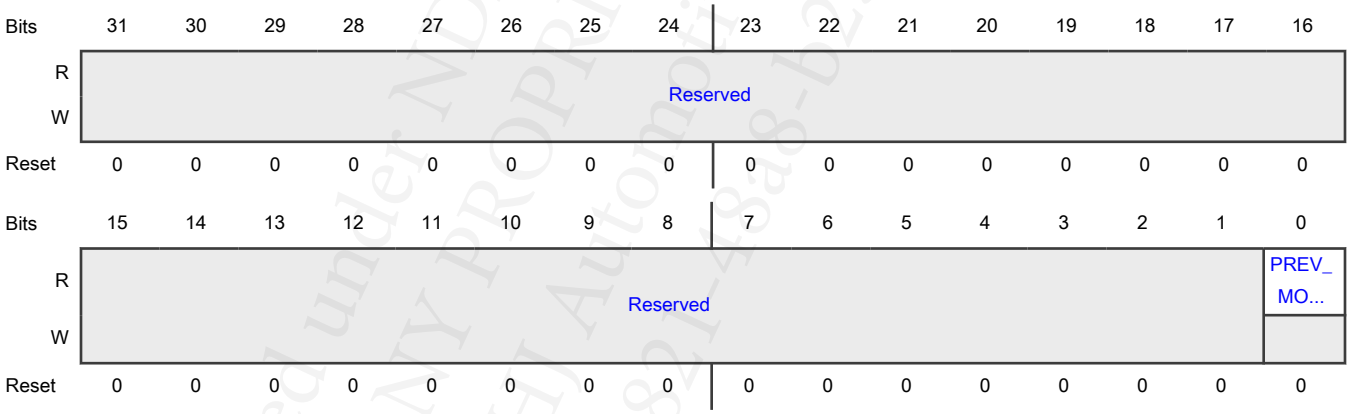
Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 MODE_UPD	Mode update Writing a logic-1 to this bit, followed by a valid key combination initiates a mode change as per the MODE_CONF register.

32.4.5 Mode Status Register (MODE_STAT)



Offset

Register	Offset
MODE_STAT	Ch

Function

This register provides the status of the previous mode. In case of standby exit, if the reset event status register of MC_RGM are set, then contents of this register should be ignored.

Diagram

Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 PREV_MODE	Previous mode This bit shows the status of the previous mode.

Table continues on the next page...

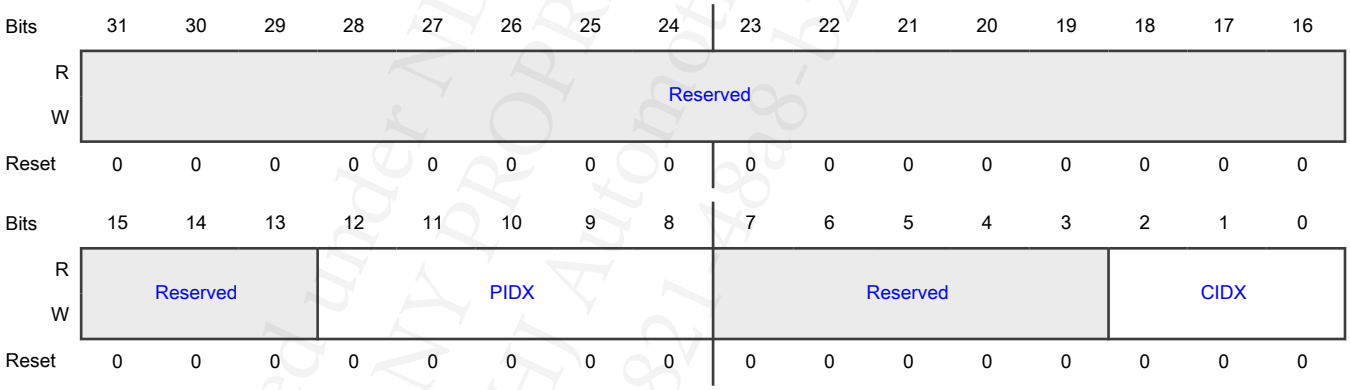
Table continued from the previous page...

Field	Function
	0b - The previous mode was reset (any reset). 1b - The previous mode was standby.

32.4.6 Main Core ID Register (MAIN_COREID)

Offset

Register	Offset
MAIN_COREID	10h



Function

This register provides the ID of the main core sequencing the operation for the standby sequence. Core ID is required for entering in the standby mode, and using this MC_ME locates the WFI instruction execution of the main core. The core ID in this register is specified by the partition index along with the core index.

NOTE

Before initiating a standby entry sequence, the contents of this register should point to the correct main core. Providing non-existing or incorrect core ID leads to unpredictable hardware behavior.

Diagram

Fields

Field	Function
31-13 —	Reserved This field is reserved and read returns zeros.
12-8 PIDX	Partition index Provides the partition index of the main core. Only values 0 - 3 can be written.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-3 —	Reserved This field is reserved and read returns zeros.
2-0 CIDX	Core index Provides the core index of the main core inside the partition.

32.4.7 Partition 0 Process Configuration Register (PRTN0_PCONF)

Offset

Register	Offset
PRTN0_PCONF	100h

Function

This register provides a configuration for the hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_PCONF and PRTN0_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

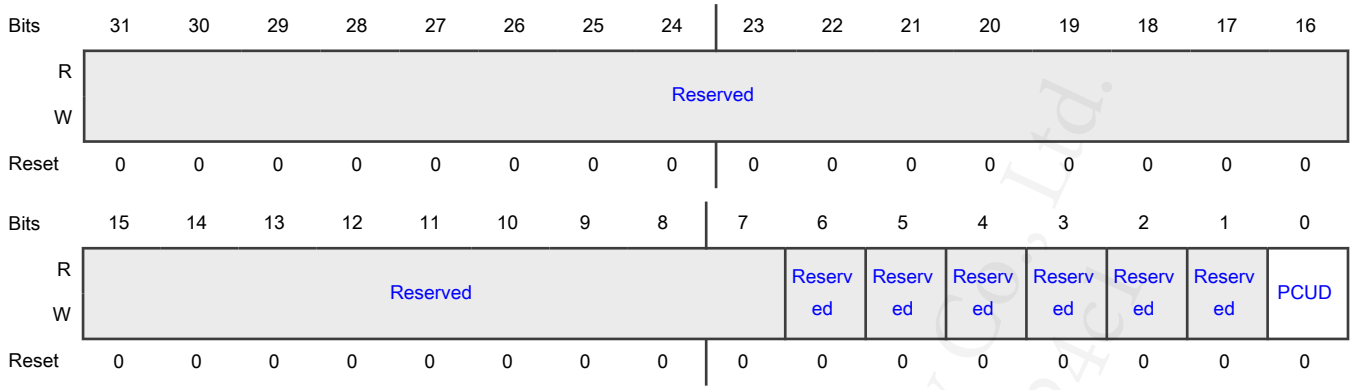
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. The software must not perform any writes to this field. This field must remain unchanged and always equal to its reset value. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

32.4.8 Partition 0 Process Update Register (PRTN0_PUPD)

Offset



Register	Offset
PRTN0_PUPD	104h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

32.4.11 Partition 0 COFB Set 0 Clock Enable Register (PRTN0_COFB0_CLKEN)

Offset

Register	Offset
PRTN0_COFB0_CLKEN	130h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 0. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

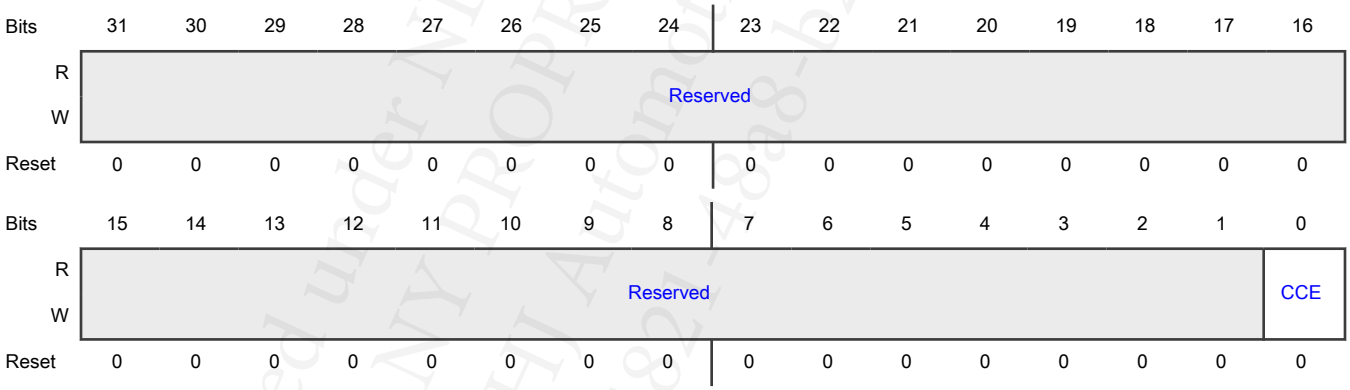
32.4.12 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)



Offset

Register	Offset
PRTN0_CORE0_PCONF	140h

Function

This register provides configurations for the Core 0 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE0_PUPD and PRTN0_CORE0_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

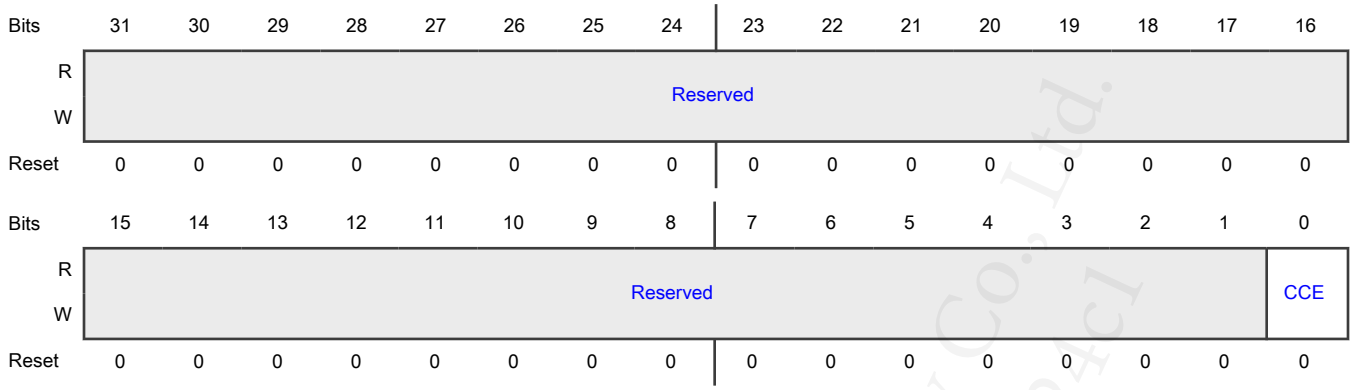
31-2 ADDR	Address Core 1 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

32.4.20 Partition 0 Core 2 Process Configuration Register (PRTN0_CORE2_PCONF)

Offset



Register	Offset
PRTN0_CORE2_PCONF	180h

Function

This register provides configurations for the Core 2 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE2_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE2_PUPD and PRTN0_CORE2_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

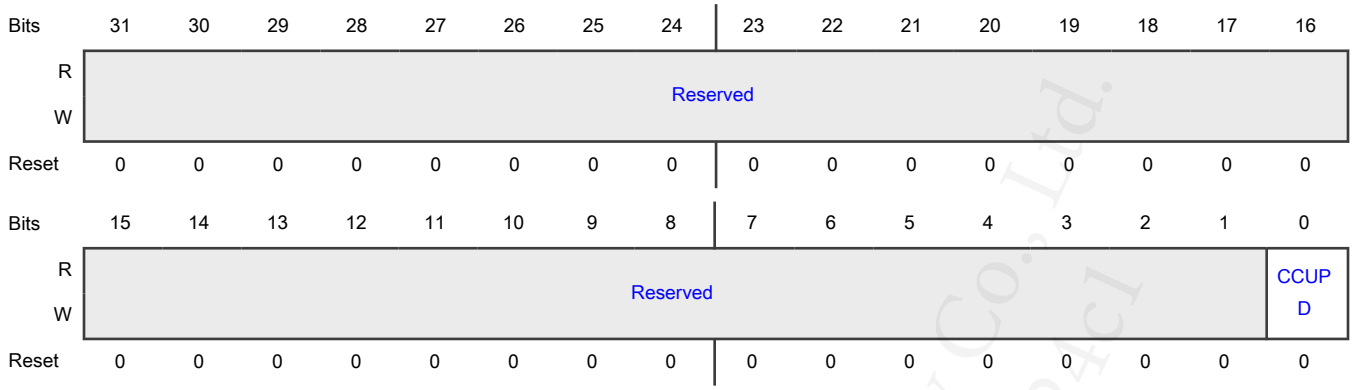
Diagram

Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 2 clock enable This bit controls whether the clock to Core 2 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

32.4.21 Partition 0 Core 2 Process Update Register (PRTN0_CORE2_PUPD)

Offset



Register	Offset
PRTN0_CORE2_PUPD	184h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE2_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

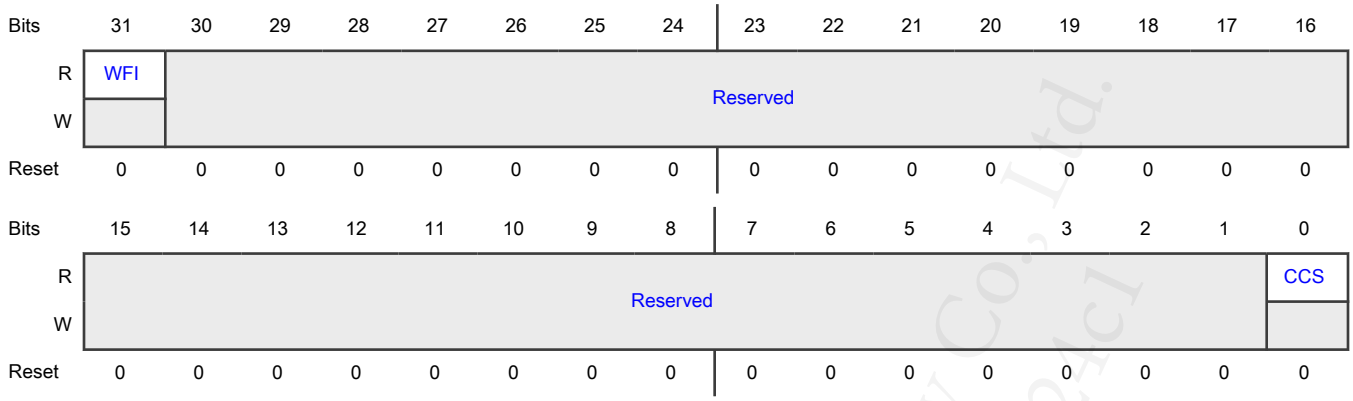
Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 2 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 2 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

32.4.22 Partition 0 Core 2 Status Register (PRTN0_CORE2_STAT)

Offset



Register	Offset
PRTN0_CORE2_STAT	188h

Function

This register provides the status corresponding to Core 2 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 2.

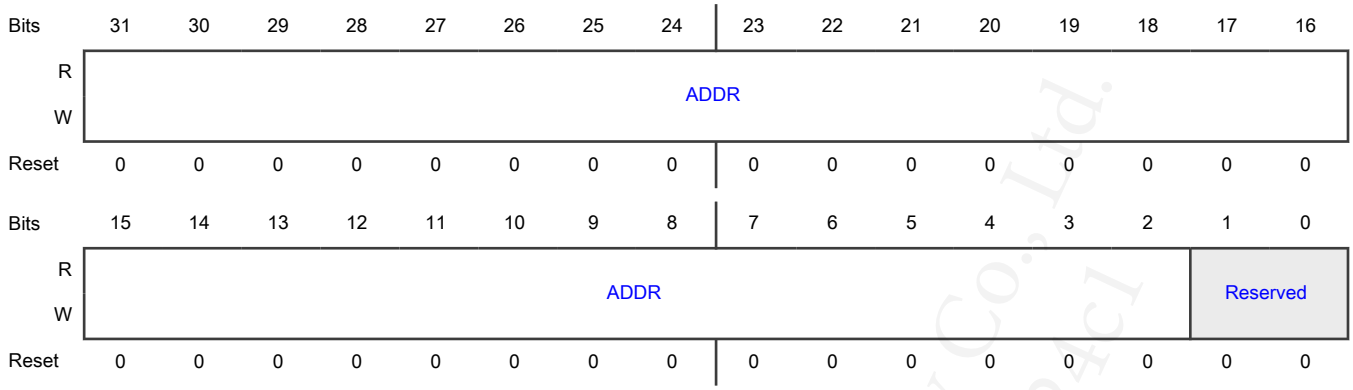
Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 2 in partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 2 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

32.4.23 Partition 0 Core 2 Address Register (PRTN0_CORE2_ADDR)

Offset



Register	Offset
PRTN0_CORE2_ADDR	18Ch

Function

This register contains the boot address for Core 2 in partition 0.
