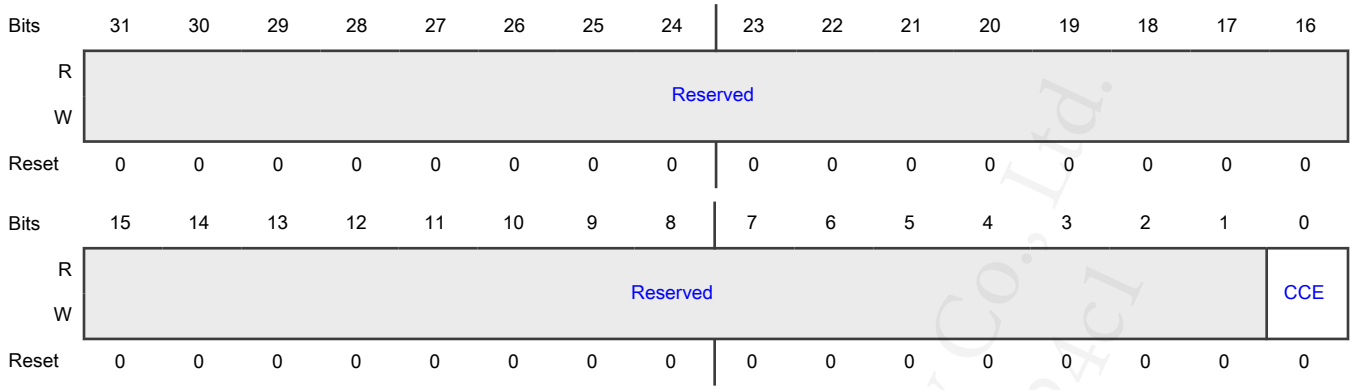
32.4.24 Partition 0 Core 3 Process Configuration Register (PRTN0_CORE3_PCONF)

Offset



Register	Offset
PRTN0_CORE3_PCONF	1A0h

Function

This register provides configurations for the Core 3 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE3_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE3_PUPD and PRTN0_CORE3_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

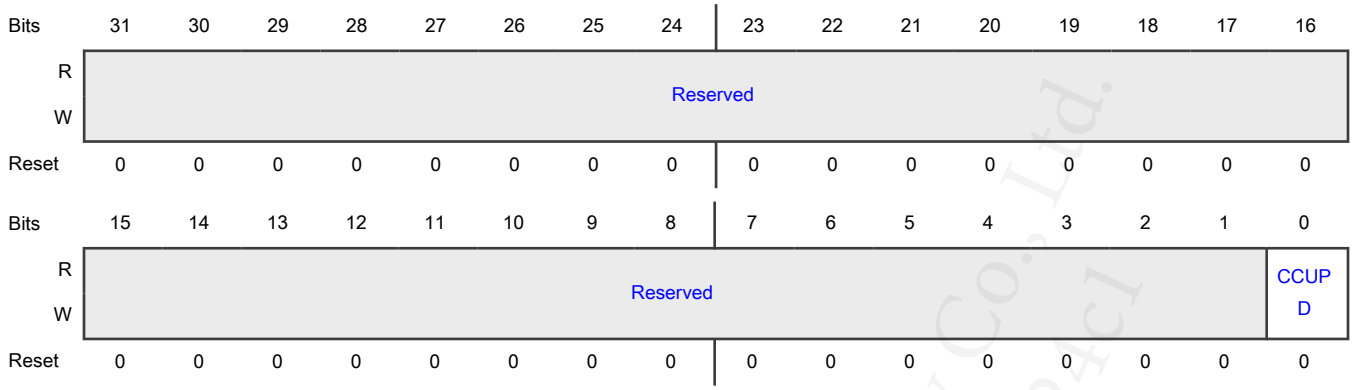
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 3 clock enable This bit controls whether the clock to Core 3 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

32.4.25 Partition 0 Core 3 Process Update Register (PRTN0_CORE3_PUPD)

Offset



Register	Offset
PRTN0_CORE3_PUPD	1A4h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE3_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

32.4.51 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)

Offset

Register	Offset
PRTN2_COFB0_CLKEN	530h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

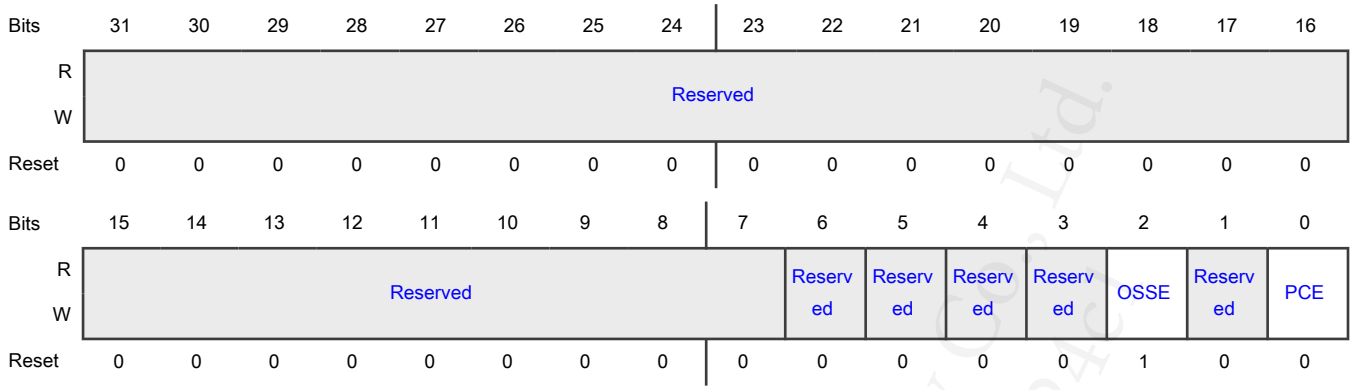
32.4.52 Partition 3 Process Configuration Register (PRTN3_PCONF)

Offset

Register	Offset
PRTN3_PCONF	700h

Function



This register provides a configuration for the hardware processes corresponding to partition 3. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN3_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN3_PCONF and PRTN3_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

32.4.53 Partition 3 Process Update Register (PRTN3_PUPD)

Offset

Register	Offset
PRTN3_PUPD	704h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 3. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN3_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

32.5 Partition processes

Each of the processes inside the partition controls register space and corresponds to a control signal provided to that partition. A partition can include a core, or COFBs, or both. The MC_ME hardware processes provide control and status via signals provided to partitions. Each partition can be assigned a signal for control and a signal for status. Each of the control signals implements functionality for the partition. For example, clock gating and peripheral control.

The hardware process can be triggered and monitored using a set of three registers:

- Configuration register; for example, Partition n Process Configuration register
- Update register; for example, Partition n Process Update register
- Status register; for example, Partition n Status register

Similar registers exist for cores inside the partition.

The process setup and triggering procedure is shown in Figure 176. Each of the processes is independent of others and can be triggered or retriggered in parallel or sequential to other processes. The triggering or retriggering mechanism remains the same.

c8c462e5-8214-8a5-251-390d3ab624c1

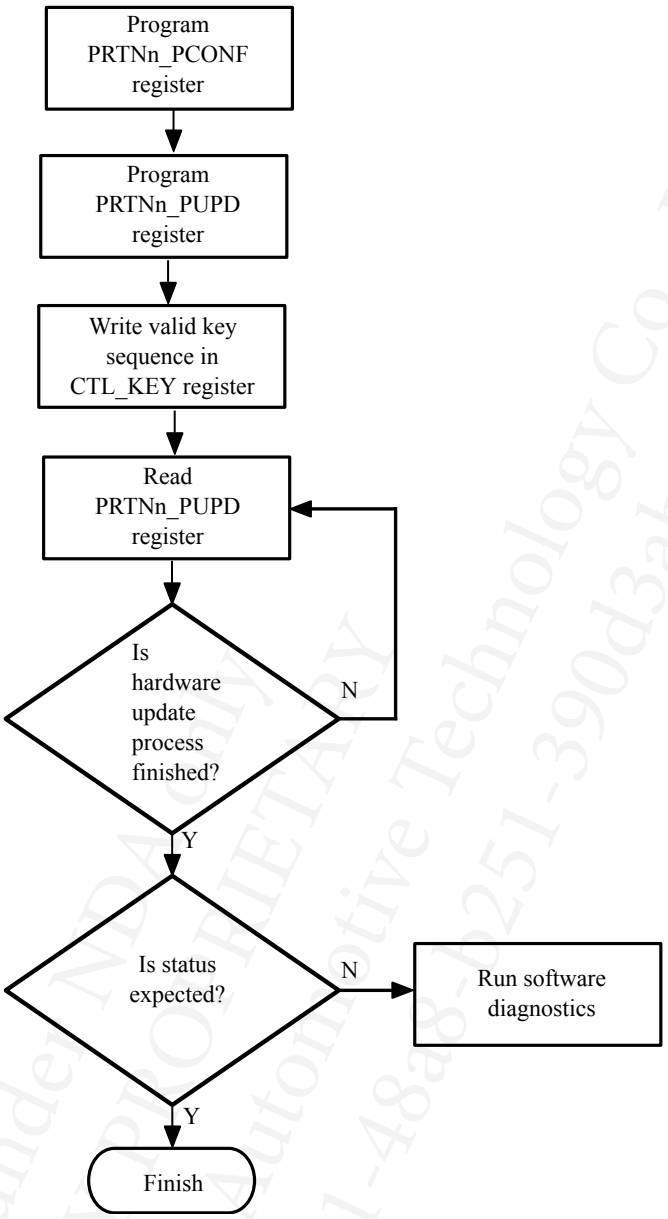

Figure 176. Partition process setup procedure

All the hardware processes are bound to finish in 256 cycles of the MC_ME configuration clock. If the actual and the expected status for a process does not match, then the diagnostics is left as a software responsibility. The software diagnostic can include further wait cycles for the status to match.

32.6 Mode transition

MC_ME implements a mode transition mechanism, whereby the mode of operation for SoC can be changed. Then module implements a mechanism that can lead to:

- Destructive reset
- Functional reset
- Standby mode entry

Destructive reset and functional reset requests from MC_ME are non-retractable transitions. After it is initiated, the other MC_ME functionality is rendered unusable and bus errors are provided for upcoming access to the MC_ME register until a reset sequence is executed by MC_RGM. Hence, it is vital that MC_RGM should never ignore or gate the reset requests from MC_ME.

For transition into the standby mode, the software should ensure that required IP blocks such as clock sources and I/O communication are in their respective inactive states before initiating a standby mode transition to MC_ME. After MC_ME initiates a power down sequence request, it cannot be retracted. The SoC enters a standby power down sequence and then reenter power-up sequence even for cases where the standby wakeup happens right at the time of initiating a power-down sequence request.

Steps for initiating the MC_ME mode transition:

1. Setup the MODE_CONF register with the corresponding target mode bit set to logic-1.
2. Perform the same update as done in the MODE_CONF register on the CONF_UPD register.
3. Write the valid control key (0x5AF0) on the CTL_KEY register.
4. Write the valid invert control key (0xA50F) on the CTL_KEY register.

Mode transition to MC_ME is initiated, after the sequence mentioned above is completed.

In step 1, if both FUNC_RST and DEST_RST in Mode Configuration Register (MODE_CONF) are 1:

- After step 4 is complete, MC_ME initiates a mode transition to a destructive (not functional) reset.
- After the chip exits reset, MC_RGM records that both MC_ME's destructive reset and MC_ME's functional reset were the reset source.

NOTE

Any hardware partition processes setup, along with mode transition, is executed in parallel to the mode transition of MC_ME.

32.7 Standby entry

MC_ME provides hardware processes that implement shutdown sequencing of on-chip resources, such as cores and COFBs. The standby entry sequencing can be achieved or implemented using these hardware processes. The order of the hardware process is determined by the software and MC_ME. It requires no restriction in sequencing of the operation. Following is an example sequence for initiating a power-down sequence for entering the standby mode for SoC. The standby entry sequence should include (but not limited to) the following steps:

1. Setting up wakeup lines
2. Shutting down cores and COFBs
3. Switching all MC_CGM muxes to clk_src_0 with PCFS
4. Powering down all clock sources except clk_src_0
5. Setting up MC_ME using the main core and initiating a standby mode transition
6. Executing WFI instruction on the main core (per Arm specification)

32.7.1 Application core shutdown

This section describes a mechanism for shutting down an application core. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence, can be further integrated with an SoC-specific task.

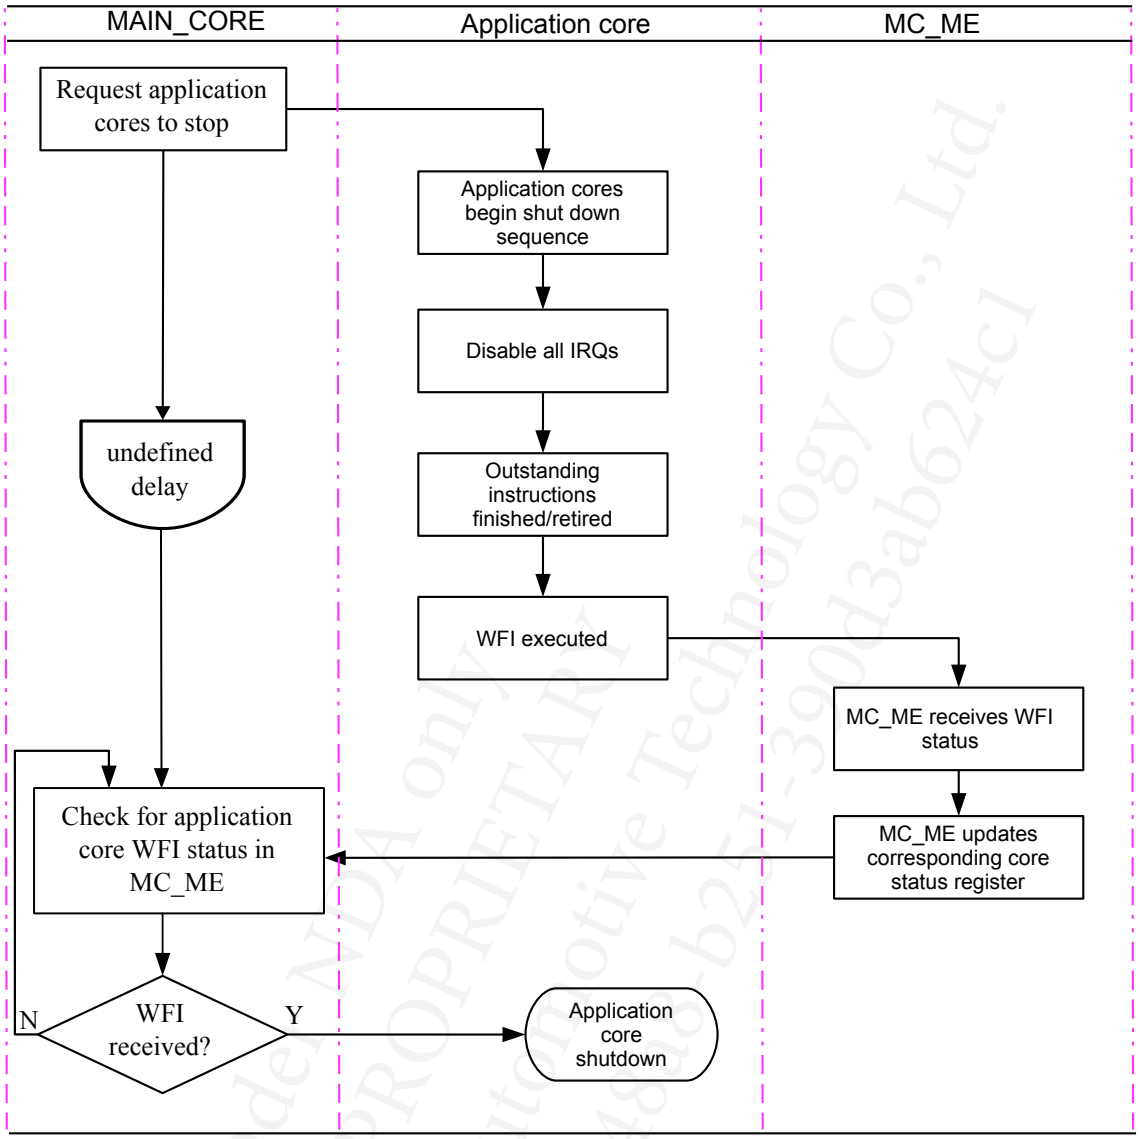

Figure 177. Application core shutdown

After the application core is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

32.7.2 Application cluster shutdown

This section describes a mechanism for shutting down an application cluster. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence can be further integrated with an SoC- specific task and can also be skipped when not required, as shown in Figure 178.

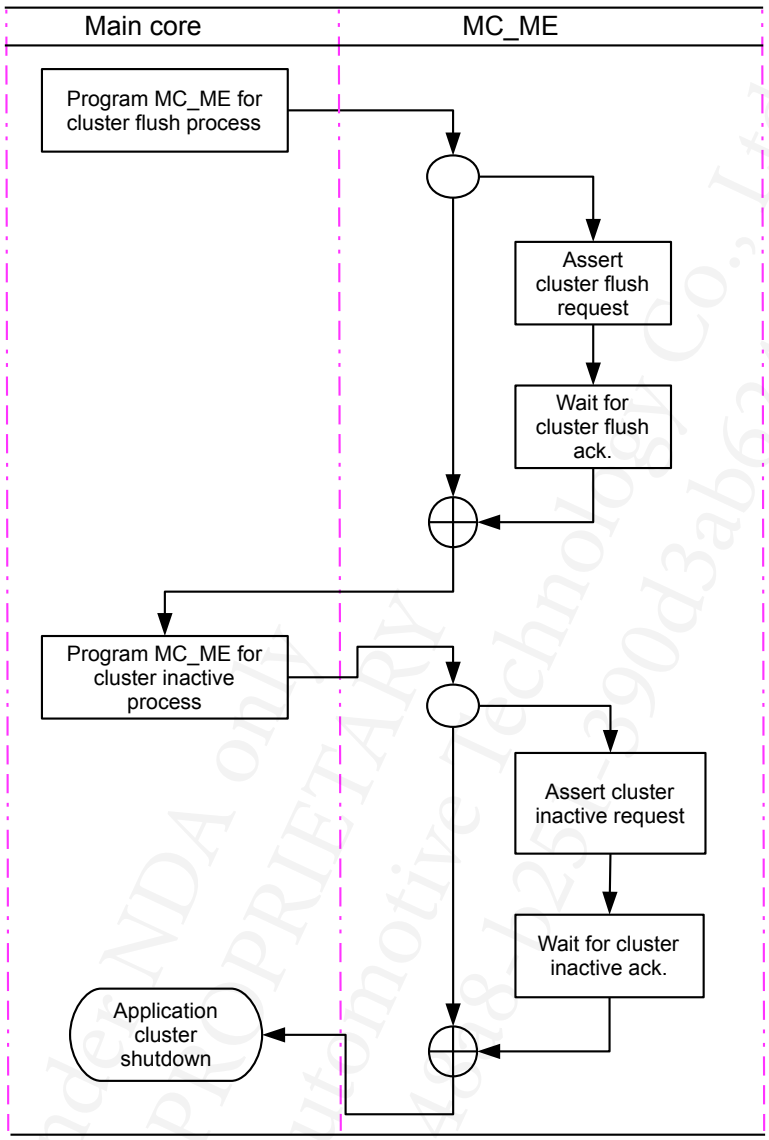

Figure 178. Application cluster shutdown

After the application cluster is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

32.7.3 Main core shutdown and standby entry

This section describes standby entry sequence along with the main core shutdown. This sequence should only be initiated after SoC is ready for entering standby and has completed all the housekeeping activities. It is necessary that the main core has completed all the operations pertaining to other (application cores) and is the last active core before initiating the standby entry sequence. See Figure 179.

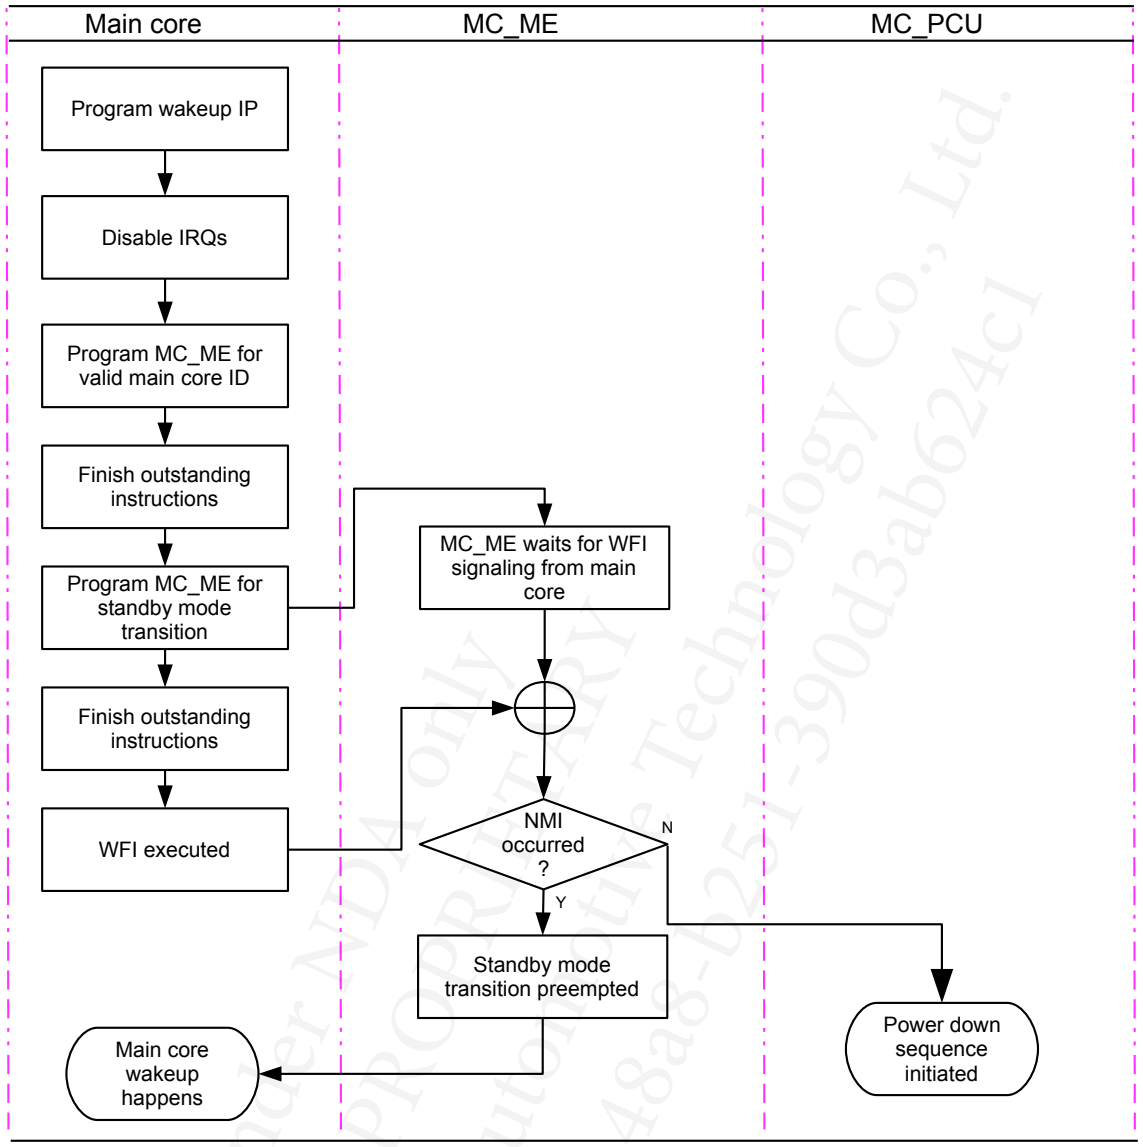

Figure 179. Standby entry sequence along with main core shutdown

NOTE

- After MC_ME initiates the power sequence to MC_PCU, it also gates the NMI signal to the main core with its clock still running. This enables the main core to remain inactive (WFI state) until it is reset and power-up again at standby exit. Therefore, it is necessary that gated NMI signal to the core should not be lost by the wakeup unit.

32.8 Glossary

WFI	Wait for interrupt
COFB	Collection of functional blocks also referred as number of peripherals

Chapter 33
Power Control Unit (MC_PCU)

33.1 Introduction

The power control unit (MC_PCU) is used for initiating a Standby mode entry that reduces the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply. The blocks inside the chip are grouped into multiple parts having this capability, which are called "power domains".

When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information, such as, power domain is lost. When you reconnect a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage. Maximum power saving is achieved by entering the Standby mode.

After the MC_ME asserts a standby entry request, MC_PCU initiates the power sequence, which is non-retractable and includes the handshake with the chip power management controller. The power-up/down sequences are handled by FSMs to ensure a smooth and safe transition into and out of the Standby mode. Exiting the Standby mode can only be done through a system wakeup event, power-on reset, destructive reset, or a functional reset.

33.2 Power sequence FSM

MC_PCU implements an FSM to initiate the power sequencing of the Standby mode entry/exit sequence for the chip.

34.1.1.3 Device Status Flag (DSF2) register status signals

The following table provides details about the captured status signals through the DSF2 (POR_WDOG_EVENT_CAPTURE2) Register.

Table 196. PMC_DSF2[DSFBIT2] signal mapping

Bit field	Bit name	Bit field description
0-31	-	Reserved Do not access this register. Accesses do not result in a transfer error.

34.1.2 Supply naming reference

The table below shows the signal names used in this Reference Manual and how they are mapped to the actual names as shown in the IOMUX file attached to this document.

Table 197. Supply naming reference

Supply name in RM	Actual supply name from IOMUX file
Core supply	VDD
PMC supply	VDD_VREF

34.2 Introduction

The PMC monitors the different power domains of the chip. It receives power domain status from different points in the chip and combines them into two outputs:

- Power-on reset event (POR event)
- Non-critical supply presence detector event (NCSPD event)

Use both outputs as a system reset placing an application into a safe state. A low-power mode exists that reduces the power consumption of the PMC by turning off some features.

34.2.1 Features

- CSPD monitoring:
  - Combines the status of all CSPDs into one POR event signal, used as a system reset source
- NCSPD monitoring:
  - Monitors the NCSPD signals and creates a combined NCSPD event based on user configuration.
- POR watchdog (POR_WDOG):
  - Causes a POR event if the counter expires.

34.2.2 Block diagram

Figure 181 shows the functional structure of the PMC.

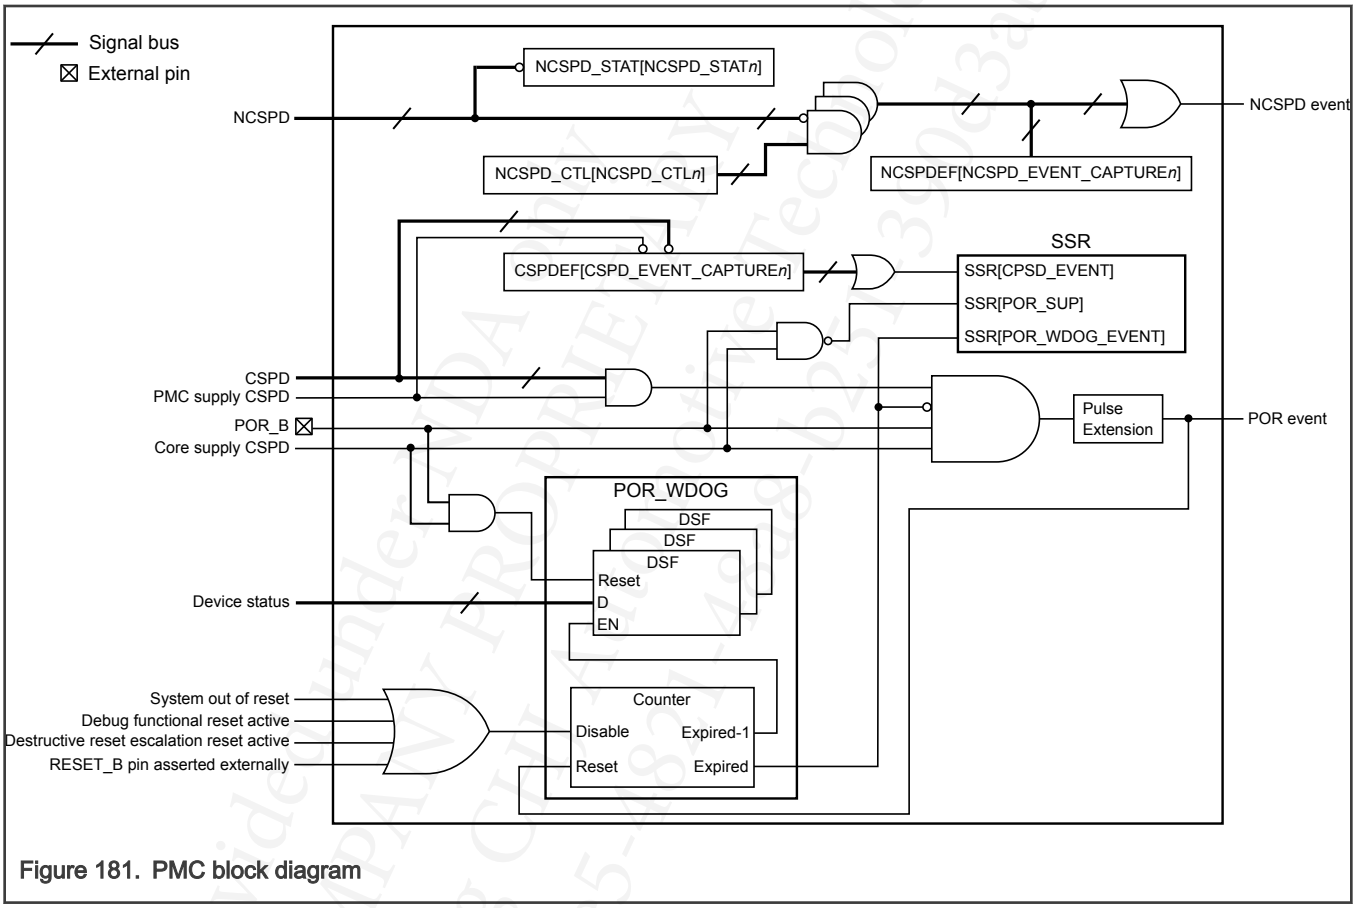

Figure 181. PMC block diagram

Guide to the diagram:

- The following input signals are active low. When those signals are logic high, the supply monitored by its SPD is operating normally.
  - NCSPD
  - CSPD
  - PMC supply CSPD
  - Core CSPD

- The output signal POR event is an active low signal.

The block diagram shows only general functionality. Standard logic, needed for power isolation, is not shown. This logic insures that the PMC supply CSPD signal is logic high when the PMC is in low-power mode.

34.2.2.1 SPD monitoring

There are two SPD types defined as follows:

- NCSPD - Non-critical SPDs are not available after reset and need to be configured before use.
  - Configure which NCSPD you need to use for you application.
  - Configure the NCSPD reaction.
  - Use a status register to show current state of an NCSPD (asynchronous).
  - Event capture register showing any event that caused previous event (synchronous).
- CSPD - Critical SPDs are always on. There is no user configuration available.
  - CSPDs cause a POR event.
  - Event capture register showing any event that caused previous POR (synchronous).

All sources that can modify one of the two output events are determined by reading registers, these register types are:

- Synchronously set registers (status registers) to observe the current state of a signal.
- Asynchronously set registers (event registers) keeping track of any event that has occurred.

The software can read the current state of the signal of interest from the respective field in the status registers, they are only for non-critical events.

Hardware writes one to the event flag register fields (CSPDEF[CSPD_EVENT_CAPTURE*n*] and NCSPDEF[NCSPD_EVENT_CAPTURE*n*]) when their corresponding signals have been in its active state. All signals involved in the generation of events are monitored by such event flag registers.

34.2.2.2 POR and NCSPD event generation

The PMC generates one POR event used as a system reset. The event is extended by the pulse extension so it stays asserted for a specified minimum time (see Data Sheet for details). It is generated by the logical combination of the following sources:

- An external power-on reset input signal (POR_B)
- A CSPD monitoring the Core supply
- A CSPD monitoring the PMC supply
- The combination of all CSPD
- The POR_WDOG counter expires (see POR watchdog for details)

In addition to the CSPD signals, the PMC receives NCSPD signals . When the NCSPD signals are individually enabled by the respective field in the Non-Critical Supply Presence Detector Control (NCSPD_CTL), they are combined into a single NCSPD event .

34.2.3 Modes of operation

The PMC can operate in different power modes:

- Full-power mode with all features available
- Standby mode

The PMC enters Standby mode by removing the PMC supply. The output of the PMC supply CSPD is isolated from the POR event generation during Standby mode. This reset cannot set the POR flag during Standby mode. All other features of the PMC stay functional in all modes.

34.3 Memory map and register definition

34.3.1 Transfer error description

The following actions cause a transfer error, but register contents does not change:

- Accessing an unused register address
- Accessing read-only registers

34.3.2 PMC register descriptions

34.3.2.1 PMC memory map

PMC base address: 4008_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Source of System Reset (SSR)	32	W1C	0000_0001h
4h	Non-Critical Supply Presence Detector Control (NCSPD_CTL)	32	RW	0000_0000h
Ch	NCSPD Status Register (NCSPD_STAT)	32	RO	0000_0000h
10h	CSPD Event Capture (CSPDEF) (CSPD_EVENT_CAPTURE)	32	W1C	See description
14h	NCSPD Event Flag (NCSPDEF) (NCSPD_EVENT_CAPTURE)	32	W1C	See description

Diagram

Fields

Field	Function
31-3 —	Reserved
2 POR_WDOG_EVENT	POR watchdog event flag Captures a POR_WDOG timeout event (see the 'Expired' output from the POR_WDOG in Figure 181). 0b - No event detected after the last clearing of the bit 1b - An event was detected
1 CSPD_EVENT	Critical supply presence detector event flag Captures an event on any CSPD failure by monitoring CSPD Event Capture (CSPDEF) (CSPD_EVENT_CAPTURE) (see the CSPD valid and PMC supply CSPD in Figure 181). **NOTE** This field can only be cleared when the CSPDEF register does not show any CSPD event. 0b - No event detected after last clearing of the bit 1b - An event was detected
0 POR_SUP	POR on core supply CSPD event flag Captures an event on the core supply CSPD valid signal or external POR_B . **NOTE** When the value of this field equals 1, you must clear all other PMC registers before they can be used. 0b - No event detected after the last time this field was cleared 1b - An event was detected

34.4 Functional description

34.4.1 Reset

Different kinds of digital logic exist in the PMC reset scheme. Table 198 defines which function asynchronous controls a PMC function.

Table 198. Reset schemes

Asynchronous source	Function impacted	Explanation
POR_B or core supply CSPD (CSPDEF[HVCPOREF])	The entire PMC except for the event flag registers (CSPDEF, NCSPDEF). CSPD and NCSPD signals set CSPDEF and NCPDEF asynchronously. SSR[CSPD_EVENT] equals zero only when CSPDEF is clear.	Reset the logic by power cycling. All other reset sources are active together with or activated by this reset (CSPD and NCSPD signals may not be active with this reset).
Module reset	NCSPD_CTL NCSPD_STAT	Reset these registers with the module reset.
Events on CSPD or NCSPD signal inputs	NCSPDEF CSPDEF SSR[CSPD_EVENT] equals 1	Set the registers asynchronously. Clear the registers by writing a one to each field.
POR_WDOG event	POR_WDOG	Reset the POR_WDOG state machine when a POR_WDOG event occurs. The DSF registers are unaffected by a POR_WDOG event.

34.4.2 Event flag registers

As described in POR and NCSPD event generation, the logical combination of signals from different sources generates the POR and the NCSPD events. Read Source of System Reset (SSR), CSPD Event Capture (CSPDEF) (CSPD_EVENT_CAPTURE), and NCSPD Event Flag (NCSPDEF) (NCSPD_EVENT_CAPTURE) to identify which of the sources activated the event. When an event occurs due to any CSPD signal or any enabled NCSPD signal, the corresponding field in the register equals one until software writes a one.

34.4.3 POR watchdog

The POR watchdog (POR_WDOG) is one of the sources of the POR event. The POR_WDOG is a simple counter. This counter starts immediately when its supply is available and the clock signal is active. When the counter exceeds it non-configurable limit, the POR_WDOG triggers the POR event. To avoid the POR event setting when the system is working correctly, the system must stop the counter before it times-out.

One clock cycle before the counter exceeds its limit ("Expired-1" sets as shown in Figure 181), the device status inputs are captured inside Device Status Flag (DSF0) (POR_WDOG_EVENT_CAPTURE0), Device Status Flag (DSF1) (POR_WDOG_EVENT_CAPTURE1), and POR_WDOG_EVENT_CAPTURE2 registers. This provides some debug capabilities showing why the POR_WDOG counter did not stop in time. Those registers are not reset when the POR_WDOG counter expires.

Chapter 35
SRAM Controller (SRAMC)

35.1 Standby SRAM

The device contains a 32 KB SRAM, called the Standby SRAM. This SRAM is separate from the system SRAM and is powered by the STANDBY power domain. This means it will retain its contents through standby entry and exit unlike the system SRAM. The Standby SRAM is located at the address 0x2400_0000. The RAM is controlled by a single SRAM controller, this is simply another instance of the system ocp2sram controller, but dedicated to the 32KB standby SRAM. The SRAM controller supports ECC protection (single bit correction, double bit detection). Single bit errors are automatically corrected. Double bit errors will cause an FCCU fault to assert. The number of single bit errors that have occurred are counted and are readable in the ERM_STDBY module (a functional reset will clear the count). See the ERM section of the spec for details on that module, the ERM_STDBY base address is 0x4404_7000. Note that the SRAM controller is NOT located in the standby power domain (only the memory array itself is in the STANDBY domain), and thus the controller will not retain it's state during standby mode. The Standby RAM controller's configuration registers are at base address 0x4402_8000.

35.2 SRAMC registers

Here are some important notes about the SRAMC registers. For detailed register descriptions, see the SRAMC register descriptions section.

- The SRAMC register map is not accessible in User Mode.
- Always configure the registers PRAMIAS and PRAMIAE for the selected memory ranges prior to utilization of the initialization feature.

35.3 Introduction

35.3.1 Overview

The SRAMC acts as an interface between the bus request from an interconnect fabric and the integrated system RAM. It converts the protocols between the bus and the dedicated RAM array interface. The primary bus request port provides a connection to the platform module interconnect for direct RAM access from various masters. It uses a simple non-blocking interface, with a pipeline of multiple outstanding transactions, to maximize the bandwidth utilization.

A device can use a single channel or multiple identical channels. Each channel supports one pipeline. The concept is to create a block of SRAM arrays with a channel that can be distributed in the floorplan in an optimal way for each device. This model provides a way to arrange the accesses in an interleaving fashion on a certain address boundary—such as a cache line—so that a line fill or write back occupies only one channel at a time, freeing other channels to respond to other requests.

A global programming model provides centralized control and status, including the initialization setup and error reports, via a common set of memory-mapped registers for all channels.

The following figure shows the block diagram for SRAMC.

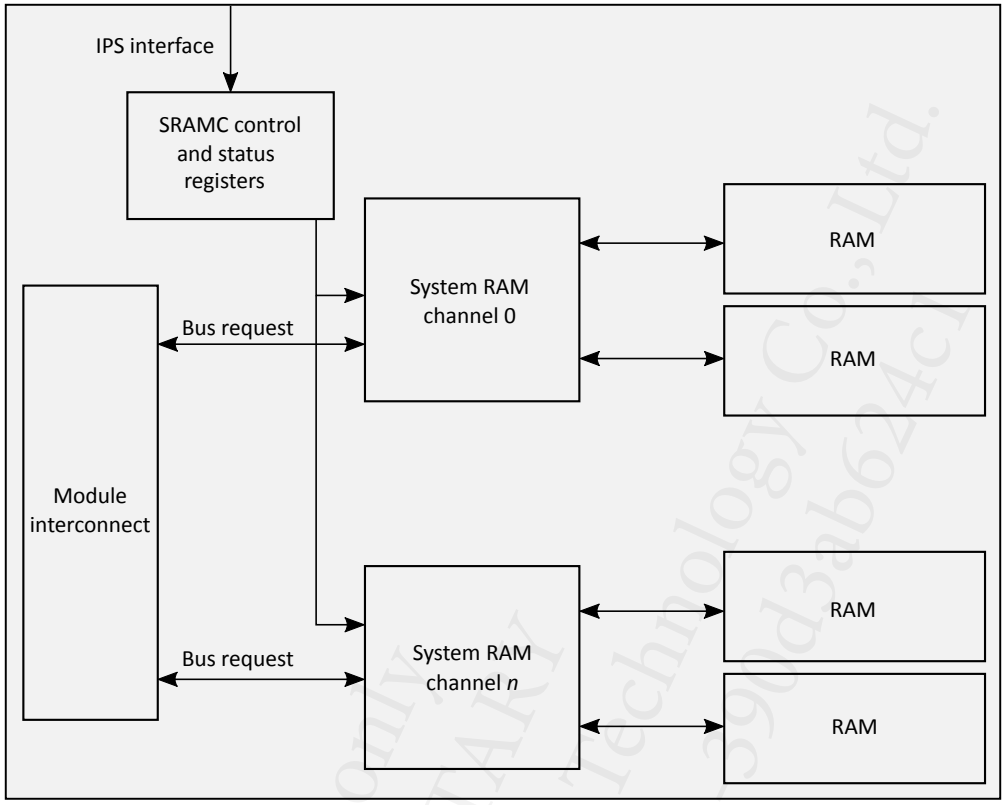

Figure 182. Block diagram

35.3.2 Features

For the RAM size and configuration implemented in this device, see the chip-specific SRAMC information.

Key features of SRAMC include:

- Each channel supports:
  - Single-beat transactions
  - Normal reads
  - Posted writes
  - Multiple outstanding transactions
- Each channel has low access latency for normal reads and posted writes:
  - 4-stage pipeline and a one-transaction latewrite buffer allowing up to four outstanding transactions
  - 3-cycle response for reads
  - 1-cycle response for 64-bit and 128-bit aligned writes
  - 3-cycle response for partial writes with read-modify-write operation for each 64-bit data
- SRAM data is covered by 8-bit ECC on a 64-bit basis using the H-matrix that includes address in the syndrome calculation, which enables single-error correction, double-error detection (SECDED).
- A global IPS interface to 4 K space of memory-mapped control and status registers for all channels
- Support for initialization of the SRAM arrays to a valid ECC state for each entry:
  - Initialization can be triggered by software

  - Initialization sequence with optional wait states, which can be used to limit power surge
  - SRAM arrays are initialized in parallel
  - Software programmable portion of the SRAM for initialization
- Support for an option to block access and suppress any error indicator for that access
- Error injection on memory read data
- Safety logic to detect a fault in the pipeline and the latewrite buffer MBIST detection to yield the array portions under test for MBIST without stalling the normal accesses for the whole MBIST operation

35.3.3 Modes of operation

The current controller only supports normal running mode. It allows MBIST to run concurrently with the normal accesses.

35.4 SRAMC register descriptions

The memory-mapped registers of SRAMC are in an address space of 4 KB and are accessible in Supervisor mode with granularity of word size. Any read or write access to the addresses in the SRAMC memory space not satisfying the above leads to transfer errors. These registers are shared by all SRAMC instances.

35.4.1 SRAMC memory map

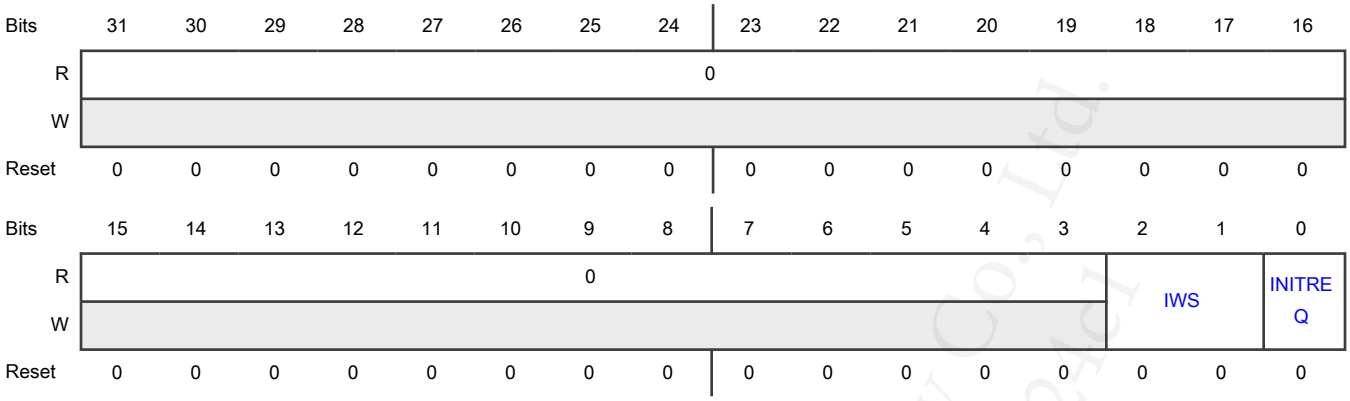
SRAMC base address: 4019_C000h

STDBY_SRAM_CFG base address: 4402_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Platform RAM Control Register (PRAMCR)	32	RW	0000_0000h
4h	Platform RAM Initialization Address Register Start (PRAMIAS)	32	RW	0000_0000h
8h	Platform RAM Initialization Address Register End (PRAMIAE)	32	RW	0001_FFFFh
Ch	Platform RAM Status Register (PRAMSR)	32	W1C	0000_0000h
10h	Platform RAM ECC Address (PRAMECCA)	32	RO	0000_0000h

35.4.2 Platform RAM Control Register (PRAMCR)

Offset



Register	Offset
PRAMCR	0h

Function

Use this register to request an initialization and specify the number of wait cycles for each memory write during the initialization.

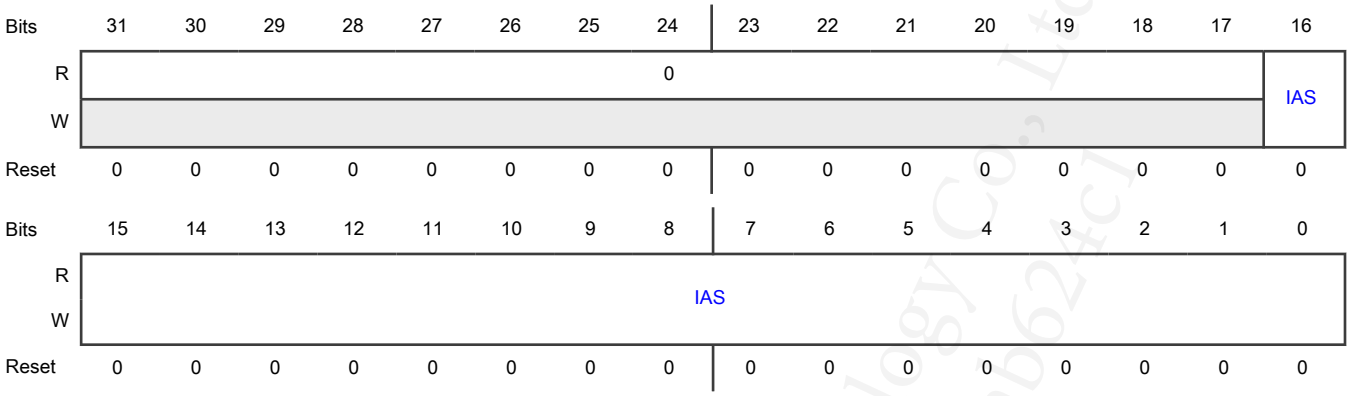
Diagram

Fields

Field	Function
31-3 —	Reserved
2-1 IWS	Initialization Wait Cycles Write to this field to specify the number of wait cycles for each memory write during the initialization. The default value of 0b00 enables back to back writes with no idle cycle in between. This feature can be used to reduce power due to several SRAM banks being written to in the same cycle. 00b - No wait cycles between memory writes 01b - One wait cycle between memory writes 10b - Two wait cycles between memory writes 11b - Three wait cycles between memory writes
0 INITREQ	Initialization Request Write 1 to this field to request an initialization of the SRAM for the range specified in the PRAMIAS and PRAMIAE registers. Each time this field is written with a 1, it causes one initialization. To start another initialization, clear the field first before writing 1 to start a new initialization. Hardware clears this bit if the status bit for initialization done (PRAMSR[IDONE]) is cleared by the software. If software writes 0 to this bit prior to completion, the initialization is aborted. 0b - No initialization is requested. 1b - An initialization is requested.

35.4.3 Platform RAM Initialization Address Register Start (PRAMIAS)



Offset

Register	Offset
PRAMIAS	4h

Function

Use this register to specify the start address for initialization.

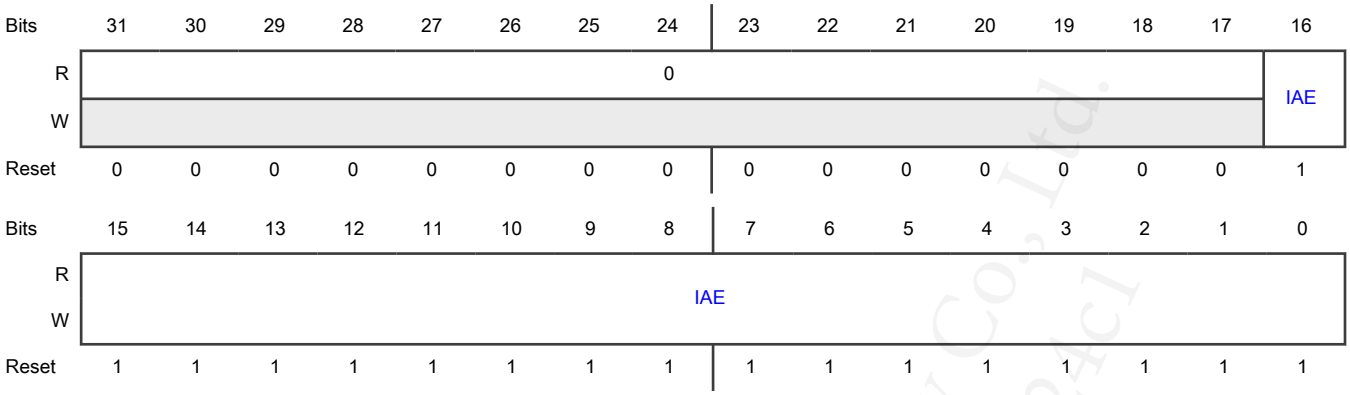
Diagram

Fields

Field	Function
31-17 —	Reserved
16-0 IAS	Initialization Start Address Specify the RAM start address for initialization in this field. The address is of the RAM address and not the bus address.

35.4.4 Platform RAM Initialization Address Register End (PRAMIAE)

Offset



Register	Offset
PRAMIAE	8h

Function

Use this register to specify the end address for initialization. The value of the end address must be greater than that of the start address.

Fields

Field	Function
31-16 —	Reserved
15-8 SYND	ECC Syndrome Value This field is associated with the ECC error in the error fields. After an error is set, this field does not change. The chip updates it with a new value after all the errors are cleared by the software.
7 SGLERR	ECC Single-bit Error Indicates if a single-bit error occurred on a previous access 0b - No single-bit error 1b - A single-bit error
6 MLTERR	ECC Multi-bit Error Indicates if a multi-bit error occurred on a pervious access 0b - No multi-bit error 1b - A multi-bit error
5 AERR	ECC Address Error Indicates an address error on a previous access 0b - No address error 1b - An address error
4 AEXT	Indicates whether address bits used in the ECC HMatrix were from external or local RAM address 0b - Address bits used in the ECC HMatrix were the local RAM address 1b - Address bits used in the ECC HMatrix were from external RAM address
3	Reserved

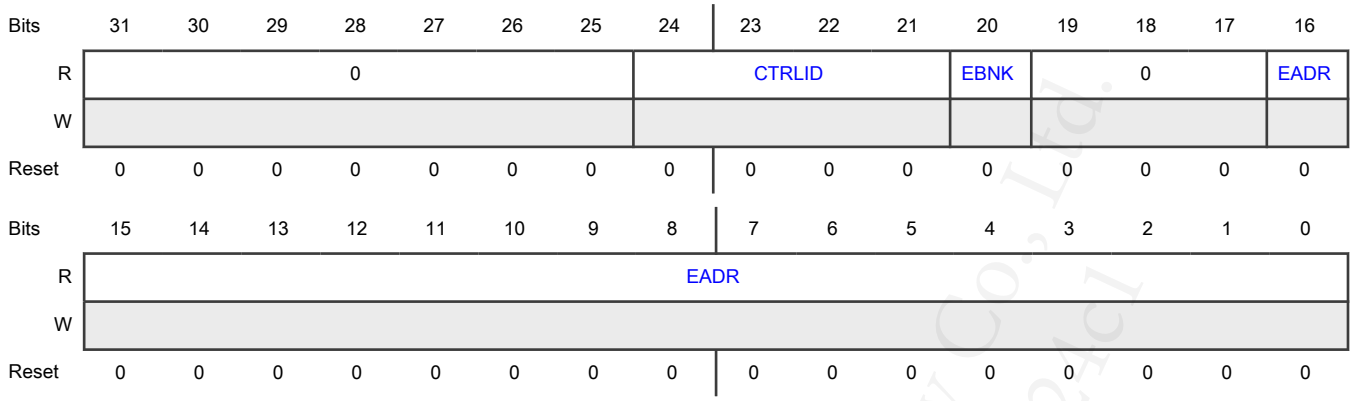
Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 IPEND	Initialization Progress Status Indicates whether initialization is in progress The software should not try to clear this bit for it will get undefined behavior. To abort the initialization, it should write to the PRAMCR[INITREQ]. 0b - Initialization is not in progress. 1b - Initialization is in progress.
1 IERR	Initialization Error Indicates whether an error that is not of an ECC error type occurred during initialization or MBIST sequence, or an access outside of the valid range 0b - No non-ECC error occurred on a previous access 1b - A non-ECC error occurred on a previous access
0 IDONE	Initialization Done Indicates whether initialization is complete 0b - Initialization is not complete. 1b - Initialization completed successfully.

35.4.6 Platform RAM ECC Address (PRAMECCA)

Offset



Register	Offset
PRAMECCA	10h

Function

Address associated with an ECC error during initialization. This is a read-only register, and any write to this register leads to transfer error.

Diagram

Fields

Field	Function
31-25 —	Reserved
24-21 CTRLID	Indicates the controller ID of the reported error. 0000b - The RAM with the error is in controller 0. ... 1111b - The RAM with the error is in controller 15.
20 EBNK	Indicates the RAM bank that has the ECC error indicated in the error fields 0b - Bank 0 has the error 1b - Bank 1 has the error
19-17 —	Reserved
16-0 EADR	The chip writes to report ECC address associated with the error indicated in the error field in PRAMSR. After an error is set, this field does not change. Chip only updates it with a new value if all the errors in the status register PRAMSR have been cleared by the software. Only the software can read this field.

35.5 Functional description

This information describes the functionality of each SRAMC channel.

35.5.1 Latency of read and write accesses

The following tables show pipeline cycles for the read, full-width write, and partial write accesses. This chip implements 3-cycle response for read and partial write. For full-width write, 1-cycle response is achieved because it can avoid read-modify-write operation.

35.5.2 Error report

When an ECC error occurs, the SRAMC reports the following: address-bit error and multi-bit error or single-bit error as well as the syndrome bus and the location of the RAM bank. Note that multi-bit error is loosely defined, which is an uncorrectable error including the address-bit error. The information is captured by the PRAMSR register, and a set of error signals are sent as module outputs.

The hardware does not change the error report until the software invalidates it. In case of a new error occurring while the current report for the previous error is still valid, a new report replaces the current report only if the current report is a single-bit error. Address-bit error and multi-bit error in the current report block subsequent errors from being reported.

There will be a single report for each error cycle for all the channel instances. Because only one location is reported, in case of multiple errors, it must select one over the others. The selection is based on the following priority:

1. It looks to see which channel has a highest priority error:
    a. Uncorrectable ECC error: This error type includes address-bit error or double-bit error. This error is not correctable, and is given the highest priority.
    b. Single-bit error: This error has the lowest priority.
2. If multiple channels have the same error types, the priority shifts from channels with lower ID to higher ID values. For a system having 16 channels, channel #0 has the highest priority whereas channel #15 has the lowest priority.
3. Within the selected channel, it selects one of the two RAM banks. If both RAM banks have errors at the same time, the bank with a higher priority error type is selected for reporting. In case of both banks having the same type of error, bank0, which holds lower doubleword (MData[63:0]), is selected for reporting.

The address that is reported is the local RAM address, along with the RAM bank. The information is captured in the PRAMECCA register.

35.6 Safety considerations

35.6.1 ECC algorithm

The ECC scheme implements a SECDED coding using the Hsiao odd-weight column criteria to produce 8-bit ECC checkbits for each SRAM banks:

- 64-bit Data: Bus_Data[63:0] for SRAM bank0
- 29-bit Address of the local SRAM address [16:0] unless specified by chip-specific SRAMC section.

35.6.2 Safety logic

Safety logic was implemented to detect a fault in the pipeline and the latewrite buffer.

- Check the integrity of the address and attributes being transported from the first stage of the pipeline to the last stage. A set of 8-bit parity signals is used, which include address and byte strobes and pipeline hit signals.[end]
- Check the integrity of the write data being transported from the first stage to the latewrite buffer. Sixteen 8-bit parity signals are used to cover two 64-bit data.
- Keep track of the write request from the bus and monitor request from the latewrite buffer to the RAM arrays. Detect any missing or any extra write to the RAM.

35.7 Initialization

The SRAMC can initialize all the RAM banks of all channels that the SRAMC controls. To initialize the banks:

- Program Platform RAM Control Register (PRAMCR), Platform RAM Initialization Address Register Start (PRAMIAS), and Platform RAM Initialization Address Register End (PRAMIAE)

All RAM banks are written in parallel from the lowest address entry to the highest. When the process is complete, a set of status signals is written in Platform RAM Status Register (PRAMSR). This register's fields reflect the status information. The information should be sufficient to determine:

- If the RAM has been initialized successfully
- If the RAM initialization has failed

NOTE

During initialization, access from any master must be prohibited.

Perform the following procedure to initialize the RAM banks:

1. Determine the bus address range to be initialized, and compute the equivalent range in the local memory address. This must identify the lower and upper bound addresses in local memory to set up Platform RAM Initialization Address Register Start (PRAMIAS) and Platform RAM Initialization Address Register End (PRAMIAE).
2. Write the lower bound local memory address to PRAMIAS[IAS].
3. Write the upper bound local memory address to PRAMIAE[IAE].
4. Start initialization by writing 1 to PRAMCR[INITREQ].

35.7.1 Initialization sequence examples

35.7.1.1 Example 1: Configuration of a single pipeline, non-interleaving system, 64-bit data (1 memory bank)

1. Considering the system base address (base_addr) as 4230_0000h and the bus address range to be initialized (bus_addr) as 4230_0040h to 4230_0080h, compute the equivalent range (lower and upper bound addresses) in local memory (mem_addr) by using the following equation:

   local_bus_addr[31:0] = bus_addr - base_addr

   mem_addr[16:0] = local_bus_addr[31:0] > 3

   Calculation result:

   Lower bound: for bus address 4230_0000h, local memory address = 8h

   Upper bound: for bus address 4230_0080h, local memory address = 10h
2. Write the lower bound local memory address to PRAMIAS[IAS].
3. Write the upper bound local memory address to PRAMIAE[IAE].
4. Start initialization by writing 1 to PRAMCR[INITREQ].

The software configured with this sequence writes to the addresses from 8h to 10h of a single RAM bank. It first writes to the address at the lower bound (that is, 8h), and increments it by one write for the next nine cycles, to end at the upper bound address (that is, 10h). That is, the software writes nine times to the RAM bank. For each write, the data is 0 and the address bits used in the ECC is the local memory address.

35.7.1.2 Example 2: Configuration of a single pipeline, non-interleaving system, 128-bit data (2 memory bank)

1. Considering the system base address (base_addr) as 3178_0000h and the bus address range to be initialized (bus_addr) as 3178_0080h to 3178_0110h, compute the equivalent range (lower and upper bound addresses) in local memory (mem_addr) by using the following equation:

   local_bus_addr[31:0] = bus_addr - base_addr

   mem_addr[16:0] = local_bus_addr[31:0] > 4

   Calculation result:

   Lower bound: for bus address 3178_0080h, local memory address = 8h

   Upper bound: for bus address 3178_0110h, local memory address = 11h
2. Write the lower bound local memory address to PRAMIAS[IAS].
3. Write the upper bound local memory address to PRAMIAE[IAE].
4. Start initialization by writing 1 to PRAMCR[INITREQ].

The software configured with this sequence writes to the addresses from 8h to 10h of both the RAM bank. It first writes to the address at the lower bound (that is, 8h), and increments it by one write for the next nine cycles, to end at the upper bound address (that is, 10h). That is, the software writes nine times to each of the two RAM banks (a total of 18 double-words). For each write, the data is 0 and the address bits used in the ECC is the local memory address, resulting in both banks having the same ECC check-bits at each location.

Chapter 36
DDR Subsystem

36.1 Chip-specific DDR information

36.1.1 Feature configuration

The DDR subsystem on this chip does not implement DDR4. Disregard its references in this document.

36.1.2 Mapping of masters and AXI ports of DDR controller

Table 203. Mapping of AXI ports and masters

AXI port	Master
AXI_0	All the non-core masters and HSE : 128 bit data width
AXI_1	All the Cortex-A53s : 128 bit data width
AXI_2	All the Cortex-M7s (except HSE) and DMA : 64 bit data width

36.1.3 Exclusive access monitors

DDR Controller supports eight exclusive access monitors based on the selected configuration. Here is the limitation per AXI port at NoC level:

Table 204. AXI ports and number of monitors

AXI Port 0	Number of monitors
AXI_0	6
AXI_1	3
AXI_2	3

In PCFGR_n register, rdwr_ordered_en field must be set to 1 when the software coherency is required. For details, see "Software coherency for AXI ports" section in DDR Subsystem.

36.1.4 AXI-urgent signals of DDR memory

AXI-urgent signals are disabled in this chip. Ignore any references to the same or its related content.

36.1.5 ECC and parity errors

All the DDR interrupts related to parity, ECC, or CRC errors are connected to FCCU.

36.1.6 Speculative access of DDR memory

Before you initialize DDR, speculative access of DDR memory can generate fault or unexpected behavior. Therefore, you must configure the core programming to disable speculative access of this region.

36.2 Overview

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The DDR subsystem integrates several submodules to provide a complete memory interface solution for several high-performance memory types.

36.2.1 Supported DRAM types

The DDR subsystem supports the following DRAM types:

- DDR3L
- LPDDR4

36.2.2 Memory controller (MC)

The Memory Controller (MC) peforms the following functions:

- Accepts memory access requests from up to three slave application-side host ports connected to the MC through standard AMBA AXI4 bus interfaces (also know as AXI port interfaces or XPIs).
- Queues requested transactions internally and schedules them for access to the DRAM, satisfying the DRAM protocol timing requirements, transaction priorities, and dependencies between the transactions.
- Uses flexible address mapper logic to allow application-specific mapping of row, column, bank, bank group, and rank bits.

36.2.3 Physical interface (PHY)

The Physical Interface (PHY) launches and captures data to and from the external DRAM. It provides:

- Initialization
- DRAM interface training
- Delay line calibration and VT compensation
- Impedance calibration and VT compensation
- Programmable configuration controls

36.3 Architecture

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section contains a system diagram of an example DDR subsystem application, with descriptions of the main architectural components.

36.3.1 Block diagram

The following diagram illustrates the DDR subsystem.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-9251-390d3ab624c2

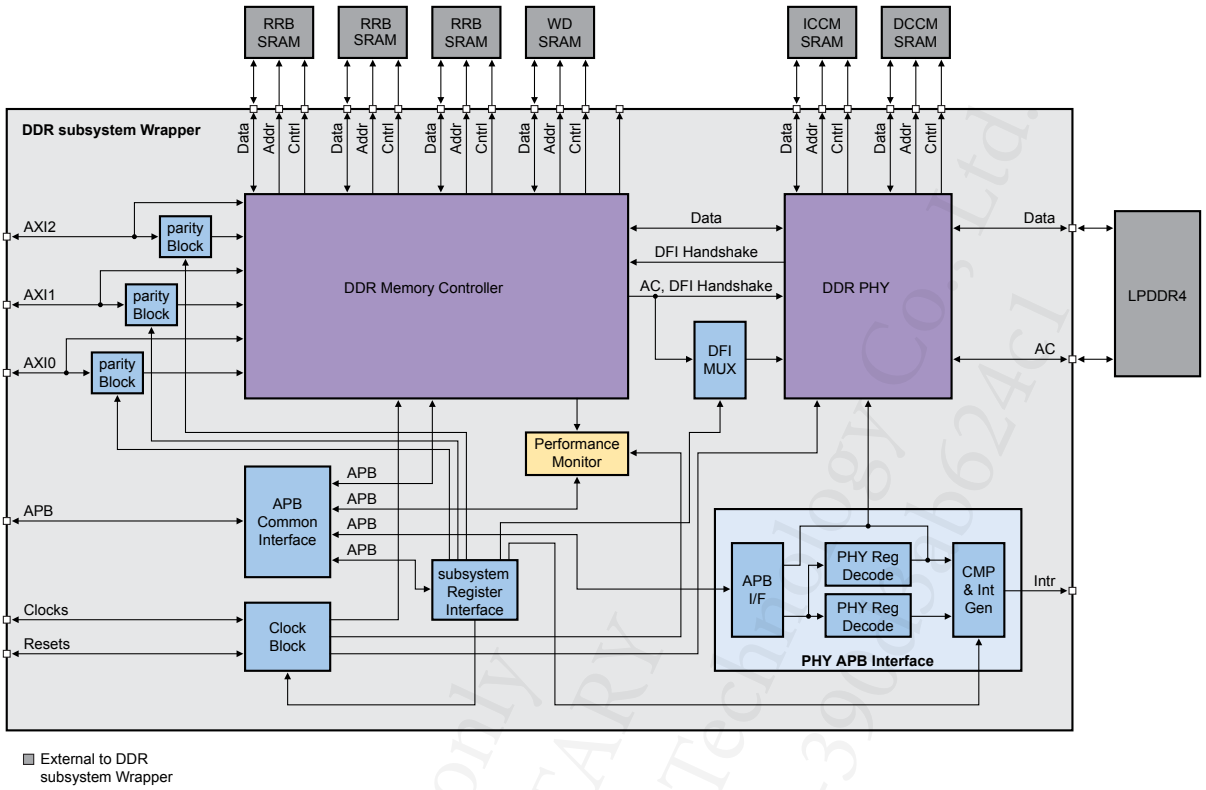

Figure 183. System diagram

36.3.2 Parity block

Each application-side host port (AXI port) connects to the MC through a parity block. Each parity block contains three parity generators to generate one bit of parity either per word or per byte for the AXI write data, write addresses, and read addresses of the corresponding port. OCPARCFG*n* controls parity enabling and parity type for all three parity blocks.

The MC generates parity for the write data, write addresses, and read addresses of each of the three AXI ports.

36.3.3 Performance monitor

The Performance Monitor consists of counter logic driven by various MC performance logging signals.

36.3.3.1 Performance signals/counters

There are no performance counters inside the uMCTL2 controller, so performance signals are brought out to the interface of the uMCTL2 controller within DDR-Subsystem, where a set of 4 x 32 bit counters are implemented. These counters are used to monitor the Performance log specific PERF signals from uMCTL2-Controller based on defined connectivity within DDR-Subsystem. A limited set of Performance log signals are utilized within these Performance monitors.

Monitored signals are:

36.3.3.1.1 Generic monitored signals

Table 205. Generic monitored signals

Signal	Description
WAQ_COUNT_0[3:0]	The number of used positions in the write queue FIFO (queue is 8 deep)
WAQ_POP_0	One write granted by port arbiter
RAQ_WCOUNT_0[3:0]	Number of used positions in read queue - depth is 8
RAQ_POP_0	One read granted by port arbiter
LPR_CREDIT_CNT[6:0]	Number of available low priority read CAM slots free
HPR_CREDIT_CNT[6:0]	Number of available high priority read CAM slots free
WR_CREDIT_CNT[6:0]	Number of available write CAM slots free
stat_ddrc_reg_selfref_type[1:0]	self-refresh status and type • 00 : not in self refresh • 11 : self-refresh by automatic means • 10 : caused by SW/HW interface

36.3.3.1.2 Perf specific signals monitored

These form two groups, selected by the CSV field below [3:0] one bit of which is fed to the counter.

Table 206. Group 0

CSV[3:0]	Signal	Description
0000	perf_hif_rd	asserts for every read command to the DDRC
0001	perf_hif_wr	assert for every write command to the DDRC
0010	perf_hif_rmw	assert for every read modify write to the DDRC
0011	perf_hif_hi_pri_rd	assert for every high priority read
0100	perf_hpr_req_with_nocredit	high performance request when full

Table 207. Group 1

CSV[3:0]	Signal	Description
0000	perf_rdwr_transitions	assert for every read->write or write->read transition
0001	perf_op_is_precharge	assert for every precharge issued
0010	perf_op_is_activate	assert for every activate issued
0011	perf_op_is_load_mode	assert for every MRW or MRR
0100	perf_op_is_mwr	
0101	perf_op_is_rd	
0110	perf_op_is_rd_activate	
0111	perf_op_is_refresh	
1000	perf_op_is_wr	
1001	perf_raw_hazard	RAW or WAW hazard

The actual performance function is performed by a set of counters which can be configured to count a number of the available signals described above. Selection of the value for each counter is done via the config registers. There is one register for each counter.

36.3.3.1.3 Counter control register

31:24 CSV : Count_value_select[7:0] : Used to select which performance signal is to be applied for counting, defined by the table below

23:16 CP : Count_parameter[7:0] : Used to pass a parameter to the counter to limit the count for counterN , see table below

Counter0 is special in that it always counts “time” and when expired causes a lock on itself.
Counter0 start counting, if counter0 is enabled by configuring COUNTER_0_CTRL_REG_ADDR[CNTR_EN]=1 and COUNTER_0_CTRL_REG_ADDR[CNTR_CLR] =1.

Counter0 & COUNTER_0_CTRL_REG_ADDR[CNTR_OFL] is cleared by setting COUNTER_0_CTRL_REG_ADDR[CNTR_CLR] =0.

Logically the counterN start counting if both Counter0 and the corresponding counterN are enabled. It stops counting when either the counterN overflows or counter0 overflows . But this counter functionality also depends on setting of COUNTER_0_CTRL_REG_ADDR[CNTR_CLR] =1, which can mask the enable (CNTR_EN) specific dependency. Therefore, this counterN start incrementing with the value of the “CNTR_INCR_N” selected based on CSV just after setting the COUNTER_0_CTRL_REG_ADDR[CNTR_CLR] =1

CNTR_INCR_N is generated by the following table

CSV[7:0]	Value	comment
8’h00	No increment (zero)	Counter will stop incrementing.
8’h01	stat_ddrc_reg_selfref_type = CP[1:0]	Counts when ram is running vs self refresh
8’h04	RAQ_POP_0 = 1	Number of reads[Not applicable]
8’h05	WAQ_POP_0 = 1	Number of writes

Table continues on the next page...

Table continued from the previous page...

CSV[7:0]	Value	comment
8'h08	RAQ_WCOUNT_0[3:0] = CP[3:0]	Read Queue depth is fixed number X (Number of used positions) [Not applicable]
8'h09	WAQ_WCOUNT_0[3:0] = CP[3:0]	Write Queue depth is fixed number X (Number of used positions)
8'h10	LPR_CREDIT_CNT[6:0] = CP[6:0]	LP read cam has X entries (Number of available CAM free slots)
8'h11	HPR_CREDIT_CNT[6:0] = CP[6:0]	HP read cam has X entries(Number of available CAM free slots)
8'h12	WR_CREDIT_CNT[6:0] = CP[6:0]	write cam has X entries (Number of available CAM free slots)
8'h2X	Group 0 counts from perf signals	See above
8'h3X	Group 1 counts from perf signals	

Note that the intent here is to take samples for the period from resetting the counter0 until it expires again, causing an interrupt, once that happens the values can be read from counterN and then a new set of sample can be taken.

NOTE

We only take EXACT queue depths so we have to repeat to gain a histogram of values.

36.3.3.1.4 MRR read data register

This is a separate read only register which collects status from the controller directly – it's not really related to the perf counters. Its function is

If hif_mrr_data_valid Then

MRR[31:0] := hif_mrr_data[31:0]

Else

MRR[31:0] := MRR[31:0]

In effect it holds the value last supplied from the DRAM controller, it's a simple status read register

This acts as a single register repeated 16 times in the upper part of the perf counter space. These are all pointing to the same register to ensure that the address map is filled up.

36.3.4 APB common interface

This is a custom logic block designed to provide a common APB interface to all internal slaves within the DDR subsystem, thus unifying the register space for software access to DDR subsystem. APB common interface module directs the APB traffic from the single host side APB port to the correct APB interface on either the controller or the PHY.

36.4 Features

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

36.4.1 DDR MC feature list

The MC supports the following features:

- Support for DDR4 protocol up to DDR4-3200 speed grade
- Support for LPDDR4 protocol up to LPDDR4 3200 speed grade
- 1:2 frequency ratio architecture
- Up to three (03) host ports using AMBA AXI4 protocol
  - Support for AXI burst types: Incremental and wrap
  - AXI clock synchronous to the controller clock
  - Exclusive access support
  - Read reorder buffer with reduced latency options (for example, bypass)
- Direct software request control or programmable internal control for ZQ short calibration cycles for DDR3 and DDR4 modes
- Support for ZQ long calibration after self-refresh exit for DDR3 and DDR4 modes.
- Direct software request control or programmable internal control for ZQ calibration cycles for LPDDR4 mode.
- Support for ZQ calibration after SR-Power down exit for LPDDR4 mode.
- Support for ZQ Reset feature through software for LPDDR4 mode.
- Dynamic scheduling to optimize bandwidth and latency
- Read and write buffers in fully associative CAMs, 32 Reads and 32 Writes.
- Delayed writes for optimum performance on DRAM data bus
- Support "Out of order" command execution to maximizes the DRAM efficiency
- Programmable DRAM parameters
- Supports BL16 burst length
- Supports 1,2 memory ranks
- Control options to avoid starvation of lower priorities
- Guaranteed coherency for write-after-read (WAR) and read-after-write (RAW) hazards
- Write combine to allow multiple writes to the same address to be combined into a single write to DRAM; supported for same starting address
- Paging policy selectable by configuration registers as any of the following:
  - Leave pages open after accesses, or
  - Close page when there are no further accesses available in the controller for that page, or
  - Auto-Precharge with each access, with an optimization for page-close mode which leaves the page open after a flush for read-write and write-read collision cases
- Supports automatic DRAM power-down entry and exit caused by lack of transaction arrival for programmable time
- Supports automatic Clock Stop entry and exit caused by lack of transaction arrival
- Supports self-refresh entry and exit as follows:
  - Supports automatic self-refresh entry and exit caused by lack of transaction arrival for programmable time
- Support for self-refresh entry and exit under software control
- Support for explicit DRAM mode register updates under software control
- Flexible address mapper logic to allow application specific mapping of row, column,bank, and rank bits
- Programmable support for 1T or 2T timing
- User-selectable refresh control options:

  - Controller-generated auto-refreshes at programmable average intervals
  - In multi-rank designs, an offset can be applied to each rank's refresh timer to allow rank refreshes to expire at different times (this can increase efficiency by allowing traffic to continue to other ranks while a given rank is being refreshed)
- Ability to group up to 8 controller-generated refreshes together to be issued consecutively (this reduces the frequency of page closings, increases overall efficiency)
  - When LPDDR4 is used, per-bank refreshes are scheduled for banks with no traffic in the CAM to minimize impact of refreshes on throughput.
  - When controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle for a programmable period of time
  - Ability to disable controller-generated auto-refreshes
  - Ability to issue a refresh through direct software request
  - When LPDDR4 is used, user-selectable ability to perform per-bank refreshes rather than all-banks refreshes
  - When DDR4 is used, fine granularity refresh can be selected
  - When controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle and does not have any HIF transactions to the DRAM rank/bank address for a programmable period of time
- INLINE-ECC support, when controller is configured for 32-bit/16-bit DRAM data width, including the following:
  - Support for single error correction/double error detection (SEC/DED)
- Automatic data scrubbing of correctable errors
- Support for highly efficient read-modify-write when byte enables are used with ECC enabled
- Automatic logging of both correctable and uncorrectable errors
- Ability to "poison" the write data by adding uncorrectable errors, for use in testing ECC error handling

NOTE

1. The DDR4 CRC-Retry feature is disabled based on hardware configuration of DDR subsystem.

36.4.2 PHY features

The PHY supports the following features:

- 8-bit, 16-bit and 32-bit wide SDRAMs
- Support 8-bit and 16-bit DDR3 and DDR4 DRAM devices
- Support 16-bit per channel LPDDR4 DRAM devices
- Support VT compensated delay lines for DQS centering, read/write leveling, and per bit de-skew
- PHY independent, firmware-based training using an embedded calibration processor
  - Utilizes a specialized hardware acceleration engine
  - Automatic periodic retraining through PHY MASTER Interface
  - Support for (LPDDR4) Command Bus eye training relative to CK
  - Support for Write Leveling to compensate for CK-DQS timing skew
  - Support for Write Training: DQS to DQ: Two modes of training are available in LPDDR4:
    - Command-based FIFO WR/RD with user patterns
    - An internal DQS clock-tree oscillator, to determine the need for, and the magnitude of, required periodic training
- Data bus VREFDQ training

- Read training:
  - DQ bit deskew training using DRAM mode registers
  - DQS to DQ eye centering training using DRAM array
- LVSTL IO calibration and ODT calibration
- Three inactive idle states:
  - DFI_LP Mode: most clocks and delay lines gated
  - PHY Inactive: leakage only
  - PHY Retention: Core power removed, most I/Os powered down, SDRAMs held in self-refresh
- Voltage and temperature compensated delay lines used for:
  - Centering the clock in the address/command window
  - Centering the strobes in the data eyes
  - Read/write leveling
  - Per-bit deskew
- Includes a low-jitter PLL for both PHY clock generation and DRAM clock generation
  - Only one PLL is required per DDR PHY
  - Integrated PLL bypass to support 50 to 666 MT/s
- Flexible pre and postamble
  - Support for 1 or 2 clock write preamble
  - Support for static or toggling read preamble of 1 or 2 tCK
  - Support for 0.5 or 1.5 tCK read postamble
- Support for a SW controllable DQ bit and AC bit swizzling
- Includes the PHY utility block (PUB)
  - Soft IP Verilog design that includes PHY control features, such as read/write leveling and data eye training
  - APB and JTAG interfaces for register access
- JTAG register interface for easy test access
- Direct override programming available for all VREF, ODT, drive strength, and timing delays to facilitate debug and characterization
- DDR3 Burst Chop
- DRAM addressing up to 4Gb
- MRR reads and MPC write/read
- Data bus inversion
- Mode register readout
- Support Programmable input on-die termination (ODT) for IOs
- Support Programmable output impedance for IOs
- Support PVT-compensated ODT and output impedance for IOs
- Support Retention feature keeps SDRAMs in self-refresh during VDD power down
- Support Separate driver and receiver I/O power-down control
- Support PAD and internal loopback modes

36.5 Functional description

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The MC converts system bus transactions into memory commands on the DFI interface that are compliant with the DDR protocols.

36.5.1 Exclusive access

The MC controller supports the AXI Exclusive Access feature.

All exclusive read transactions have an EXOKAY response (except in the case of an ECC uncorrectable error). Successful exclusive write accesses have an EXOKAY response, unsuccessful exclusive write accesses return an OKAY response. If an exclusive write fails, the data mask for the exclusive write is forced low so the data is not written. Masked writes or RMW must be supported when using exclusive access.

The exclusive access monitor compares the exclusive write transaction address, size, length, ID and port number against the exclusive read transaction address, size, length, ID and port number, and only accepts an exclusive write when these parameters match. Otherwise, the exclusive write is considered as fail. In some cases SLVERR response may be returned for exclusive access transactions. For more information about this, see “Read Data and Response Channel” and “Write Response Channel” description.

NOTE

- The read response SLVERR is generated for an exclusive read transaction for ECC configurations, when ECC is enabled and an uncorrectable error is detected. The master, upon receiving a SLVERR to an exclusive read command should not complete the exclusive operation by sending an exclusive write command. If it does, the MC monitors return EXOKAY if there is no violation.
- The maximum number of bytes that are monitored as a region per address cannot exceed 128 bytes. The AXI exclusive transaction length must always be a power of two.
- When all the monitors are active, further exclusive read should not be issued. If this happens, one of the active monitors is evicted using a round robin control and new exclusive read is accepted. The selection of the monitor to be evicted is based on a pointer which rotates across all the locations when a new exclusive read is received.

36.5.2 Software coherency for AXI ports

For information about how the MC handles in-order execution of commands to the same address, see Address collision handling. For the commands issued at the AXI port, the logic in the MC protects against all types of software coherency hazards when the AXI master waits for write (read) response before sending the next same address read (same address write) or vice versa.

Some special AXI masters expect an ordering relationship between the reads and writes when the opposite direction transactions are sent without waiting for the previous response. For these special cases, additional logic should be instantiated in the AXI port interface (XPI) to enforce the order of acceptance within the reads and writes between the AXI and HIF interfaces at the MC.

This logic is included by setting of the hardware parameter UMCTL2_RDWR_ORDERED_n (Enabled for all three AXI ports in Hardware configuration) and enabled by the register PCFGR_n.rdwr_ordered_en. When this feature is enabled and read and write transactions are presented at the same cycle, the pre-arbiter gives precedence to read transactions, incrementing the write transaction order token by 1 with respect to the read transaction order token.

For example, if the last order token issued was equal to 0, then the read order token will be equal to 1 and the write order token will be equal to 2.

36.5.3 Host interface (HIF)

HIF is an internal interface when the MC is configured to include a multi-port arbiter (the hardware parameter UMCTL2_INCL_ARB is set to 1). In this case, the AXI Port Interface (XPI) and/or Port Arbiter handle all signals on this interface. Read, write, and RMW requests as well as write data are received through the HIF. Following the receipt and acceptance of a write or RMW request, the MC requests write data from the interface.

The interface subsequently provides the independently timed write data in the requested order (matches the order in which requests are made to the MC). Read, write, and RMW requests are provided through a common command bus if UMCTL2_DUAL_HIF = 0.

Both read and write requests can be reordered later, before being output on the DFI interface. Requests to the MC are throttled in two ways:

- A credit mechanism that ensures that buffer space is available for any request to the MC, prior to the request being made.
- An independent stall mechanism that throttles requests when address collisions take place or if entering self-refresh through the software self-refresh or hardware low power self-refresh.

Data is handled separately. The MC throttles data by potentially waiting after it receives a write or RMW request before requesting the associated data. If there is collision, then the throttling lasts until the collision is cleared in the MC.

Once write data is requested, it is always accepted by the MC. However, if RMW requests are present, the write data can be throttled using the 'hif_wdata_stall' signal.

36.5.4 Partial writes

A Partial Write is where the number of write data beats is less than the number required for a normal (full) write for the MEMC_BURST_LENGTH.

When UMCTL2_PARTIAL_WR = 1 (as set in hardware configuration), the MC issues the minimum number of DRAM bursts on the DDR interface required, dependent on the number of HIF write data beats and the HIF address alignment with respect to the DRAM Column address - as DRAM Writes must be sent BL-aligned.

36.5.5 XPI queues information

The controller interface provides the information about the address queues in the XPI. The information involves address queues for both read and write, and for reads separate information for blue/red queues in case dual queue is selected for that specific port (UMCTL2_XPI_USE2RAQ_$ = 1).

In some cases, an AXI WRAP command at the input may be split into two internal INCR commands and are pushed separately into the queue. This can be recognized when split is asserted. When split and push are high, it means that the first generated INCR command has been pushed into the queue, and the following push means that the second generated INCR command has been pushed into the queue.

36.5.6 Overview of DFI interface

The MC contains a DFI interface, that connects the MC to a DFI-compliant PHY, and to transfer address, control, and data to the PHY. In case of DDR PHY, the MC interfaces to a PUB block, which acts as the DFI PHY interface. The MC, including its DFI Interface, runs at:

Half data rate (HDR) clock (referred to as 1:2 frequency ratio mode in the DFI Specification) You can get more information about the DFI interface from the following specifications:

- DDR PHY Interface (DFI) Specification, Revision 3.1 (Preliminary), 21 March 2014 and DDR PHY Interface (DFI) Specification, Preliminary DFI 4.0 Specification - Addendum to DFI 3.1, 2 April 2014

The DFI interface is sub-divided into the following interface groups:

- **Control interface:** The Control interface is a reflection of the DRAM control interface including address, bank, chip select, row strobe, column strobe, write enable, clock enable and ODT control, as applicable for the memory technology
- **Write data interface:**The Write data interface handles the transmission of write data across the DFI interface. The DFI Specification defines signals and timing relationships. The timing of this interface is user-configurable, to support all DFI-compliant PHYs through the DFITMG0.dfi_tphy_wrlat and DFITMG0.dfi_tphy_wrdata registers.
- **Read data interface:**The Read data interface handles the return of read data across the DFI interface. The DFI Specification defines signals and timing relationships. The timing of this interface is user-configurable, to support all DFI-compliant PHYs through the DFITMG0.t_rddata_en register.

- **Update interface:**During system operation, the system may require updates to the internal settings to compensate for environmental conditions. To ensure that updates do not interfere with signals on the DRAM interface, the DFI interface supports update modes where the DFI read, write, and Control interface is suspended from the normal activity.
- **Status interface:** The DFI interface requires status information for initialization and clock control to the DRAM devices. These signals are used to convey information between the MC and PHY.
- **Training** (PHY-Independent mode supported by the MC): Write and read leveling function performed in a DFI-compliant PHY with no MC interaction.
- **Low power control interface:** This interface consists of signals that are used to inform the PHY of a low power mode opportunity, as well as how quickly the MC requires the PHY to resume normal operation.

1:2 Frequency ratio mode considerations:

The MC, including its DFI interface runs at the half data rate (HDR) clock (referred to as 1:2 frequency ratio mode in the DFI Specification), so all DFI command and address signals are twice the width of the equivalent DDR DRAM signals. DFI data signals are four times the width of the equivalent DDR DRAM signals. The MC operates with an HDR clock. The PHY handles HDR-to-SDR conversion on the address bus to memory and HDR/DDR conversion on the data buses. In 1:2 frequency ratio mode, core_ddrc_core_clk runs at half the frequency of CK/CK#.

For DFI command and address signals in DFI 1:2, the DFI protocol refers to phase 0 (_p0)and phase 1 (_p1) but there are no such *_p0 and *_p1 signals in the MC. Instead, the lower half of the bits corresponds to phase 0 and the upper half of the bits corresponds to phase 1.

Consider the following example:

- In system that has 32 bits of DRAM in DFI 1:2, dfi_wrdata[127:0] is the case. dfi_wrdata[63:0] corresponds to dfi_wrdata_p0 and dfi_wrdata[127:64] corresponds to dfi_wrdata_p1. Similarly, dfi_wr-data_en[7:0] is the case. dfi_wrdata_en[3:0] corresponds to dfi_wrdata_en_p0 and dfi_wrdata_en[7:4] corresponds to dfi_wrdata_en_p1. Similarly, dfi_wrdata_mask[15:0] is the case. dfi_wrdata_mask[7:0] corresponds to dfi_wrdata_mask_p0 and dfi_wrdata_mask[15:8] corresponds to dfi_wr-data_mask_p1.

  For dfi_rddata_valid/dfi_rddata/dfi_rddata_dbi signals in DFI 1:2, the DFI protocol refers to word 0 (_w0) and word 1 (_w1). But, there are no such *_w0 and *_w1 signals in the MC. Instead, the lower half of the bits correspond to word 0 and the upper half of the bits correspond to word 1.
- In system that has 32 bits of DRAM in DFI 1:2, dfi_rddata[127:0] is the case. dfi_rddata[63:0] corresponds to dfi_rddata_w0 and dfi_rddata[127:64] corresponds to dfi_rddata_w1. Similarly, dfi_rd-data_valid[7:0] is the case. dfi_rddata_valid[3:0] corresponds to dfi_rddata_valid_w0 and dfi_rddata_valid[7:4] corresponds to dfi_rddata_valid_w1. Similarly, dfi_rddata_dbi[15:0] is the case. dfi_rddata_dbi[7:0] corresponds to dfi_rddata_dbi_w0 and dfi_rddata_dbi[15:8] corresponds to dfi_rddata_dbi_w1.

36.5.7 Low power software interface

Low Power Interface In a DDR memory subsystem, it is advantageous to place the PHY in a low power state when the MC has knowledge that the memory subsystem remains idle for a period of time. Depending on the state of the system, the MC communicates state information to the PHY allowing the PHY to enter the appropriate power saving state.

Software control is provided in DFILPCFG0/DFILPCFG1 registers (see UMCTL2_REGS) for the following:

- This is an optional interface for a DFI-compliant PHY. The interface signals always exist in the MC. But the software can enable this interface in self-refresh and/or power-down and/or deep power-down mode and/or maximum power saving mode - DFILPCFG0.dfi_lp_en_pd, DFILP-CFG0.dfi_lp_en_sr, DFILPCFG0.dfi_lp_en_dpd and DFILPCFG1.dfi_lp_en_mpsm respectively.
- Software control over what is driven on dfi_lp_wakeup signal (and its associated timing) in self-refresh or power-down or deep power-down or maximum power saving mode - DFILP-CFG0.dfi_lp_wakeup_pd, DFILPCFG0.dfi_lp_wakeup_sr, DFILPCFG0.dfi_lp_wakeup_dpd and DFILPCFG1.dfi_lp_wakeup_mpsm respectively.
- The timing of this DFI low power interface - DFILPCFG0.dfi_tlp_resp.

- ctl_idle output pin is a sideband signal (not specified in DFI) supported by PHY to trigger the PHY's Anti-Aging feature. This is driven the same as dfi_lp_req if enabled through soft-ware (DFIMISC.ctl_idle_en = 1 and DFI Low Power Interface is also enabled through DFILP-CFG0/DFILPCFG1).

36.5.8 Transaction service control

The transaction service control allows you to carefully manage the following:

- Costly read/write bus turn-arounds
- Priorities of read requests to generally favor high priority traffic while also preventing starvation of low priority traffic

This functionality is implemented in a simple 2-state machine for each traffic type with completely configurable controls. The states of the 2-state machine determine when reads/writes are serviced and the relative priority (high priority versus low priority reads) at any given moment.

Transactions in the MC are separated into five categories:

- Low Priority Reads (LPR)
- Variable Priority Reads (VPR)
- High priority reads (HPR)
- Normal priority writes (NPW)
- Variable priority writes (VPW)

36.5.9 Page policy

36.5.9.1 Explicit auto-precharge (Per Command)

The explicit auto-precharge feature can enable auto-precharge on a per-command basis. If the HIF signal hif_cmd_autopre is set during a valid command, then the auto-precharge bit for that command is set when it is sent to the DRAM. If you do not want to use the per-command auto-precharge feature, then this bit can be tied to 1'b1 or 1'b0. Tying it to 1'b1 causes all the commands to be executed with auto-precharge, and tying it to 1'b0 causes no commands to be executed with auto-precharge. For AXI configurations, the HIF signal hif_cmd_autopre is tied to 0 internally, and is not accessible to the user.

36.5.9.2 Intelligent precharges

The SCHED.pageclose register (see UMCTL2_REGS Registers) enables precharge commands to be issued smartly through auto-precharges or explicit precharges. The exact functionality depends on the value programmed in SCHED1.pageclose_timer:

- If SCHED.pageclose is set to 1 and SCHED1.pageclose_timer = 0, a bank is kept open while there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is executed with auto-precharge. The intelligent precharge logic considers only the CAM or CAM region that is currently active, i.e. while executing reads it looks at the LPR or HPR region of the read CAM (whichever is active at the time) and does not look at transactions in the other region of the read CAM or in the write CAM; while executing writes the logic does not look at transactions in the LPR or HPR regions of the read CAM.

  Whenever a mode switch occurs between LPR, HPR and writes, the page context is lost and therefore, a redundant auto-precharge may be issued followed by an explicit activate to the same bank or only an explicit precharge may be issued instead of an auto-precharge. The read and write commands that are executed as part of the ECC scrub requests are also executed with explicit precharge if the page needs to be closed.
- SCHED.pageclose is set to 1 and SCHED1.pageclose_timer >0, a bank is kept open while there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is not executed with auto-precharge. Instead, a timer is started with page-close_timer as the initial value

  There is a timer on a per bank basis. The timer decrements unless the next read or write in the CAM to a bank is a page hit. It resets to pageclose_timer value if the next read or write in the CAM to a bank is a page hit. Once the timer reaches zero, an explicit precharge is scheduled. Prior to a bank's timer expiring, an explicit precharge may also be scheduled if the transaction scheduler chooses a CAM entry that is a row miss to the same bank.

- If SCHED.pageclose is set to 0, the bank remains open only until there is a need to close it (to open a different page or for page timeout or refresh timeout). This is also known as open page policy. The open page policy can be overridden by setting the per command auto pre bit on the HIF interface (hif_cmd_autopre) as described in “Explicit Auto-Precharge (Per Command. When the multi-port arbiter is configured, the HIF signal hif_cmd_autopre is tied to 0 and you do not have control over it.

36.5.9.3 Address collision handling

The MC can execute transactions out-of-order while ensuring that all transactions appear as if they are executed in the order in which they are received. Every transaction that requires a response from the MC arrives with a token number which is provided back to the core as part of the response. Since the MC queues transactions prior to execution, it is possible that multiple transactions to the same DRAM address can arrive before the first transaction to that address is issued. For address collision, two HIF addresses are considered the same address if all of the HIF address bits (except for the LSB column values) are the same. That is, the “collision” ignores the LSB column values when comparing addresses.

To enforce ordering of accesses to the same address, the MC uses the following algorithm:

1. **New read colliding with queued read:** This collision causes no problems. The two reads can end up being executed out-of-order.
2. **New write colliding with queued write:** If write combine is enabled, the MC overwrites the data for the old write with that from the new write and only performs one write transaction (write combine). For more information about this, see “Write Combine” section.
3. **New read (or write) colliding with queued write (or read) respectively:** In this case, the MC performs the following sequence:
    a. Holds the new transactions in a temporary buffer
    b. Applies flow control back to the SoC core to prevent more transactions from arriving.
    c. Flushes the internal queue holding the colliding transaction until that transaction is serviced.
    d. Accepts the new transaction and removes flow control.
4. **New read colliding with both read and write:** This can happen when a read collides with an RMW command. In this case, the reads are flushed until the read collision is cleared, then the writes are flushed in the same manner as described in the Step 3.
5. New write colliding with both read and write: This can happen when a write collides with an RMW command.
    - If write combine is enabled, the new write is combined with write part of queued RMW.
    - If write combine is disabled, the new write is held in a temporary buffer until the RMW has completed.
6. **New RMW colliding with queued write:** In this case, the new RMW is stored in a temporary buffer until the queued write is completed.

36.5.9.4 Write combine

The write combine feature can combine multiple writes to the same address into a single write to DRAM. When a new write collides with a queued write in the CAM:

- If write combine is enabled, the MC overwrites the data for the old write with that from the new write and only performs one write transaction (write combine).
- If write combine is disabled, the MC performs the following sequence:
    1. Holds the new write transaction in a temporary buffer.
    2. Applies flow control back to the SoC core to prevent more transactions from arriving.

36.5.9.4.1 Registers related to transaction service control

The following are the registers related to the Transaction Service Control:

- Low priority read transaction store
  - PERFLPR1.lpr_max_starve
  - PERFLPR1.lpr_xact_run_length
- High priority read transaction store
  - PERFHPR1.hpr_max_starve
  - PERFHPR1.hpr_xact_run_length
- Write transaction store
  - PERFWR1.w_max_starve
  - PERFWR1.w_xact_run_length
- Bus turn-around control
  - SCHED.prefer_write
  - SCHED.rdwr_idle_gap

36.5.10 Overview of quality of service

In a SoC based sub-systems, Quality of Service (QoS) are extremely important in distributing the available resources (bandwidth or latency) amongst the different devices, in a fair mechanism to meet the overall performance requirements.

In any SoC based on-chip communication system, there will be multiple Masters trying to communicate with different Slaves through Interconnect. Interconnect is used to route the traffic between the Masters and Slaves. There are potential chances of bandwidth sensitive Master starving for data and latency sensitive Master requirements are not met. This impacts the overall performance of the sub-system. QoS addresses these kinds of performance issues in sub-system.

Traffic classes: The MC supports different traffic classes that are distinguished from each other by the arqos signal.

36.5.10.1 Read classes

- **Low priority read (LPR):** It is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. LPR is always treated as low priority in the port abiter (PA) and in the MC. There are timeout mechanisms that can be used to prevent starvation for both the PA and the MC. When there is a timeout in the PA, that port becomes the highest priority (priority0). When there is a timeout in the LPR store in the MC (in other words, LPR store becomes critical), the LPR entries are served before HPR entries.
- **Variable priority read (VPR):** It is also called as the maximum latency bound traffic for meeting real time deadlines in video or audio applications. VPR traffic shares the same resources with LPR in the MC. But, based on the configuration, it may have a dedicated queue (red or blue) in the XPI. It has the same priority as LPR, but lower priority than HPR for the PA. For the MC, VPR has the same initial priority as LPR. Each command tagged as VPR has an associated latency timer. When expired, VPR transactions have the highest priority in the controller, both in the PA and in the MC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.
- **High priority read (HPR):** It has allocated resources. If the XPIs are configured to have dual read address queues, then the red queue can be allocated to HPR. For the MC, HPR traffic goes to its own dedicated store. HPR traffic has higher priority than LPR. HPR is meant for latency critical but not real time applications such as CPU.

36.5.10.2 Write classes

- **Normal priority write (NPW):** It is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. It is always treated as normal priority in the PA and MC. There are timeout mechanisms that can be used to prevent starvation for the PA. When there is a timeout in the PA, that port becomes the highest priority (priority0).
- **Variable priority write (VPW):** It is also called as the maximum latency bound traffic to meet real time deadlines in video or audio applications. VPW traffic shares the same resources with NPW in the MC. For the MC, VPW has the same initial priority as NPW. Each command tagged as VPW has an associated latency timer. When expired, VPW transactions have

the highest priority in the controller, both in the PA and in the MC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.

36.5.11 Significance of urgent signal on QoS

The application master can indicate to the uMCTL2 Port Arbiter that it is going to starve soon by asserting the AXI sideband signals like arurgent and awurgent. These sideband signals can be asserted anytime and are not associated with any particular command. When an arurgnet or wurgent signal is asserted, the priority of that port becomes the highest (Priority0) and that causes the read/write direction to switch immediately at the Port Arbiter level if enabled by PCFGR_n[rd_port_urgent_en] and PCFGW_n[wr_port_urgent_en]. These AXI-Urgent signals also assert the hif_go2critical_wr/ hif_go2critical_lpr/_hpr signals at the HIF interface level, which forces the read/write direction switch within DDRC, if enabled by PCCFG[go2critical_en].

36.6 ECC scrubber

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

ECC Scrubber (SBR) is a block which initiates periodic background read commands to the MC. The purpose behind periodic scrubbing is to increase the reliability of the system by correcting single-bit ECC errors in time, before they turn into uncorrectable 2-bit errors. With Inline ECC, scrub feature of the MC is not supported, for this reason RMW command is initiated by the Scrubber itself for every single-bit ECC error detected. Scrub command is a read of one memory burst (for example, BL8) which is sent to the MC periodically with the lowest priority. The SBR consumes one of the ports of the Port Arbiter (PA) as a requester. The SBR terminates and dumps the read data. For Inline ECC the Scrubber itself initiates the required RMW commands as necessary to fix single-bit ECC errors.

- The controller does not scrub automatically for each correctable read error (for Inline ECC, always ECCCFG0.dis_scrub = 1).
- ECC Scrubber (SBR) block is enhanced to issue fully masked (all bytes disabled) single read-modify-write command after detecting a correctable read error (a new HIF signal hif_rdata_corr_ecc_err is provided).
- For arbiter configurations only.

36.6.1 Scrub period

Scrub interval (tSCRUBI) is defined as number of clock cycles between two scrub read commands. Scrub period is defined as the time needed to read every memory location of the entire DRAM address range. The period ranges from 2 hours to 12 hours depending on the tSCRUBI setting, memory size, and clock frequency. The register SBRCTL.scrub_interval[12:0] counts in multiples of 512 cycles. With inline-ECC, whenever SBRCTL.scrub_intrval is programmed to 0, the scrubber will not issue any RMW command to the MC if a single bit ECC errors are detected.

36.6.2 Normal operation

For Inline ECC a minimum of 8 bursts (1 block) is issued to the MC each time; the amount of burst sent is set by programming SBRCTL[scrub_burst] [2:0] register. Each time tSCRUBI counter times out, a scrub command (or a burst of commands for Inline ECC) is pushed to a scrub queue (8-deep), which is then immediately issued to the MC.The SBR counters halt if more than 8 scrub commands are collected and pending inside the scrub queue due to the MC being busy. The SBR starts the reads from address 0 up to the maximum address as defined by some of the controller parameters and address map register settings.

The address range is automatically calculated. However, for debugging purpose (for example, to speed up testing of it), the start address can be overridden by the external signal sbr_address_start_mask, while the maximum address range can be overridden by the external signal, Scrubber address range mask. If there are outstanding read commands on flight issued by the SBR, SBRSTAT[scrub_busy] register is asserted.

For inline ECC configurations that use an ECC scrubber, if the Scrubber address range mask signal is set to any of these values: unprotected region, ECC region, or zero, the scrubber loops back to the starting address even after it completes writing or scrubbing the last memory location. SBRSTAT[scrub_done] is not always asserted.

Therefore, the end of the initialization write operation cannot be determined, and a software timer is required to determine the period to initialize or scrub the memory space. This is done using the scrubber. You also need to stop the scrubber by writing 0 to SBRCTL[scrub_en], after the time is over.

NOTE

In Inline ECC configurations , the 'ECC Scrub' feature is not supported and is always disabled by setting the ECCCFG0[dis_scrub] = 1'b1.

36.6.3 Low power operation -software controlled

If the MC is in one of the software controlled low power modes such as self-refresh, deep power-down (DPD), or maximum power saving mode (MPSM), it is recommended to follow the procedure mentioned below:

- Before entering into any of the software controlled low power modes, disable the SBR by setting SBRCTL.scrub_en to 0.
- If scrubbing is required in this low power mode, the whole address range can be quickly scrubbed by issuing back-to-back scrub read commands.
  - Software must wake up the MC and initialize the DRAM/PHY as necessary.
  - To start the SBR in an accelerated rate, write SBRCTL[scrub_interval] to 0 and enable the SBR.
  - Once the SBR scrubs the entire DRAM range, sbr_done_intr interrupt signal is asserted. In addition, SBRSTAT.scrub_done software status bit is set which can be polled by the software. The scrubbing operation continues until SBR is disabled.

NOTE

Note that sbr_done_intr signal and scrub_done register are never set if the SBR is operating in its normal mode (SBRCTL[scrub_interval] > 0).

  - If the software does not want to wait for the complete scrubbing operation to finish, SBRCTL[scrub_interval] can be set to a non-zero value anytime. The SBR will re-start the scrub commands from the start address.
  - Disabling the SBR or setting the SBRCTL[scrub_interval] back to its normal operating value (tSCRUBI) which is greater than 0 clears both the interrupt signal and the status bit.

NOTE

When you use scrubber in the Inline ECC mode, the SBR counter reaches the configured SBRCTL[scrub_interval] and the controller is in the LP mode. In this case the next set of SBR reads is not generated.

Therefore, disable SBR during the Low-Power mode by writing 0 to SBRCTL[scrub_during_lowpower].

36.6.4 Initialization writes

The above sections refer to scrub read commands. The SBR block can be used to initialize the memories with a defined pattern. SBRCTL.scrub_mode should be programmed to 1. SBRWDATA0 can be programmed with the desired pattern.

After PHY and DRAM initialization, perform the following steps:

- If MEMC_INLINE_ECC is defined and ECC is enabled, set ECCCFG1.ecc_parity_region_lock to 1.
  1. Ensure that PCTRL_n.port_en are set to 0, block the AXI ports from taking the transaction.
  2. Set SBRCTL.scrub_mode = 1.
  3. Set SBRCTL.scrub_interval = 0.
  4. Set the desired pattern through SBRWDATA0 register.
  5. Enable the SBR by programming SBRCTL.scrub_en = 1.
  6. Poll SBRSTAT.scrub_done = 1 (all scrub writes commands have been sent).
  7. Poll SBRSTAT.scrub_busy = 0 (all scrub writes data have been sent).
  8. Disable SBR by programming SBRCTL.scrub_en = 0.
  9. Prepare for normal scrub operation (Reads) by programming SBRCTL.scrub_mode = 0 and SBRCTL.scrub_interval to tSCRUBI.

10. Enable the SBR by programming SBRCTL.scrub_en = 1. 11. Enable AXI ports by programming PCTRL_n.port_en = 1.

36.7 Overview of inline ECC support

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The main features of Inline ECC :

- ECC parity (code) is stored together with the data without using a dedicated sideband memory device.
- Inline ECC is a necessity for LPDDR4 due to device characteristics and device topology.
  - Inline ECC is supported with LPDDR4, DDR4 (BG rotation address mapping), and DDR3 protocols.
- The supported memory data widths are 16, and 32.
- For inline ECC, 64/8 SECDED Hamming code is used:
  - Data to ECC ratio is 8/1

36.7.1 Address map

There are few definitions mentioned below:

- **Data block:** 8 burst accesses of data (a burst can be DRAM BL8 or BL16).
- **Super-block:** Block with ECC parity (9 burst accesses).
- **Hole:** ECC parity + wasted region of the memory.
- **Usable memory size:** All the data blocks that fits.
- **Usable size ratio:** Usable memory size/Full memory size.
- **Utilization percentage:** The percentage of memory used for Data and ECC.

When Inline ECC is enabled, the highest three column bits must be mapped to the highest address map position possible. The controller flexible address mapping scheme is constrained so that the highest system address space is reserved for ECC parity and waste as one region as shown in Figure below. For the normal data in all remaining regions, the system address is linear and continuous. The reason for the waste is due to how the memory is divided for ease of implementation. Data to ECC ratio is 8 to 1 (divide by 9), but the memory is mapped 7 to 1 (divide by 8 which is a power of 2).

- Usable size ratio is 7/8 = 87.5%.
- Utilization percentage is (7/8 + (1/8*7/8)) = 63/64 = 98.4% and the remaining becomes the waste. The unprotected wasted area can still be accessible by the system, but not in linear and continuous fashion.

Figure 184.

For LPDDR4 and DDR3, for best Inline ECC performance, it is recommended to have address mapping such that Data and ECC to be mapped to the same bank and page.

For DDR4, it is recommended to have bank group rotation address mapping. In this case ECC parity is in a different bank and bank group than the data

36.7.2 Selectable protected regions

The memory is divided into eight regions. To maintain uninterrupted linear system address space, ECC hole maps to the top of the system address.The ECC hole size, including the waste, is 1/8 of the memory size. Except for the last region, which is the ECC hole, the remaining seven regions can be set to be either ECC protected or not. This feature allows ECC protection only on the critical safe areas of the memory. Remaining unprotected addresses can be accessed with no performance overhead since ECC commands are not injected.

The register ECCCFG0.ecc_region_map[6:0] indicates whether each region is ECC protected or not. To protect a region, set the corresponding bit to 1, otherwise set to 0.

Figure 185. ECC Regions Example

36.7.3 Locking of ECC region

The ECC region comprises two separate sub-regions:

1. Used sub-region:
   - ECC parity area for ECC protected regions.

2. Unused sub-region:
    - ECC parity area for unprotected regions (reserved but not used by inline ECC logic).
    - Waste region, which is never used by inline ECC logic.

The Used sub-region is locked/unlocked by the register ECCCFG1.ecc_region_parity_lock. The Unused sub-region is locked/unlocked by the register ECCCFG1.ecc_region_waste_lock.

In normal conditions, the user software should not access the Used region of the ECC hole and therefore should be kept locked. However, for debugging or error injection purposes into ECC parity, it can be unlocked by the ecc_region_parity_lock register. If required, for normal transfers, the user software can access the Unused region of the ECC hole and therefore can be kept unlocked using the ecc_region_waste_lock register. However, it should be noted that the Unused region is not consecutive in terms of system addresses and it is interleaved with the Used region.

Locking the ECC hole sub-regions from access means the following:

- Any write or RMW request to this region is discarded, while the HIF output hif_wdata_ptr_addr_err is asserted.
- Any read request to this region is executed to the memory, but without the ECC check and returns all zeros, while the output hif_rdata_addr_err is asserted.

For AXI configurations, any assertion of hif_wdata_ptr_addr_err or hif_rdata_addr_err also results in SLVERR/ERROR response. When Inline ECC is disabled in the software, all the memory space can be accessed.

36.7.4 Error injection through software (ECC data poisoning)

ECC error injection is useful for system-level software validation. There is no dedicated hardware support for it. However, errors can be easily injected through the software by unlocking the ECC region through the ecc_region_parity_lock register and overriding certain ECC parity bits. When the corresponding addresses are read from a protected memory region, ECC errors are generated as correctable or uncorrectable, depending on the type of error introduced.

36.7.5 Performance

The idle command latency of the controller increases by one core clock cycle with inline ECC.

- Full block write: No additional latency
    - ECC burst is appended after 8 data bursts, the write data response is generated normally after each data burst.
    - Back to back full write blocks can be streamed with 88.9% application port efficiency and 100% DDR efficiency (this assumes single block channel).
    - For writes, the overhead command is not appended until the block channel is overridden or flushed. For example, for four block channels, it is possible to achieve 100% utilization up to 8*4 sequential/interleaving write bursts.
- For block read: BL/2 additional latency (4 DDR cycles for BL8, eight DDR cycles for BL16)
    - First, read the ECC burst, then read the eight consecutive data bursts. The first read command of the block channel incurs the latency.
    - Back to back full read blocks can be streamed with 88.9% application port efficiency and 100% DDR efficiency.

36.7.6 Interrupts related to inline ECC

The following are the interrupts for Inline ECC:

- ecc_corrected_err_intr
- ecc_uncorrected_err_intr
- ecc_ap_err_intr

36.8 Refresh controls

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

36.8.1 Overview of refresh controls

Refresh can be issued using the auto-refresh feature or using the direct software request of the refresh command. The “RFSHCTL3.dis_auto_refresh” register bit selects the refresh method. When this bit is set to 1, the MC uses direct software request of refresh command. When it is set to 0, the internal auto-refresh feature is used.

The purpose of refresh control is to:

- Reduce the bandwidth impact of refresh cycles
- Increase the likelihood of refreshes being serviced during idle periods
- Provide fine-gain control of the trading-off the above benefits (to gather refreshes) versus the increased worst case latencies associated with gathering refreshes
- Allow traffic to flow to other ranks while a given rank is being refreshed (for multi-rank configurations of the MC only)

36.8.2 Refresh using direct software request of refresh command

Follow these steps to put the MC in direct software request of refresh command mode:

1. Set the RFSHCTL3.dis_auto_refresh bit to 1. When the register bit set, the MC checks for any pending refreshes. Any pending refreshes are issued right away using the ‘critical refresh’ feature inside the MC. After these refreshes are issued, all the refresh timers inside the MC are reset to 0. They are re-activated only when the auto-refresh feature is enabled.
2. The SoC core must keep track of the refresh requirements of the DRAM.
3. The refresh command can be issued by setting the register bits DBGCMD.rank*_refresh to 1. When the rank*_refresh request is stored in the MC, the corresponding register bit is automatically cleared. The SoC core can initiate a rank*_refresh operation only if DBGSTAT.rank*_refresh_busy is low. The MC issues refresh to the DRAM at the earliest.
4. Software-driven refresh commands for each rank are loaded into a 9-entry buffer, and are issued by the MC on the DFI as soon as it is legal to do so (the MC must wait tRFC(min) between each refresh request). If the buffer saturates, the DBGSTAT.rank*_refresh_busy remains asserted to prevent software from initiating further refreshes.

NOTE

- Application can give a burst of back-to-back refresh commands without polling the DBGSTAT.rank*_refresh_busy register field to reduce the time between the software refresh commands to a minimum with the following risk:
  - If the refresh buffer is not empty when the burst starts or the burst is longer than 9 refresh commands, the buffer saturates (DBGSTAT.rank*_refresh_busy is asserted) and some APB writes given in the burst are not added to the buffer. This means that the number of APB writes do not reflect the number of REF commands sent out to the memory.
- For LPDDR4 configuration manual refreshes (RFSHCTL3.dis_au-to_refresh = 1) may not be used if the PHY Master Interface is enabled (DFIPHYMSTR.dfi_phymstr_en = 1).

36.8.3 Refresh using auto refresh feature inside the MC

The MC provides advanced refresh controls. Besides fully-configurable refresh constraints (tRFC(min) and tREFI), the MC can also be programmed to gather refreshes to each rank of DRAM to reduce the bandwidth consumed by refreshes and to increase the likelihood that refreshes can be serviced during an idle period.

Fine-grain control of the refreshes ensures these benefits can be balanced against worst case latencies associated with servicing refreshes together. Staggered refresh timers for multi-rank configurations of the MC allow transactions to continue to other ranks while refreshes are taking place to just one rank.

To minimize the worst case impact of a forced refresh cycle, the MC can be programmed to issue single refreshes at a time by forcing RFSHCTL0.refresh_burst = 0. It can be programmed to burst up to 8 refreshes (RFSHCTL0.refresh_burst = 7) in non-DDR4 modes. In LPDDR4 mode, with per-bank refresh enabled (RFSHCTL0.per_bank_refresh = 1), the maximum refresh burst supported by MC is 64 (RFSHCTL0.refresh_burst = 63). In DDR4 mode, if using Fine Granularity Refresh feature, the number of refreshes that can be bursted is up to 16 refreshes in Fixed 2x mode and up to 32 in Fixed 4x mode. Burst refresh can be used to minimize the bandwidth lost to closing pages for refresh and to increase the likelihood that refreshes can be serviced during idle periods. It can also be programmed to any number in between to trade-off the benefits of each.

36.8.3.1 Single refresh

When using single refresh (RFSHCTL0.refresh_burst = 0), the MC issues refreshes every time the refresh timer (tREFI) expires. This is the optimal mode of operation for systems that minimize the maximum latency associated with refresh cycles.

36.8.3.2 Burst refresh

When burst refresh is enabled (RFSHCTL0.refresh_burst > 0), the MC issues refreshes in bursts of (RFSHCTL0.refresh_burst+1) refreshes at one time. Bursting refreshes reduces the total latency associated with those refreshes by reducing the number of pre-charges and activates required for refresh, as banks must be precharged only once to perform the entire group of refreshes, instead of once for each refresh.

36.8.3.3 Speculative refresh

When tREFI has expired at least once, the MC can also perform speculative refreshes. This is done by automatically inserting refreshes when there are no transactions pending in the CAM to a rank/bank address. The RFSHCTL0.refresh_to_x1_x32 register determines how long the transactions must not be stored in the CAM before considering inserting these speculative refreshes. Each time a speculative refresh is performed, the count of tREFI expirations is decremented, and thereby increasing the time before a critical refresh is required.

This also ensures that speculative refreshes never occur more often than is required to keep the DRAM properly refreshed. If a new read or write transaction is accepted by the MC during speculative refresh, the MC services it as soon as legally possible. Most often it entails waiting for the required NOP cycles after a refresh before performing an activate and then servicing the read or write. If the MC has begun closing pages for a speculative refresh but has not yet issued the refresh when the new transaction arrives, the speculative refresh is canceled.

36.8.4 Per-bank Refresh (LPDDR4 only)

If RFSHCTL0.per_bank_refresh is set to 1 , the MC performs per-bank refreshes instead of all-bank refreshes. In this case, RFSHTMG.t_rfc_nom_x1_x32 and RFSHTMG.t_rfc_min should be set to the appropriate values for per-bank refresh (tREFIpb and tRFCpb respectively). In this mode, the MC keeps track of which bank is being refreshed at any time, and is able to schedule commands to other banks immediately before and after the per-bank refresh commands, resulting in potential efficiency gains. To improve the accuracy of per-bank refresh timing, set RFSHTMG.t_rfc_nom_x1_sel to 1 and program RFSHTMG.t_rfc_nom_x1_x32 accordingly.

For LPDDR4, the per-bank refresh command can be issued in any bank order. The MC can send the per-bank refresh to banks as a priority, where no transactions pending in the CAM or the bank is precharged. Also, the MC does not send the per-bank refresh command to multiple ranks at the same time, as the command contains a bank address, and the MC cannot specify multiple bank addresses with one command.

36.8.5 Fine granularity refresh (DDR4 only)

This feature is supported only by DDR4. As the device density increases, tRFC gets longer and limits the performance. Consequently, frequent refresh with shorter tRFC may be advantageous in certain traffic scenarios. DDR4 allows the following types of fine granularity refresh modes. They are set by programming the DRAM mode register MR3 A[8:6] and RFSHCTL3.refresh_mode registers:

- 000: Fixed 1x (normal mode)
- 001: Fixed 2x

- 010: Fixed 4x
- 101: On-the-fly 1x/2x (not supported by the MC)
- 110: On-the-fly 1x/4x (not supported by the MC)

The MC only supports Fixed mode refresh modes. The mode of operation has to be programmed both in the DRAM mode register and RFSHCTL3.refresh_mode registers. This must happen before the deassertion of reset or when controller is in self-refresh mode, similar to other static registers. When updating refresh mode in self-refresh, INIT4.emr3 must be updated as well, because the value written to the DRAM through automatic MR3 command is taken from INIT4.emr3, not RFSHCTL3.refresh_mode. Fixed 2x and Fixed 4x modes have shorter tREFI and tRFC (min) values compared to Fixed 1x mode. The following restrictions apply when using Fine Granularity Refresh mode:

- On-the-fly refresh modes are not supported
- Only Fixed 1x refresh mode operation is allowed if Temperature Controlled Refresh (TCR) is enabled in the DRAM (MR4 A[3:2])
- Multi-purpose register (MPR) reads and writes are not allowed when the Controller is in Fixed 2x or Fixed 4x modes.
    1. Move the controller and DRAM into self-refresh
    2. Change the controller operation to Fixed 1x mode (RFSHCTL3.refresh_mode = 3'b000)
    3. Program the DRAM operation to Fixed 1x mode (INIT4.emr3 = 3'b000)
    4. Exit self-refresh On exiting self-refresh, the controller automatically issues MR3 write and puts the DRAM in Fixed 1x mode. It is now possible to perform MPR operation as the controller and DRAM are in Fixed 1x mode. If the system wants to put the controller and DRAM back into Fixed 2x or Fixed 4x mode, it should repeat the above steps by moving the controller back into self-refresh, changing the refresh mode and the exiting self-refresh.
- RFSHCTL0.refresh_burst has the following restrictions:
    - In Fixed 1x mode, this must be less than 8
    - In Fixed 2x mode or on-the-fly 2x mode, this must be less than 16
    - In Fixed 4x mode or on-the-fly 4x mode, this must be less than 32
- DDR4 protocol requires the following requirements before self-refresh entry:
    - Even number of refreshes required in Fixed 2x mode
    - Multiple of four refreshes required in Fixed 4x mode

The controller takes care of this requirement. Note that the controller enters self-refresh only after waiting for all ranks to meet the above requirements (especially the even/multiple of four requirement for Fixed 2x/Fixed 4x modes). Hence, larger the difference between refresh_timer*_start_value_x32 settings, longer the wait before self-refresh entry occurs.

36.8.6 Constraints on refresh_timerX_start_value_x32

The refresh_timerX_start_value_x32 register fields control the relative timing of refreshes to different ranks. The register fields must obey the following constraint: refresh_timerX_start_value_x32 + RoundUp(RFSHTMG.t_rfc_min/32) < RFSHTMG.t_rfc_nom_x1_x32

If RFSHTMG.t_rfc_nom_x1_sel is set, RoundDown(RFSHTMG.t_rfc_nom_x1_x32/32) should be used in the above constraint. Also, note that the register field refresh_timerX_start_value_x32 cannot be changed after initialization. So the value of the register RFSHTMG.t_rfc_nom_x1_x32 used above should be anticipated as the minimum value which will be used, considering frequency change, fine granularity refresh, etc.

36.9 ZQ calibration

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

36.9.1 Overview of ZQ calibration

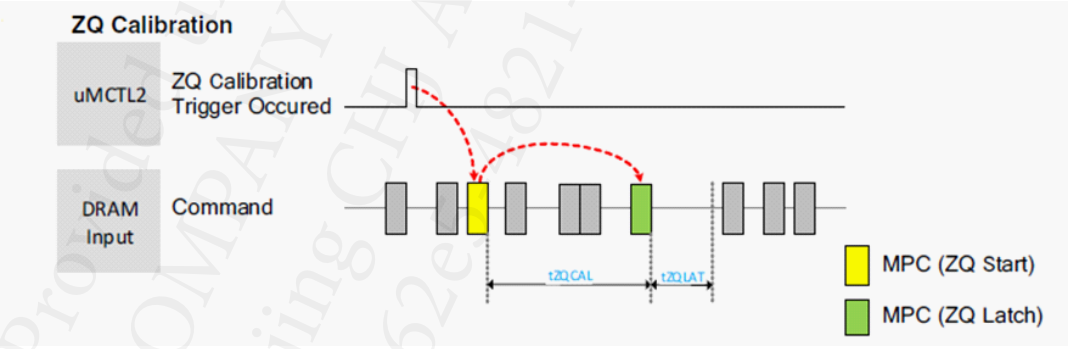
This feature is applicable to DDR3/DDR4 and LPDDR4. The MC uses ZQ calibration command to calibrate DRAM RON (Resistor ON) and ODT (On-Die Termination) values over PVT (Process, Voltage, Temperature). DDR3/DDR4 and LPDDR4 SDRAMs need more time to calibrate RON and ODT at initialization and relatively less time to perform periodic calibrations.

36.9.2 DDR3/DDR4 devices

ZQCL (ZQ Calibration Long) command is used as follows:

- To perform the initial calibration during the power-up initialization sequence. This command is allowed a timing period of tZQinit determined by INIT5. dev_zqinit_x32 to perform full calibration and the transfer of values.
- To perform long ZQ Calibration after exiting from self-refresh mode (or after exiting from maximum power saving mode in DDR4 mode). This command is allowed a timing period of tZQOPER, deter-mined by ZQCTL0._t_zq_long_nop. This command is automatically issued when ZQCTL0.dis_srx- _zqcl (ZQCTL0.dis_mpsmx_zqcl) is set to 0. To disable issuing ZQCL after self-refresh exit (after maximum power saving mode exit in DDR4 mode), set ZQCTL0.dis_srx_zqcl (ZQCTL0.dis_mpsmx- _zqcl) to 1.

ZQCS (ZQ Calibration Short) command is used to perform periodic calibration to account for VT (Voltage/Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter tZQCS (determined by ZQCTL0._t_zq_short_nop).



ZQCS can be performed automatically on a regular interval or through direct software request.. In DDR3/DDR4 mode, the ZQ Calibration commands are sent out encoded on the DFI command bus as mentioned in the JEDEC Specification. The MC performs no other activities for the duration of tZQinit, tZQOPER and tZQCS. The quiet time on the DRAM channel helps in accurate calibration of DRAM RON and ODT. All banks are precharged and tRP met before the MC issues the ZQ Calibration commands.

36.9.3 LPDDR4 devices

The MC supports all the ZQ calibration commands that are supported by the JEDEC Specification. ZQ calibration sequence uses the following MPC commands:

- ZQCal Start
- ZQCal Latch

The ZQCal Start command is used to initiate DRAM's calibration procedure. The ZQCal Latch command is used to capture the result and load it into DRAM's drivers. ZQCal Latch command can be issued after tZQCAL (determined by ZQCTL0._t_zq_long_nop) has expired and all DQ Bus operations have completed. If a ZQ calibration is triggered, those commands are sent out consecutively to the DRAM by the MC.

ZQCal Start and ZQCal Latch command can be performed automatically at a regular interval or through direct software request. Furthermore, both commands are issued automatically after SR-Powerdown exit if ZQCTL0. dis_srx_zqcl is set to 0. To disable issuing of both commands after SR-Powerdown exit, set ZQCTL0. dis_srx_zqcl to 1.

Do not change the following mode register fields following a ZQCal Start command and before tZQCAL has expired:

- PU-Cal (Pull-up Calibration VOH Point) - MR3:OP[0]

- PDDS (Pull Down Drive Strength and Rx Termination) - MR3:OP[5:3]
- DQ-ODT (DQ ODT Value) - MR11:OP[2:0]

36.9.4 Automatic and software Initiated ZQCS

The MC issues a ZQCS command in the following ways:

- **Automatic ZQCS by the MC:**

  In this case, the MC sends ZQCS commands to DRAM periodically. The interval is determined by ZQCTL1.t_zq_short_interval_x1024. This method is used if ZQCTL0.dis_auto_zq is set to 0. In LPDDR4 mode, the MC sends MPC-based ZQ calibration commands (ZQCal Start and ZQCal Latch) instead of ZQCS command.

- **ZQCS using direct software request:**

  In this case, the SoC core sends a ZQCS command through software by setting DBGCMD.zq_calib_short to 1. When the ZQCS request is stored in the MC, the register bit is automatically cleared. It is recommended not to set DBGCMD.zq_calib_short signal in init, self-refresh, deep power-down operating modes or maximum power saving mode (MPSM). The SoC core can initiate a ZQCS operation only if DBGSTAT.zq_calib_short_busy is low. The DBGSTAT.zq_calib_short_busy signal goes high in the clock after the MC accepts a ZQCS request. It goes low when the ZQCS operation is initiated in the MC. For proper DRAM operation, user/SoC core should schedule this command frequently. This method is used if ZQCTL0.dis_auto_zq is set to 1. In LPDDR4 mode, the MC sends MPC-based ZQ calibration commands (ZQCal Start and ZQCal Latch) instead of ZQCS command and it is recommended not to set DBGCMD.zq_calib_short signal in init or SR-Powerdown or Deep Power Down operating mode (this can be checked by observing STAT.operating_mode and STAT.selfref_state).

  For self-refresh (except LPDDR4) or SR-Powerdown(LPDDR4), command is scheduled after SR/SR-Powerdown is exited. For Deep Power Down or MPSM, command is not scheduled although ZQSTAT.zq_calib_short_busy is de-asserted.

36.9.5 LPDDR4 ZQ reset command

In LPDDR4 mode, it is recommended not to set this signal in init or SR-Powerdown or Deep Power Down operating modes (this can be checked by observing STAT.operating_mode and STAT.selfref_state). The SoC core can initiate a ZQ Reset operation only if ZQSTAT.zq_reset_busy is low. This signal goes high in the clock after the MC accepts a ZQ Reset request. It goes low when the ZQ reset command is issued to the DRAM and the associated NOP period is completed.

For self-refresh (except LPDDR4) or SR-Powerdown(LPDDR4), command is scheduled after SR/SR-Powerdown is exited. For Deep Power Down, command is not scheduled although ZQSTAT.zq_reset_busy is de-asserted.

36.10 MRR/MPR specific sequences

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

36.10.1 Mode register read and write operations

This section explains how to perform mode register reads and writes through software. Mode Register Reads (MRR) are applicable only to LPDDR4 and are used to read configuration and status data from mode registers in the SDRAM. Mode Register Writes (MRW or MRS) are applicable to all supported DDR protocols and are used to write configuration data to mode registers in the SDRAM. For DDR4 , the uMCTL2 also supports Multi-Purpose Register (MPR) reads and writes.

Access to the mode register is initiated by programming the MRCTRL0 and MRCTRL1 registers. It must be done in following steps:

1. Poll mr_wr_busy[mr_wr_busy] until it is 0. This checks that there is no outstanding MR transaction. No writes should be performed to MRCTRL0 and MRCTRL1, if mr_wr_busy[mr_wr_busy] =1.
2. Write the mr_type[mr_type], mr_addr[mr_addr], mr_rank[mr_rank] and (for MRWs) mr_data[mr_data] to define the MR transaction.
3. In a separate APB transaction, write the mr_wr[mr_rank] to 1. This bit is self-clearing and triggers the MR transaction. The uMCTL2 then asserts the mr_wr_busy[mr_wr_busy], while it performs the MR transaction to SDRAM and no further accesses can be initiated until it is de-asserted.

Note for Mode Register Write:

MRW transactions can be specified for either any single rank or any combination of serval ranks, by programming mr_rank[mr_rank]. If any part of the SDRAM's MR register is updated by software, it is also the responsibility of the software to update corresponding INIT*.*mr* so that it is aligned to the SDRAM's MR register.

Note for Mode Register Read:

MRR transactions should only be performed to one rank at a time, to avoid bus contention. When a MRR is performed, the mode register contents are available on hif_mrr_data, qualified by hif_mrr_data_valid, after the mode register read command is issued by the uMCTL2 to the SDRAM.

36.10.2 Multi-purpose register (MPR for DDR4 only)

This section describes how MPR Reads and MPR Writes are performed. The DDR4 SDRAMs contain four 8-bit programmable MPR which can be used for DQ training, CA parity log, MRS read out , or for vendor specific purposes. You can access MPRs when SDRAM is in MPR mode and the value of mpr_en[mpr_en] is 1.

Sequence of MPR Write operation:

1. Issue MRS command to SDRAM MR3 to put the SDRAM into MPR mode. The register mpr_en[mpr_en] must be 0. The MPR page selection, MR3[1:0] also be selected.
2. Wait until mr_wr_busy[mr_wr_busy] is 0. Write mr_data[mr_data].
3. Write MRCTRL0, where mr_addr[mr_addr] = MPR Location, mr_type[mr_type] = write , mr_wr[mr_wr] =1 and mpr_en[mpr_en] =1.
4. Issue MRS command to SDRAM MR3 to exit the SDRAM from MPR mode. The mpr_en[mpr_en] must be 0.

Sequence of MPR Read operation:

1. Issue MRS command to SDRAM MR3 to put the SDRAM into MPR mode. The register mpr_en[mpr_en] must be 0. The MPR page selection, MR3[1:0] and read format, MR3[12:11] must also be selected at this time.
2. Wait until mr_wr_busy[mr_wr_busy] is 0. Write mr_data[mr_data], where mr_data[mr_data][1:0]=00.
3. Write MRCTRL0, where mr_addr[mr_addr] = MPR Location, mr_type[mr_type] =read , mr_wr[mr_wr] =1 and mpr_en[mpr_en] =1. This causes the uMCTL2 to issue the MPR Read. The mode register contents are available on hif_mrr_data, qualified by hif_mrr_data_valid. When this data is received, it is safe to move to the next step.
4. Issue MRS command to SDRAM MR3 to exit the SDRAM from MPR mode. The register MRCTRL0.mpr_en must be 0.

36.11 ODT control

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

36.11.1 Overview of ODT control

By default, ODT to memories (dfi_odt) is driven to all zeros. The register inputs control the following:

- ODTMAP.rank*_wr_odt: The value desired for ODT following a write command.
- ODTCFG.wr_odt_delay: The number of cycles to delay following a write command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- ODTCFG.wr_odt_hold: The number of cycles to hold the programmed write value after it is first driven.
- ODTMAP.rank*_rd_odt: The value desired for ODT following a read command.
- ODTCFG.rd_odt_delay: The number of cycles to delay following a read command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- ODTCFG.rd_odt_hold: The number of cycles to hold the programmed read value after it is first driven.

NOTE

- ODT control for memories is not required for LPDDR4. It is a DDR3/DDR4 specific feature.
- For LPDDR4, set ODTMAP.rank*_wr/rd_odt to all zero because the ODT feature is automatically turned ON/OFF. In addition, the DRAMTMG13.odtloff register field must be appropriately programmed.
- DDR4 Dynamic ODT mode is not supported by the MC.

  All of these must be set by the SoC core before taking the MC out of reset. They are then applied to every read or write issued by the MC. To avoid overlap of ODT for reads and writes, the following constraints must be enforced:

1:2 Frequency Ratio Mode:

- ODTCFG.wr_odt_hold <= 2 * RANKCTL.diff_rank_wr_gap + MSTR.burst_rdwr
  - If burst chop is enabled (MSTR.burstchop = 1), use burst_rdwr/2 in the above equation
- ODTCFG.rd_odt_hold <= 2*RANKCTL.diff_rank_rd_gap + MSTR.burst_rdwr
  - If burst chop is enabled (MSTR.burstchop = 1), use burst_rdwr/2 in the above equation
- ODTCFG.wr_odt_delay + ODTCFG.wr_odt_hold <= ODTCFG.rd_odt_delay + 2 * DRAMTMG2.wr2rd
  - For DDR4, use wr2rd_s in the above equation
- ODTCFG.rd_odt_delay + ODTCFG.rd_odt_hold <= ODTCFG.wr_odt_delay + 2 * DRAMTMG2.rd2wr
- ODTCFG.wr_odt_delay >= DFITMG1.dfi_t_cmd_lat (DDR4 only)

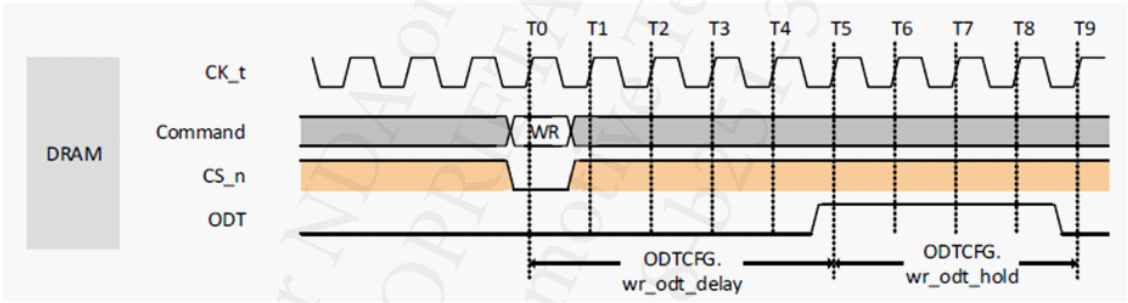


Figure 186. WR ODT timing diagram

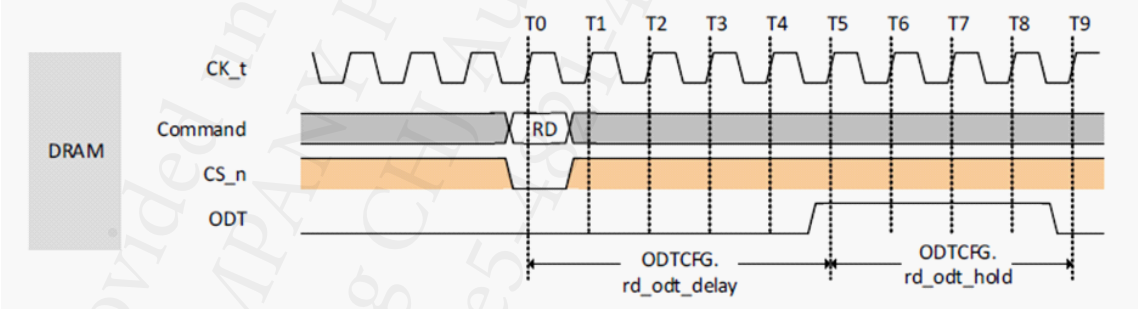

Figure 187. RD ODT timing diagram

36.12 Programming considerations

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides information about how to program certain types of registers and fields.

36.12.1 Programming fields based on multiples of DFI clock cycles

The MC contains three timers that issue pulses at these multiples of the DFI clock:

- Every 32 clock cycles
- Every 1024 clock cycles
- Every 4096 clock cycles

Some timing register field values are stated based on these multiples. These fields have "x32", "x1024", or "x4096" in the field name. For example, an "x32" field counts pulses of the 32-clock cycle timer. The periods tracked by these fields start without any guaranteed relation to the phase of the associated timer. Therefore, for "x32" fields:

- A value of 0 gives no delay.
- A value of 1 gives a 1 to 32 cycle delay.
- A value of 2 gives a 33 to 64 cycle delay, and so on.

For "x1024" fields:

- A value of 0 gives no delay.
- A value of 1 gives a 1 to 1024 cycle delay.
- A value of 2 gives a 1025 to 2048 cycle delay, and so on.

For "x4096" fields:

- A value of 0 gives no delay.
- A value of 1 gives a 1 to 4096 cycle delay.
- A value of 2 gives a 4097 to 8192 cycle delay, and so on.

For a minimum delay, the field value must be set to the smallest number for which the resulting delay is ALWAYS greater than or equal to the required delay. For a maximum delay or nominal refresh, the value must ensure that the delay is ALWAYS less than or equal to the required delay.

36.12.2 Converting times into clock cycles

Most of the DRAM timing register fields call for values stated in clock cycles. But the value in an DRAM datasheet may be stated in time, such µs, ns, or ps. These datasheet values are primarily minimum timings. Before using them to calculate a value to program into a field, divide the specified time by the DRAM clock period (tCK) and round any fraction up to the next integer value.

The exceptions to this rule are maximum timings, where the result should be rounded down rather than up. These maximum timings include:

- RFSHTMG[t_rfc_nom_x32]
- DRAMTMG0[t_ras_max]

Certain DRAM timing register fields clariy this by using the following functions in their descriptions:

- RoundUp (X/Y), which means that if X divided by Y does not result in a whole integer, round the result up to the next integer value. For example: RoundUp(1000/150) = 7, and RoundUp(1050/150) = 7.
- RoundDown (X/Y), which means that if X divided by Y does not result in a whole integer, round the result down to the next integer value. For example: RoundUp(1000/150) = 6, and RoundUp(1050/150) = 7.

36.12.3 Programming mode

Each field description specifies the programming mode for that field. The programming mode describes when the field can be written to. The options are:

Programming mode	Description
Static	Can be written only when the MC is in reset.
Dynamic	Can be written at any time during operation.
Quasi-dynamic Group 1	Can be written when the MC is in reset and when no read/write traffic is present at the DFI.
Quasi-dynamic Group 2	Can be written when the MC is in reset and when the MC is in the Self Refresh, Deep Power Down, or Maximum Power Saving Mode states.
Quasi-dynamic Group 3	Can be written when the MC is in reset and when the MC is empty (idle).
Quasi-dynamic Group 4	Can be written when the MC is in reset and depending on the frequency mode (MSTR[frequency_mode]).

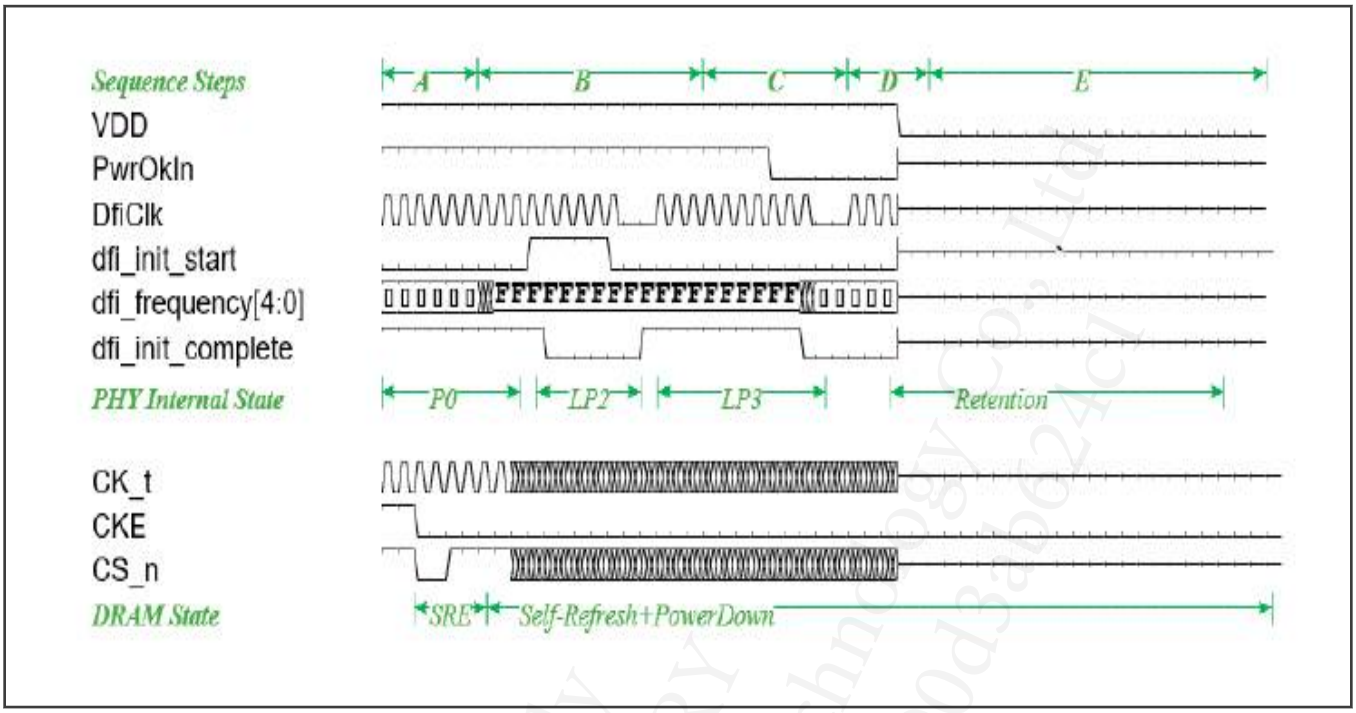
NOTE

Some fields are programmable under more than one quasi-dynamic group.

If OCCAPCFG[occap_en] = 1, you must poll SWSTAT[sw_done_ack] until it becomes 0 before modifying quasi-dynamic registers.

36.12.4 Standby power state (LP3/IO Retention)

The LP3/IO Retention power state is a non-operational low power state. The standby power state has the following properties:



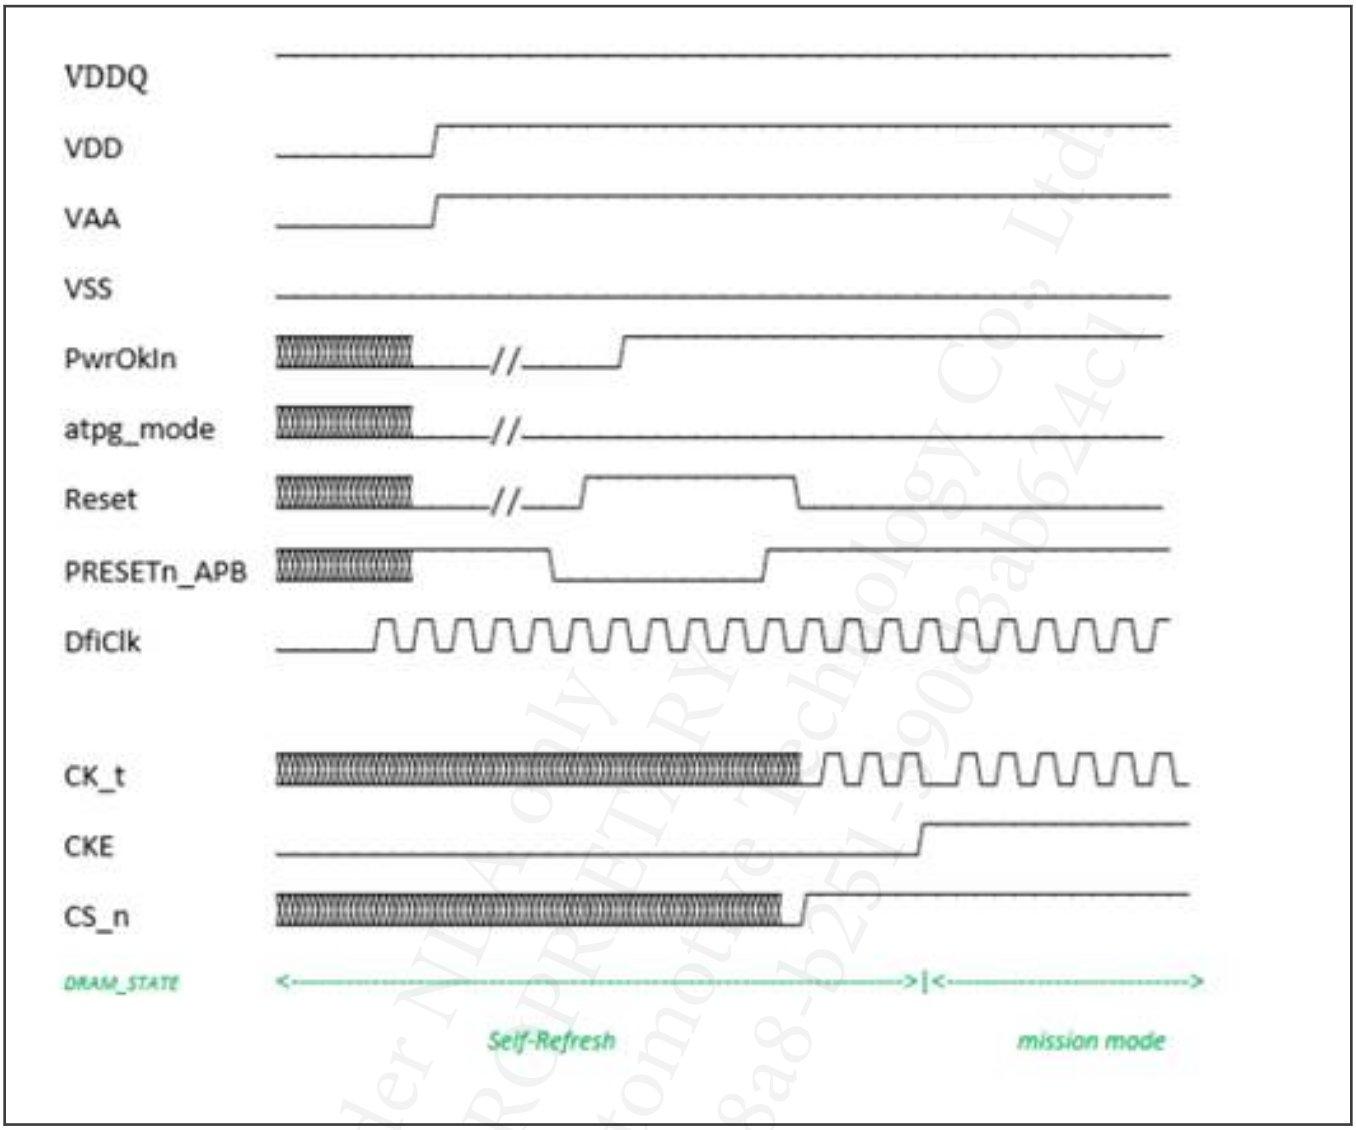
- This is the lowest possible power state for the PHY.
- In this power state, the DRAM may either be in self-refresh, or in Reset.
- The core VDD and VAA power supplies can be powered down in this state. If the core VDD power supply is shut off, power consumption is predominantly determined by the device leakage on VDDQ, the device leakage on VDDQLP, and the number of active CKE lanes.
- The state of CKE and MEMRESET pins will be pReserved at their last values when the core VDD is shut off. VDDQ must remain valid for the value of the pins to be Reserved.
- The Standby power state is entered via a Frequency Change sequence, using the dfi_init_start and dfi_freq[4:0] interface

NOTE

- When entering or exiting LP3/IO Retention, the DFI interface must be held in a valid state until PwrOkIn is set to 0. While in LP3/IO Retention, the DRAM signals required for proper IO Retention will maintain the appropriate state (including CKE and MEMRESET pins).
- The Memory controller may ignore the dfi_phyupd_req signals during LP3.
- When DfiClk stops(LP3 mode), then DFiCtlClk can also be clock gated or stopped.

The phy LP3 state is for deep sleep, in which the DFICLK can be gated; and additionally the PHY PLL is placed into maximum Powerdown mode. The power-saving of LP3 are only in the reduction of the standby current of the PHY PLL. However, the exit latency from this state is estimated at 35uS (since the PHY PLL requires a full initialization after entering Powerdown).

Preliminary Information
COMPANY CONFIDENTIAL
Beijing Autonomous Technology Co., Ltd.
c8c462_2021-04-26-10-51-39-0a1ab6a4a1



Sequence of LP3/ IO Retention Enter steps:

- Use the DFI interface to put the DRAM into Self-Refresh or Reset.
- Transition the PHY to the LP3 / IO Retention state by using a DFI Frequency Change operation.
- Set the PwrOkIn signal to 0. This will enable the data retention feature on the CKE and MEMRESET pins. These pins will hold the current values.
  - Remaining PHY input signals must be valid, inactive states for at least 10ns after the PwrOkIN de-asserting edge.
  - The PHY input clocks are not required to toggle after the de-asserting edge of PowerOkIN.
- Turn off the core VDD and VAA supplies. The VDDQ and VDDQLP power supply must remain active during LP3/IO Retention.
- All PHY input values are now don't cares and can go to X in simulations.

Sequence of LP3/IO Retention Exit steps:

- The VDDQ and VDDQLP power supply will already be active, restore the core VDD and VAA power supplies.
- Start clocks and reset the PHY
- Initialize the PHY configuration
- Reload the save training state
- Load the PHY Initialization Engine image
- Initialize the PHY to mission mode through a DFI initialization request
- The PHY is ready for mission-mode transactions.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e_482148812431390d8b624c1

The following requirements must also be addressed when exiting LP3/IO Retention mode:

- For retention exit, all rules regarding resetting the PHY and enabling the clocks apply a standard reset sequence.
- Since the CKE* and MEMRESET pin state must be protected , special care must be taken to ensure that the following signals:
  - Atpg_mode = 1’b0
  - PwrOkIn = 1’b0
- The (BypassModeEn*, WRSTN) signals may be defined at VDD power-on, but must be driven to Zero at least 10ns prior to the asserting edge of PwrOklin.

Fields

Field	Function
31-9 —	Reserved
8 bl_exp_mode	Burst expansion mode Selects half of the memory burst length (BL) as the XPI burst expansion packet length. Applies to both read and write expansion. When using Partial Writes (UMCTL2_PARTIAL_WR == 1), half BL burst expansion avoids or minimizes the t_ccd_l penalty for DDR4 or the t_ccd_mw penalty for LPDDR4. Therefore, you should use it only for DDR4 or LPDDR4 DRAM. When not using data mask (DBICTL[dm_en] == 0), the MC does not support half BL burst expansion if any of these conditions are true: • Partial Writes disabled (UMCTL2_PARTIAL_WR == 0) • Partial Writes enabled (UMCTL2_PARTIAL_WR == 1) AND — For LPDDR4, all of these conditions are true: ◦ Half bus width (MSTR[data_bus_width] == 01) ◦ MC BL8 (MEMC_BURST_LENGTH == 8) ◦ DRAM BL16 (MSTR[burst_rdwr] == 1000) — For DDR4, all of these conditions are true:

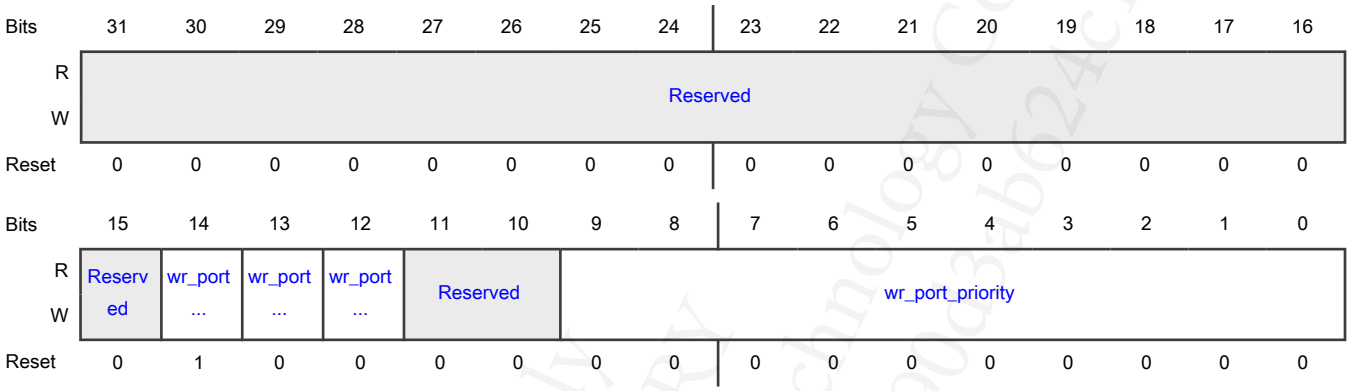
13 rd_port_urgent_en	Read AXI urgent sideband enable

Table continues on the next page...

Table continued from the previous page...



Field	Function
	Enables the AXI urgent sideband signal (arurgent). If enabled and the master asserts arurgent, that port becomes the highest priority port. Also, if enabled and go to critical is enabled (PCCFG[go2critical_en]), the MC asserts co_gs_go2critical_lpr or co_gs_go2critical_hpr to the MC. **NOTE** The master can assert arurgent any time and for as long as needed, independent of address handshaking. It is not associated with any particular command. Programming Mode: Static 0b - Disable 1b - Enable
12 rd_port_aging_en	Read aging enable Enables the aging function for the port read channel. Programming Mode: Static 0b - Disable 1b - Enable
11-10 —	Reserved
9-0 rd_port_priority	Read aging counter value Specifies the initial value to be loaded into the read aging counters. The MC loads the counters with this value after reset or after each grant to the corresponding port. The aging counters count down every clock cycle that a port is requested but not granted. The five most significant bits (msb) of the counter sets the priority of the read channel for a particular port. That port's priority increases as the five msb decrease. When the aging counter reaches zero, the corresponding port channel has the highest priority (timeout condition – Priority0). For multi-port configurations, if using external dynamic priority inputs (arqos), you cannot use the aging counters to set port priorities (timeout is still applicable). For single-port configurations, the aging counters only matter to force read-write direction switching when they timeout (become 0). In this case, you can still use the external dynamic priority input (arqos), for reads only, to set the MC read priority: low priority read (LPR) or high priority read (HPR) on a command-by-command basis. **NOTE** The two least-significant bits (lsb) of this field are tied low (00b) internally. Programming Mode: Static

Fields

Field	Function
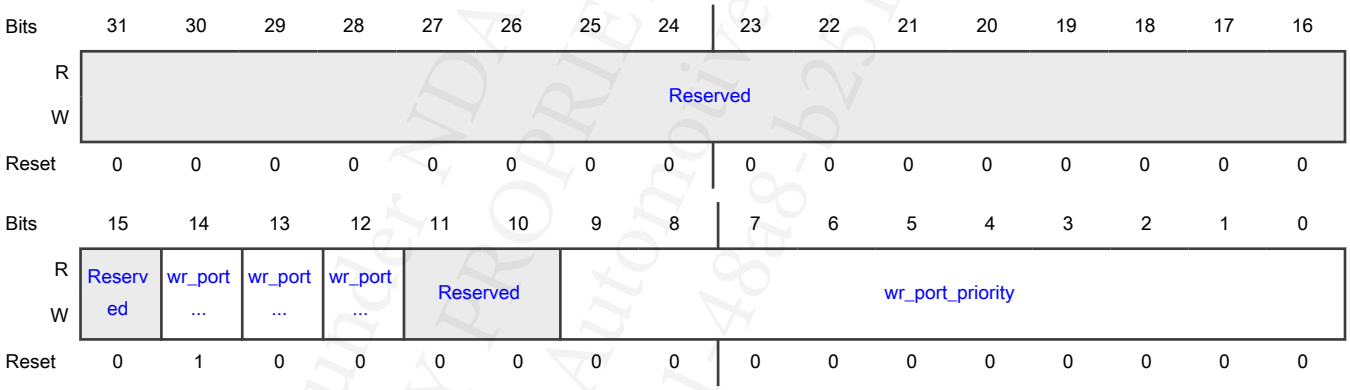
31-17 —	Reserved
16 rdwr_ordered_en	Enable ordered read/writes. If set to 1, preserves the ordering between read transaction and write transaction issued to the same address, on a given port. In other words, the controller ensures that all same address read and write commands from the application port interface are transported to the DFI interface in the order of acceptance. This feature is useful in cases where software coherency is desired for masters issuing back-to-back read/write transactions without waiting for write/read responses. Note that this register has an effect only if necessary logic is instantiated via the UMCTL2_RDWR_ORDERED_n parameter. Programming Mode: Static
15 —	Reserved
14 rd_port_pagematch_en	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register. Programming Mode: Static
13 rd_port_urgent_en	If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to MC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command). Programming Mode: Static
12 rd_port_aging_en	If set to 1, enables aging function for the read channel of the port. Programming Mode: Static
11-10 —	Reserved
9-0	Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle

Table continues on the next page...

Table continued from the previous page...



Field	Function
rd_port_priority	where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the MC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis. Note: The two LSBs of this register field are tied internally to 2'b00. Programming Mode: Static

9-0 rd_port_priority	Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the MC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis. Note: The two LSBs of this register field are tied internally to 2'b00. Programming Mode: Static

Fields

Field	Function
31-15	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
14 wr_port_pagematch_en	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register. Programming Mode: Static
13 wr_port_urgent_en	If set to 1, enables the AXI urgent sideband signal (awurgent). When enabled and awurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_wr signal to the MC is asserted if enabled in PCCFG.go2critical_en register. Note that awurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command). Programming Mode: Static
12 wr_port_aging_en	If set to 1, enables aging function for the write channel of the port. Programming Mode: Static
11-10 —	Reserved
9-0 wr_port_priority	Determines the initial load value of write aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the write aging counter sets the initial priority of the write channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level. For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (awqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. Note: The two LSBs of this register field are tied internally to 2'b00. Programming Mode: Static

36.13.25 Scrubber Control (SBRCTL)

Offset

Register	Offset
SBRCTL	B2Ch

Diagram

Fields

Field	Function
31-21 —	Reserved
20-8 scrub_interval	Scrub interval. (512 x scrub_interval) number of clock cycles between two scrub read commands. If set to 0, scrub commands are issued back-to-back. This mode of operation (scrub_interval=0) can typically be used for scrubbing the full range of memory at once before or after SW controlled low power operations. After completing the full range of scrub while scrub_interval=0, scrub_done register is set and sbr_done_intr interrupt signal is asserted. This mode can't be used with Inline ECC: If MEMC_INLINE_ECC is 1 and scrub_interval is programme to 0, then RMW logic inside scrubber is disabled. New programmed value will take effect only after scrubber is disabled by programming scrub_en to 0. Unit: Multiples of 512 sbr_clk cycles. Programming Mode: Dynamic
7 —	Reserved
6-4 scrub_burst	Scrub burst count. Determines the number of back-to-back scrub read commands that can be issued together when the controller is in one of the HW controlled low power modes, both normal operation mode and low-power mode with Inline ECC. During these modes, the period of the scrub burst becomes "scrub_burst*scrub_interval" cycles. (Inline ECC): 1: 8 reads, 2: 16 reads, 3: 32 reads. New programmed value will take effect only after scrubber is disabled by programming scrub_en to 0. Programming Mode: Dynamic
3 —	Reserved

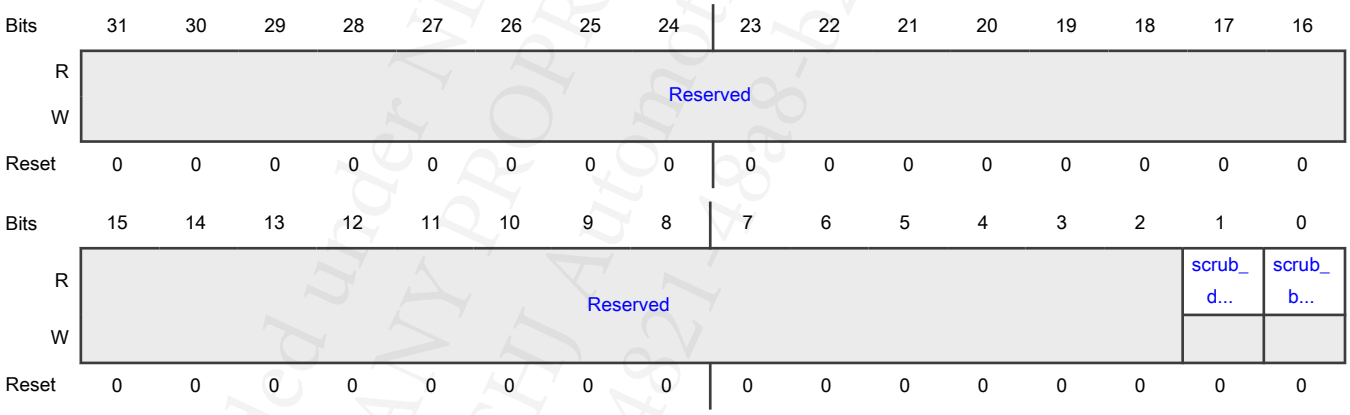
Table continued from the previous page...



Field	Function
2 scrub_mode	scrub_mode:0 ECC scrubber will perform reads scrub_mode:1 ECC scrubber will perform writes Programming Mode: Dynamic
1 scrub_during_lowpower	Continue scrubbing during low power. If set to 1, burst of scrubs will be issued in HW controlled low power modes. There are two such modes: automatically initiated by idleness or initiated by Hardware low power interface. If set to 0, the scrubber will not attempt to send commands while the MC is in HW controlled low power modes. In this case, the scrubber will remember the last address issued and will automatically continue from there when the MC exits the LP mode. Programming Mode: Dynamic
0 scrub_en	Enable ECC scrubber. If set to 1, enables the scrubber to generate background read commands after the memories are initialized. If set to 0, disables the scrubber, resets the address generator to 0 and clears the scrubber status. This bitfield must be accessed separately from the other bitfields in this register. Programming Mode: Dynamic

Diagram

Fields

Field	Function
31-30 device_config	Device configuration Selects the configuration of the DRAM device. Programming Mode: Static 00b - x4 device 01b - x8 device 10b - x16 device 11b - x32 device

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-28 —	Reserved
27-24 active_ranks	Active ranks Selects the number of active ranks. This field is present only for multi-rank configurations. Each bit represents one rank: 1 = rank is populated; 0 = rank is not populated. For two-rank configurations, bits 26–27 are reserved. The lsb is the lowest rank number. Programming Mode: Static **NOTE** All values not listed below are reserved. 0001b - One rank populated 0011b - Two ranks populated 1111b - Four ranks populated. Valid only in a four-rank configuration.
23-20 —	Reserved
19-16 burst_rdwr	DRAM burst length Selects the burst length (BL) used to access the DRAM. This selection must match the burst length mode register setting in the DRAM. Programming Mode: Static **NOTE** All values not listed below are reserved. 0001b - BL2. Only supported for mDDR and if the MC is operating at 1:1 frequency ratio. Not supported with AXI ports if MEMC_BURST_LENGTH = 8. 0010b - BL4 0100b - BL8. You must use BL8 for DDR3, DDR4 and LPDDR3. You must use BL8 for BC4/BC8 on-the-fly mode for DDR3 and DDR4. 1000b - BL16. Only supported for mDDR, LPDDR2, and LPDDR4. You must use BL16 for LPDDR4.
15 dll_off_mode	Dll-off mode Selects DLL-off mode for low frequency operation. DLL-on mode is for normal frequency operation. Programming Mode: Quasi-dynamic Group 2 0b - DLL-on mode 1b - DLL-off mode
14	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
13-12 data_bus_width	Data bus width Selects the portion of the DQ bus width (excluding any ECC width) used by the DRAM. Programming Mode: Static **NOTE** The following bus-width restrictions apply. The DDR subsystem supports: • Half bus width only when the DRAM bus width is a multiple of 16 • Quarter bus width only when the DRAM bus width is a multiple of 32 and the configuration parameter MEMC_QBUS_SUPPORT = 1. 00b - Full DQ bus width 01b - Half DQ bus width 10b - Half DQ bus width 11b - Reserved
11 geardown_mode	Geardown Selects geardown mode (2N) or normal mode (1N). In 2N mode, the address, command, and control signals are asserted for 2 clock cycles. You can write this field only when the MC is in the Self Refresh state. **NOTE** Geardown mode is not supported if: • Configuration parameter MEMC_CMD_RTN2IDLE = 1 • Configuration parameter UMCTL2_SHARED_AC = 1 (in Shared-AC mode) and the register value is don't care Programming Mode: Quasi-dynamic Group 2 0b - Normal (1N) mode 1b - Geardown (2N) mode
10 en_2t_timing_mode	2T timing Selects 1T or 2T timing. In 2T timing, all command signals (except chip select) are held for 2 clocks on the DRAM bus, and chip select is asserted on the second cycle of the command.

Table continues on the next page...

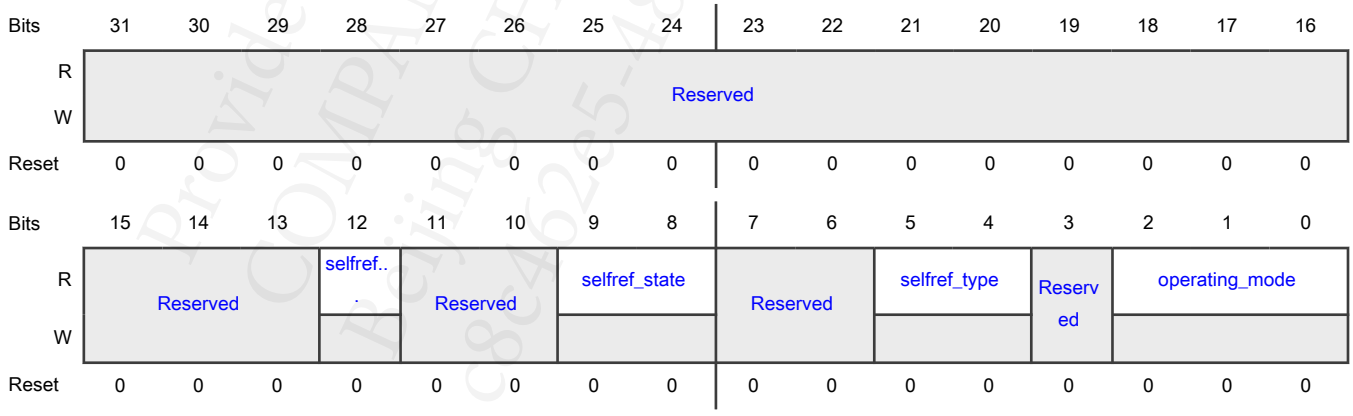
COMPANY CONFIDENTIAL
Beijing CHJ Automotive Technology Co.,Ltd.
c8c462a-4821-4823-b251-390d3ab624c1

Table continued from the previous page...

Field	Function
	Programming Mode: Static **NOTE** 2T timing is not supported: p> • For LPDDR2, LPDDR3, or LPDDR4 • If the configuration parameter MEMC_CMD_RTN2IDLE = 1 • In DDR4 geardown mode • In Shared-AC dual channel mode and the register value is don't care 0b - 1T timing 1b - 2T timing
9 burstchop	Burst Enable burst chop (BC4 or 8 on-the-fly) in DDR3 or DDR4. The subsystem exercises burst chop for reads only in HIF configurations (UMCTL2_INCL_ARB not set) and if in full bus width mode (data_bus_width = 00) and if MEMC_BURST_LENGTH is equal to 8 or 16. The subsystem exercises burst chop for writes only if partial writes are enabled (UMCTL2_PARTIAL_WR = 1) and if CRC is disabled (CRCPARCTL1[crc_enable] is equal to 0). BC4 (fixed) mode is not supported. Programming Mode: Static 0b - Disabled 1b - Enabled
8-6 —	Reserved
5 lpddr4	LPDDR4 Selects LPDDR4 DRAM. Only present in systems that support LPDDR4. Programming Mode: Static 0b - Not selected 1b - Selected
4 ddr4	DDR4 Selects DDR4 DRAM. Only present in systems that support DDR4. Programming Mode: Static 0b - Not selected 1b - Selected
3	LPDDR3

Table continues on the next page...

Table continued from the previous page...



Field	Function
lpddr3	Selects LPDDR3 DRAM. Only present in systems that support LPDDR3. Programming Mode: Static 0b - Not selected 1b - Selected
2 lpddr2	LPDDR2 Selects LPDDR2 DRAM. Only present in systems that support LPDDR2. Programming Mode: Static 0b - Not selected 1b - Selected
1 —	Reserved
0 ddr3	DDR3 Selects DDR3 DRAM. Only present in systems that support DDR3. Programming Mode: Static 0b - Not selected 1b - Selected

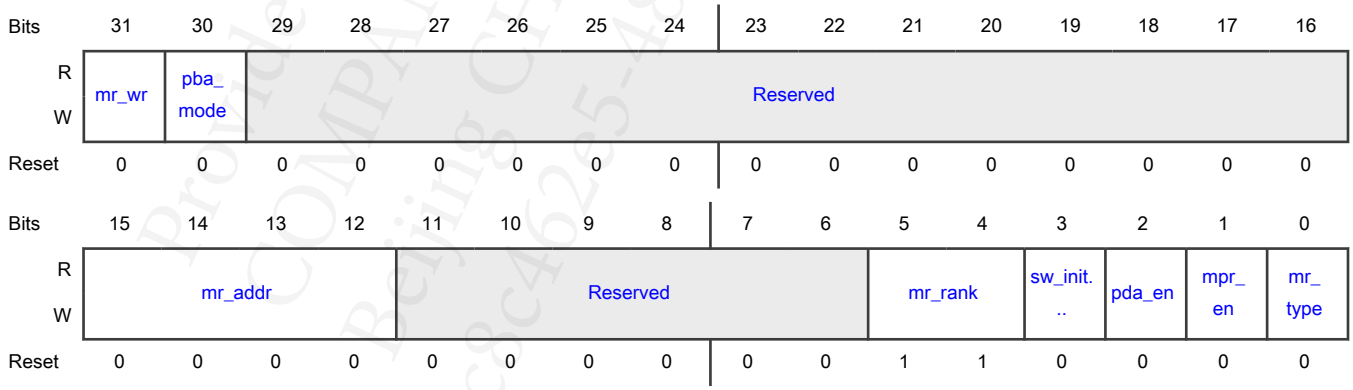
2-0 operating_mode	Operating state Indicates the current operating state. Programming Mode: Static 000b - Init 001b - Normal 010b - Power Down 011b - Self Refresh. LPPD4: Self Refresh Power Down 1xxb - mDDR, LPDDR2, LPDDR3, or DDR4: Deep Power Down or Maximum Power Saving

36.14.4 Mode Register read/write control 0 (MRCTRL0)

Offset

Register	Offset
MRCTRL0	10h

Function



Controls and initates an DRAM Mode Register read or write transaction.

NOTE

Enable only one of the following functions at any given time:

- Software Intervention (sw_init_int)
- Per DRAM Addressability (pda_en)
- Multi Purpose Register (mpr_en)

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4625-4821-43c8-b251-390d3ab624c1

Fields

Field	Function
31 mr_wr	Mode Register read/write Triggers a Mode Register read or write operation. When the MR operation is complete, the MC automatically clears this field. You must write the other fields in this register in a separate transaction before writing this field. Do not write to this field while DRAM is intializing or is in the Deep Power Down or Maximum Power Saving Mode states. Programming Mode: Dynamic
30 pba_mode	Per buffer addressability Selects per buffer addressability (PBA) mode. If both pda_en and pba_en are selected, the MC initiates PBA access instead of PDA. MRSTAT[pda_done] indicates the completion of PBA access just as it does for PDA. Programming Mode: Dynamic 0b - PDA 1b - PBA
29-16 —	Reserved
15-12 mr_addr	Mode Register address Selects the Mode Register to be written to. For Mode Register addressing in LPDDR2, LPDDR3, and LPDDR4, see MRCTRL1[mr_data]. This signal is also used for writing to control words of the register chip on RDIMMs and LRDIMMs. In that case, it corresponds to the bank address bits sent to the RDIMM or LRDIMM. For DDR4, bits 15-14 correspond to the bank group bits. Therefore, bit 15 as well as bits 14-12 must be set to an appropriate value that is considered both the address mirroring of UDIMMs, RDIMMs, or LRDIMMs, and the output inversion of RDIMMs or LRDIMMs. Programming Mode: Dynamic 0000b - MR0 0001b - MR1 0010b - MR2 0011b - MR3 0100b - MR4 0101b - MR5 0110b - MR6 0111b - MR7
11-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5-4 mr_rank	Rank access Selects which ranks are accessed by the Mode Register operation (mr_wr). In typical operation, you access all ranks. However, for multi-rank UDIMMs, RDIMMs, and LRDIMMs that implement address mirroring, you may need to access individual ranks. Each bit selects one rank and lsb is rank 0. Examples: Assume MC is configured for 2 ranks. • 0b01 - Select rank 0 only. • 0b10 - Select rank 1 only. • 0b11 - Select rank 0 and 1. Programming Mode: Dynamic
3 sw_init_int	Software intervention Allows software intervention via MRCTRL0/MRCTRL1 before the automatic DRAM initialization routine. DDR4: Initialize the DDR4 RCD (MR7) before automatic DRAM initialization. LPDDR4: Program additional mode registers before automatic DRAM initialization. For dual-channel DRAM, you must program both channels first. Programming Mode: Dynamic **NOTE** You must write 0 to this field after completing software intervention; otherwise, the DRAM initialization routine will not re-start. 0b - Not allowed 1b - Allowed
2 pda_en	Per DRAM addressability Selects Per DRAM Addressability (PDA) mode. Programming Mode: Dynamic 0b - MRS 1b - MRS in PDA mode
1 mpr_en	Multi-purpose register Selects MRS or WR/RD for MPR operation. **NOTE** The DDR subsystem supports WR/RD for MPR operation only for DDR4. Programming Mode: Dynamic

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - MRS 1b - WR/RD for MPR
0 mr_type	Mode Register operation Selects whether the next Mode Register operation is read or write. Use only for for LPDDR2, LPDDR3, LPDDR4, or DDR4 DRAM. Programming Mode: Dynamic 0b - Write 1b - Read

36.14.5 Mode Register Read/Write Control 1 (MRCTRL1)

Offset

Register	Offset
MRCTRL1	14h

Function

Specifies data for a Mode Register write operation.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

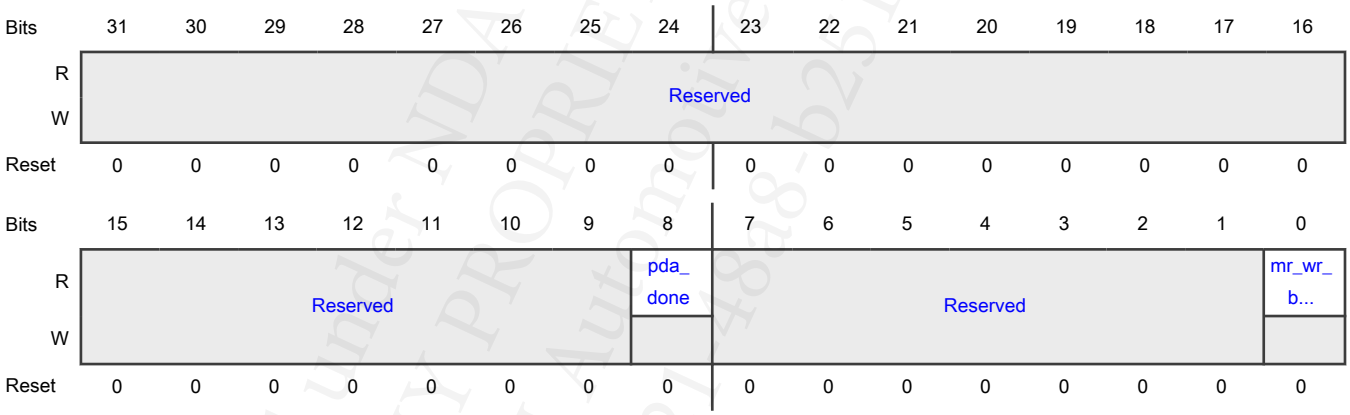
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

Table continued from the previous page...

Field	Function
17-0 mr_data	Mode Register write data Write data for all non-LPDDR2, non-LPDDR3, and non-LPDDR4 DRAM. For LPDDR2, LPDDR3, and LPDDR4, bits 15–8 are the Mode Register address and bits 7–0 are the write data. Programming Mode: Dynamic

36.14.6 Mode Register Read/Write Status (MRSTAT)



Offset

Register	Offset
MRSTAT	18h

Function

Controls when Mode Register read or write operations can be initiated.

Diagram

Fields

Field	Function
31-9 —	Reserved
8 pda_done	PDA operation complete Indicates whether a MR operation in PDA or PBA mode has completed. This signal goes high when three consecutive MRS commands related to the PDA or PBA mode are issued to the DRAM. It goes low when MRCTRL0[pda_en] becomes 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The SoC core may initiate a MR write operation in PDA or PBA mode only if pda_done = 0. Therefore, we recommended you write 0 to MRCTRL0[pda_en] after pda_done goes high to prepare for the next PDA operation. Programming Mode: Dynamic 0b - In progress or not yet started 1b - Completed
7-1 —	Reserved
0 mr_wr_busy	MR busy Indicates that a Mode Register (MR) operation is in progress. This signal goes high in the clock after the MC accepts the MR write or read request. It goes low when the MR write or read command is issued to the DRAM. The SoC core may initiate a MR write operation only if mr_wr_busy = 0. We recommended that you do not perform MR write or read commands when mr_wr_busy = 1. Programming Mode: Dynamic 0b - Not busy 1b - Busy

36.14.7 Mode Register Read/Write Control 2 (MRCTRL2)

Offset

Register	Offset
MRCTRL2	1Ch

Function

Selects the devices for Mode Register Set operation in PDA mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	mr_device_sel															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

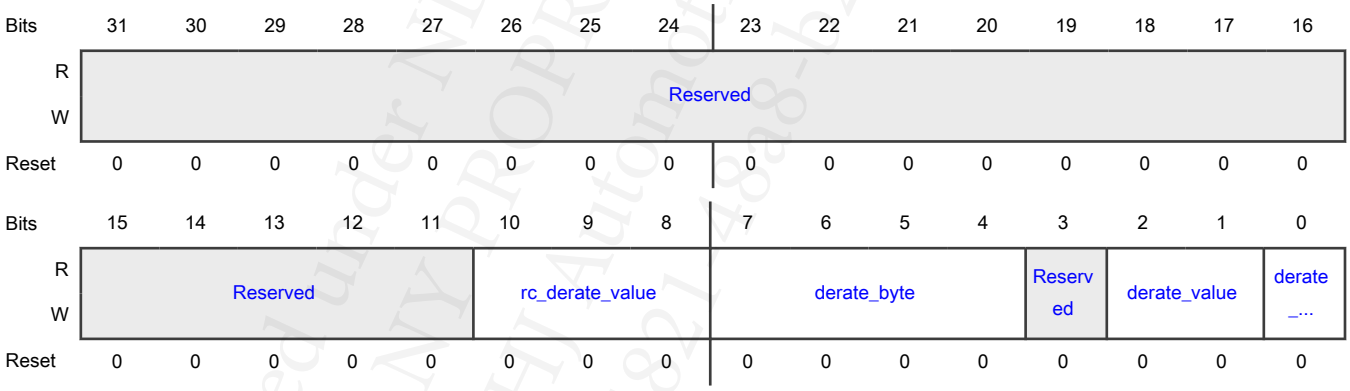
Fields

Field	Function
31-0 mr_device_sel	MRS device select Selects to which devices to apply a Mode Register Set (MRS) command in PDA mode. Each bit represents one device. For example, bit 0 corresponds to device 0, bit 1 corresponds to device 1, and so on. Programming Mode: Dynamic Here are the permitted values for each bit: 00000000000000000000000000000000b - Do not apply 00000000000000000000000000000001b - Apply



36.14.8 Temperature derate enable (DERATEEN)

Offset

Register	Offset
DERATEEN	20h

Function
Controls temperateure derating operation.

Diagram

Fields

Field	Function
31-11 —	Reserved
10-8 rc_derate_value	tRC derate value

Table continues on the next page...

Table continued from the previous page...

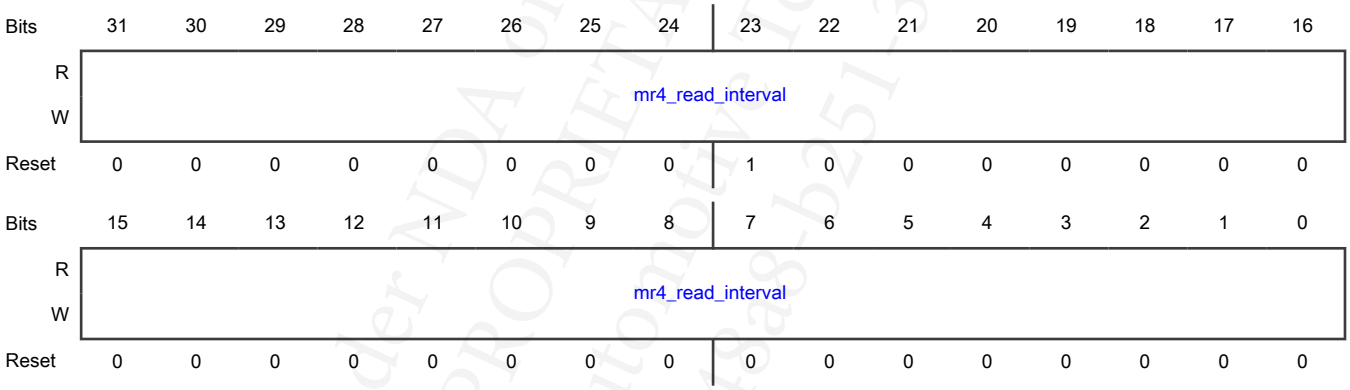
Field	Function
	Specifies the derate value of tRC for LPDDR4 DRAM. Determine the required cycles for derating by dividing 3.75 ns by the core_ddrc_core_clk period and rounding up to the next integer. Set this field to that value minus 1. **NOTE** This field is present only in systems that support LPDDR4 DRAM. Programming Mode: Quasi-dynamic Group 2, Group 4 000b - Derating uses +1 001b - Derating uses +2 010b - Derating uses +3 011b - Derating uses +4
7-4 derate_byte	Derate byte Selects which byte of the MR read data to use for derating. **NOTE** This field is present only in systems that support LPDDR2, LPDDR3, or LPDDR4 DRAM. Programming Mode: Static
3 —	Reserved
2-1 derate_value	Derate value Selects the derating value. **NOTE** This field is present only in systems that support LPDDR2, LPDDR3, or LPDDR4 DRAM. • For all LPDDR2 speed grades: Set to 0 because the derating value of +1.875 ns is less than the core_ddrc_core_clk period. • For LPDDR3 and LPDDR4: If the core_ddrc_core_clk period is less than 1.875 ns, set to 1; otherwise, set to 0. Programming Mode: Quasi-dynamic Group 2, Group 4 00b - Derating uses +1 01b - Derating uses +2
0 derate_enable	Derate enable Enables timing parameter derating using the value in MR4. **NOTE** This field is present only in systems that support LPDDR2, LPDDR3, or LPDDR4 DRAM. It must be 0 for any other DRAM types.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Programming Mode: Dynamic 0b - Disable 1b - Enable

36.14.9 Temperature derate interval (DERATEINT)



Offset

Register	Offset
DERATEINT	24h

Function

Specifies the internal between two MR4 read operations in DFI clock cycles. This interval derates the timing parameters.

Diagram

Fields

Field	Function
31-0 mr4_read_interval	MR4 read interval The interval between two MR4 read operations in DFI clock cycles. **NOTE** • Do not set this field to zero. • This field is present only in systems that support LPDDR2, LPDDR3, or LPDDR4 DRAM. Programming Mode: Static

Provided under NDA only

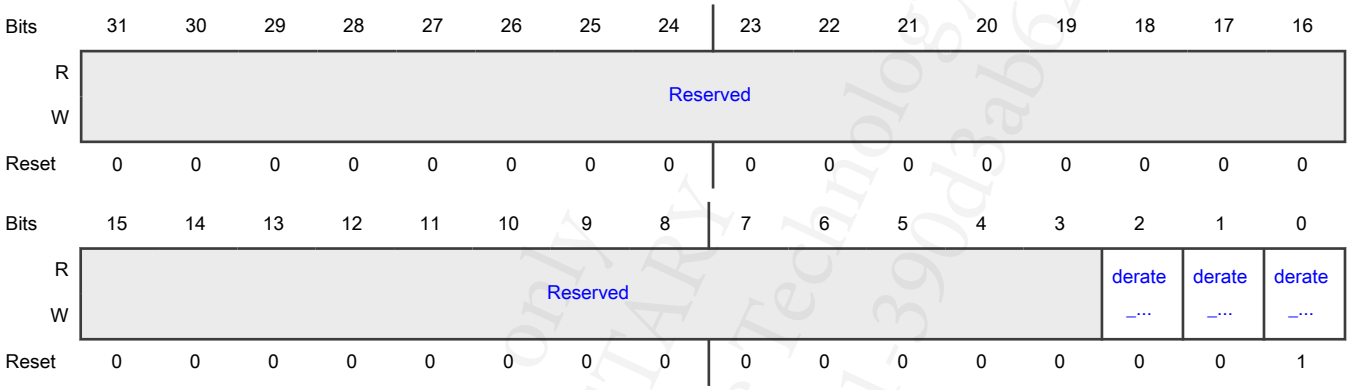
36.14.10 Temperature derate control (DERATECTL)



Offset

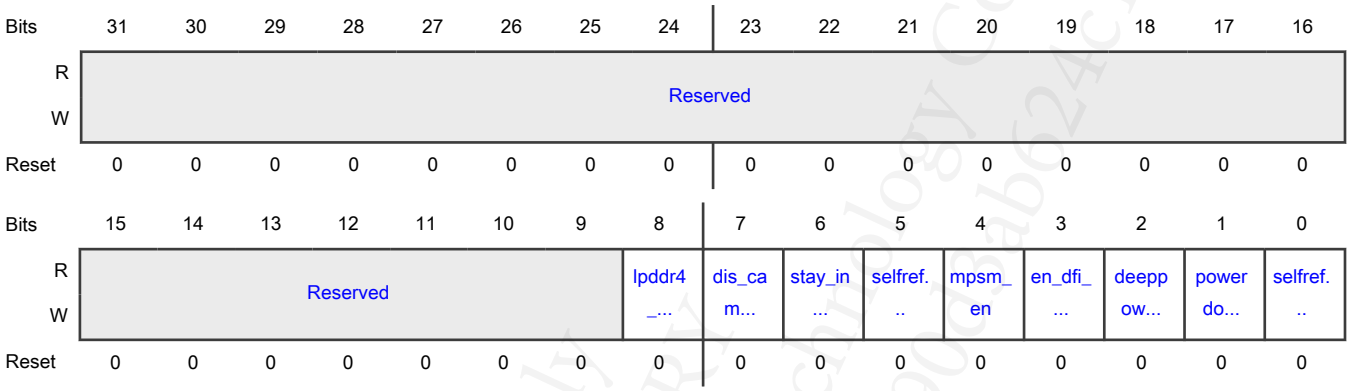
Register	Offset
DERATECTL	2Ch

Function

Specifies temperature derate behavior.

Diagram

Fields



Field	Function
31-3 —	Reserved
2 derate_temp_limit_intr_force	Temperature derate limit interrupt clear Forces assertion of the temperature derate limit interrupt. To force interrupt assertion, write 1 to this field. At the end of the force operation, the MC automatically clears the field. Programming Mode: Dynamic
1 derate_temp_limit_intr_clr	Temperature derate limit interrupt clear Clears the temperature derate limit interrupt. To clear the interrupt, write 1 to this field. At the end of the clear operation, the MC automatically clears the field. Programming Mode: Dynamic
0 derate_temp_limit_intr_en	Temperature derate limit interrupt enable Enables the temperature derate limit interrupt. Programming Mode: Dynamic 0b - Disable 1b - Enable

36.14.11 Low power control (PWRCTL)

Offset

Register	Offset
PWRCTL	30h

Diagram

Fields

Field	Function
31-9 —	Reserved
8 lpddr4_sr_allowed	LPDDR4 SRPD-SR transition Specifies if the transition from Self Refresh Power Down state to Self Refresh state and back is allowed. **NOTE** You cannot modify this field while selfref_sw == 1. Programming Mode: Dynamic 0b - Prohibit transition 1b - Allow transition
7 dis_cam_drain_selfref	Skip CAM draining Specifies whether the MC can put DRAM into the Self Refresh state without draining the content-addressable memory (CAM). **NOTE** • You cannot modify this field while selfref_sw == 1. • This release does not support dis_cam_drain_selfref = 1. dis_cam_drain_selfref must equal 0. Programming Mode: Dynamic

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - CAMs must be drained 1b - CAMs do not have to be drained (unsupported)
6 stay_in_selfref	Stay in self refresh Controls whether the MC can transition DRAM out of the Self Refresh state. Self Refresh is an intermediate state when entering or exiting Self Refresh Power Down for LPDDR4 DRAM. Programming Mode: Dynamic 0b - Allow transition 1b - Prohibit transition
5 selfref_sw	Software self refresh Triggers immediate entry into or exit from the Self Refresh state as long as the MC is not in any of these conditions: • initializing • in the Deep Power Down state • in maximum power saving mode Programming Mode: Dynamic 0b - Exit 1b - Entry
4 mpsm_en	Maximum power saving mode enable Enables the MC to put DRAM into maximum power saving mode (MPSM) when the transaction story is empty. To bring the MC out of MPSM, write 0 to this field. Applies only to systems that support DDR4 DRAM. For all other DRAM types, do not set this field to 1. Affects performance only. If the PHY DWC_AC_CS_USE parameter is disabled, the MC does not support MPSM because the MPSM exit sequence requires the chip-select signal to toggle. **NOTE** If the value of INIT0[skip_dram_init] is 2'b11, you must write 2'b01 to INIT0[skip_dram_init] by entering the self-refresh mode through PWRCTL[selfref_sw], the value of which is 1'b1. This needs to be done before writing 1 to PWRCTL[mpsm_en]. Programming Mode: Dynamic 0b - Disable 1b - Enable
3 en_dfi_dram_clk_disable	Enable DFI DRAM clock disable

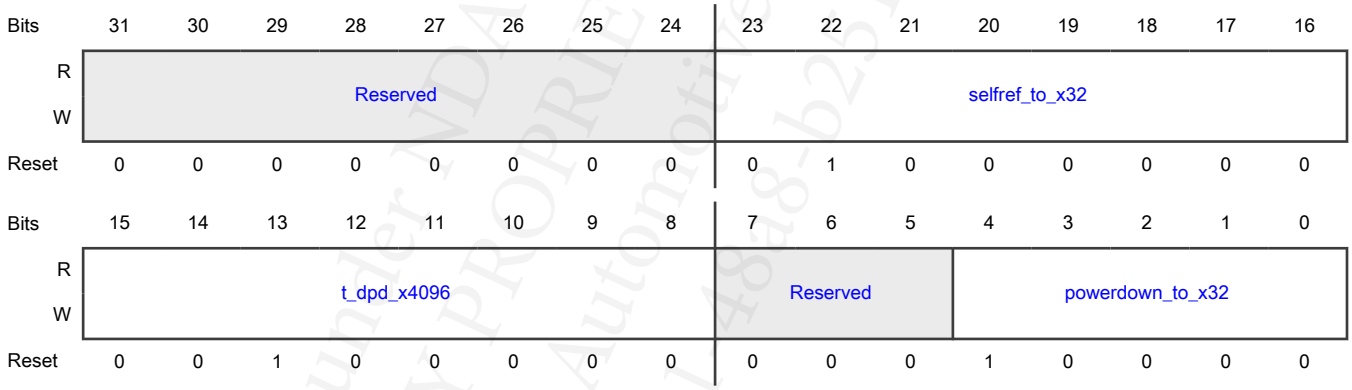
Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the MC to assert DFI DRAM Clock Disable (dfi_dram_clk_disable) if a clock is not required by the DRAM. The MC can assert DFI DRAM Clock Disable under the following restrictions: • DDR2 or DDR3: can only be asserted in the Self Refresh state • DDR4: can be asserted in the following states: — Self Refresh — Maximum Power Saving • mDDR, LPDDR2, LPDDR3: can be asserted in the following states: — Self Refresh — Power Down — Deep Power Down — Normal operation (clock stop) • LPDDR4: can be asserted in the following states: — Self Refresh Power Down — Power Down — Deep Power Down — Normal operation (clock stop) Programming Mode: Dynamic 0b - Disable 1b - Enable
2 deeppowerdown_en	Deep power down enable Enables the MC to put DRAM into the Deep Power Down state when the transaction store is empty. To bring the MC out of Deep Power Down, write 0 to this field. The MC performs automatic DRAM initialization when exiting Deep Power Down. **NOTE** • Applies only to systems that support mDDR, LPDDR2, or LPDDR3 DRAM. For all other DRAM types, do not set this field to 1. • Affects performance only. Programming Mode: Dynamic
1 powerdown_en	Power down enable Enables the MC to put DRAM into the Power Down state after a programmable number of cycles (PWRTMG[powerdown_to_x32]). Programming Mode: Dynamic 0b - Disable

Table continues on the next page...

Table continued from the previous page...



Field	Function
	1b - Enable
0 selfref_en	Self-refresh enable Enables the MC to put DRAM into the Self Refresh state after a programmable number of cycles (PWRTMG[selfref_to_x32]). Programming Mode: Dynamic 0b - Disable 1b - Enable

Field	Function
	Specifies the time period, in multiples of 32 DFI clock cycles, before the critical refresh or page timer expires. You must issue a critical refresh before the end of this time. The recommended value is the default value of 2h. **NOTE** • This value must always be less than the internal t_rfc_nom/32. If RFSHTMG[t_rfc_nom_x1_sel]is equal to 0, then t_rfc_nom is equal to (RFSHTMG[t_rfc_nom_x1_x32] * 32). If RFSHTMG[t_rfc_nom_x1_sel]is equal to 1 (for LPDDR2, LPDDR3, and LPDDR4 per-bank refresh only), then t_rfc_nom is equal to RFSHTMG[t_rfc_nom_x1_x32]. • For LPDDR2, LPDDR3, or LPDDR4, if derating is enabled (DERATEEN[derate_enable]), the internal t_rfc_nom may be divided by four. Programming Mode: Dynamic - Refresh Related
19-17 —	Reserved
16-12 refresh_to_x1_x32	Speculative refresh period Specifies the time of the DRAM bus being idle before the MC initiates a speculative refresh, if the refresh timer (tRFCnom, also known as tREFI) has expired at least once but not enough times to trigger a burst refresh (refresh_burst + 1). The specified value is in DFI clock cycles or multiples of 32 DFI clock cycles depending on RFSHTMG[t_rfc_nom_x1_sel]. Speculative refreshes continue successively until there are no pending refreshes or until the MC receives new read or write commands. **NOTE** Affects performance only. Programming Mode: Dynamic - Refresh Related
11-10 —	Reserved
9-4 refresh_burst	Burst refresh Specifies the number refresh timeouts allowed to accumulate before the MC blocks traffic and forces the refreshs to execute. Closing pages to perform a refresh encurs a one-time penalty for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty for page closings.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	A higher number for refresh_burst slightly increases utilization; a lower number decreases the worst-case latency associated with refreshes. **NOTE** • For information about burst refresh, see section 3.9 of the DDR2 JEDEC specification, JESD79-2F.pdf. • For DDR2 and DDR3, refresh is always per rank, not per bank. Rank refresh can be accumulated over (8 * tREFI) cycles using burst refresh. • For DDR4, in Fine Granularity Refresh state, you can postpone up to 8 refreshes in 1X mode, 16 refreshes in 2X mode, and 32 refreshes in 4X mode. If using PHY-initiated updates, you must ensure that tRFCmax is not violated due to a PHY-initiated update occurring shortly before a refresh burst is due. In this situation, the MC delays the refresh burst until the PHY-initiated update is complete. • For LPDDR2, LPDDR3, and LPDDR4, in per-bank refresh (per_bank_refresh == 1) you postpone up to 64 refreshes. Programming Mode: Dynamic - Refresh Related 000000b - One-refresh burst 000001b - Two-refresh burst All other values - (Value + 1)-refresh burst
3 —	Reserved
2 per_bank_refresh	Per-bank refresh enable Enables per bank refresh, which allows traffic to flow to other banks while each bank refreshes. **NOTE** • This field is present only in systems that support LPDDR2, LPDDR3, or LPDDR4 DRAM. It must be 0 for any other DRAM types. • Per-bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3 and LPDDR4 devices. Programming Mode: Static 0b - All-bank refresh 1b - Per bank refresh
1-0 —	Reserved

RFSHCTL3	60h

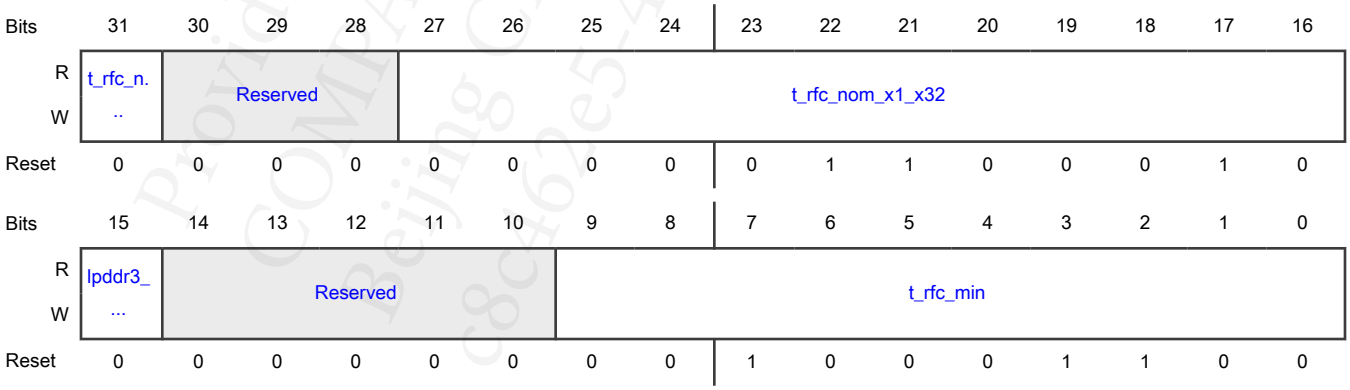
Diagram

Fields

Field	Function
31-7 —	Reserved
6-4 refresh_mode	Fine granularity refresh mode Selects the Fine Granularity Refresh (FGR) mode of operation. **NOTE** • This field applies only to DDR4 DRAM (MSTR[ddr4]equal to 1). • You must set the FGR mode while the MC is in the Reset or Self Refresh states. Changing FGR mode during normal operation is not allowed. Making this a dynamic register will be supported in future version of the MC. • If auto-refresh is disabled (dis_auto_refresh == 1), only Fixed 1x mode is supported. • The on-the-fly modes are not supported in this version of the MC. Programming Mode: Quasi-dynamic Group 2 000b - Fixed 1x (normal mode) 001b - Fixed 2x 010b - Fixed 4x All other values - Reserved
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...



Field	Function
—	
1 refresh_update_level	Refresh update level Specifies by toggling (from 0 to 1 or 1 to 0) that the refresh registers have been updated. The MC automatically updates the refresh registers when exiting reset. **NOTE** Do not toggle this field when the MC is in reset (core_ddrc_rstn == 0). Programming Mode: Dynamic
0 dis_auto_refresh	Auto refresh disable Disables auto-refresh generated by the MC. When auto-refresh is disabled, the SoC core must generate refreshes using DBGCMD[rankn_refresh]. When dis_auto_refresh transitions from 0 to 1, the MC immediately schedules any pending refreshes. **NOTE** • You can change this field on the fly. • For DDR4: If Fine Granularity Refresh is enabled (RFSHCTL3[refresh_mode]), this field must be 0. Programming Mode: Dynamic - Refresh Related 0b - Enable 1b - Disable

36.14.17 Refresh Timing (RFSHTMG)

Offset

Register	Offset
RFSHTMG	64h

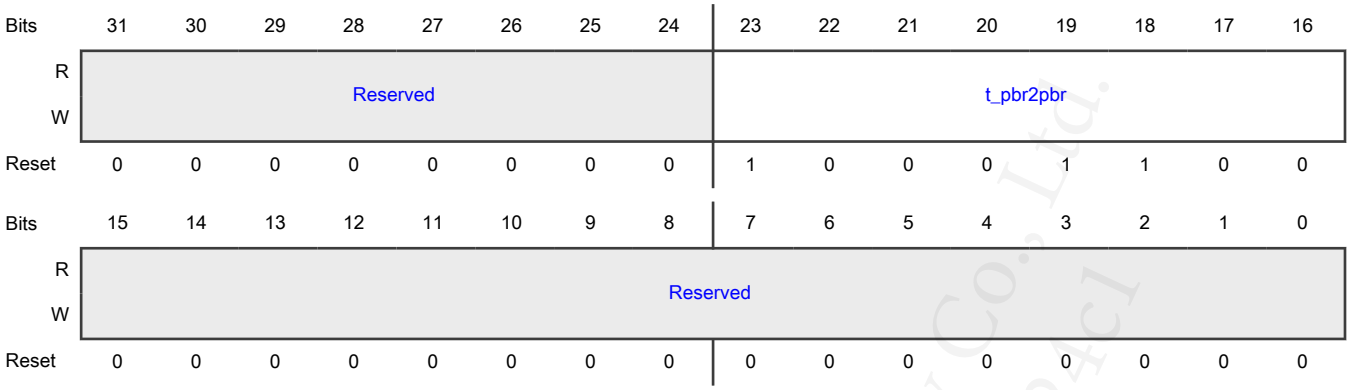
Diagram

Fields

Field	Function
31 t_rfc_nom_x1_sel	Refresh units Specifies whether the t_rfc_nom_x1_x32 and RFSHCTL0[refresh_to_x1_x32] values are in DFI clock cycles or multiples of 32 DFI clock cycles (x1 or x32). Programming Mode: Dynamic - Refresh Related
30-28 —	Reserved
27-16 t_rfc_nom_x1_x32	Average refresh interval per rank Specifies the average time interval between refreshes per rank. The specified value is in DFI clock cycles or multiples of 32 DFI clock cycles depending on RFSHTMG[t_rfc_nom_x1_sel]. When the MC is operating at: • 1:1 frequency ratio, set t_rfc_nom_x1_x32 to RoundUp(tRFCI/tCK) • 1:2 frequency ratio, set t_rfc_nom_x1_x32 to RoundUp(RoundUp(tRFCI/tCK)/2) In both cases, if t_rfc_nom_x1_sel == 0, divide the result by 32 and round down. **NOTE** • For DDR2, DDR3, and DDR4: JEDEC specifies 7.8 µs. • For DDR4: The tREFI value depends on the refresh mode. You should program the appropriate value from the specification based on RFSHCTL3[refresh_mode]. • For mDDR, LPDDR2, LPDDR3, and LPDDR4: See the relevant JEDEC specification. • For LPDDR2, LPDDR3, and LPDDR4: — If using all-bank refreshes (RFSHCTL0[per_bank_refresh] equal to 0), use tREFIab in the above calculations. — If using per-bank refreshes (RFSHCTL0[per_bank_refresh] equal to 1), use tREFIpb in the above calculations. **NOTE** • t_rfc_nom_x1_x32 must be greater than 1. • If t_rfc_nom_x1_sel == 1, t_rfc_nom_x1_x32 must be greater than t_rfc_min. • If t_rfc_nom_x1_sel == 0, t_rfc_nom_x1_x32 * 32 must be greater than t_rfc_min. • For non-DDR4 or DDR4 in Fixed 1x mode: t_rfc_nom_x1_x32 must be less than or equal to 0xFFE. • For DDR4 in Fixed 2x mode: t_rfc_nom_x1_x32 must be less than or equal to 0x7FF. • For DDR4 in Fixed 4x mode: t_rfc_nom_x1_x32 must be less than or equal to 0x3FF. Programming Mode: Dynamic - Refresh Related
15 lpddr3_trefbw_en	Burst refresh window parameter enable

Table continues on the next page...

Table continued from the previous page...



Field	Function
	Specifies whether to use the Burst Refresh Window (tREFBW) parameter. **NOTE** This field applies only to certain LPDDR3 DRAM devices that comply with earlier versions of the JEDEC LPDDR3 specification. Programming Mode: Static 0b - tREFBW not used 1b - tREFBW used
14-10 —	Reserved
9-0 t_rfc_min	Refresh cycle time minimum Specifies the minimum time in DFI clock cycles from refresh to refresh or refresh to activate. When the MC is operating at: • 1:1 frequency ratio, set t_rfc_min to RoundUp(tRFCmin/tCK) • 1:2 frequency ratio, set t_rfc_min to RoundUp(RoundUp(tRFCmin/tCK)/2) **NOTE** • For LPDDR2, LPDDR3, and LPDDR4: — If using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab. — If using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb. • For DDR4: The tRFCmin value in the above equations depends on the refresh mode (fixed 1X, 2X, or 4X) and the device density. Programming Mode: Dynamic - Refresh Related

23-16 t_pbr2pbr	Per-bank refresh to per-bank refresh different bank time Specifies the time interval between a per-bank refresh and a per-bank refresh of a different bank. When the MC is operating at: • 1:1 frequency ratio, set t_pbr2pbr to RoundUp(tpbR2pbR/tCK) • 1:2 frequency ratio, set t_pbr2pbr to RoundUp(RoundUp(tpbR2pbR/tCK)/2) **NOTE** • This field applies only to LPDDR DRAM in per-bank refresh (RFSHCTL0[per_bank_refresh]). • The tpbR2pbR value in the above equations depends on the device density. You should program the appropriate value from the JEDEC LPDDR4 spec. Programming Mode: Dynamic - Refresh Related
15-0 —	Reserved

36.14.19 ECC Configuration 0 (ECCCFG0)

Offset

Register	Offset
ECCCFG0	70h

Diagram

Fields

Field	Function
31-30 ecc_region_map_granu	Selectable protected region granularity Specifies the portion of memory space occupied by each selectable protected region in the ECC region map (ecc_region_map). Programming Mode: Static 00b - 1/8 of memory space 01b - 1/16 of memory space 10b - 1/32 of memory space 11b - 1/64 of memory space
29-27 —	Reserved
26-24 ecc_ap_err_threshold	Address parity error threshold Specifies the number of ECC errors (correctable or uncorrectable) that can occur within one burst before the MC indicates an ECC address parity error (ECCAPSTAT[ecc_ap_err]). The value must be less than the total number of ECC checks within one burst: (DRAM Data width) x (DRAM BL)/64 Programming Mode: Static
23-22 —	Reserved
21-16 blk_channel_idle_time_x32	Block channel idle time Specifies the time interval, in multiples of 32 DFI clock cycles, of no access through the host interface (HIF) to protected regions that causes the MC to flush all block channels. To flush a block channel, the MC injects a write ECC command if there is any write in the block and then stops tracking the block address. Programming Mode: Quasi-dynamic Group 3

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000000b - Invalid value.
15 —	Reserved
14-8 ecc_region_map	Selectable protected region map Specifies which of the lowest seven memory regions (the selectable protected regions) are protected with ECC. Each bit corresponds to each of the lowest seven regions, with the lsb corresponding to the lowest address region. Unselected regions (corresponding bit == 0) are unprotected. This field interacts with ecc_region_map_granu, which specifies how many regions the total memory space is divided into: 8, 16, 32, or 64 regions. For example: To protect all of the memory space: • ecc_region_map = 0b1111111 • ecc_region_map_granu = 0 (eight total regions) To protect only the first 1/64 of the memory space: • ecc_region_map = 0b0000001 • ecc_region_map_granu = 3 (64 total regions) In this last example, the region map is: • Regions 63–56 are dedicated ECC. • Regions 55–7 are not protected (not in the selectable protected regions) • Regions 6–1 are not protected (corresponding bits = 0) • Region 0 is protected (corresponding bit = 1) **NOTE** • The highest 1/8 of the memory space is always an ECC region. • If inline ECC is enabled (ecc_mode == 1), 0b0000000 is an invalid value. You must specify at least one protected region. Programming Mode: Quasi-dynamic Group 3
7 —	Reserved
6 ecc_ap_en	Address protection enable Enables address protection. This field applies only in inline ECC mode. Programming Mode: Static 0b - Disable 1b - Enable

Table continues on the next page...

Fields

Field	Function
31-12 —	Reserved
11-8 active_blk_channel	Active block channels Specifies the number of active block channels. Use this value to limit the number of available channels. For example, set this value to 0 to have only one active channel, and therefore disable block interleaving. Programming Mode: Quasi-dynamic Group 3
7 blk_channel_active_term	Block channel active terminate enable Enables termination of block channel on a full-block read or write (all addresses within the block are read or written). Programming Mode: Static 0b - Disable (use only for debug purposes) 1b - Enable (default for normal operation)
6 —	Reserved
5 ecc_region_waste_lock	ECC waste region lock Locks the portion of the ECC region that is not either the ECC parity section or a designated selectable protected region. When locked, an access of this region generates an error. When unlocked, you can access the region like any other non-ECC protected region. 0b - Unlocked 1b - Locked
4 ecc_region_parity_lock	ECC parity section lock

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Locks the parity section of the ECC region, the highest 1/8 of memory address space. This region stores ECC parity data for the protected region. When locked, an access of this region generates an error. When unlocked, you can access the region like any other non-ECC protected region. Programming Mode: Quasi-dynamic Group 3 0b - Unlocked 1b - Locked
3-2 —	Reserved
1 data_poison_bit	Data poison bits Selects one or two bits of data poisoning. Applies only if ECC data poisoning is enabled (data_poison_en). Programming Mode: Quasi-dynamic Group 3 0b - Two bits (uncorrectable) 1b - One bit (correctable)
0 data_poison_en	ECC data poisoning enable Enables ECC data poisoning. When ECC data poisoning is enabled, the MC introduces errors on writes to the address specified by ECCPOISONADDR0 and ECCPOISONADDR1. Programming Mode: Quasi-dynamic Group 3 "ECC Data Poisoning is not supported with INLINE-ECC feature (you must write 0 to ECCCFG1[data_poison_en]). There is a software method to inject errors to ECC parity bits with inline ECC. **Software method:** Errors can be easily injected through the software by unlocking the ECC region through the ecc_region_parity_lock register and overriding certain ECC parity bits. When the corresponding addresses are read from a protected memory region, ECC errors are generated as correctable or uncorrectable, depending on the type of error introduced."

36.14.50 DIMM Control (DIMMCTL)

Offset

Register	Offset
DIMMCTL	F0h

Diagram

Fields

Field	Function
31-15 —	Reserved
14	Disable RCD outputs to B-side DRAMs. This field is used only when the uMCTL2 disables CAL mode. This value is written to F0RC0 DA[3] before and after disabling CAL mode. It is recommended to set

Table continues on the next page...

Table continued from the previous page...

Field	Function
rcd_b_output_disabled	it to ~DIMMCTL.dimm_output_inv_en except for debug. - 1 - Disable B outputs - 0 - Enable B outputs Programming Mode: Static
13 rcd_a_output_disabled	Disable RCD outputs to A-side DRAMs. This field is used only when the uMCTL2 disables CAL mode. This value is written to F0RC0 DA[2] before and after disabling CAL mode. It is recommended to set it to 0 except for debug. - 1 - Disable A outputs - 0 - Enable A outputs Programming Mode: Static
12 rcd_weak_drive	Weak Drive mode to set to the RCD. This field is used only when the uMCTL2 disables CAL mode. When weak drive mode in the RCD is enabled during initialization, this field should be set to 1. When RCD is not used, this field should be set to 0. - 1 - Enable Weak Drive mode - 0 - Disable Weak Drive mode Programming Mode: Static
11-7 —	Reserved
6 lrdimm_bcom_cmd_prot	Protects the timing restrictions (tBCW/tMRC) between consecutive BCOM commands defined in the Data Buffer specification. When using DDR4 LRDIMM, this bit must be set to 1. Otherwise, this bit must be set to 0. Programming Mode: Static
5 dimm_dis_bg_mirroring	Disabling Address Mirroring for BG bits. When this is set to 1, BG0 and BG1 are NOT swapped even if Address Mirroring is enabled. This will be required for DDR4 DIMMs with x16 devices. - 1 - BG0 and BG1 are NOT swapped. - 0 - BG0 and BG1 are swapped if address mirroring is enabled. Programming Mode: Static
4 mrs_bg1_en	Enable for BG1 bit of MRS command. BG1 bit of the mode register address is specified as RFU (Reserved for Future Use) and must be programmed to 0 during MRS. In case where DRAMs which do not have BG1 are attached and both the CA parity and the Output Inversion are enabled, this must be set to 0, so that the calculation of CA parity will not include BG1 bit. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. If address mirroring is enabled, this is applied to BG1 of even ranks and BG0 of odd ranks. - 1 - Enabled - 0 - Disabled Programming Mode: Static
3 mrs_a17_en	Enable for A17 bit of MRS command. A17 bit of the mode register address is specified as RFU (Reserved for Future Use) and must be programmed to 0 during MRS. In case where DRAMs which do not have A17 are attached as DDR4 RDIMM/LRDIMM and the Output Inversion is enabled, this must be set to 0, so that the calculation of CA parity will not include A17 bit. To keep a consistency with the RCD, DA[3] in F0RC08 of the RCD also needs to be set to 1 (i.e. Disabled) Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. - 1 - Enabled - 0 - Disabled Programming Mode: Static
2 dimm_output_inv_en	Output Inversion Enable (for DDR4 RDIMM/LRDIMM implementations only). DDR4 RDIMM/LRDIMM implements the Output Inversion feature by default, which means that the following address, bank address and bank group bits of B-side DRAMs are inverted: A3-A9, A11, A13, A17, BA0-BA1, BG0-BG1. Setting this bit ensures that, for mode register accesses generated by the uMCTL2 during the automatic initialization routine and enabling of a particular DDR4 feature, separate A-side and B-side mode register accesses are generated. For B-side mode register accesses, these bits are inverted within the uMCTL2 to compensate for this RDIMM/LRDIMM inversion. It is recommended to set this bit always, if using DDR4 RDIMMs/LRDIMMs. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. - 1 - Implement output inversion for B-side DRAMs. - 0 - Do not implement output inversion for B-side DRAMs. Programming Mode: Static

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 dimm_addr_mirr_en	Address Mirroring Enable (for multi-rank UDIMM implementations and multi-rank DDR4 RDIMM/LRDIMM implementations). Some UDIMMs and DDR4 RDIMMs/LRDIMMs implement address mirroring for odd ranks, which means that the following address, bank address and bank group bits are swapped: (A3, A4), (A5, A6), (A7, A8), (BA0, BA1) and also (A11, A13), (BG0, BG1) for the DDR4. Setting this bit ensures that, for mode register accesses during the automatic initialization routine, these bits are swapped within the uMCTL2 to compensate for this UDIMM/RDIMM/LRDIMM swapping. In addition to the automatic initialization routine, in case of DDR4 UDIMM/RDIMM/LRDIMM, they are swapped during the automatic MRS access to enable/disable of a particular DDR4 feature. Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses. This is not supported for mDDR, LPDDR2, LPDDR3 or LPDDR4 SDRAMs. Note: In case of x16 DDR4 DIMMs, BG1 output of MRS for the odd ranks is same as BG0 because BG1 is invalid, hence dimm_dis_bg_mirroring register must be set to 1. - 1 - For odd ranks, implement address mirroring for MRS commands to during initialization and for any automatic DDR4 MRS commands (to be used if UDIMM/RDIMM/LRDIMM implements address mirroring) - 0 - Do not implement address mirroring Programming Mode: Static
0 dimm_stagger_cs_en	Staggering enable for multi-rank accesses (for multi-rank UDIMM, RDIMM and LRDIMM implementations only). This is not supported for mDDR, LPDDR2, LPDDR3 or LPDDR4 SDRAMs. Note: Even if this bit is set it does not take care of software driven MR commands (via MRCTRL0/MRCTRL1), where software is responsible to send them to seperate ranks as appropriate. - 1 - (DDR4) Send MRS commands to each ranks seperately - 1 - (non-DDR4) Send all commands to even and odd ranks seperately - 0 - Do not stagger accesses Programming Mode: Static

Field	Function
31-12 —	Reserved
11-8 diff_rank_wr_gap	Different rank write gap Specifies the time gap in DFL clock cycles between data responses when performing consecutive writes to differnt ranks. Use this field to switch PHY delays to match the rank requirements. You should consider both the PHY and ODT requirements when specifying this value: • PHY requirement: — tphy_wrcsgap (see the PHY databook for this value) — If CRC is enabled, increase the gap value by 1. — If write preamble is set to 2tCK (DDR4 only), increase the gap value by 1. — If write postamble is set to 1.5tCK (LPDDR4 only), increase the gap value by 1. • ODT requirement: — The value in this register takes care of the ODT switch-off timing requirement when switching ranks during writes. — For LPDDR4: With DQ ODT enabled, the gap value must be a minimum of: ODTLoff – ODTLon – BL/2 + 1 When the MC is operating at: • 1:1 frequency ratio, diff_rank_wr_gap should be the larger of the PHY requirement or the ODT requirement. • 1:2 frequency ratio, diff_rank_wr_gap should be the larger value divided by two and rounded up to the next integer. **NOTE** • This field applies only to multi-rank configurations. • For DDR4-LRDIMM, refer to the TWRRD timing requirements in the JEDEC DDR4 Data Buffer (DDR4DB01) specification. • For other DRAM: the gap value must be a minimum of ODTCFG[wr_odt_hold] – BL/2. Programming Mode: Quasi-dynamic Group 2
7-4 diff_rank_rd_gap	Different rank read gap Specifies the time gap in DFL clock cycles between data responses when performing consecutive reads to differnt ranks. Use this field to switch PHY delays to match the rank requirements. You should consider both the PHY and ODT requirements when specifying this value: • PHY requirement: — tphy_rdcsgap (see the PHY databook for this value) — If read preamble is set to 2tCK (DDR4 only), increase the gap value by 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— If read postamble is set to 1.5tCK (LPDDR4 only), increase the gap value by 1. • ODT requirement: — The value in this register takes care of the ODT switch-off timing requirement when switching ranks during reads: diff_rank_rd_gap must be a minimum of ODTCFG[rd_odt_hold] – BL/2. When the MC is operating at: • 1:1 frequency ratio, diff_rank_rd_gap should be the larger of the PHY requirement or the ODT requirement • 1:2 frequency ratio, diff_rank_rd_gap should be the larger value divided by two and rounded up to the next integer **NOTE** • This field applies only to multi-rank configurations. • For DDR4-LRDIMM, refer to the TRDRD timing requirements in the JEDEC DDR4 Data Buffer (DDR4DB01) specification. Programming Mode: Quasi-dynamic Group 2
3-0 max_rank_rd	Rank Maximum Reads Specifies the maximum number of reads that can be scheduled consecutively to the same rank. Reads to the same rank can be performed back-to-back. Reads to different ranks require additional gap, which you specify in diff_rank_rd_gap. This is to avoid possible data bus contention as well as to give PHY enough time to switch the delay when changing ranks. The MC arbitrates for bus access on a cycle-by-cycle basis; therefore, after a read is scheduled, there are only a few clock cycles (determined by the value in diff_rank_rd_gap) in which only reads from the same rank are eligible to be scheduled. This prevents reads from other ranks from having fair access to the data bus. After the numbers of consecutive reads specified in this field, the scheduler inserts a delay equal to diff_rank_rd_gap to allow all ranks a fair opportunity to be scheduled. Higher numbers increase bandwidth utilization, lower numbers increase fairness. You can disable this feature by setting this field to 0. When set to 0, the MC stays on the same rank as long as commands are available for it. The minimum programmable value is 0 (feature disabled) and the maximum is Fh. FOR PERFORMANCE ONLY. **NOTE** • Applies to multi-rank configurations. • Affects performance only. Programming Mode: Static

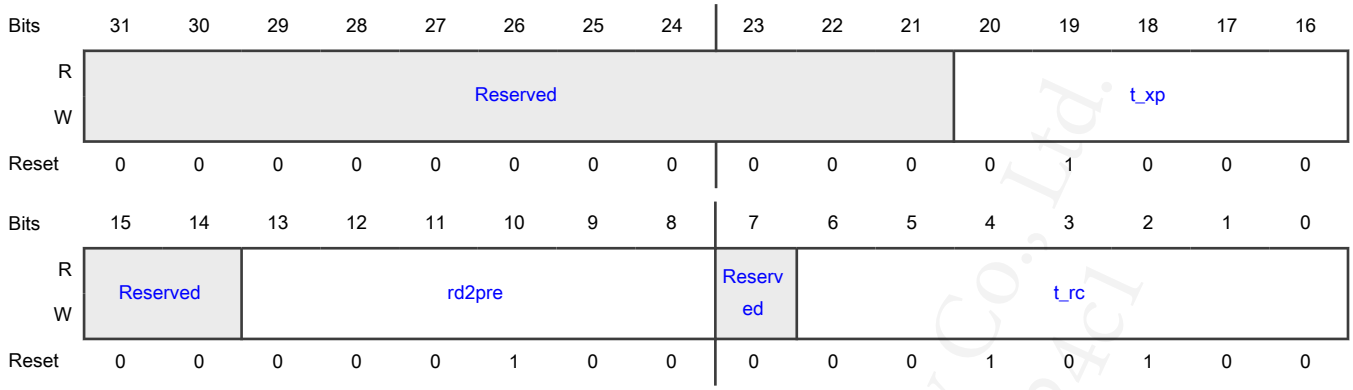
Fields

Field	Function
31 —	Reserved
30-24 wr2pre	Write to precharge minimum interval Specifies the minimum time interval, in DFI clock cycles, between write and precharge to the same bank. Use the following equation to determine the correct value: (WL + BL/2 + tWR) + 15 ns where: • WL is write latency. • BL is burst length. This must match the value in the BL field of the mode register to the DRAM. The MC does not support BST (burst terminate) at this time. • tWR is write recovery time. This comes directly from the DRAM specification. The parenthetical portion of the equation equals approximately eight cycles. Therefore, at 400 MHz, wr2pre should be 14 clock cylces. The value is less at lower frequencies. For LPDDR2, LPDDR3, and LPDDR4, add one extra cycle. When the MC is operating at: • 1:2 frequency ratio and 1T command timing, divide the above value by 2 (no rounding up). • 1:2 frequency ratio and 2T command timing or LPDDR4, divide the above value by 2 and round up. **NOTE** Depending on the PHY, when using LRDIMM you may need to adjust wr2pre to compensate for the extra cycle of latency through the LRDIMM. Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4
23-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...



Field	Function
21-16 t_faw	Four active window (tFAW) Specifies the sliding time window, in DFI clock cycles, in which a maximum of 4-bank activates are allowed in an 8-bank configuraiton. When the MC is operating in 1:2 frequency ratio, t_faw should be RoundUp(tFAW/2). In a 4-bank design, set t_faw to 1h independent of the frequency ratio. **NOTE** This field applies only when eight or more banks (or banks x bank groups) are present. Programming Mode: Quasi-dynamic Group 2, Group 4
15 —	Reserved
14-8 t_ras_max	Activate to precharge maximum interval Specifies the maximum time interval, in multiples of 1024 DFI clock cycles, between activate and precharge to the same bank: tRAS(max). This is the maximum time that a page can be kept open. When the MC is operating at: • 1:1 frequency ratio, t_ras_max should be RoundDown(tRAS(max)/tCK/1024). • 1:2 frequency ratio, t_ras_max should be RoundDown((RoundDown(tRAS(max)/tCK/1024) – 1)/2) Programming Mode: Quasi-dynamic Group 2, Group 4 0000000b - Invalid value
7-6 —	Reserved
5-0 t_ras_min	Activate to precharge minimum interval Specifies the minimum time interval, in DFI clock cycles, between activate and precharge to the same bank: tRAS(min). When the MC is operating at: • 1:2 frequency ratio and 1T command timing, t_ras_min should be tRAS(min)/2 (no rounding up) • 1:2 frequency ratio and 2T command timing or LPDDR4 mode, t_ras_min should be RoundUp(tRAS(min)/2) Programming Mode: Quasi-dynamic Group 2, Group 4

Fields

Field	Function
31-30 —	Reserved
29-24 write_latency	Write latency Specifies the time interval, in DFI clock cycles, from a write command to write data on the DRAM interface. You must set this to WL (write latency). When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up to the next integer. **NOTE** • This field does not apply to DDR2 and DDR3 (unless MEMC_TRAINING is set), because the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols. • For all protocols, you must also program DFITMG0 and DFITMG1 to control the read and write latencies. Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4
23-22 —	Reserved
21-16 read_latency	Read Latency Specifies the time interval, in DFI clock cycles, from a read command to read data on the DRAM interface. You must set this to RL (read latency). When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up to the next integer. **NOTE** • This field does not apply to DDR2 and DDR3 (unless MEMC_TRAINING is set), because the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols. • For all protocols, you must also program DFITMG0 and DFITMG1 to control the read and write latencies. Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4
15-14 —	Reserved
13-8 rd2wr	Read To Write Minimum Time Specifies the minimum time interval, in DFI clock cycles, from a read command to a write command. For DDR4, it's the minimum interval from a read command to a write command for the same bank. This interval includes the time for bus turnaround, and all per-bank, per-rank, and global constraints. Use the following equations to determine the correct value:

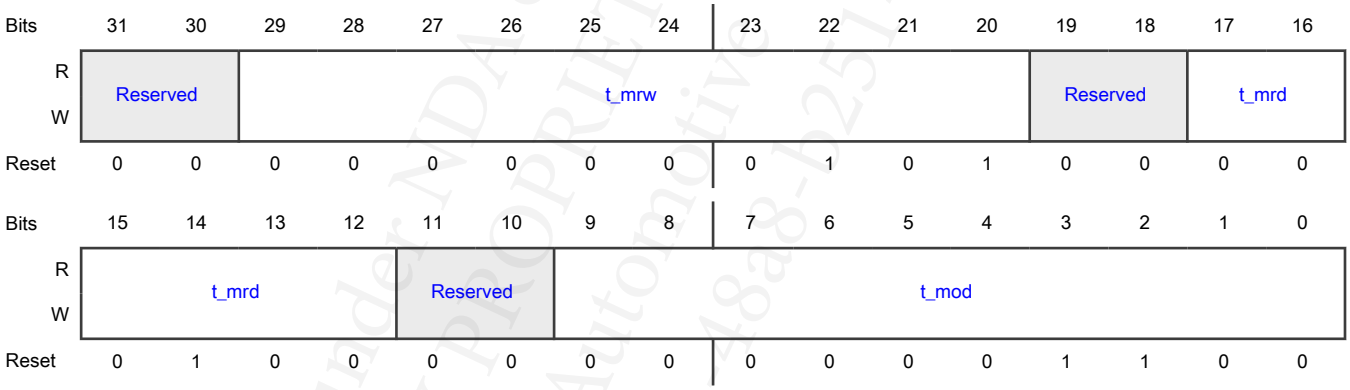
Table continues on the next page...

Table continued from the previous page...

Field	Function
	• DDR2, DDR3, mDDR: RL + BL/2 + 2 - WL • DDR4: RL + BL/2 + 1 + WR_PREAMBLE - WL • LPDDR2, LPDDR3: RL + BL/2 + RU(tDQSCKmax/tCK) + 1 - WL • LPDDR4 (DQ ODT Disabled): RL + BL/2 + RU(tDQSCKmax/tCK) + WR_PREAMBLE + RD_POSTAMBLE - WL • LPDDR4 (DQ ODT Enabled): RL + BL/2 + RU(tDQSCKmax/tCK) + RD_POSTAMBLE - ODTLon - RU(tODTon(min)/tCK) + 1 Where: • WL is write latency • BL is burst length. Must match the value programmed in the BL bit of the DRAM Mode Register. • RL is read latency (CAS latency) • WR_PREAMBLE is 1 for 1tCK write preamble or 2 for 2tCK write preamble. Unique to DDR4 and LPDDR4. • RD_POSTAMBLE is 0.5 for 0.5tCK read postamble or 1.5 for 1.5tCK read postamble. This is unique to LPDDR4. For LPDDR2, LPDDR3, or LPDDR4, if derating is enabled (DERATEEN[derate_enable] is equal to 1), you should use derated tDQSCKmax. When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up to the next integer. Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4
7-6 — 5-0 wr2rd	Reserved Write To Read Minimum Time Specifies the minimum time interval, in DFI clock cycles, from a write command to a read command. For DDR4, it's the minimum interval from a write command to a read command for the same bank. This interval includes the time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Use the following equations to determine the correct value: • DDR4: CWL + PL + BL/2 + tWTR_L • LPDDR2, LPDDR3, LPDDR4: WL + BL/2 + tWTR + 1 • Others: CWL + BL/2 + tWTR Where: • CWL is CAS write latency • WL is write latency • PL is parity latency

Table continues on the next page...

Table continued from the previous page...



Field	Function
	• BL is burst length. Must match the value programmed in the BL bit of the DRAM Mode Register. • tWTR_L is internal write to read command delay for same bank group (directly from the DRAM specification). For DDR4, if using 2tCK write preamble, increase by one. • tWTR is internal write to read command delay (directly from the DRAM specification). When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up to the next integer. Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Field	Function
31-30 —	Reserved
29-20 t_mrw	tMRW Specifies the time interval, in DFI clock cycles, to wait after a Mode Register write (MRW) or Mode Register read (MRR) for LPDDR2, LPDDR3, or LPDDR4 DRAM. For LPDDR2 DRAM, specifies the time interval from MRW or MRR to all other commands. For LPDDR3 DRAM, specifies the time internal from MRW or MRR to another MRW or MRR.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Depending on the type of DRAM, follow these guidelines: • LPDDR2: typically requires a value of 5 • LPDDR3: typically requires a value of 10 • LPDDR4: Set to the larger of tMRW or TMRWCKEL When the MC is operating at 1:2 frequency ratio, divide value calculated above by 2 and round up to next integer. Programming Mode: Quasi-dynamic Group 2, Group 4
19-18 —	Reserved
17-12 t_mrd	tMRD Specifies the time interval, in DFI clock cycles, to wait after a MR write or read. Depending on the type of DRAM, tMRD is: • DDR2, mDDR: the time from MRS to any command • DDR3, DDR4: the time from MRS command to MRS command • LPDDR2: not used • LPDDR3, LPDDR4: the time from MRS command to non-MRS command Apply the following modifications to tMRD as necessary: • If CAL mode is enabled (DFITMG1[dfi_t_cmd_lat] > 0): add tCAL • For DDR4: If using C/A parity, use tMRD_PAR(tMOD + PL) instead When the MC is operating at 1:2 frequency ratio, use RoundUp(tMRD/2). Programming Mode: Quasi-dynamic Group 2, Group 4
11-10 —	Reserved
9-0 t_mod	tMOD Specifies the time interval, in DFI clock cycles, between a load mode (MR) command and a following non-load mode command. This field applies only to DDR3 and DDR4. Apply the following modifications to tMOD as necessary: • If CAL mode is enabled (DFITMG1[dfi_t_cmd_lat] > 0): add tCAL • For DDR4: — If using C/A parity, tMOD_PAR(tMOD + PL) — If using MPR writes, tMOD + AL

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— If using MPR writes and C/A parity, tMOD_PAR + AL When the MC is operating at 1:1 frequency ratio, use the value calculated above. When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up to the next integer. Programming Mode: Quasi-dynamic Group 2, Group 4

Fields

Field	Function
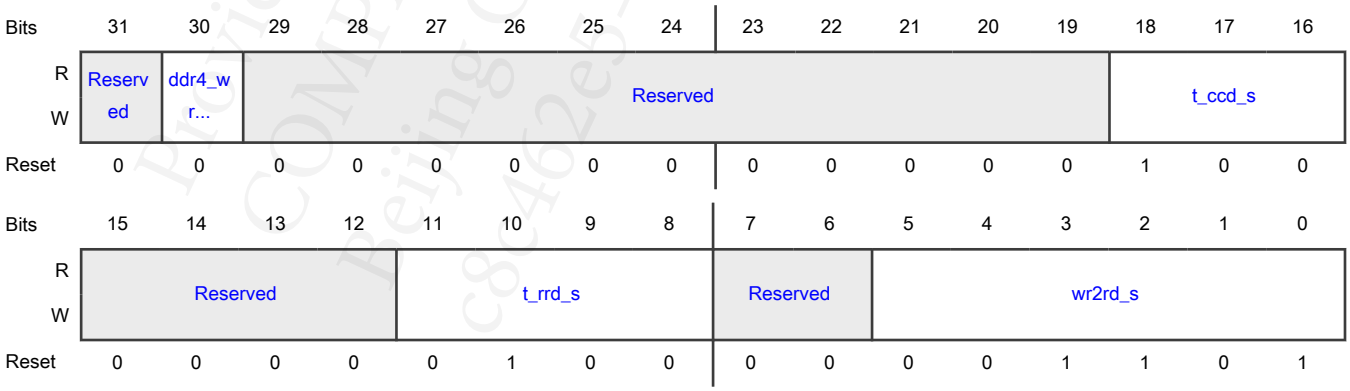
31 —	Reserved
30-24	tXS_FAST: Exit Self Refresh to ZQCL, ZQCS and MRS (only CL, WR, RTP and Geardown mode). When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided

Table continues on the next page...

Table continued from the previous page...



Field	Function
t_xs_fast_x32	by 2 and round up to next integer value. Note: This is applicable to only ZQCL/ZQCS commands. Note: Ensure this is less than or equal to t_xs_x32. Unit: Multiples of 32 DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
23 —	Reserved
22-16 t_xs_abort_x32	tXS_ABORT: Exit Self Refresh to commands not requiring a locked DLL in Self Refresh Abort. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Note: Ensure this is less than or equal to t_xs_x32. Unit: Multiples of 32 DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
15 —	Reserved
14-8 t_xs_dll_x32	tXSDLL: Exit Self Refresh to commands requiring a locked DLL. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Note: Used only for DDR2, DDR3 and DDR4 SDRAMs. Unit: Multiples of 32 DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
7 —	Reserved
6-0 t_xs_x32	tXS: Exit Self Refresh to commands not requiring a locked DLL. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Note: Used only for DDR2, DDR3 and DDR4 SDRAMs. Unit: Multiples of 32 DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4

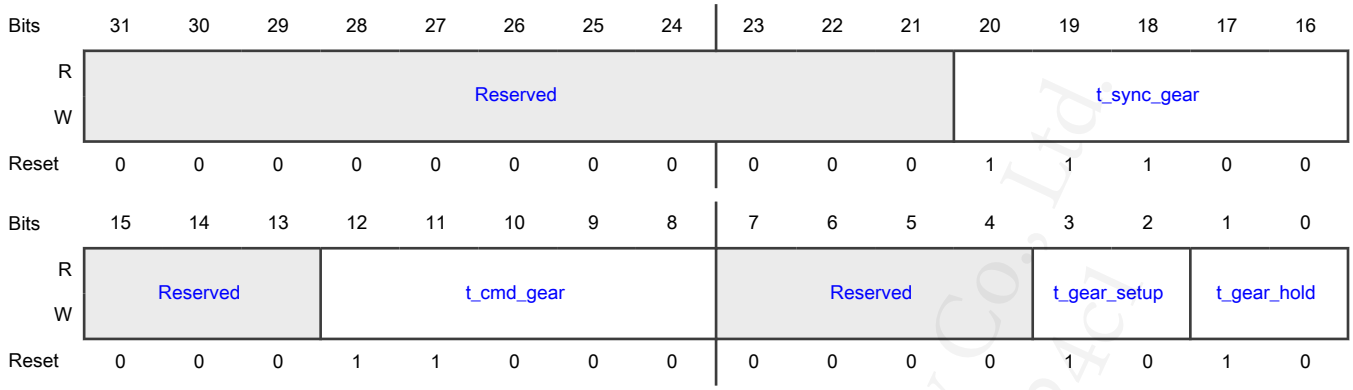
36.14.61 DRAM Timing 9 (DRAMTMG9)

Offset

Register	Offset
DRAMTMG9	124h

Diagram

Fields



Field	Function
31 —	Reserved
30 ddr4_wr_preamble	DDR4 Write preamble mode - 0: 1tCK preamble - 1: 2tCK preamble Present only with MEMC_FREQ_RATIO=2 Programming Mode: Quasi-dynamic Group 2, Group 4
29-19 —	Reserved
18-16 t_ccd_s	tCCD_S: This is the minimum time between two reads or two writes for different bank group. For bank switching (from bank "a" to bank "b"), the minimum time is this value + 1. When the controller is operating in 1:2 frequency ratio mode, program this to (tCCD_S/2) and round it up to the next integer value. Present only in designs configured to support DDR4. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
15-12 —	Reserved
11-8 t_rrd_s	tRRD_S: Minimum time between activates from bank "a" to bank "b" for different bank group. When the controller is operating in 1:2 frequency ratio mode, program this to (tRRD_S/2) and round it up to the next integer value. Present only in designs configured to support DDR4. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
7-6 —	Reserved
5-0 wr2rd_s	CWL + PL + BL/2 + tWTR_S Minimum time from write command to read command for different bank group. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Present only in designs configured to support DDR4. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the DRAM - tWTR_S = internal write to read command delay for different bank group. This comes directly from the DRAM specification. WTR_S should be increased by one if DDR4 2tCK write preamble is used. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

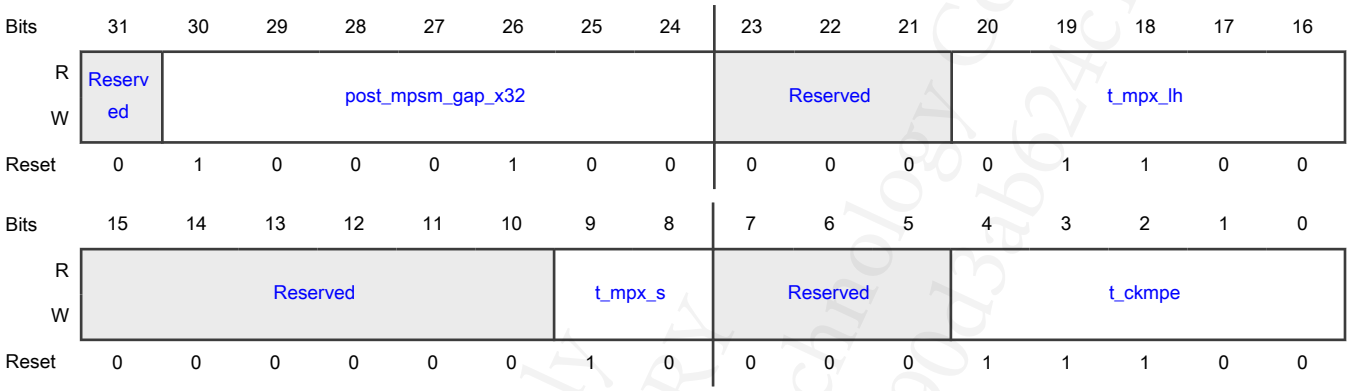
Diagram

Fields



Field	Function
31-21 —	Reserved
20-16 t_sync_gear	Indicates the time between MRS command and the sync pulse time. This must be even number of clocks. For DDR4-2666 and DDR4-3200, this parameter is defined as tMOD(min)+4nCK tMOD(min) is greater of 24nCK or 15ns 15ns / .625ns = 24 Max value for this register is 24+4 = 28 When the controller is operating in 1:2 mode, program this to (tSYNC_GEAR/2) and round it up to the next integer value. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
15-13 —	Reserved
12-8 t_cmd_gear	Sync pulse to first valid command. For DDR4-2666 and DDR4-3200, this parameter is defined as tMOD(min) tMOD(min) is greater of 24nCK or 15ns 15ns / .625ns = 24 Max value for this register is 24 When the controller is operating in 1:2 mode, program this to (tCMD_GEAR/2) and round it up to the next integer value. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
7-4 —	Reserved
3-2 t_gear_setup	Geardown setup time. Minimum value of this register is 1. Zero is invalid. For DDR4-2666 and DDR4-3200, this parameter is defined as 2 clks When the controller is operating in 1:2 frequency ratio mode, program this to (tGEAR_setup/2) and round it up to the next integer value. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4
1-0 t_gear_hold	Geardown hold time. Minimum value of this register is 1. Zero is invalid. For DDR4-2666 and DDR4-3200, this parameter is defined as 2 clks When the controller is operating in 1:2 frequency ratio mode, program this to (tGEAR_hold/2) and round it up to the next integer value. Unit: DFI clock cycles. Programming Mode: Quasi-dynamic Group 2, Group 4

Fields

Field	Function
31 dis_auto_zq	Disable automatic ZQCS|MPC Disables MC generation of the ZQ calibration short (ZQCS | MPC) command. If disabled, software can issue the ZQ calibration command through DBGCMD[zq_calib_short]. If enabled, the MC generates ZQ calibration commands based on ZQCTL1[t_zq_short_interval_x1024]. Programming Mode: Dynamic 0b - Enable 1b - Disable
30	Disable ZQCL|MPC on SR|SRPD exit

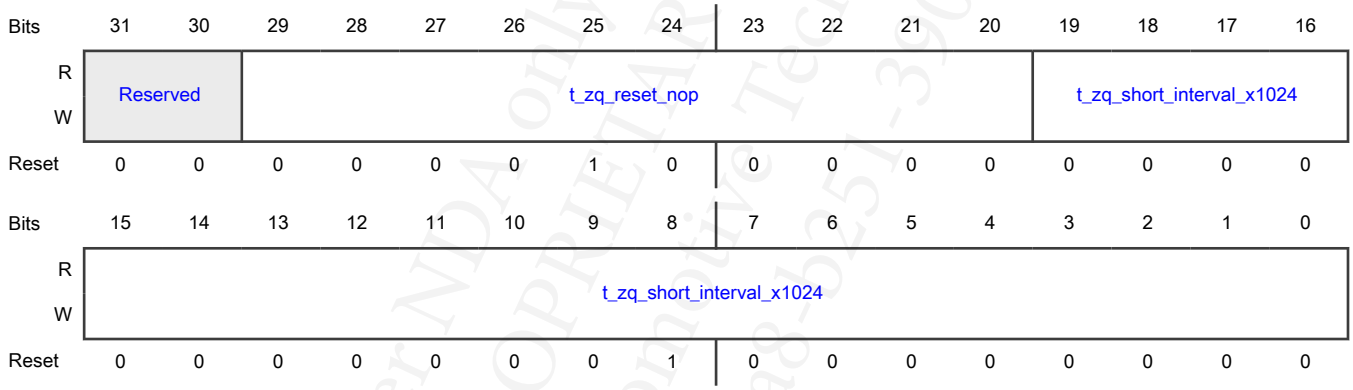
Table continues on the next page...

Table continued from the previous page...

Field	Function
dis_srx_zqcl	Disables the issuing of the ZQ calibration (ZQCL|MPC) command on exit from the Self Refresh or Self Refresh Power Down modes. Programming Mode: Quasi-dynamic Group 2, Group 4 0b - Enable 1b - Disable
29 zq_resistor_shared	Shared ZQ resistor Specifies whether to share the ZQ resistor between ranks. If the ZQ resistor is shared, then the MC sends ZQ calibration commands (ZQinit | ZQCL | ZQCS | MPC) to one rank at a time with the necessary time interval (tZQinit | tZQCL | tZQCS | tZQCAL | tZQLAT) to prevent overlap. Programming Mode: Static 0b - No shared 1b - Shared
28 dis_mpsmx_zqcl	Disable ZQCL on MPSM exit Disables the issuing of the ZQ calibration long (ZQCL) command on exit from Maximum Power Saving Mode (MPSM). This field applies only to DDR4 DRAM. **NOTE** If Shared AC mode is enabled (UMCTL2_SHARED_AC == 1), write 1 to this field. Software can send ZQCS after exiting MPSM. Programming Mode: Static 0b - Enable 1b - Disable
27 —	Reserved
26-16 t_zq_long_nop	tZQoper (DDR3, DDR4) | tZQCL (LPDDR2, LPDDR3) | tZQCAL (LPDDR4) Specifies the time interval, in DFI clock cycles, of NOP required after issuing a ZQ calibration long (ZQCL) or ZQ start (MPC) command to the DRAM. When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up. Programming Mode: Static
15-10 —	Reserved
9-0 t_zq_short_nop	tZQCS (DDR3, DDR4, LPDDR2, LPDDR3) | tZQLAT (LPDDR4)

Table continues on the next page...

Table continued from the previous page...



Field	Function
	Specifies the time interval, in DFI clock cycles, of NOP required after issuing a ZQ calibration short (ZQCS) or a ZQ Latch (MPC) command to the DRAM. When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up. Programming Mode: Static

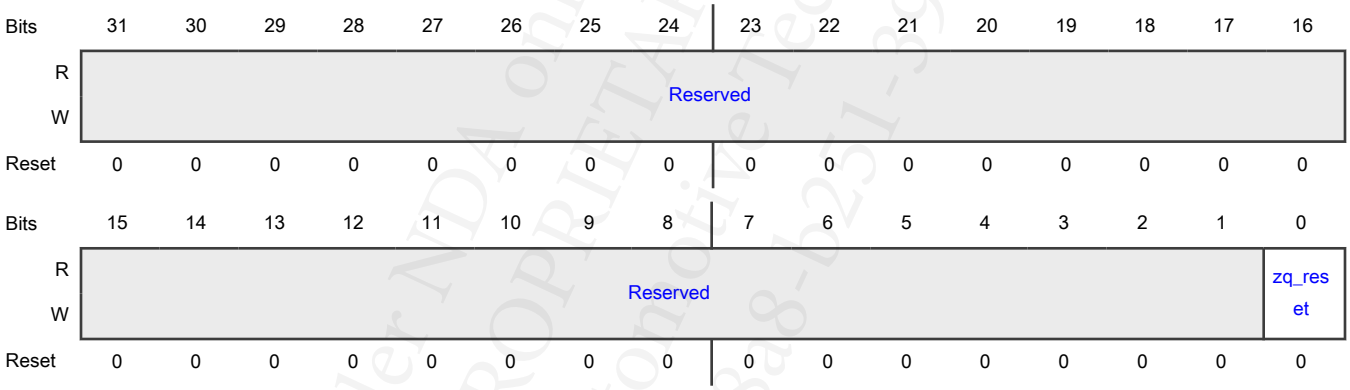
Fields

Field	Function
31-30 —	Reserved
29-20 t_zq_reset_nop	ZQreset NOP Specifies the time interval, in DFI clock cycles, of NOP required after issuing a ZQ calibration reset (ZQreset) command to DRAM. When the MC is operating at 1:2 frequency ratio, divide the calculated value by 2 and round up. This field applies only to LPDDR2, LPDDR3, or LPDDR4 DRAM. Programming Mode: Static
19-0	ZQ calibration short interval

Table continues on the next page...

Table continued from the previous page...



Field	Function
t_zq_short_interval_x1024	Specifies the average time interval, in multiples of 1024 DFI clock cycles, between automatic ZQ calibration (ZQCS | MPC) commands. This field is ignored if automatic ZQ calibration is disabled (ZQCTL0[dis_auto_zq] == 1). This field applies only to DDR3, DDR4, LPDDR2, LPDDR3, or LPDDR4 DRAM. Programming Mode: Static

36.14.70 ZQ Control 2 (ZQCTL2)

Offset

Register	Offset
ZQCTL2	188h

Diagram

Fields

Field	Function
31-1 —	Reserved
0 zq_reset	Setting this register bit to 1 triggers a ZQ Reset operation. When the ZQ Reset operation is complete, the uMCTL2 automatically clears this bit. It is recommended NOT to set this register bit if in Init, in Self-Refresh(except LPDDR4) or SR-Powerdown(LPDDR4) or Deep power-down operating modes. For Self-Refresh(except LPDDR4) or SR-Powerdown(LPDDR4) it will be scheduled after SR(except LPDDR4) or SPRD(LPDDR4) has been exited. For Deep power down, it will not be scheduled, although ZQSTAT.zq_reset_busy will be de-asserted. This is only present for designs supporting LPDDR2/ LPDDR3/LPDDR4 devices. Programming Mode: Dynamic

Fields

Field	Function
31-29 —	Reserved
28-24 dfi_t_ctrl_delay	DFI control delay Specifies the time interval, in DFI clock cycles, between assertion or deassertion of the DFI control signals and the reflection of those control signals at the PHY-DRAM interface. If the DFI clock and the memory clock are not phase-aligned, round this timing parameter up to the next integer. Programming Mode: Quasi-dynamic Group 4 **NOTE** If using RDIMM or LRDIMM, you must increment this value for an extra cycle of latency.
23 dfi_rddata_use_dfi_phy_clk	DFI or DFI PHY clock for read control Selects whether dfi_t_rddata_en represents DFI clock (HDR) or DFI PHY clock (SDR) cycles. Determines whether the MC generates the dfi_rddata_en, dfi_rddata, and dfi_rddata_valid signals based on the DFI clock (HDR) or the DFI PHY clock (SDR). Refer to the PHY specification for the correct value. Programming Mode: Static 0b - DFI clock (HDR) 1b - DFI PHY clock (SDR)
22-16 dfi_t_rddata_en	Time to read data enable Specifies the time interval, in DFI or DFI PHY clock cycles (DFITMG0[dfi_wrdata_use_dfi_phy_clk]), from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. This value corresponds to the trddata_en DFI parameter. Refer to the PHY specification for the correct value. Programming Mode: Quasi-dynamic Group 1, Group 4
15	DFI or DFI PHY clock for write control

Table continues on the next page...

Table continued from the previous page...

Field	Function
dfi_wrdata_use_dfi_phy_clk	Selects whether dfi_tphy_wrlat and dfi_tphy_wrdata represent DFI clock (HDR) or DFI PHY clock (SDR) cycles. Determines whether the MC generates the dfi_wrdata_en, dfi_wrdata, and dfi_wrdata_mask signals based on the DFI clock (HDR) or the DFI PHY clock (SDR). Refer to the PHY specification for the correct value. Programming Mode: Static 0b - DFI clock (HDR) 1b - DFI PHY clock (SDR)
14 —	Reserved
13-8 dfi_tphy_wrdata	Write data driven Specifies the time interval, in DFI or DFI PHY clock cycles (DFITMG0[dfi_wrdata_use_dfi_phy_clk]), between assertion of dfi_wrdata_en to the driving of the associated write data on the dfi_wrdata_en signal. This value corresponds to the tphy_wrdata DFI timing parameter. See the PHY specification for the correct value. **NOTE** The maximum supported value is 8. Updating DFITMG0[dfi_tphy_wrlat] or DFITMG0[dfi_wrdata_use_dfi_phy_clk] as part of a frequency change procedure may cause metastability and/or glitches in the dfi_phyupd_ack and dfi_ctrlupd_req signals. To avoid these problems, do this: 1. Write 1b to DFIUPD0[dis_auto_ctrlupd]. 2. Disable the PHY-Update request. Programming mode: Quasi-dynamic Group 4
7-6 —	Reserved
5-0 dfi_tphy_wrlat	Write latency Specifies the time interval, in DFI or DFI PHY clock cycles DFITMG0[dfi_wrdata_use_dfi_phy_clk], from the write command to write data enable (dfi_wrdata_en). This value corresponds to the tphy_wrlat DFI timing parameter. See the PHY specification for the correct value. **NOTE** LPDDR4 does not support values greater than 60. Updating DFITMG0[dfi_tphy_wrlat] or DFITMG0[dfi_wrdata_use_dfi_phy_clk] as part of a frequency change procedure may cause metastability and/or glitches in the dfi_phyupd_ack and dfi_ctrlupd_req signals. To avoid these problems, do this: 1. Write 1'b1 to DFIUPD0[dis_auto_ctrlupd].

Diagram

Fields

Field	Function
31 dis_auto_ctrlupd	Disable automatic update request

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Disables automatic MC generation of the update request. When disabled, the core must issue the update request (DBGCMD[ctrlupd]). Programming Mode: Quasi-dynamic Group 2 0b - Enable 1b - Disable
30 dis_auto_ctrlupd_srx	Disable automatic update request on SRX Disables automatic MC generation of the update request on exit from Self Refresh state. Programming Mode: Static 0b - Enable 1b - Disable
29 ctrlupd_pre_srx	Update request on SRX Specifies whether the MC sends an update request before or after existing the Self Refresh state. If automatic update on Self Refresh exit is disabled (dis_auto_ctrlupd_srx == 1), this field has no effect. Programming Mode: Static 0b - After 1b - After
28-26 —	Reserved
25-16 dfi_t_ctrlup_max	Maximum update request time Specifies the maximum time interval, in DFI clock cycles, that the MC controller can assert the udate request (dfi_ctrlupd_req) signal. The lowest valid value is 40h. Programming Mode: Static
15-10 —	Reserved
9-0 dfi_t_ctrlup_min	Update request latency Specifies the minimum time interval, in DFI clock cycles, for assertion of the MC-initiated update request (dfi_ctrlupd_req) signal. The MC expects the PHY to respond within this interval. If the PHY does not respond, the MC deasserts the update request after dfi_t_ctrlup_min plus 2 cycles. The lowest valid value is 3. Programming Mode: Static

Fields

Field	Function
31-24 —	Reserved
23-16 dfi_t_ctrlupd_interval_min_x1024	Minimum update interval Specifies the minimum time interval, in multiples of 1024 DFI clock cycles, between MC-initiated DFI update requests (generated when the MC is idle). This timer resets with each update request; when the timer expires, the MC sends an update request (dfi_ctrlupd_req) and blocks traffic until it receives the update acknowledgement (dfi_ctrlupd_ackx). Set this value higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the MC is idle. The minimum allowed value is 1. **NOTE** The value must be less than the value in dfi_t_ctrlupd_interval_max_x1024. Programming Mode: Static
15-8 —	Reserved
7-0	Maximum update interval

Table continues on the next page...

Table continued from the previous page...

Field	Function
dfi_t_ctrlupd_interval_max_x1024	Specifies the maximum time interval, in multiples of 1024 DFI clock cycles, between MC-initiated DFI update requests (generated when the MC is idle). This timer resets with each update request; when the timer expires, the MC sends an update request (dfi_ctrlupd_req) and blocks traffic until it receives the update acknowledgement (dfi_ctrlupd_ackx). PHY can use this idle time to recalibrate the delay lines to the DLLs. It can also use the time to reset the PHY FIFO counters in the event of data capture errors. Updates are needed to maintain calibration over PVT, but frequent updates may impact performance. The minimum allowed value is 1. **NOTE** The value must be greater than the value in dfi_t_ctrlupd_interval_min_x1024. Programming Mode: Static

Offset

Register	Offset
DFIMISC	1B0h

Diagram

Fields

Field	Function
31-13 —	Reserved
12-8 dfi_frequency	Operating frequency Specifies the operating frequency of the system. The PHY defines the number of supported frequencies and the mapping of signal values to clock frequencies. Programming Mode: Quasi-dynamic Group 1
7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 dis_dyn_adr_tri	Disable Dynamic Tristating Disables PHY-specific Dynamic Tristating. If Dynamic Tristating is enabled, the MC issues a special IDLE command on the DFI while dfi_cs is inactive. If the PHY detects the special IDLE command, it makes the command/address bus high impedance (Hi-Z). Dynamic Tristating works only if the MC is operating at 1:2 frequency ratio, regardless of MSTR[en_2t_timing_mode]. Therefore, it does not work if either of the following conditions is true: • MEMC_FREQ_RATIO == 1 • MEMC_PROG_FREQ_RATIO == 1 AND MSTR[frequency_ratio] == 1 The special IDLE command means the following codes with the case where all the dfi_cs is 1: • (phase 0 and 1) dfi_ras_n=1 • (phase 0 and 1) dfi_cas_n= 1 • (phase 0 and 1) dfi_we_n= 1 • (phase 0 and 1) dfi_bank [0]= 0 • (phase 0 and 1) dfi_act_n= 1 Programming Mode: Quasi-dynamic Group 3 0b - Enable 1b - Disable
5 dfi_init_start	PHY init start Triggers the PHY init start request. if " DFIMISC[dfi_init_start] is triggered ,while dfi_phymstr_req (PHY request control of DFI interface) is active, it can result in the PHY Master request being acknowledged(dfi_phymstr_ack=1) while dfi_init_start is active. This simultaneously occurring of both these signals is illegal for the Synopsys PHYs. This can lead to unexpected behavior / protocol violation. Therefore, before writing 1 to "DFIMISC[dfi_init_start]" ,write 0 to DFIPHYMSTR[dfi_phymstr_en] to disable the PHY Master. Programming Mode: Quasi-dynamic Group 3
4-3 —	Reserved

Field	Function
31-29 —	Reserved
28-24 addrmap_col_b9	Column address bit 9 Depending on the bus width mode, selects the host interface (HIF) address bit to use as: • Full bus width: column address bit 9 • Half bus width: column address bit 11 (for LPDDR2 and LPDDR3: bit 10) • Quarter bus width: column address bit 13 (for LPDDR2 and LPDDR3: bit 11) The valid values are 0 to 7, 31, and x, where x is a valid value in the inline ECC configuration. The internal base is 9. The MC determines the selected HIF address bit by adding the internal base to the value of this field. If not used, write 31 (11111b) to this field. In this case, the HIF address bit to use is 0. If the following conditions apply, the highest three column address bits must map to the highest three valid HIF address bits: • Inline ECC configuration (MEMC_INLINE_ECC == 1) • ECC enabled (ECCCFG0[ecc_mode]>0) If column bit 9 is the highest column address bit, you must set this value to the highest valid HIF address bit minus the internal base (highest HIF bit – 9) If column bit 9 is the second highest column address bit, you must set this value to the second highest valid HIF address bit minus the internal base minus one (highest HIF bit – 9 – 1) If column bit 9 is the third highest column address bit, you must set this value to the highest valid HIF address bit minus the internal base minus two (highest HIF bit – 9 – 2) **NOTE** For DDR2, DDR3, and mDDR (per the JEDEC specifications), column address bit 10 is reserved for indicating auto-precharge, and therefore no source address bit can be mapped to column address bit 10. LPDDR2 and LPDDR3 have a dedicated bit in the CA bus for auto-precharge, so these DRAM types use column address bit 10. Programming Mode: Static
23-21 —	Reserved
20-16 addrmap_col_b8	Column address bit 8 Depending on the bus width mode, selects the host interface (HIF) address bit to use as: • Full bus width: column address bit 8 • Half bus width: column address bit 9 • Quarter bus width: column address bit 11 (for LPDDR2 and LPDDR3: bit 10)

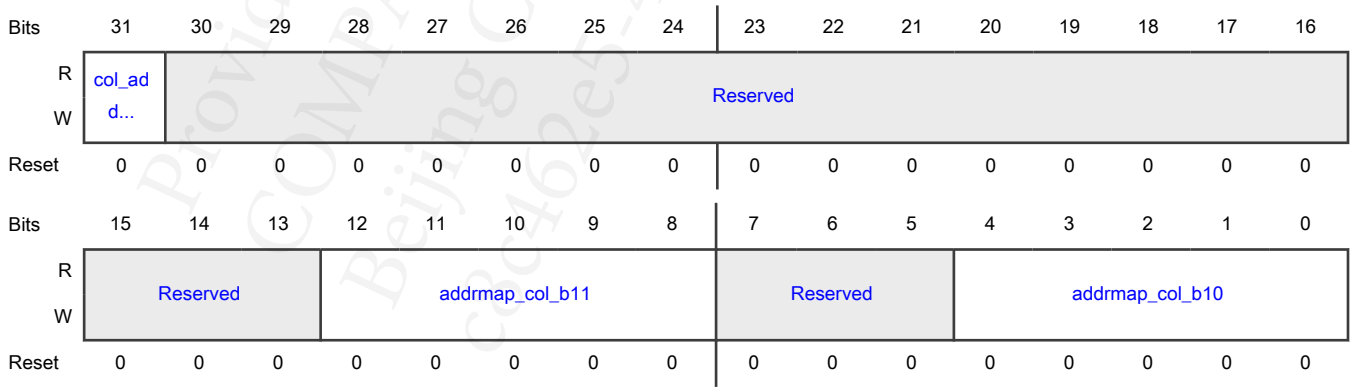
Table continues on the next page...

Table continued from the previous page...

Field	Function
	The valid values are 0 to 7, 31, and x, where x is a valid value in the inline ECC configuration. The internal base is 8. The MC determines the selected HIF address bit by adding the internal base to the value of this field. If not used, write 31 (11111b) to this field. In this case, the HIF address bit to use is 0. If the following conditions apply, the highest three column address bits must map to the highest three valid HIF address bits: • Inline ECC configuration (MEMC_INLINE_ECC == 1) • ECC enabled (ECCCFG0[ecc_mode]>0) If column bit 8 is the second highest column address bit, you must set this value to the second highest valid HIF address bit minus the internal base minus one (highest HIF bit – 8 – 1) If column bit 8 is the third highest column address bit, you must set this value to the highest valid HIF address bit minus the internal base minus two (highest HIF bit – 8 – 2) **NOTE** For DDR2, DDR3, and mDDR (per the JEDEC specifications), column address bit 10 is reserved for indicating auto-precharge, and therefore no source address bit can be mapped to column address bit 10. LPDDR2 and LPDDR3 have a dedicated bit in the CA bus for auto-precharge, so these DRAM types use column address bit 10. Programming Mode: Static
15-13 —	Reserved
12-8 addrmap_col_b7	Column address bit 7 Depending on the bus width mode, selects the host interface (HIF) address bit to use as: • Full bus width: column address bit 7 • Half bus width: column address bit 8 • Quarter bus width: column address bit 9 The valid values are 0 to 7, 31, and x, where x is a valid value in the inline ECC configuration. The internal base is 7. The MC determines the selected HIF address bit by adding the internal base to the value of this field. If not used, write 31 (11111b) to this field. In this case, the HIF address bit to use is 0. If the following conditions apply, the highest three column address bits must map to the highest three valid HIF address bits: • Inline ECC configuration (MEMC_INLINE_ECC == 1) • ECC enabled (ECCCFG0[ecc_mode]>0) If column bit 7 is the third highest column address bit, you must set this value to the highest valid HIF address bit minus the internal base minus two (highest HIF bit – 7 – 2) Programming Mode: Static

Table continues on the next page...

Table continued from the previous page...



Field	Function
7-5 —	Reserved
4-0 addrmap_col_b6	Column address bit 6 Depending on the bus width mode, selects the host interface (HIF) address bit to use as: • Full bus width: column address bit 6 • Half bus width: column address bit 7 • Quarter bus width: column address bit 8 The valid values are 0 to 7, 31, and x, where x is a valid value in the inline ECC configuration. The internal base is 6. The MC determines the selected HIF address bit by adding the internal base to the value of this field. If not used, write 31 (11111b) to this field. In this case, the HIF address bit to use is 0. If all of the following conditions apply, column bits 8, 7, and 6 must map to the highest three valid HIF address bits. Therefore, you must set this value to the highest valid HIF address bit minus the internal base minus two (highest HIF bit – 6 – 2): • Inline ECC configuration (MEMC_INLINE_ECC == 1) • ECC enabled (ECCCFG0[ecc_mode]>0) • Number of column address bits == 10 • Half bus width Programming Mode: Static

Diagram

Fields

Field	Function
31 —	Reserved
30-24 rdwr_idle_gap	Specifies the time interval, in DFI clock cycles, for the preferred transaction store to be empty before switching to the alternate transaction store, if the alternate store is not empty. The default preferred transaction store is the read (both low- and high-priority) transaction store. The alternative transaction store is the write transaction store. If prefer_write is set to 1, then the preferred and alternative stores are reversed: write is preferred and read is alternate. When this field is set to 0x00, transaction store switching happens immediately when the switching conditions become true. **NOTE** Affects performance only. Programming Mode: Static
23-13 —	Reserved
12-8 lpr_num_entries	Low-priority transaction store entries Specifies the number of entries in the low-priority transaction store minus 1. The number of entries available for the high-priority transaction store is (MEMC_NO_OF_ENTRY – (lpr_num_entries + 1)). Set to the maximum value to allocate all entries to the low-priority transaction store. Setting to 0 allocates one entry to the low-priority transaction store and the rest to the high-priority transaction store.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE In ECC configurations, the numbers of Write credits and Low Priority Read credits issued are both one less than in non-ECC configurations. The MC reserves one entry each in the Write and Low Priority Read CAMS to store RMW requests resulting from single-bit error correction operation. Programming Mode: Static
7-3 —	Reserved
2 pageclose	Paging policy Specifies the paging policy for precharge operations. See Intelligent precharges for a complete explanation of the intertaction between pageclose and SCHED1[pageclose_timer]. **NOTE** Affects performance only. Programming Mode: Quasi-dynamic Group 3
1 prefer_write	Prefer writes over reads Tells the bank selector to prefer writes over reads. **NOTE** For debug only. Programming Mode: Static 0b - No preference 1b - Prefer writes over reads
0 force_low_pri_n	Force low priority Forces all incoming transactions to low priority. The MC treats all High Priorority Read (HPR) and Variable Priority Read (VPR) commands as Low Priority Read (LPR) commands, and all Variable Priority Write (VPW) commands as Normal Priority Write (NPW) commands. This is an active low signal. Forcing incoming transactions to low priority implicitly turns off the Bypass path for read commands. Affects performance only. Programming Mode: Static 0b - Force low priority 1b - Do not force low priority

Field	Function
—	
26 dbg_wr_q_empty	This field is used for debug purposes. When its value is 1, all the write command queues and write data buffers inside the memory controller are empty. With the field's value as 1, if the controller enters Self-Refresh mode using the low-power entry sequence, it is expected to have executed all the commands in its queues, with the write and read data drained. However, you can write 1 both to this field and the DBGCAM.[dbg_rd_q_empty] field only when there are no reads and writes in the DDR controller. Therefore, you need to monitor both these fields simultaneously to get the status of the pending transactions in uMCTL2.
25 dbg_rd_q_empty	This field is used for debug purposes. When its value is 1, all the read command queues and read data buffers inside the memory controller are empty. With the field's value as 1, if the controller enters Self-Refresh mode using the low-power entry sequence, it is expected to have executed all the commands in its queues, with the write and read data drained. However, you can write 1 both to this field and the DBGCAM.[dbg_wr_q_empty] field only when there are no reads and writes in the DDR controller. Chapter 37
DDR General Purpose Registers (DDR_GPR)

37.1 Introduction

DDR_GPR:

- Drives the specific input ports of the DDR module, giving you further configurable options to use the module in different ways
- Helps in capturing some status outputs of the DDR module
- Supports the debugging of the DDR module

37.2 DDR_GPR register descriptions

37.2.1 DDR_GPR memory map

DDR_GPR base address: 4007_C600h

Offset	Register	Width (In bits)	Access	Reset value
0h	Configuration 0 (DDR_Config_0)	32	RW	0000_0000h
4h	Configuration 1 (DDR_Config_1)	32	RW	0000_0000h
8h	Configuration 2 (DDR_Config_2)	32	RW	0000_0000h
Ch	Configuration 3 (DDR_Config_3)	32	RO	0000_0000h
10h	Configuration 4 (DDR_Config_4)	32	RO	0000_0000h
14h	Configuration 5 (DDR_Config_5)	32	RW	0000_0000h
1Ch	LP3 IO Retention Control (DDR_RET_CONTROL)	32	RW	0000_0001h

37.2.2 Configuration 0 (DDR_Config_0)

Diagram

Fields

Field	Function
31 PERF_CNT_FULL_MASK	Monitor Counter Full Interrupt Enables and disables the "monitor counter full" interrupt. 0b - Disable 1b - Enable
30-27 sbrAddressRangeMask_35_32	Scrubber Address Range Mask Bits 35:32 Limits the address range that the ECC scrubber can generate. The full address range mask is 36 bits wide. sbrAddressRangeMask_35_32 contains bits 35:32 of the full mask. DDR_Config_2[sbrAddressRangeMask] contains the remaining bits. For normal scrubber operation, write a 0 to this field. Use other values only for debug purposes. Valid values are 2^n-1, where n=0–33. You must also ensure that the value does not exceed the memory capacity.
26-23 sbrAddressStartMask_35_32	Scrubber Address Start Mask Bits 35:32 Specifies part of the starting address which the ECC scrubber generates. The full scrubber address start mask is 36 bits wide. sbrAddressStartMask_35_32 contains bits 35:32 of the full mask. DDR_Config_1[sbrAddressStartMask] contains the remaining bits. For normal scrubber operation, write a 0 to this field. Use other values only for debug purposes. Valid values are 2^n-1, where n=0–33. You must also ensure that the value: • Does not exceed the memory capacity • Is less than the value defined by the full address range mask
22-16 WRECC_CREDIR_CNT	WRECC Credit Provides the number of available slots (free positions) of write ECC WR content addressable memory (CAM). Each slot holds a DRAM burst synchronous to the DDR core clock (800 MHz). The value is decremented/incremented as commands flow in/out of the write ECC CAM.
15	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
14 memory_ret	Memory Data Retention Controls the retention of memory data in Standby mode. In Standby mode, address and data inputs are disabled. Data stored in the memory is retained, but the memory cannot be accessed for reads or writes. 0b - Do not retain 1b - Retain
13-0 —	Reserved

37.2.7 Configuration 5 (DDR_Config_5)

Offset

Register	Offset
DDR_Config_5	14h

Function

Contains the mapped safety logic (the RCCU set/clear logic) for AXI inside the DDR subsystem.

Each AXI instance has two RCCUs—main and dummy. Each RCCU compares two data sources (SRC_A and SRC_B) that enter and exit the AXI interface, and sends an alarm under the circumstances described in Figure 188.

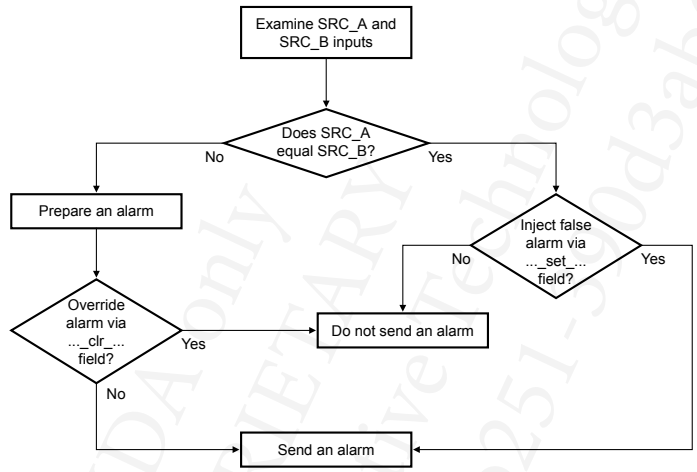

Figure 188. RCCU alarm flow

Chapter 38
Quad Serial Peripheral Interface (QuadSPI)

38.1 Chip-specific QuadSPI configuration

38.1.1 Overview

The QuadSPI module and associated PHY provide a common memory interface to single, dual, quad, and octal NOR flash memory, including Hyperflash memory. The primary use case of the QuadSPI is for interfacing with external flash memory and octal PSRAMs. The flash memory interface supports the following external NOR flash memories:

- 8-bit wide bus (x8) DDR NOR, OctaFlash™, XTRM, and HyperFlash™ flash memories
- 4-bit wide bus (x4) SDR and DDR quad NOR flash memories
- Cypress QuadFlash memory
- Octal PSRAM memory

For QuadSPI pin-mapping, see the device 'Input Muxing' tab in the IOMUX spreadsheet attached to this document.

For the target frequencies, see the chip data sheet.

38.1.2 Supported modes

The table below provides an overview of the QuadSPI modes supported.

Table 209. QuadSPI modes supported

Frequency (MHz)	DDR / SDR	Slave delay chain Setting (DLL)	Slave delay chain Setting (Tap selection)	DQS Setting	Flash type	Flash interface
66	DDR	ON	AUTO	Pad Loopback (dummy)	Quad Flash (1.8 V)	QuadSPI flash A interface QuadSPI flash B interface
66	DDR	ON	AUTO	Pad Loopback (dummy)	Quad Flash (3.3 V)	QuadSPI flash B interface
104	SDR	OFF	BYPASS	Pad Loopback (dummy)	Quad Flash (3.3 V)	QuadSPI flash B interface
133, 100, 40	SDR	OFF	BYPASS	Pad Loopback (dummy)	Octal Flash (1.8 V)	QuadSPI flash A interface QuadSPI flash B interface
133	SDR	OFF	BYPASS	Pad Loopback (dummy)	Quad Flash (1.8 V)	QuadSPI flash A interface QuadSPI flash B interface

Table continues on the next page...

Table 209. QuadSPI modes supported (continued)

Frequency (MHz)	DDR / SDR	Slave delay chain Setting (DLL)	Slave delay chain Setting (Tap selection)	DQS Setting	Flash type	Flash interface
200, 166, 133, 100	DDR	ON	MANUAL	External DQS (Edge-aligned)	Octal Flash (1.8 V)	100/133 are supported on both A and B interface. 166/200 are supported on flash A interface only.

38.1.3 QuadSPI clocking

The ratio of bus clock to flash clock must not be less than 1:5. The ratio of bus clock to internal reference clock must not be less than that derived from the formula below. For more details, see the chip data sheet.

The flash read timing must meet the following condition:

The total time period of the number of clock cycles required to fetch the next *n* bits of data (where *n* can be 64, 32, or 16) from flash memory must be greater than two bus clock periods.

Derive DDR octal writes using the following equation:

(3 x flash clock period) + (3 x bus clock period) < (8 x flash clock period)

38.1.4 QuadSPI limitations

The implementation of QuadSPI in this chip has the following limitations:

- This chip does not support WRAP* transactions for AHB read.
- Any speculative access of the QuadSPI memory mapped region 00000000h-20000000h before you configure QuadSPI might result in unexpected chip behavior. Therefore, in this situation, you must use core programming to disable speculative access of that region.
- QuadSPI AHB region 00000000h-1FFFFFFF is non-cacheable.
- It is required that the application must rely on the FCCU fault for the ECC error handling by writing '0' to the QuadSPI RSER[CRCBIE] and RSER[CRCAIE]. In cases where FCCU is not configured (for example, in the customer bootloader), these fields must be enabled.

38.1.5 Chip-specific feature configuration

QuadSPI instance on this chip does not support Peripheral chip select (PCS). Disregard its references in this chapter.

QuadSPI instance on this chip supports Auto-learning feature at 66MHz only. For more details, see the chip Data Sheet.

NOTE

Reset (flush) the QSPI AHB buffer and the IPS domain before the first AHB read transaction, or if you reconfigure them.

38.2 Introduction

The QuadSPI module acts as an interface to a single or two external SFM devices, each with up to eight bidirectional data lines.

38.2.1 Features

QuadSPI supports the following features:

- Flexible sequence engine to support various flash memory vendor devices. As there is no specific standard, the module supports various kinds of flash memories from different vendors. See Serial flash memory devices for example sequences.
- Single, dual, and quad modes of operation supported for Quad flash memories
- Octal and single IO modes of operation supported for Octal flash memories
- Double Data Rate (DDR)/Double Transfer Rate (DTR) mode in which the data is generated on every edge of the serial flash memory clock
- Flash memory data strobe signal to support data sampling in DDR and Single Data Rate (SDR) mode
- Support for HyperFlash memory
- Support for Macronix Octal Data integrity features such as ECC and R/W parity (CRC1)
- Support for parallel writes through register-mapped interface in single I/O mode
- Ability to connect two identical serial flash memory devices and access them simultaneously for data read operations, forming one (virtual) flash memory with doubled readout bandwidth
- AHB master to read RX buffer data through AMBA AHB (64-bit width interface) or IPS registers space (32-bit access) and fill TX buffer via IPS registers space (32-bit access)
  - AHB master can be a DMA with a configurable inner loop size
- Multi-master accesses are allowed, but only a single master access is supported with On-the-fly AES decryption (OTFAD)
  - Flexible and configurable buffer for each master—total available buffer size is 1024 bytes.
- All AHB accesses to flash memory devices are directly memory mapped to the chip system memory
- Programmable sequence engine to cater to future command/protocol changes and ability to support all existing vendor commands and operations. The software needs to select the corresponding sequence according to the connected flash memory device.
  - Support for all types of addressing
- Support for interaction with OTFAD

38.2.2 RX buffer push event

To add the valid entries into the RX buffer

By default, each buffer push event adds two entries to the RX buffer because the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash memory device, it is possible for the very last buffer push event that only one entry is added.

RBSR[RDBFL] is incremented by the number of entries added to the RX buffer.

38.2.3 RX buffer POP event

To remove valid entries from the RX buffer

Each buffer POP event removes (RBCT[WMRK] + 1) valid entries from the buffer. BSR[RDBFL] is decremented by the same number and RBSR[RDCTR] is incremented accordingly.

38.2.4 Block diagram

The following figure shows a block diagram of the QuadSPI module.

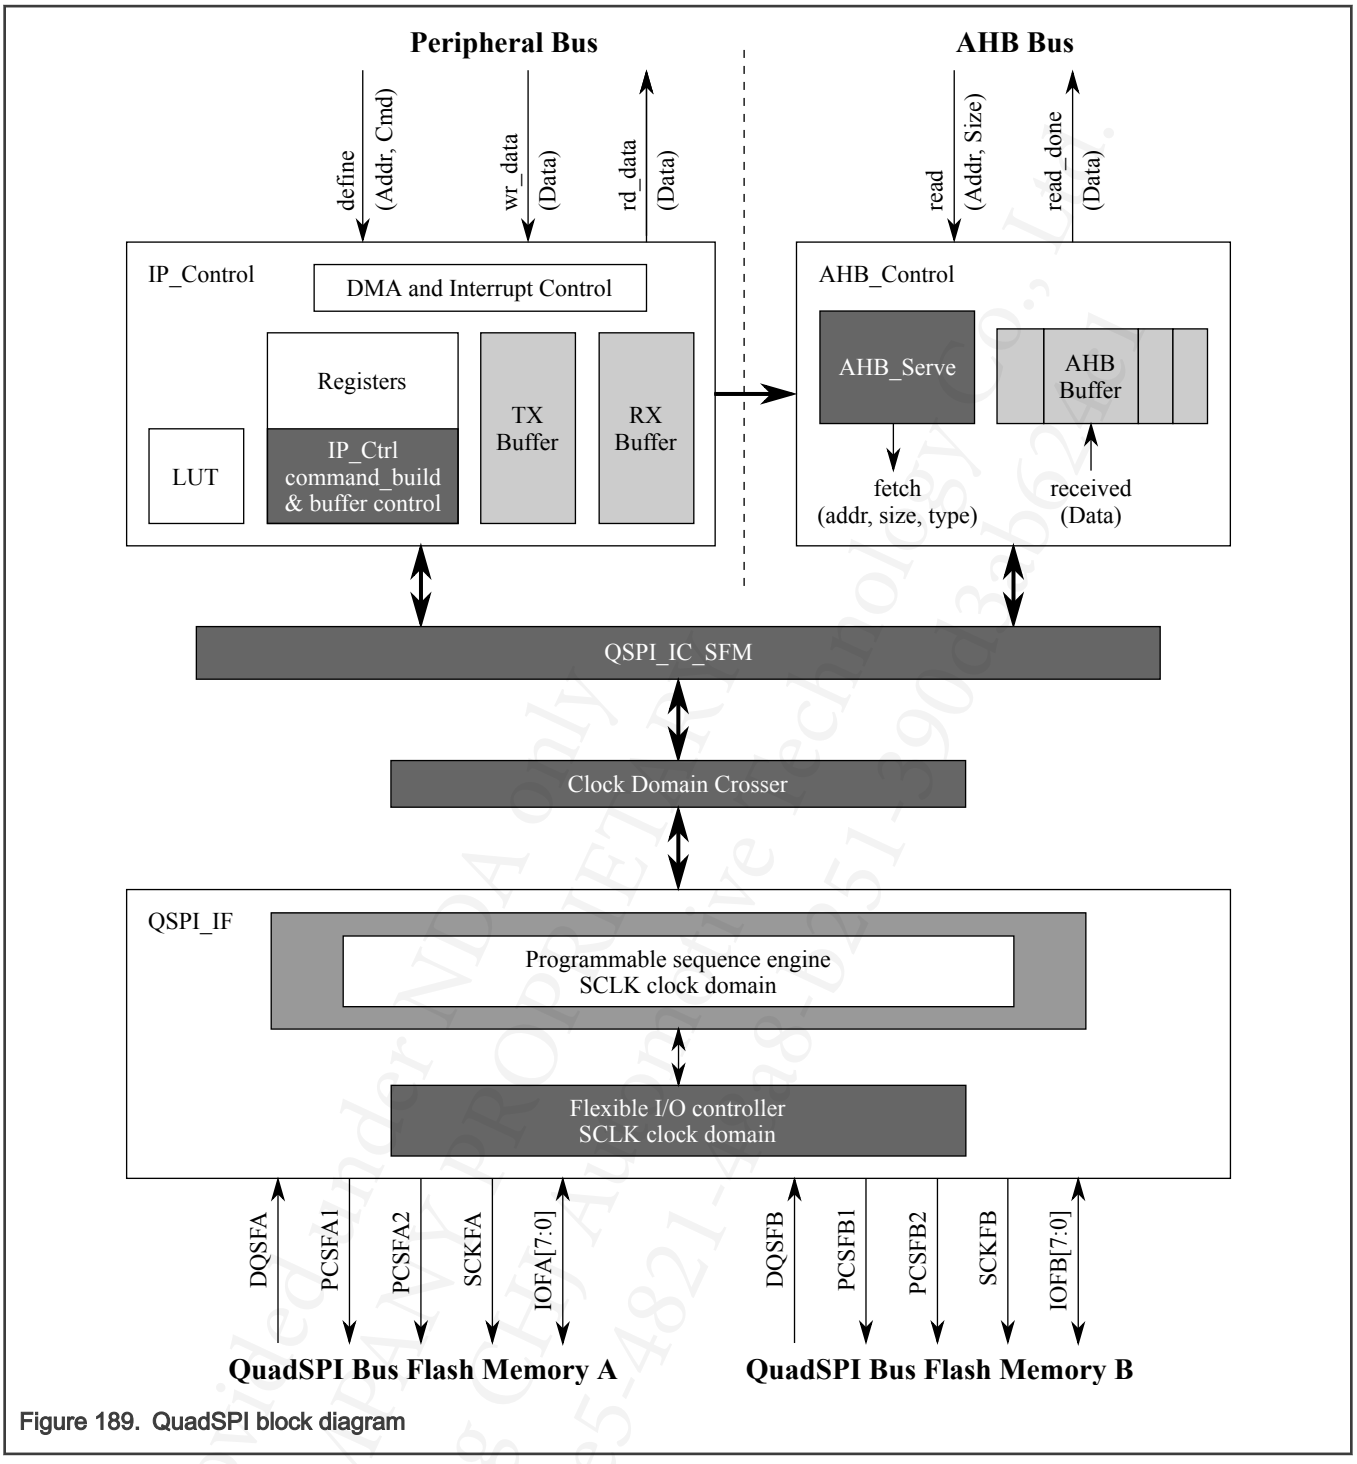

Figure 189. QuadSPI block diagram

38.2.5 QuadSPI modes of operation

QuadSPI supports the following modes of operation:

- Normal mode: You can use this mode for write or read accesses to an external serial flash memory device. See Normal mode for details.
  - Serial flash memory write: You can program data into the flash memory through the IP interface only. See Flash memory programming for details.

— Serial flash memory read: Read the contents of the serial flash memory device. Two separate read channels are available through the RX buffer and AHB buffer. See Flash memory read for details.

- Module Disable mode: You can use this mode for disabling serial flash memory clock and AHB command. The clock to the non-memory mapped logic in QuadSPI can be stopped in the Module Disable mode. The module enters the mode by setting MCR[MDIS].

38.3 External signal description

This section provides the external signal information for the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

Table 210. Signal properties

Signal name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash Memory A1	O	This signal is the chip select for the serial flash memory device A1 that represents the first device in a dual-die package flash memory A or the first of the two flash memory devices that share IOFA. See Dual-die flash memories for details.
PCSFA2	Peripheral Chip Select Flash Memory A2	O	This signal is the chip select for the serial flash memory device A2 that represents the second device in a dual-die package flash memory A or the second of the two flash memory devices that share IOFA. See Dual-die flash memories for details.
PCSFB1	Peripheral Chip Select Flash memory B1	O	This signal is the chip select for the serial flash memory device B1 that represents the first device in a dual-die package flash memory B or the first of the two flash memory devices that share IOFB. See Dual-die flash memories for details.
PCSFB2	Peripheral Chip Select Flash Memory B2	O	This signal is the chip select for the serial flash memory device B2 that represents the second device in a dual-die package flash memory B or the second of the two flash memory devices that share IOFB. See Dual-die flash memories for details.
SCKFA	Serial Clock Flash Memory A	O	This signal is the serial clock output to the serial flash memory device A.
SCKFB	Serial Clock Flash B	O	This signal is the serial clock output to the serial flash memory device B.
IOFA[7:0]	Serial I/O Flash memory A	I/O	These signals are the data I/O lines to/from the serial flash memory device A. See Driving external signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash memory device may change their function according to the SFM Command executed, leaving them as control inputs when single and dual instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1].
IOFB[7:0]	Serial I/O Flash Memory B	I/O	These signals are the data I/O lines to/from the serial flash memory device B. See Driving external signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash memory device may change their function according to the SFM command executed, leaving

Table continues on the next page...

Table 210. Signal properties (continued)

Signal name	Function	Direction	Description
			them as control inputs when single and dual instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFB[0] and expects data on IOFB[1].
DQSFA	Data Strobe signal Flash Memory A	I	This is the data strobe signal for port A. Some flash memory vendors provide the Data Read Strobe (DQS) signal to which the read data is aligned in DDR mode.
DQSFB	Data Strobe signal Flash Memory B	I	This is the data strobe signal for port B. Some flash memory vendors provide the DQS signal to which the read data is aligned in DDR mode.
INTA	ECC error signal for Flash Memory A	I	Flash Memory A drives this signal to active low value in case of an ECC error.
INTB	ECC error signal for Flash Memory B	I	Flash Memory B drives this signal to active low value in case of an ECC error.

38.3.1 Driving external signals

Single/dual/quad/octal instructions

Depending on the serial flash memory device connected to the QuadSPI module, there are instructions using a different number of data lines:

- Single pad: Single line I/O with one data out and one data in line to/from the serial flash memory device
- Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPI module
- Quad pad: Quad line I/O with four bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPImodule
- Octal pad: Octal line I/O with eight bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPI module

The different phases of the serial flash memory access scheme are shown in the following figure.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48b2-b213-90d3a6b4c

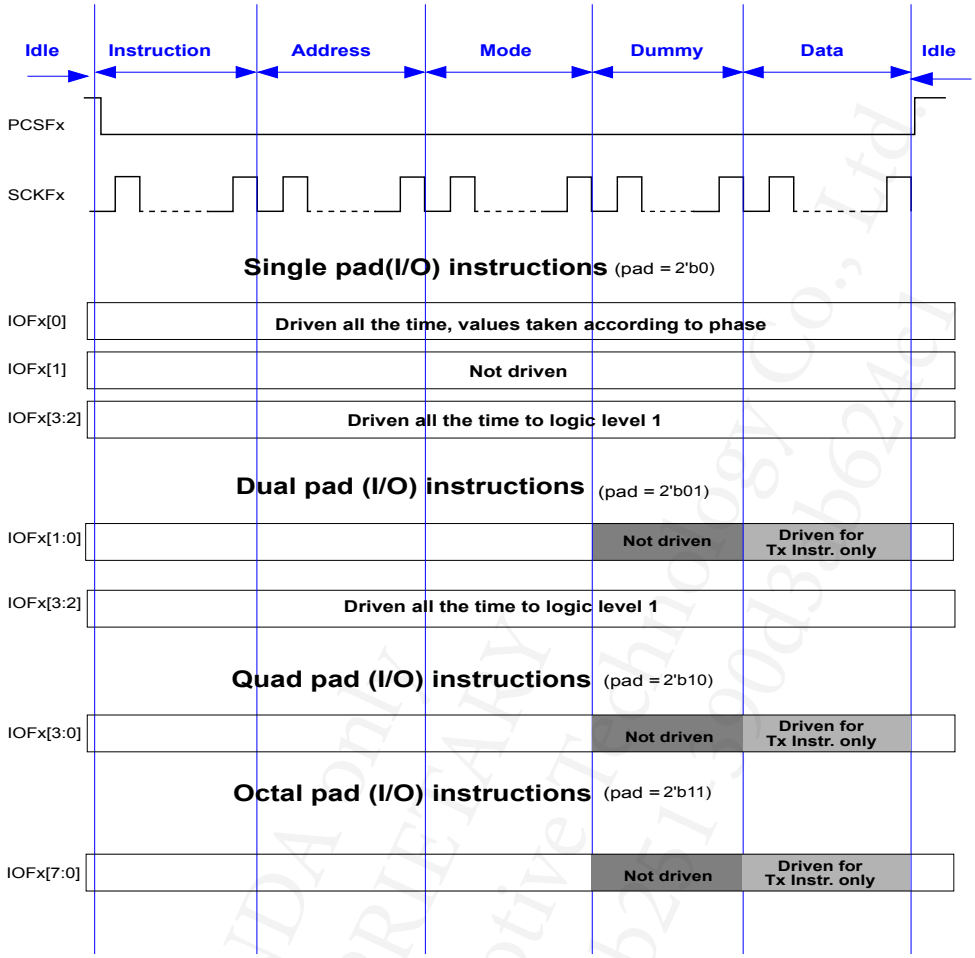

Figure 190. Serial flash memory access scheme

Following are the different phases and the I/O driving characteristics of the QuadSPI module:

- Idle: Serial flash memory device not selected – no interaction with the serial flash memory device and the IOFx signals are driven.
- Instruction: Serial flash memory device selected – the instruction is sent to the serial device and all the IOFx signals are driven.
- Address: Serial flash memory address is sent to the device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Mode: Mode bytes are sent to the serial flash memory device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Dummy: Dummy clocks are provided to the serial flash memory device. See Figure 190 for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

— This phase is not applicable for all the SFM commands.

— All read commands in Dual pad, Quad pad or Octal pad modes must use dummy phase before read phase. Note that this restriction is not applicable to Single-pad mode.

- Data: Serial flash memory data are sent to or received from the serial flash memory device. See the preceding figure for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

This phase is not applicable for all the SFM commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases. In the individual flash memory mode, this applies to the selected flash memory device. In the parallel flash memory mode, this applies to both the serial flash memory devices simultaneously.

Access to a single, individual serial flash memory device

See Serial flash memory access schemes for details.

Read access to two serial flash memory devices attached to the QuadSPI module in parallel. See Serial flash memory access schemes for details.

38.4 Memory map and register definition

This section provides the memory map and register definitions for the QuadSPI module.

38.4.1 Register write access

Following are the write access restriction terms that apply to all the registers:

- Register write access restriction

  For each register field, the write access conditions are specified in the detailed register description.

  The following table provides a description of the write access conditions. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 211. Register write access restrictions

Condition	Description
Anytime	No write access restriction
Disabled mode	Write access only if MCR[MDIS] = 1
Normal mode	Write access only if the module is in the normal mode

- Register write access requirements

  You can access all registers using 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16-bit or 32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each affected register.

38.4.2 QuadSPI register descriptions

This section provides the memory map and register definitions for the QuadSPI module.

Access to the following addresses does not result in a transfer error:

- 4h
- 24h
- 168h

38.4.2.2 Module Configuration Register (MCR)

Offset

Register	Offset
MCR	0h

Function

This register holds configuration data associated with the QuadSPI operation.

NOTE

When out of reset, after first initial MCR programming and exiting module disable mode (that is, when the value of MCR[MDIS] is 0), you must write 1 to MCR[SWRSTSD] and release it after six (three system and three flash memory) clock cycles.

Special write-access is permitted in different modes:

- CK2_DCARS_FB, CKN_FB_EN, DQS_FB_SEL, CK2_DCARS_FA, CKN_FA_EN, DQS_FA_SEL: Disabled mode
- ISD3FB, ISD2FB, ISD3FA, ISD2FA: Disabled mode
- All other fields: Anytime

Table continued from the previous page...

Field	Function
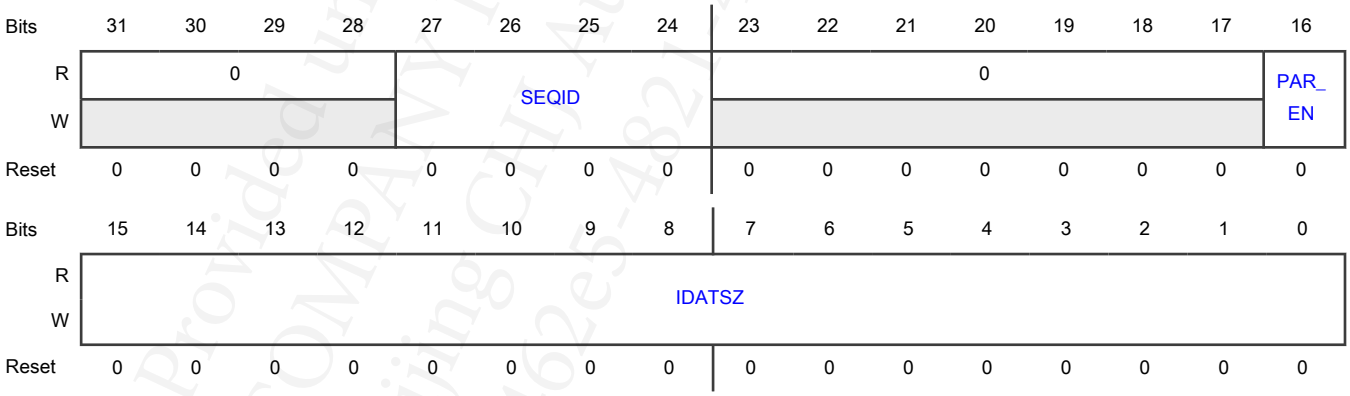
	1b - Serial flash memory domain flops are reset. This field does not reset configuration registers. It is advisable to reset both the serial flash memory domain and AHB domain at the same time. Resetting only one domain might lead to side effects. **NOTE** The software resets need the clock to be running to propagate to the design. The value of MCR[MDIS] should therefore be 0 when the software reset bits are asserted. Also, before they can be deasserted again (by specifying 0 as the value for MCR[SWRSTSD]), it is recommended to specify 1 as the value for MCR[MDIS]. After the software resets are deasserted, the normal operation can be started by specifying 0 as the value for MCR[MDIS].

38.4.2.3 IP Configuration Register (IPCR)

Offset

Register	Offset
IPCR	8h



Function

This register provides all the configuration required for an IP-initiated command, which can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash memory is initiated per the sequence pointed to by this field. See Normal mode for details on command triggering and command execution.

Special write-access is permitted if:

- SR[IP_ACC]=0

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHY Automotive Technology Co., Ltd.

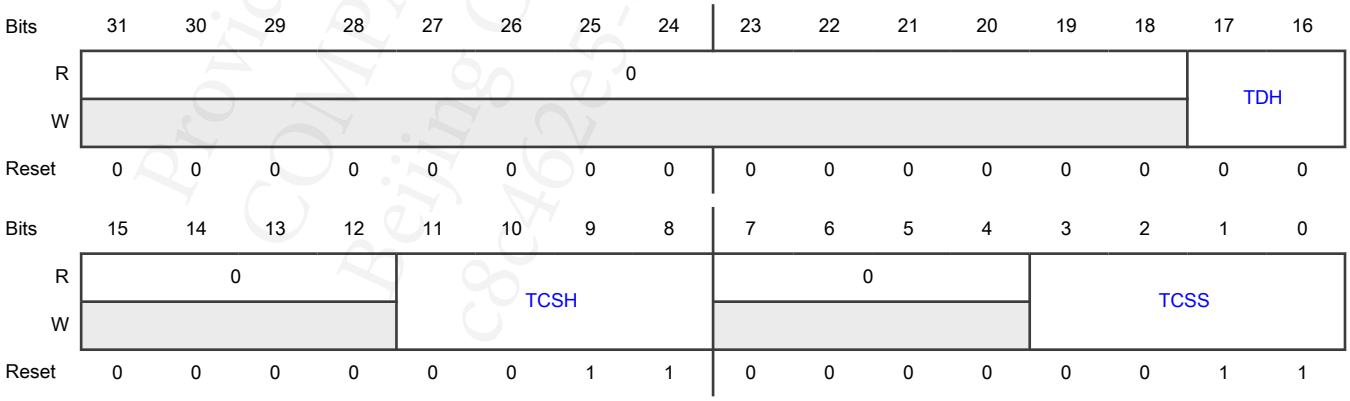
Fields

Field	Function
31-28 —	Reserved
27-24 SEQID	Points to a sequence in the LUT This field defines bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. See LUT for details. A write to this field triggers a transaction on the serial flash memory interface.
23-17 —	Reserved
16 PAR_EN	If the value of this field is 1, a transaction to two serial flash memory devices is triggered in the parallel mode. See Parallel flash memory mode for details.
15-0 IDATSZ	IP data transfer size This field defines the data transfer size, in bytes, of the IP command.

38.4.2.4 Flash Memory Configuration Register (FLSHCR)

Offset

Register	Offset
FLSHCR	Ch



Function

This register contains the timings that are specific to the flash memory device. The QuadSPI controller must meet these timings for the device to function correctly.

Special write-access is permitted if:

- SR[AHB_ACC] = 0
- SR[IP_ACC] = 0

Diagram

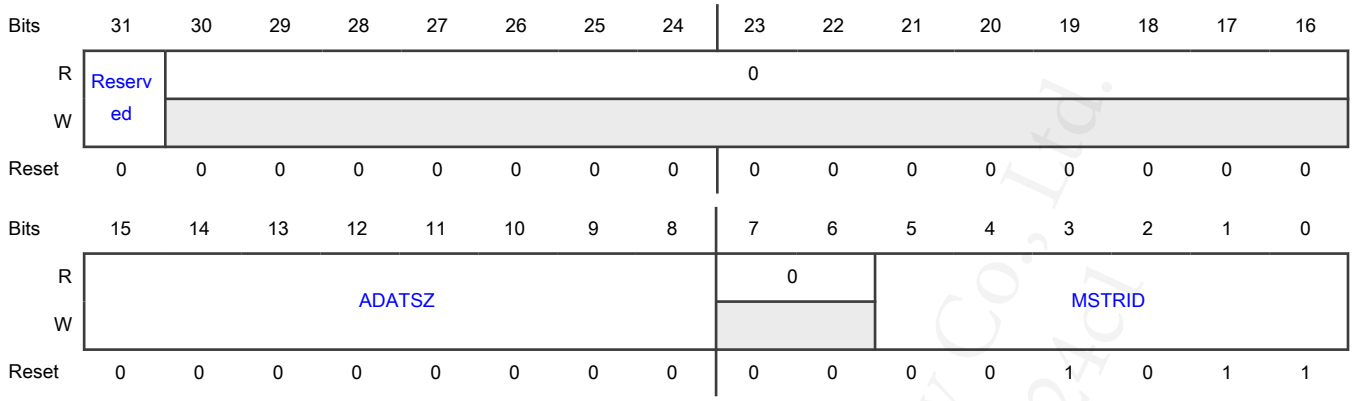
Fields

Field	Function
31-18 —	Reserved
17-16 TDH	Serial flash memory data in hold time This field helps in meeting the data in hold time requirement of a flash memory. It is valid only in the DDR mode. **NOTE** This field should be set to 0x00 in the SDR mode (MCR[DDR_EN]=0). See Data input hold requirement of flash memory for details. The valid TDH programming options are shown below and the other combinations are invalid. 00b - Data aligned with the posedge of internal reference clock of QuadSPI 01b - Data aligned with 2x serial flash memory half clock
15-12 —	Reserved
11-8 TCSH	Serial flash memory CS hold time This hold time is in terms of serial flash memory clock cycles, and it must be greater than or equal to three flash memory clock cycles .
7-4 —	Reserved
3-0 TCSS	Serial flash memory CS setup time This setup time is in terms of serial flash memory clock cycles, and it must be greater than or equal to two flash memory clock cycles.

38.4.2.5 Buffer 0 Configuration Register (BUF0CR)

Offset

Register	Offset
BUF0CR	10h



Function

This register provides the configuration for any read access routed to buffer0, which happens when the master port number of the incoming AHB request matches BUF0CR[MSTRID]. Any buffer "miss" leads to a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram

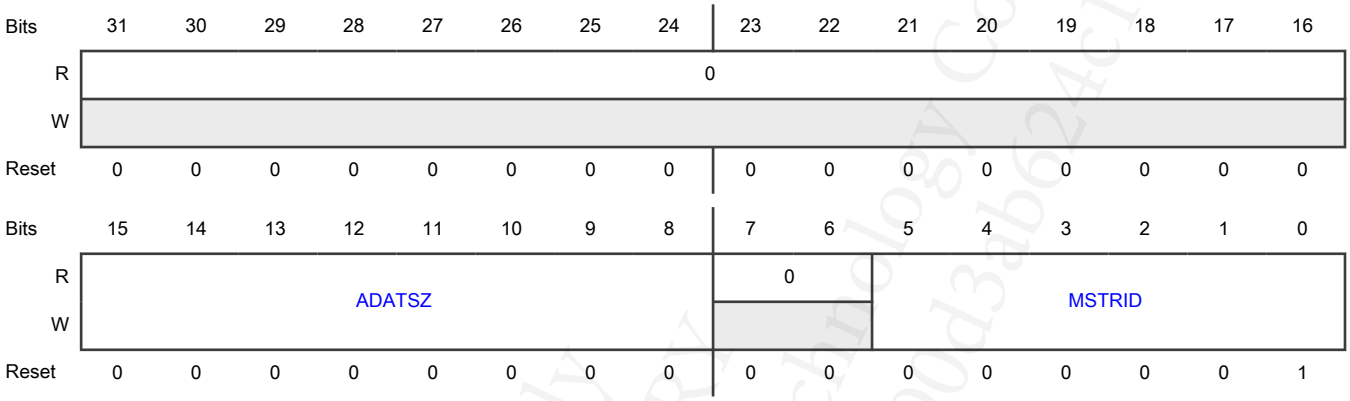
Fields

Field	Function
31 —	Reserved
30-16 —	Reserved
15-8 ADATSZ	AHB data transfer size Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of the buffer. If OTFAD is enabled, the QuadSPI module prefetches only that much data from flash memory such that the prefetch never crosses the 1 KB boundary.
7-6 —	Reserved
5-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 0 Any AHB read access with this master port number is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.

38.4.2.6 Buffer 1 Configuration Register (BUF1CR)

Offset

Register	Offset
BUF1CR	14h



Function

This register provides the configuration for any access routed to buffer 1, which happens when the master port number of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram

Fields

Field	Function
31-16 —	Reserved
15-8 ADATSZ	AHB data transfer size This field defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets the transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer. If OTFAD is enabled, the QuadSPI module prefetches only the required data from the flash memory so that the prefetch never crosses the 1 KB boundary.
7-6 —	Reserved
5-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 1 Any AHB read access with this master port number is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.

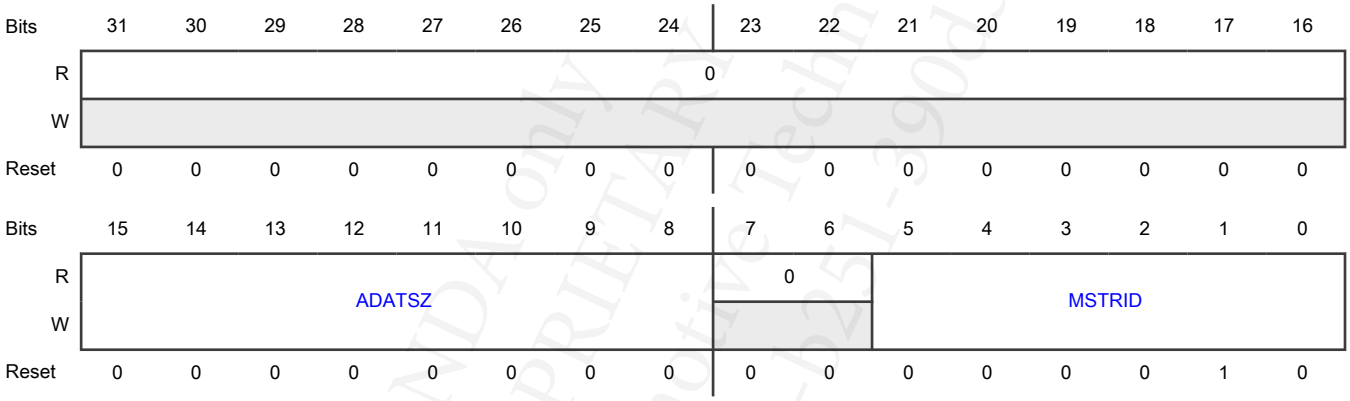
38.4.2.7 Buffer 2 Configuration Register (BUF2CR)

Offset

Register	Offset
BUF2CR	18h



Function

This register provides the configuration for any access routed to buffer 2, which happens when the master port number of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram

Fields

Field	Function
31-16 —	Reserved
15-8 ADATSZ	AHB data transfer size This field defines the read data transfer size in 8 bytes of an AHB triggered read access to the serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer. If OTFAD is enabled, the QuadSPI module prefetches only the required data from the flash memory such that the prefetch never crosses the 1 KB boundary.
7-6 —	Reserved
5-0	Master ID

Table continues on the next page...

Table continued from the previous page...

Field	Function
MSTRID	The ID of the AHB master associated with BUFFER2. Any AHB read access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers are different.

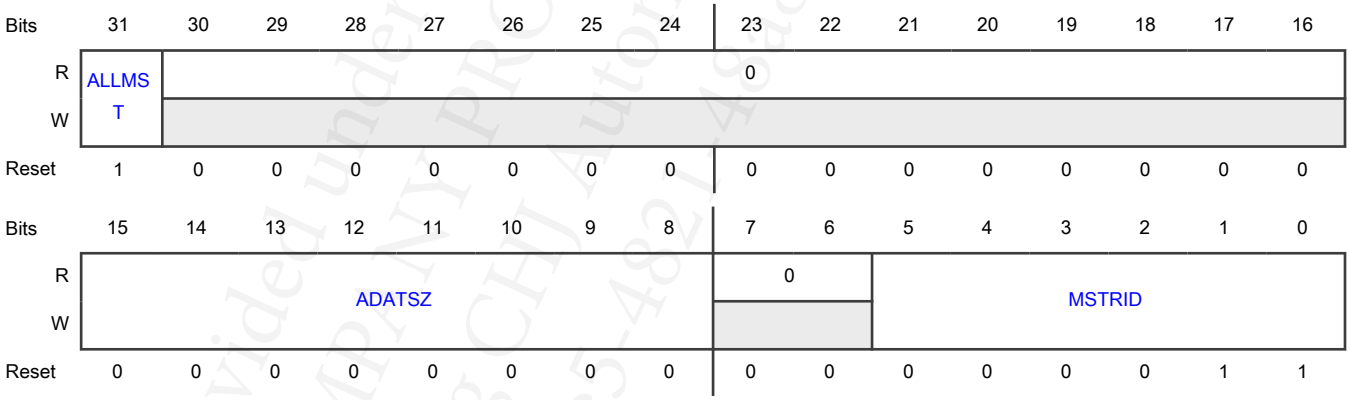
38.4.2.8 Buffer 3 Configuration Register (BUF3CR)

Offset

Register	Offset
BUF3CR	1Ch

Function

This register provides the configuration for any access to buffer 3.



An access is routed to buffer 3 when the master port number of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

In case the value of the ALLMST field is not 1, any such transaction (where master port number does not match any of the MSTRID fields) is returned with an ERROR response.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram

Fields

Field	Function
31 ALLMST	All master enable

Table continues on the next page...

Table continued from the previous page...

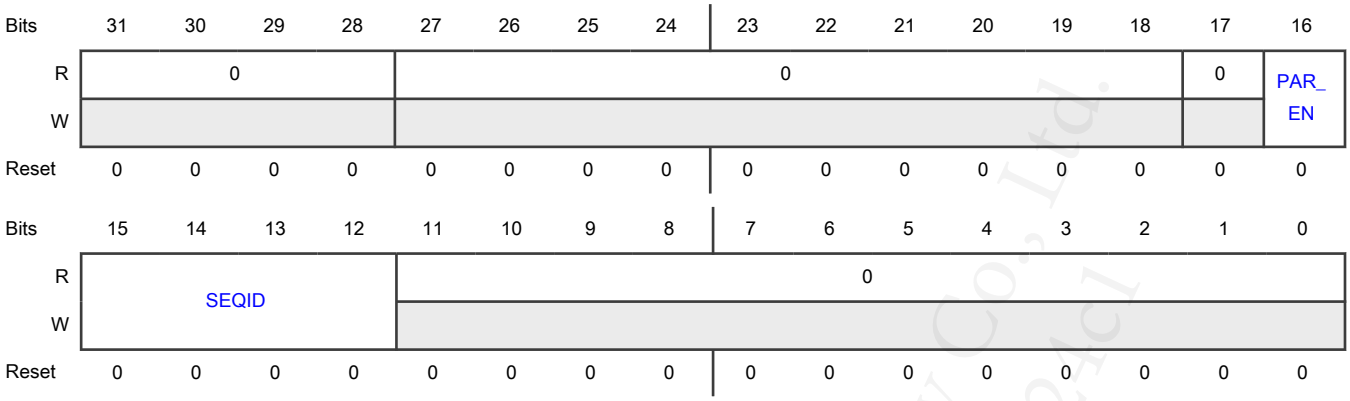
Field	Function
	When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0, buffer1, or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30-16 —	Reserved
15-8 ADATSZ	AHB data transfer size Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer. If OTFAD is enabled, the QuadSPI module prefetches only the required data from the flash memory so that the prefetch never crosses the 1 KB boundary.
7-6 —	Reserved
5-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 3. Any AHB read access with this master port number is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.

38.4.2.9 Buffer Generic Configuration Register (BFGENCR)

Offset

Register	Offset
BFGENCR	20h

Function



This register provides generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by the SEQID field. If the value of the PAR_EN field is 1, all the buffer accesses result in parallel accesses to the flash memories.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

38.4.2.14 DLL Flash Memory A Configuration Register (DLLCRA)

Offset

Register	Offset
DLLCRA	60h

Function

This register configures DLL and slave delay chain for flash memory A.

The value of the DLLEN field must be 1 after all reference (FREQEN, DLL_REFCNTR, DLLRES, SLAVE_AUTO_UPDT) delay chain configurations are programmed.

See DLL and delay chain usage for the programming sequence.

NOTE

See the chip data sheet for information on programming register fields.

Diagram

Fields

Field	Function
31 CRC_WNDW_FB	CRC address window configuration 0b - Calculates parity (CRC) over fixed address window within the denoted flash memory B chunk size boundary. 1b - Calculates parity (CRC) over incremental window of flash memory B chunk size irrespective of address.
30-25 CHUNKSIZE_FB	Chunk size for flash memory B Defines the chunk size (in terms of 4 Bytes) after parity should be inserted and compared by the QuadSPI controller for flash memory B. Values 0x1, 0x2, ... implies 4 bytes, 8 bytes ... so on.
24 BYTE_SIZE_FB	Byte size for flash memory B It can be programmed anytime. Enables single byte read/write parity with FlashB configuration register. This field overrides chink-size used for Flash data array. You must write 1 to this field before any read/write operation on the flash memory internal registers. And you must write 0 to this field before reading flash memory data array.
23 CRCEN_FB	CRC parity checker logic 0b - Disables parity mechanism. In case of parity error, set to "0" to clear parity error. Only supported for DDR octal commands. 1b - Enables CRC parity checker logic for flash memory B read paths. Set this field after programming CHUNK_SIZEB, CRCBEN_FB and CRCBIN_FB.
22 CRCBEN_FB	Adds CRC bar parity from flash memory B output to QuadSPI controller.
21 CRCBIN_FB	Adds CRC bar parity to flash memory B input from QuadSPI controller
20-16 —	Reserved

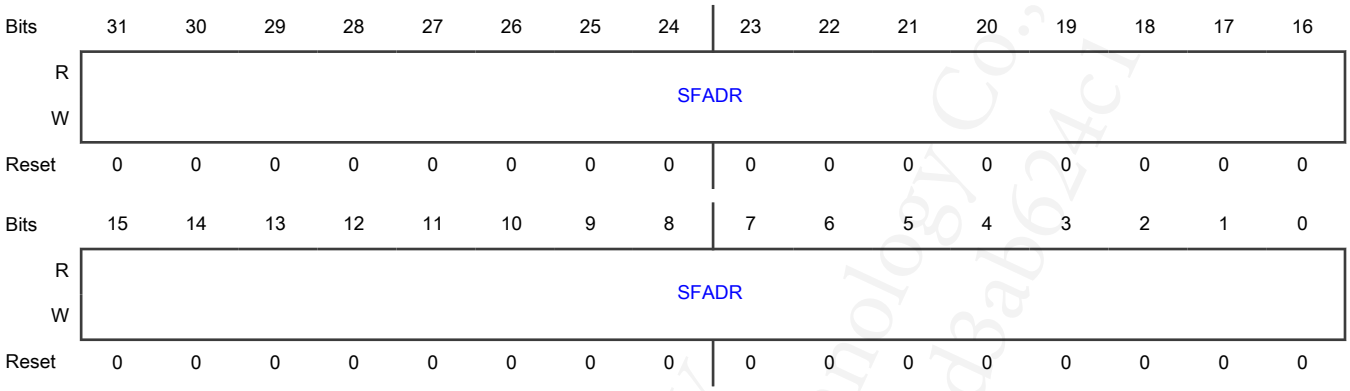
Field	Function
15 CRC_WNDW_FA	CRC address window configuration 0b - Calculates parity (CRC) over fixed address window within the denoted flash memory A chunk size boundary. 1b - Calculates parity (CRC) over incremental window of flash memory A chunk size, irrespective of address.
14-9 CHUNKSIZE_FA	Chunk size for flash memory A Defines the chunk size (in terms of 4 bytes) after parity is inserted and compared by the QuadSPI controller for flash memory A. Values 0x1, 0x2, and so on indicate 4 bytes, 8 bytes, and so on.
8 BYTE_SIZE_FA	Byte size for flash memory A This field can be programmed any time. It enables single-byte, read/write parity with flash memory A configuration register. The field overrides the chunk size used for flash memory data array. You must write 1 to this field before any read/write operation on the flash memory internal registers. And you must write 0 to this field before reading flash memory data array.
7 CRCEN_FA	CRC parity checker logic 0b - Disables parity mechanism. In case of parity error, set it to 0 to clear parity error. Only supported for DDR Octal commands. 1b - CRC parity checker logic for flash memory A read paths. Configure this field after programming CHUNK_SIZEA, CRCBEN_FA and CRCBIN_FA.
6 CRCBEN_FA	Adds CRC bar parity from flash memory A output to QuadSPI controller
5 CRCBIN_FA	Adds CRC bar parity to flash memory A input from QuadSPI controller
4-0 —	Reserved

38.4.2.17 Serial Flash Memory Address Register (SFAR)

Offset

Register	Offset
SFAR	100h

Function



The module automatically translates this address on the memory map to the address on the flash memory. When operating in a 24-bit mode, only bits 23-0 are sent to the flash memory. In the 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 when the value of SFACR[CAS] is 0. For example, if the value of SFACR[CAS] is 3, then bits 26-3 are sent to the flash memory as its page address in case flash memory is operating in a 24-bit mode. The total number of address bits requested by the flash memory, as

its page and column address, must not be more than 32 bits. See Table 212 for the mapping between the access mode and the SFAR content and Normal mode for details on command triggering and command execution. The software must ensure that the serial flash memory address provided in the SFAR register lies in the valid flash memory address range, as defined in Table 212.

Special write-access is permitted if:

- SR[IP_ACC] = 0

Diagram

Fields

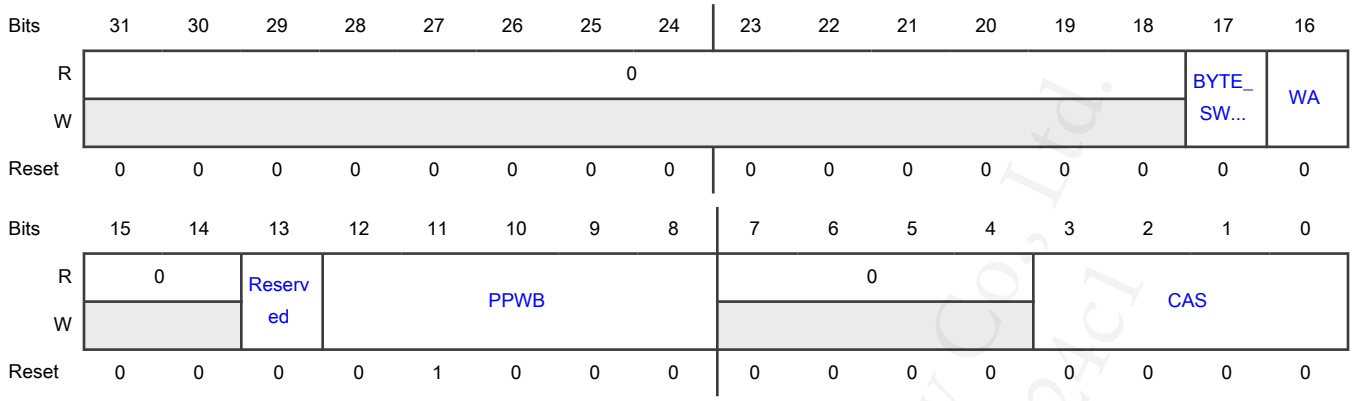
Field	Function
31-0 SFADR	Serial flash memory address

38.4.2.18 Serial Flash Memory Address Configuration Register (SFACR)

Offset

Register	Offset
SFACR	104h

Function



This register contains the address requirements that are specific to serial flash memory. These requirements must be configured according to the connected flash memory, for the controller to function properly. The module automatically translates the address of SFAR on the memory map or the incoming address on the AHB bus to the column address on the flash memory. For example, if a flash memory needs 3 bits as its column address, then only the lower three bits of the SFAR/AHB address are sent to the flash memory as its column address. The software should ensure that the serial flash memory address provided in SFAR or the incoming AHB address lies in the valid flash memory address range.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

Fields

Field	Function
31-18 —	Reserved
17 BYTE_SWAP	Byte swapping In case of Octal DDR mode, this field controls whether a word unit composed of 2 bytes from posedge and negedge of a single DQS cycle needs to be swapped. 0b - One word of two bytes at [nth, n+1th] address 1b - One word of two bytes at [n+1th, nth] address
16 WA	Word addressable Defines whether the serial flash memory is a byte addressable flash memory or a word addressable flash memory. According to the configuration of this field, the address is remapped to the flash memory interface. See Address scheme for details. 0b - Byte addressable serial flash memory mode 1b - Word (2-byte) addressable serial flash memory mode
15-14 —	Reserved
13 —	Reserved
12-8 PPWB	Page program boundary Flash memory-specific page program boundary size should be programmed in Log2 (size in bytes) format. The default is 8 = log2(256) for a 256-byte page program size.
7-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

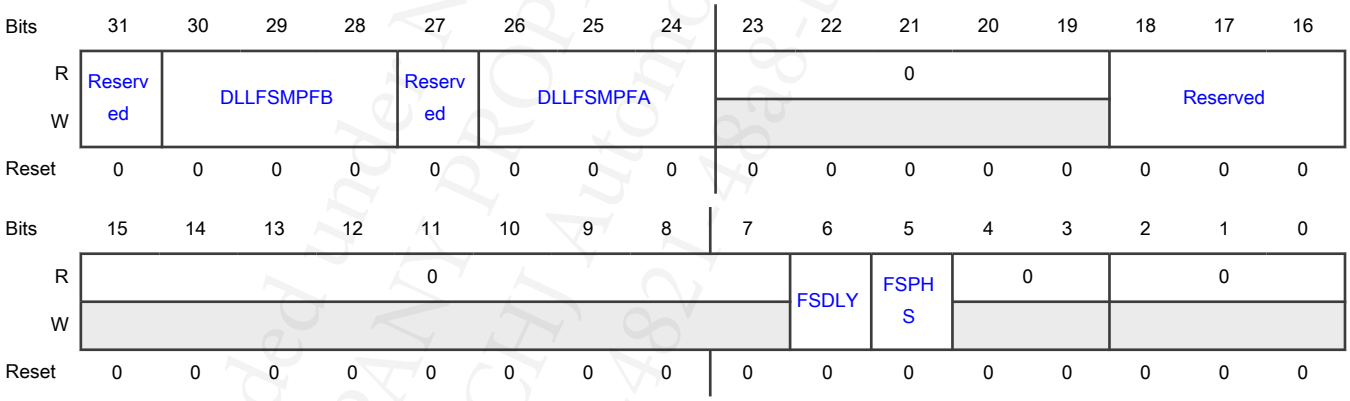
Field	Function
3-0 CAS	Column address space Defines the width of the column address. If the column address is, for example, [2:0] of SFAR/AHB address, then CAS must be 3. If there is no column address separation in any serial flash memory, the value of this field must be specified as 0.

38.4.2.19 Sampling Register (SMPR)

Offset

Register	Offset
SMPR	108h

Function



This register allows configuration of how the incoming data from the external serial flash memory devices is sampled in the QuadSPI module.

NOTE

See the chip data sheet for programming the register fields.

Special write-access is permitted in the disabled mode.

Diagram

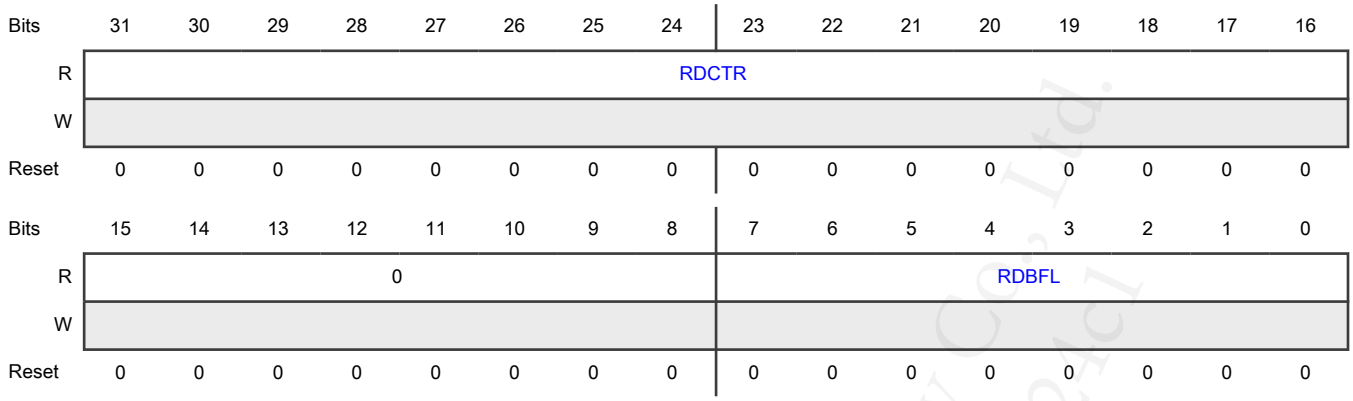
38.4.2.20 RX Buffer Status Register (RBSR)



Offset

Register	Offset
RBSR	10Ch

Function

This register contains information related to the receive data buffer.

Diagram

Fields

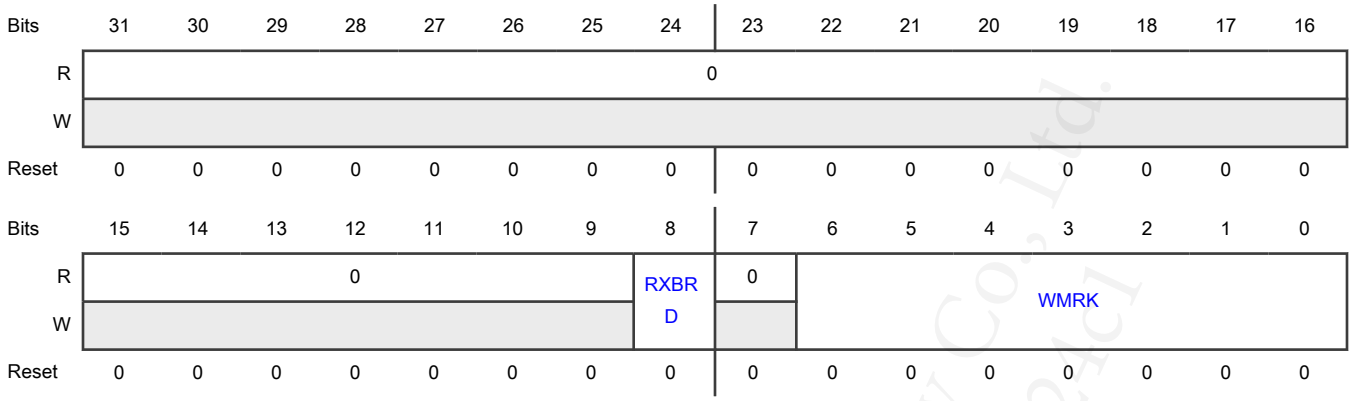
Field	Function
31-16 RDCTR	Read counter Indicates the number of 4-byte entries removed from the RX buffer. For example, a value of 0x2 indicates that 8 bytes have been removed. It is incremented by the number (RBCT[WMRK] + 1) on RX buffer POP event. The RX buffer can be popped using DMA or FR[RBDF]. The RSER[RBDDE] defines which pop should be pursued. For details, see AHB RX Data Buffer Register (ARDB0 - ARDB127) and Data Transfer from the QuadSPI Module Internal Buffers.
15-8 —	Reserved
7-0 RDBFL	RX buffer fill level Indicates the number of 4-byte entries available in the RX buffer. For example, a value of 0x2 indicates 8 bytes are available.

38.4.2.21 RX Buffer Control Register (RBCT)

Offset

Register	Offset
RBCT	110h

Function



This register contains control data related to the receive data buffer.

Field	Function
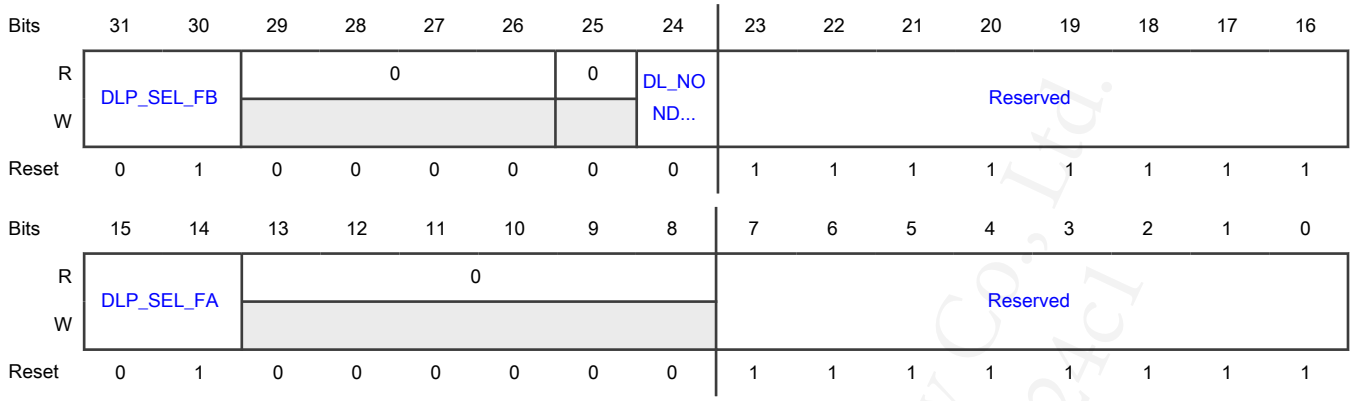
SLVA_LOCK	High-frequency slave delay chain locked. The field is configured when the slave decoder is updated with DLLCRA[SLV_UPD] and is reset after you configure SLV_UPD to 0.
13 DLLA_RANGE_ERR	DLL master delay chain The value 1 indicates that DLL master delay chain is working out of delay range because of incorrect DLL configuration.
12 DLLA_FINE_UNDERFLOW	Fine delay chain underflow The value 1 indicates that fine delay chain underflow has occurred.
11-8 —	Reserved
7-4 DLLA_SLV_FINE_VAL	Fine delay cells in slave delay chain This value indicates the total number of fine delay cells (1 delay unit) selected in the slave delay chain.
3-0 DLLA_SLV_COARSE_VAL	Coarse delay cells in slave delay chain This value indicates the total number of coarse delay cells (16 delay units) selected in the slave delay chain.

38.4.2.24 Data Learning Configuration Register (DLCR)

Offset

Register	Offset
DLCR	130h



Function

This register is used for programming the data learning settings.

- A flash memory device that supports data learning but cannot provide more than 10 bits of data learn pattern must be considered as non-DLP Flash. For Non-DLP flash devices, you must read at least 16 bits data learn pattern from a known location.
- You must program different learning pattern on the two data pins–IO1 and IO3. This is required to accommodate pessimistic data skew between the different IO lines.

R	0								TRBFL							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 TRCTR	Transmit counter This field indicates how many entries of 4 bytes have been written into the TX buffer by host accesses. It is reset to 0 when a 1 is written to MCR[CLR_TXF]. It is incremented on each write access to the TBDR register when another word has been pushed onto the TX buffer. When it is not cleared, the TRCTR field wraps around to 0. See TX Buffer Data Register (TBDR) for details.
15-8 —	Reserved
7-0 TRBFL	TX buffer fill level

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field contains the number of entries of 4 bytes each available in the TX buffer for the QuadSPI module to transmit to the serial flash memory device. The value of this field can reach maximum up to the total TX buffer size.

38.4.2.28 TX Buffer Data Register (TBDR)

Offset

Register	Offset
TBDR	154h

Function

This register provides access to the circular TX buffer of depth 256, so the total size is 256 * 4 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash memory device. See Table 220 for the byte ordering scheme. A write transaction on the flash memory with data size of less than 32 bits leads to the removal of one data entry from the TX buffer. The valid bits are used and the rest of the bits are discarded.

Special write-access is permitted if:

- SR[TXFULL] = 0

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWRACC	Asserted when AHB write access is enabled
3 —	Reserved
2 AHB_ACC	AHB read access Asserted when the currently executed transaction is initiated by the AHB bus
1 IP_ACC	IP access Asserted when transaction currently executed is initiated by the IP bus
0 BUSY	Module busy Asserted when module is currently busy handling a transaction to an external flash memory device

38.4.2.31 Flag Register (FR)

Offset

Register	Offset
FR	160h

Function

This register provides all available flags about SFM command execution and arbitration, which may serve as the source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash memory device itself but only to the behavior and conditions visible in the QuadSPI module.

Special write-access is permitted in the enabled mode.

Fields

Field	Function
31 DLPFF	Data learning pattern failure flag This field is set when the DATA_LEARN instruction is encountered in a sequence, but no sampling point is found for the data learning pattern.
30-29 —	Reserved
28 DLLABRT	DLL abort 1b - This field is set whenever DLL is unlocked while reading data from the flash memory.
27 TBFF	TX buffer fill flag Before writing to the TX buffer, this field should be cleared. Then, it should be read back. If it is set, the TX buffer can include more data. If the field remains cleared, the TX buffer can be considered as full. See TX buffer operation for details.
26 TBUF	TX buffer underrun flag This field is set if the module tries to pull data when the TX buffer is empty. The IP command leading to the TX buffer underrun is continued (data sent to the serial flash memory device is undefined). Here, a valid underrun means that it should have occurred during the transaction so that few bytes (that is, less than 4 bytes) are left in FIFO and the remaining are filled with "FFFFh". The software should initiate a TX transaction only when 128 bits are written in the TX buffer. This field does not set if transfer is less than 128 bits. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF]. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF].
25 —	Reserved
24 DLLUNLCK	DLL unlock 1b - This field is set whenever DLL unlock event occurs, irrespective of flash memory access.
23 ILLINE	Illegal instruction error flag This field is set when an illegal instruction is encountered by the controller in any of the sequences. As soon as the field is set, you must assert MCR[SWRSTSD] and MCR[SWRSTHD]. That is, reset the flash memory and AHB domain after reconfiguring the correct sequence instruction. See Table 218 for a list of legal instructions.
22-21 —	Reserved
20 —	Reserved
19-18 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 RBOF	RX buffer overflow flag This field is set when no more data can be pushed into the RX buffer from the serial flash memory device. The IP command leading to this condition is continued until the number of bytes in IPCR[IDATSZ] are read from the serial flash memory device. The content of the RX buffer remains unchanged.
16 RBDF	RX buffer drain flag This field is set if SR[RXWE] is asserted. Writing 1 to this field triggers one of the following actions: • If the RX buffer has up to RBCT[WMRK] valid entries, then the flag is cleared. • If the RX buffer has more than RBCT[WMRK] valid entries and the RSER[RBDDE] field is not set (flag driven mode), an RX buffer POP event is triggered. The flag remains set if the RX buffer contains more than RBCT[WMRK] valid entries after the RX buffer POP event is complete. The flag is cleared if the RX buffer contains less than or equal to RBCT[WMRK] valid entries after the RX buffer POP event is complete. See the "Receive Buffer Drain Interrupt or DMA Request" section in Normal mode interrupt and DMA requests for details.
15 AAEF	AHB abort error flag This field is set in case software abort is asserted in an ongoing AHB transaction. The field should be cleared before starting any new AHB transaction.
14 AITEF	AHB illegal transaction error flag This is set whenever there is no response generated from QuadSPI to AHB bus in case of an illegal transaction and the watchdog timer expires. The timer value is considered as a parameter.
13 —	Reserved
12 ABOF	AHB buffer overflow flag This is set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if BUFxCR[ADATSZ] is programmed incorrectly. The AHB command leading to this condition is continued until the number of entries according to BUFxCR[ADATSZ] have been read from the serial flash memory device. The content of the AHB buffer is not changed.
11 IUEF	IP command usage error flag This is set when in parallel flash memory mode, the execution of an IP command is started with more than one pad enabled and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_v2 command. See Table 218 for the related commands.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Communication with the serial flash memory device is terminated before the execution of WRITE/ WRITE_v2 command by the QuadSPI module.
10 CRCAEF	Sets when there is CRC or ECC error for flash memory A 0b - CRCEF interrupt is not generated. 1b - CRCEF interrupt is generated.
9 CRCBEF	Sets when there is CRC or ECC error for flash memory B 0b - CRCEF interrupt is not generated. 1b - CRCEF interrupt is generated.
8 PPWF	Page-program wait flag after flash memory write flag This field indicates page-program wait flag after flash memory write.
7 IPAEF	IP command trigger during AHB access error flag This is set when the following condition occurs: • A write access occurs to IPCR[SEQID] and the SR[AHB_ACC] field is set. Any command leading to the assertion of the IPAEF field is ignored.
6 IPIEF	IP command trigger could not be executed error flag This is set when the SR[IP_ACC] and SR[AWRACC] fields are set (that is, an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the IPCR. Any command leading to the assertion of the IPIEF flag is ignored. • Write access to the SFAR • Write access to the RBCT
5 —	Reserved
4 —	Reserved
3-1 —	Reserved
0 TFF	IP command transaction finished flag This field is set after the QuadSPI module completes a running IP command. If an error occurs, and the related error flags are valid in the same clock cycle, the TFF flag is asserted.

38.4.2.32 Interrupt and DMA Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	164h

Function

This register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each field of the FR enabled as source for an interrupt prevents the QuadSPI module from entering the Stop mode or Module Disable mode when this flag is set.

Special write-access is permitted in the "Anytime" mode.

38.4.2.33 Sequence Pointer Clear Register (SPTRCLR)

Offset

Register	Offset
SPTRCLR	16Ch

Function

This register provides fields to reset the IP and buffer sequence pointers. The sequence pointer contains the index of instructions within the LUT entry that is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index is stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in the IPCR or BFGENCR.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25-24 —	Reserved
23-20 —	Reserved
19-18 —	Reserved
17	Prefetch disable

Table continues on the next page...

Table continued from the previous page...

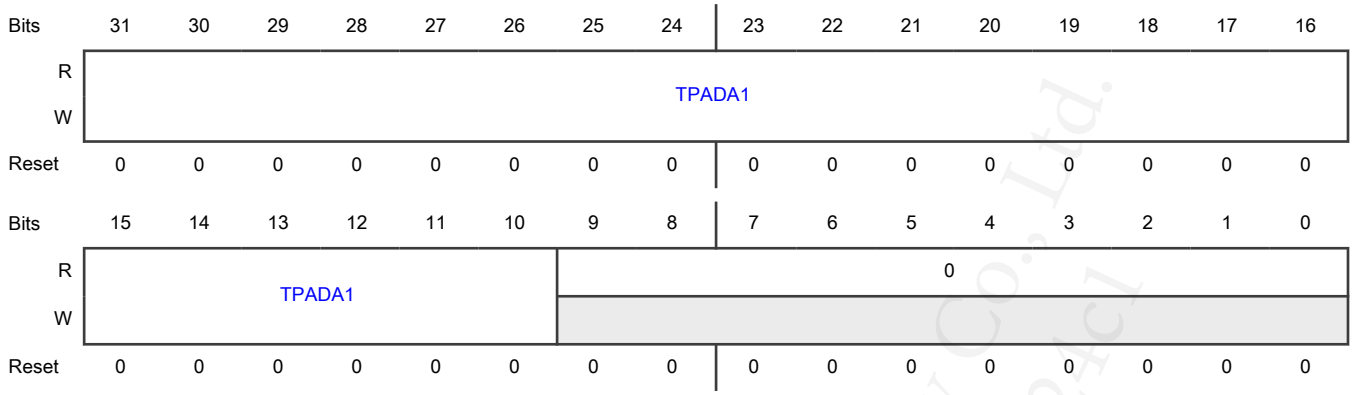
Field	Function
PREFETCH_DIS	This field should be configured to disable the prefetch mechanism of receiver. It is not based on dynamic programming. Therefore, it should be programmed initially at once. When this field is set, then during an ongoing flash memory read, any subsequent AHB read is checked for buffer hit. However, after the end of flash memory read, as soon as chip select is deasserted, any subsequent AHB read results in flushing of the current AHB buffer data and issues fresh flash memory transaction if the AHB buffer data is not updated with the flash memory.
16 ABRT_CLR	Flash memory Abort/AHB buffer clear This is a dynamic field. Writing a 1 to it, irrespective of the prefetch disable, clears the AHB buffer pointers and also aborts any ongoing flash memory transaction (if any) and rejects any ongoing AHB read with an error response (if any). QuadSPI sets this field to 0 after clearing the AHB buffer pointers.
15-9 —	Reserved
8 IPPTRC	IP pointer clear This is a self-clearing field. 1b - Clears the sequence pointer for IP accesses as defined in IPCR.
7-1 —	Reserved
0 BFPTRC	Buffer pointer clear This is a self-clearing field. 1b - Clears the sequence pointer for AHB read accesses as defined in BFGENCR.

38.4.2.34 Serial Flash Memory A1 Top Address Register (SFA1AD)

Offset

Register	Offset
SFA1AD	180h

Function



This register provides the address mapping for serial flash memory A1. The difference between SFA1AD[TPADA1] and AMBA_BASE defines the size of the memory map for serial flash memory A1.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

38.4.2.41 RX Buffer Data Register (RBDR0 - RBDR63)

Offset

For a = 0 to 63:

Register	Offset
RBDRa	200h + (a × 4h)

Function

These registers provide access to individual entries in the RX buffer. See Table 220 for the byte ordering scheme.

RBDR0 corresponds to the actual position of the read pointer within the RX buffer. The number of valid entries available depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

Example 1 - RX buffer filled completely with 128 words: In this case, the address range for valid read access extends from RBDR0 to RBDR63.

Example 2 - RX buffer filled with five valid words: RX buffer fill level of RBSR[RDBFL] is 5. In this case, access to RBDR4 provides the last valid entry.

Any access beyond the range of valid RX buffer entries provides undefined results.

NOTE

To access data beyond RBDR[63], you must pop the data by using FR[RBDF]. See here for details.

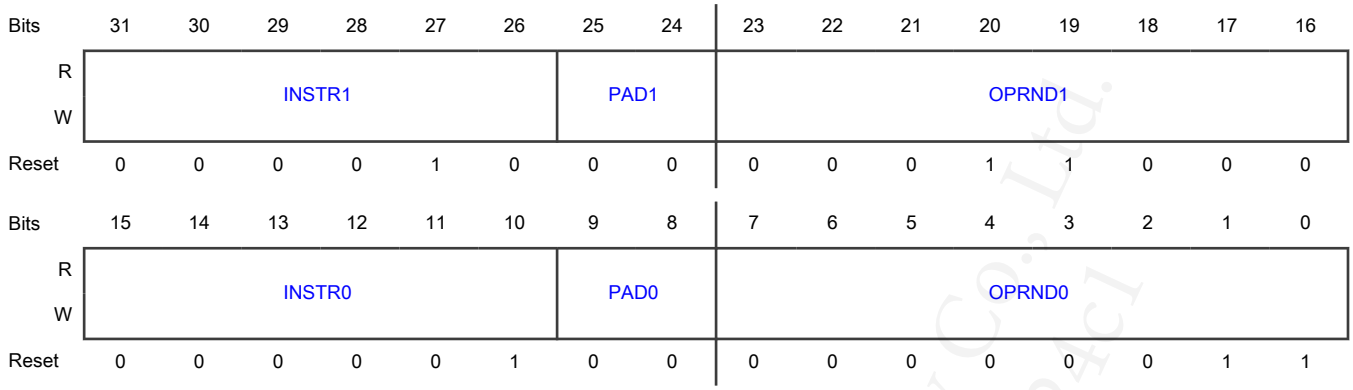
1 UNLOCK	Unlock LUT Unlocks the LUT when the following two conditions are met: • This register is written just after the LUT Key Register (LUTKEY). • The LUT key register was written with the 0x5AF05AF0 key.
0 LOCK	Lock LUT Locks the LUT when the following conditions are met: • This register is written just after the LUT Key Register (LUTKEY). • The LUT key register is written with the 0x5AF05AF0 key.

38.4.2.44 LUT Register (LUT0)

Offset

Register	Offset
LUT0	310h



Function

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence preprogrammed by Program Sequence Engine in the LUT is referred to by its index. The LUT registers act as lookup tables for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash memory transaction. There are a total of 80 LUT registers. These 80 registers are divided into groups of 5 registers that make a valid sequence. Therefore, LUT[0], LUT[5], LUT[10] ..... LUT[75] are the starting registers of a valid sequence. Each of these sets of 5 registers can have a maximum of 10 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT79. A maximum of 16 sequences can be defined at one time. See LUT that describes the LUT registers in detail.

Special write-access is permitted if the LUT is unlocked.

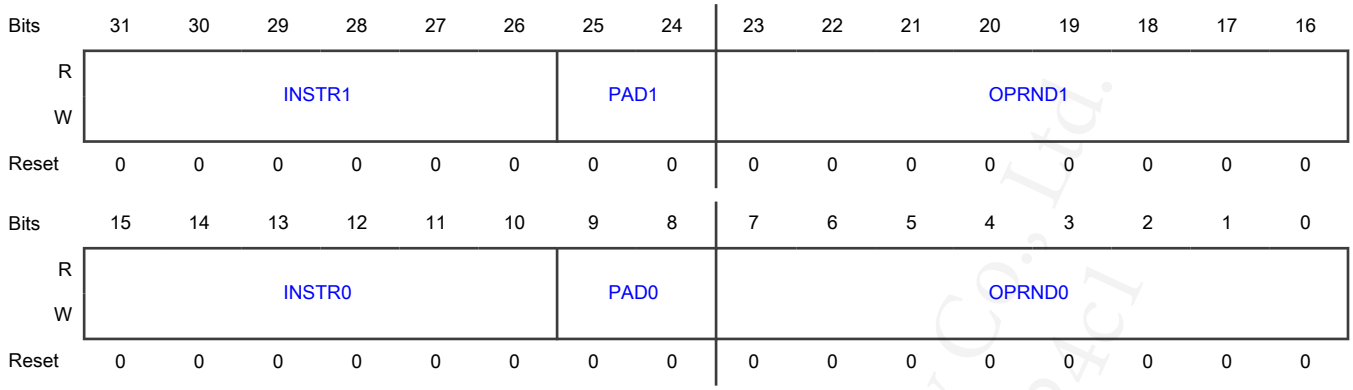
38.4.2.46 LUT Register (LUT2 - LUT79)

Offset

For a = 2 to 79:

Register	Offset
LUTa	310h + (a × 4h)



Function

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence preprogrammed by Program Sequence Engine in the LUT is referred to by its index. The LUT registers act as lookup tables for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash memory transaction. There are a total of 80 LUT registers. These 80 registers are divided into groups of 5 registers that make a valid sequence. Therefore, LUT[0], LUT[5], LUT[10] ..... LUT[75] are the starting registers of a valid sequence. Each of these sets of 5 registers can have a maximum of 10 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT79. A maximum of 16 sequences can be defined at one time. See LUT that describes the LUT registers in detail.

Special write-access is permitted if the LUT is unlocked.

38.4.3 Serial flash memory address assignment

The serial flash memory address assignment can be modified by writing into Serial Flash Memory A1 Top Address Register (SFA1AD) and Serial Flash Memory A2 Top Address Register (SFA2AD) for device A and into Serial Flash Memory B1 Top Address Register (SFB1AD) and Serial Flash Memory B2 Top Address Register (SFB2AD) for device B. The following table shows how different access modes are related to the address specified for the next SFM command. Note that this address assignment is valid for both IP and AHB commands.

Table 212. Serial flash memory address assignment

Parameter	Function	Access mode
QuadSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address First address of the serial flash memory device as presented to the QuadSPI controller. This might be the base of the serial flash memory in the system address map or it may be a remapping, for instance to 0h, performed by the system. (See the system address map file attached to this document)	
QuadSPI_ARDB_BASE	First address of the QuadSPI Rx buffer on system memory map	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash memory A1 (first device of the dual-die flash memory A, or the first of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QuadSPI_AMBA_BASE is routed to serial flash memory A1.
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash memory A2 (second device of the dual-die flash memory A, or the second of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 is routed to serial flash memory A2.
TOP_ADDR_MEMB1(TPADB1)	Top address for the external flash memory B1 (first device of the dual-die flash memory B, or the first of the two independent flash memories sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 is routed to serial flash memory B1.
TOP_ADDR_MEMB2(TPADB2) b	Top address for the external flash memory B2 (second device of the dual-die flash memory B or the second of the two independent flash memories sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 is routed to serial flash memory A2.

38.5 Flash memory mapped AMBA bus

QuadSPI_AMBA_BASE defines the address to be used as the start address of the serial flash memory device, as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash memory in the system. See the system address map for details.

Table 213. QuadSPI AMBA bus memory map

Address	Register name
QuadSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 1h)	• See Memory-mapped serial flash memory data—individual flash memory mode on flash memory A. • For information about byte ordering, see Table 220 and Table 225.
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 1h)	• See Memory-mapped serial flash memory data—individual flash memory mode on flash memory B. • For information about the byte ordering, see Table 220 and Table 225.
QuadSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 1h)	• See Parallel flash memory mode. • For information about the byte ordering, see Table 224 and Table 225.
QuadSPI_ARDB_BASE to... (32 * 4 Byte) QuadSPI_ARDB_BASE + 1FFh	• See AHB RX Data Buffer Register (ARDB0 - ARDB127). • For information about the byte ordering, see Table 220 and Table 222.

NOTE

Any read access to non-implemented addresses provides undefined results.

In case of single-die flash memory devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1, respectively (in effect, setting the size of these devices to 0). This ensures that the complete memory map is assigned to only one flash device.

The parallel flash memory mode is valid only for commands related to data read and data write in single I/O mode from serial flash memory. The first device of flash memory A needs to be paired with the first device of flash memory B and the second device of flash memory A has to be paired with the second device of flash memory B in parallel mode. This mode is selected via BFGENCR[PAR_EN] for all masters in the AHB driven mode and through IPCR[PAR_EN] in the IP-driven mode. In the parallel mode, the incoming address (SFAR address in case of IP-initiated transactions and the incoming AHB address in case of AHB-initiated transactions) is divided by 2 and sent to the two flash memories connected in parallel.

Any IP command other than data read and write (through one pad) in the parallel flash memory mode results in the assertion of FR[IUEF].

In individual flash memory modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash memory address are determined by SFADR[23:0] or SFADR[31:0] as provided in the table shown above.

In parallel flash memory mode, both flash memories are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from SFADR[24:1] or SFADR[31:1] as provided in the table above. The LSB of the SFADR field is used to select the appropriate bits of both the flash memory devices to combine the bytes corresponding to the selected address.

38.5.1 AHB bus access read considerations

Note that all logic in the QuadSPI module implementing the AHB bus access is designed to read the content of an external serial flash memory device. Therefore, the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- AHB bus read access types—NONSEQ and BUSY—are fully supported.
- AHB read access type—SEQ—is treated in the same way as NONSEQ. See Flash memory mapped AMBA bus for details.

- Early burst termination is not supported for AHB transactions.
- An AHB error response is provided on occurrence of:
  - Parity error
  - ECC error from flash memory
  - Data learning failure

  Also, interrupts (if enabled) are provided along with the AHB error response.

38.5.2 Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

Starting with address QuadSPI_AMBA_BASE, the content of the first external serial flash memory device is mapped into the address space of the device containing the QuadSPI module. Serial flash memory byte address 0h corresponds to bus address, QuadSPI_AMBA_BASE, in an increasing order. Assuming that a dual-die flash memory is connected to the first set of external pads, the address space is divided into two parts, one for each device of the dual-die package. See the following table for the address mapping. The byte ordering for 32-bit access is provided in Table 220 and for 64-bit read access, the byte ordering is provided in Table 225.

Table 214. Memory-mapped individual flash memory mode—flash memory A address scheme

Memory-mapped address 32-bit access	Memory-mapped address 64-bit access	Serial flash memory byte address	Flash memory device
QuadSPI_AMBA_BASE + 0h	QuadSPI_AMBA_BASE + 0h	0h to 3h	A1
QuadSPI_AMBA_BASE + 4h		4h to 7h	
...	...	...	
TOP_ADDR_MEMA1 - 8h	TOP_ADDR_MEMA1 - 8h	(TOP_ADDR_MEMA1- 8h) to (TOP_ADDR_MEMA1 - 0h4 -0h1)	
TOP_ADDR_MEMA1 - 4h		(TOP_ADDR_MEMA1 - 4h) to (TOP_ADDR_MEMA1 - 0h1)	
TOP_ADDR_MEMA1 + 4h	TOP_ADDR_MEMA1 + 0h	0h to 3h	A2
TOP_ADDR_MEMA1 + 0h4		4h to 7h	
...	...	...	
TOP_ADDR_MEMA2 - 8h	TOP_ADDR_MEMA2 - 8h	(TOP_ADDR_MEMA2 - 8h) to (TOP_ADDR_MEMA2 - 4h - 1h)	
TOP_ADDR_MEMA2 - 4h		(TOP_ADDR_MEMA2 - 4h) to (TOP_ADDR_MEMA2 - 1h)	

The available address range depends on the size of the external serial flash memory device. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read.

Provided under NDA only

38.5.3 Memory-mapped serial flash memory data—individual flash memory mode on flash memory B

Starting with address TOP_ADDR_MEMA2, the content of the first external serial flash memory devices is mapped into the address space of the device containing the QuadSPI module. Serial flash memory address byte address 0h corresponds to bus address, TOP_ADDR_MEMA2, in an increasing order. Assuming that a dual-die flash memory is connected to the first set of external pads, the address space is divided into two parts, one for each device of the dual-die package. See the following table for address mapping. The byte ordering for 32-bit access is provided in Table 220 and for 64-bit read access, the byte ordering is provided in Table 225.

Table 215. Memory-mapped individual flash memory mode—flash memory B address scheme

Memory-mapped address 32-bit access	Memory-mapped address 64-bit access	Serial flash memory byte address	Flash memory device
TOP_ADDR_MEMA2 + 0h	TOP_ADDR_MEMA2 + 0h	0h to 3h	B1
TOP_ADDR_MEMA2 + 0h4		0h_0004 to 0h_0007	
...	...	...	
TOP_ADDR_MEMB1 - 0h8	TOP_ADDR_MEMB1 - 0h8	(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0h8) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0h4 -0h1)	
TOP_ADDR_MEMB1 - 0h4		(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0h4) to (TOP_ADDR_MEMB1- TOP_ADDR_MEMA2- 0h1)	
TOP_ADDR_MEMB1 + 0h	TOP_ADDR_MEMB1 + 0h	0 to 3h	B2
TOP_ADDR_MEMB1 + 0h4		0h_0004 to 0h_0007	
...	...	...	
TOP_ADDR_MEMB2 - 0h8	TOP_ADDR_MEMA2 - 0h8	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1- 0h8) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0h4 - 0h1)	
TOP_ADDR_MEMB2 - 0h4		(TOP_ADDR_MEMB2- TOP_ADDR_MEMB1 - 0h4) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0h1)	

The available address range depends on the size of the external serial flash memory device. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read.

38.5.4 Parallel flash memory mode

Any of the AHB flexible buffers can be configured to work in the parallel flash memory mode by programming the value for BFGENCR[PAR_EN] to 1. When the parallel mode is set, flash memory A1 is paired with flash memory B1 and flash memory A2

is paired with flash memory B2. In the parallel mode, the software should ensure that the size of flash memory A1(A2) is equal to the size of flash memory B1(B2).

Reads from any even AHB bus address provide bits [7:4] of both serial flash memory devices and reads from any odd AHB bus address provide bits [3:0] of both flash memory devices. See the following table for address mapping. The byte ordering for 32-bit access Table 222and 64-bit read access is provided in Table 225.

Table 216. Memory-mapped parallel flash memory mode address scheme

Memory-mapped address 32-bit access	Memory-mapped address 64-bit access	Serial flash memory A byte address	Serial flash memory B byte address
QuadSPI_AMBA_BASE + 0h	QuadSPI_AMBA_BASE + 0h For details, see Parallel mode and Dual-die flash memories.	0h - 1h	0h - 1h
QuadSPI_AMBA_BASE + 4h		2h - 3h	2h - 3h
QuadSPI_AMBA_BASE + 8h	QuadSPI_AMBA_BASE + 8h	4h - 5h	4h - 5h
QuadSPI_AMBA_BASE + Ch		6h - 7h	6h - 7h
...	...	...	...
TOP_ADDR_MEMB2 - 8h	TOP_ADDR_MEMB2 - 8h	(TOP_ADDR_MEMB2 - QuadSPI_AMBA_BASE - 8h)/2	(TOP_ADDR_MEMB2 - QuadSPI_AMBA_BASE - 8h)/2
TOP_ADDR_MEMB2 - 4h		(TOP_ADDR_MEMB2 - QuadSPI_AMBA_BASE - 4h)/2 +1h	(TOP_ADDR_MEMB2 - QuadSPI_AMBA_BASE- 4h)/2 + 1h

The available address range covers 27 address bits, corresponding to 128 MB per flash memory device. The usable space depends on the size of the external serial flash memory devices. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read.

38.5.5 ARDB register descriptions

NOTE

See the system memory map in this document for the base address of the QuadSPI AHB RX data buffer.

38.5.5.1 ARDB memory map

QuadSPI_ARDB base address: 4100_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 1FCh	AHB RX Data Buffer Register (ARDB0 - ARDB127)	32	RO	0000_0000h

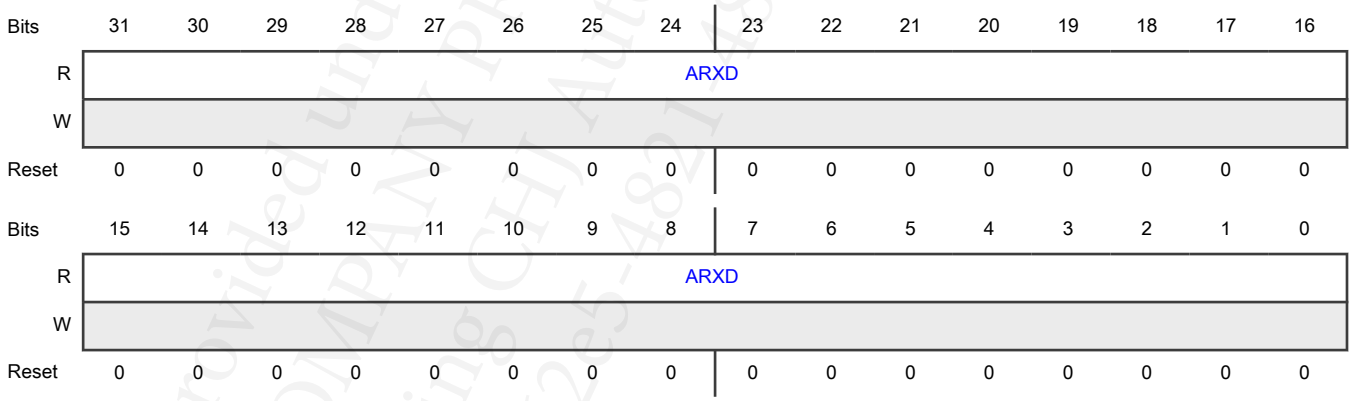
38.5.5.2 AHB RX Data Buffer Register (ARDB0 - ARDB127)

Offset

For a = 0 to 127:

Register	Offset
ARDBa	0h + (a × 4h)

Function



This register is used to read the buffer content of the RX buffer from successive addresses. ARDB0 corresponds to the RX buffer register entry corresponding to the current value of the read pointer in an increasing order.

The increment of the read pointer depends on the access scheme (DMA or flag-driven). See Flash memory read, RX buffer, data read through register interface, and AHB read for the description of successive accesses to the RX buffer content. See Byte Ordering of Serial Flash Memory Read Data for the byte ordering scheme.

Valid address range accessible in the ARDB*n* range depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

- Example 1 - RX buffer filled completely with 128 words: In this case, the address range for valid read access extends from ARDB0 to ARDB127.
- Example 2 - RX buffer filled with five valid words; RX buffer fill level RBSR[RDBFL] is 5. In this case, an access to ARDB4 provides the last valid entry.

38.6 Functional description

This section provides a functional description of the QuadSPI module.

38.6.1 Serial flash memory access schemes

The following access schemes are possible, depending on the serial flash devices attached to the QuadSPI module.

Table 217. Access schemes for serial flash memory data access

Access scheme	One flash memory device on port A	One flash memory device on port B	Two identical flash memory devices connected to port A and port B
Individual flash memory mode: access to flash memory A	**Yes**	**N/a**	**Yes**
Individual flash memory mode: access to flash memory B	**N/A**	**Yes**	**Yes**
Parallel flash memory mode: read from flash memory A and flash memory B	**N/A**	**N/A**	**Yes**

If two flash memory devices are accessed in the parallel flash memory mode, they are accessed with identical control signals. Special alignment on per-flash memory basis is not possible. The application needs to ensure that the identical signals are applicable to both the flash memory devices.

In the parallel flash memory mode, both the external serial flash memory devices appear as a single memory doubled in size with respect to one individual flash memory device.

If two different flash memory devices are attached, they can be operated only in the individual flash memory mode.

In the parallel flash memory mode, only data read commands and write command (in x1 mode) are supported. Any other IP command results in an error condition signaled by the assertion of FR[IUEF].

In the individual flash memory mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the individual flash memory mode.

38.6.2 Normal mode

This mode allows communication with an external serial flash memory device. Compared to the standard SPI protocol, this communication method uses up to four bidirectional data lines operating at high-data rates. The communication to the external serial flash memory device consists of an instruction code and optional address, mode, dummy, and data transfers. The flexible programmable core engine described below is immune to a wide variety of command or protocol differences in the serial flash memory devices provided by various flash memory vendors.

38.6.2.1 Programmable sequence engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands are provided in the following table.

Table 218. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
CMD	1d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	8-bit command value	Provide the serial flash memory with operand on the number of pads specified
ADDR	2d		Number of address bits to be sent (for example, 24d => 24 address bits required)	Provide the serial flash memory with address cycles according to the operand on the number of pads specified The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions, if the value of SFACR[CAS] is set to 0. Otherwise, the actual address takes CAS into consideration.
DUMMY	3d		Number of dummy clock cycles (should be <= 64 and > 2 cycles)	Provide the serial flash memory with dummy cycles according the operand The PAD information defines the number of pads in input mode. For example, one pad implies that pad 1 is not driven, rest all are driven. **NOTE** If DLL is enabled and N dummy cycles are needed, you must program two back-to-back DUMMY instructions: DUMMY: N-2 followed by DUMMY:2.
MODE	4d		8-bit mode value	Provide the serial flash memory with 8-bit operand on the number of pads specified
MODE2	5d	N={0,1}d	2-bit mode value	Provide the serial flash memory with 2-bit operand on the number of pads[1] specified
MODE4	6d	N={0,1,2}d	4-bit mode value	Provide the serial flash memory with 4-bit operand on the number of pads[2] specified
READ	7d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	Read data size in bytes (for AHB transactions, your application should ensure that data size	Read data from flash memory on the number of pads specified The data size can be overwritten by writing to the ADATSZ field of the BUFxCR registers for AHB-initiated transactions and to the IDATSZ field of the IP Configuration Register (IPCR) for IPS-initiated transactions.

Table continues on the next page...

Table 218. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
			is a multiple of 8 bytes)	
WRITE	8		Write data size in bytes	Write data on the number of pads specified The data size can be overwritten by writing to the IDATSZ field of IP Configuration Register (IPCR).
JMP_ON_CS	9d	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion. **NOTE** This instruction is not supported if DLL is enabled.
ADDR_DDR	10d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	Number of address bits to be sent (for example, 24d => 24 address bits required)	Provide the serial flash memory with address cycles according to the operand on the number of pads specified at each clock edge of serial flash memory clock. The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions if SFACR[CAS] is set to 0. Otherwise, the actual address takes CAS into consideration.
MODE_DDR	11d		8-bit mode value	Provide the serial flash memory with 8-bit operand on the number of pads specified at each clock edge of serial flash memory
MODE2_DDR	12d	N={0}d	2-bit mode value	Provide the serial flash memory with 2-bit operand on the number of pads specified at each clock edge of serial flash memory [3]
MODE4_DDR	13d	N={0,1}d	4-bit mode value	Provide the serial flash memory with 4-bit operand on the number of pads specified at each clock edge of serial flash memory [4].
READ_DDR	14d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d - Eight pads	Read data size in bytes (for AHB transactions, the application should ensure that data size is in multiple of 8 bytes)	Read data from flash memory on the number of pads specified at each clock edge of serial flash memory. The data size might be overwritten by writing to the ADATSZ field of the BUFxCR registers for AHB-initiated transactions and IDATSZ field of IP Configuration Register (IPCR) for IP initiated transactions.

Table continues on the next page...

Table 218. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
WRITE_DDR	15d		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash memory The data size can be overwritten by writing to the IDATSZ field of IP Configuration Register (IPCR).
DATA_LEARN	16d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	Operand[7]- • 1 - DDR mode • 0 - SDR mode Operand[6:0]- • Number of bits to be used for data learning. For example, if operand is 7, then a 7-bit data_learning pattern is read and compared.	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the value of Sampling Register (SMPR) is ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern.[5]
CMD_DDR	17d	N={0,1,2,3}d 0d - One pad 1d - Two pads 2d - Four pads 3d- Eight pads	8-bit command value	Provide the serial flash memory with the operand with number of pads specified at each clock edge of the serial flash memory.
CADDR	18d		Number of column address bits to be sent (8d means 8 bits of column address is to be sent)	Provide the serial flash memory with column address cycles according to the operand on the number of pads specified. The actual address to be provided to flash memory depends on the value of SFACR[CAS]. For example, if the value of SFACR[CAS] is 3, then the address to flash memory will be [2:0] of incoming address in case of AHB and the value of SFAR in case of IP. This is appended with 0 if SFACR[CAS] is less than number of pads for a flash memory.
CADDR_DDR	19d		Number of column address bits to be sent(8d means 8 bits	Provide the serial flash memory with column address cycles according to the operand on the number of pads specified at each clock edge of the serial flash memory. The actual address to be provided to flash memory depends on the value of SFACR[CAS]. For example, if CAS is 3, then the address to

Table continues on the next page...

Table 218. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
			of column address is to be sent)	flash memory will be [2:0] of incoming address in case of AHB and the value of SFAR in case of IP. This is appended with 0 if CAS is less than the number of pads for a flash memory.
JMP_TO_SEQ	20d	NA	Sequence number	Every time CS is deasserted, jump to the LUT sequence is pointed to by the operand. This instruction allows the programmer to join two sequences and initiates the second flash memory transaction automatically. It can be used to join write-enables with flash memory write or data learn with read. **NOTE** This instruction is not supported if DLL is enabled.
STOP	0d	NA	NA	Stop execution; deassert CS

1. For a one-pad instruction, MODE2 takes two serial flash memory clock cycles on the flash memory interface.
2. For a one-pad instruction, MODE4 takes four serial flash memory clock cycles on the flash memory interface. For a four-pad instruction, MODE4 takes one serial flash memory clock cycle on the flash memory interface.
3. For a one-pad instruction, MODE2_DDR takes one serial flash memory clock cycle on the flash memory interface.
4. For a one-pad instruction, MODE4_DDR takes two serial flash memory clock cycles on the flash memory interface. For a four-pad instruction MODE4_DDR takes half a cycle on the serial flash memory interface.
5. It is not recommended to have 0h or FFh as the data learning pattern.

The programmable sequence engine allows you to configure the QuadSPI module according to the serial flash memory connected on board. This flexible structure is compatible with new command or protocol changes from different vendors.

38.6.2.2 Flexible read xAHB buffers

To reduce the latency of the reads for AHB masters, the data read from serial flash memory is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 bytes and maximum size being the size of the complete buffer instantiated (1024 bytes). The size of buffer 0 ranges from 0 to BUF0IND. The size of buffer 1 ranges from BUF0IND to BUF1IND, buffer2 from BUF1IND to BUF2IND and, buffer 3 ranges from BUF2IND to the size of the complete buffer (1024 bytes).

Each flexible AHB buffer is associated with the following:

- An AHB master: Optionally, buffer3 may be configured as an "all master" buffer by writing 1 to BUF3CR[ALLMST]. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
- A datasize field representing the amount of data to be fetched from the flash memory on every missed access.

The master port number of every incoming request is checked and the data is returned or fetched into the corresponding associated buffer. Every missed access to the buffer causes the controller to clear the buffer and fetch the BUFxCR[ADATSZ] amount of data from the serial flash memory. As such, you need not configure the buffer size to be greater than ADATSZ because the locations greater than ADATSZ are never used. For any AHB access, the sequence pointed to by BFGENCR[SEQID] is used for the initiated flash memory transaction. The data is returned to the master as soon as the requested amount is read from the serial flash memory. The controller; however, continues to prefetch the rest of the data in anticipation of a next consecutive request. See Figure 191 that shows flexible AHB buffers.

BFGENCR[SEQID] points to an index of the LUT. See LUT for details.

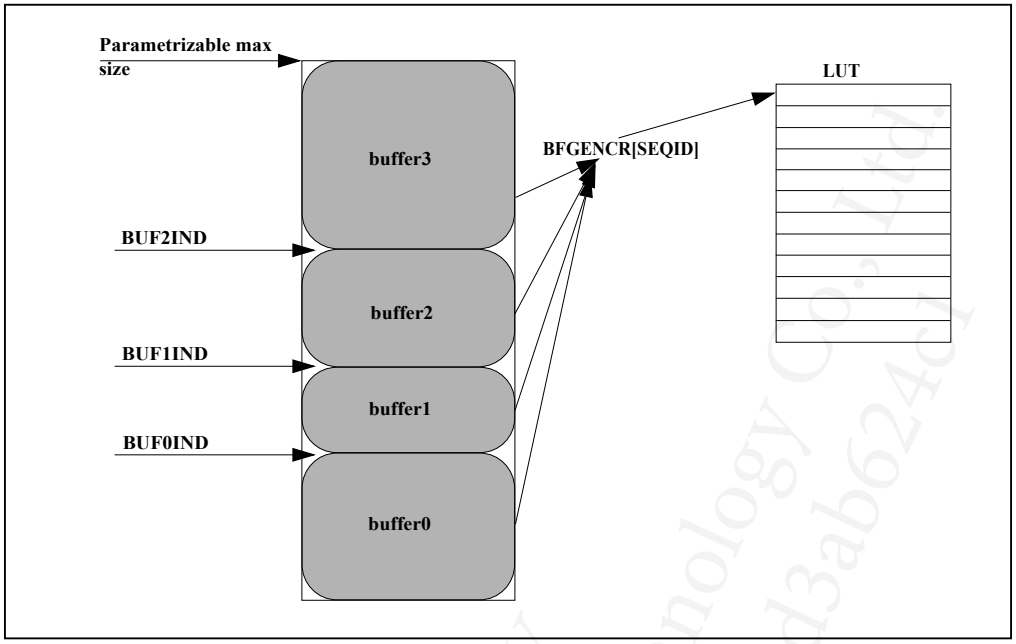

Figure 191. Flexible read AHB buffers

38.6.2.3 Abort mechanism during AHB read

Any ongoing read transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

38.6.2.4 HBURST support with AHB read

QuadSPI controller supports HBURST and HSIZE on the AHB read interface. HBURST indicates if the transfer forms part of a burst. Four, eight, and sixteen beat bursts are supported and the bursts might either be incrementing or wrapping. HSIZE indicates the size of the transfer, and supports 8-, 16-, 32-, and 64-bit data sizes. In case of WRAP accesses, QuadSPI generates aligned accesses to serial flash memory if there is no buffer hit for any incoming, non-sequential AHB read access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size, an error response is generated and the value of FR[AIBSEF] is configured as 1. The data prefetch size can be defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as 0. In case of wrap burst, data prefetch size must be greater than or equal to the wrap burst size + 32 bytes. A few examples are shown in the figure below:

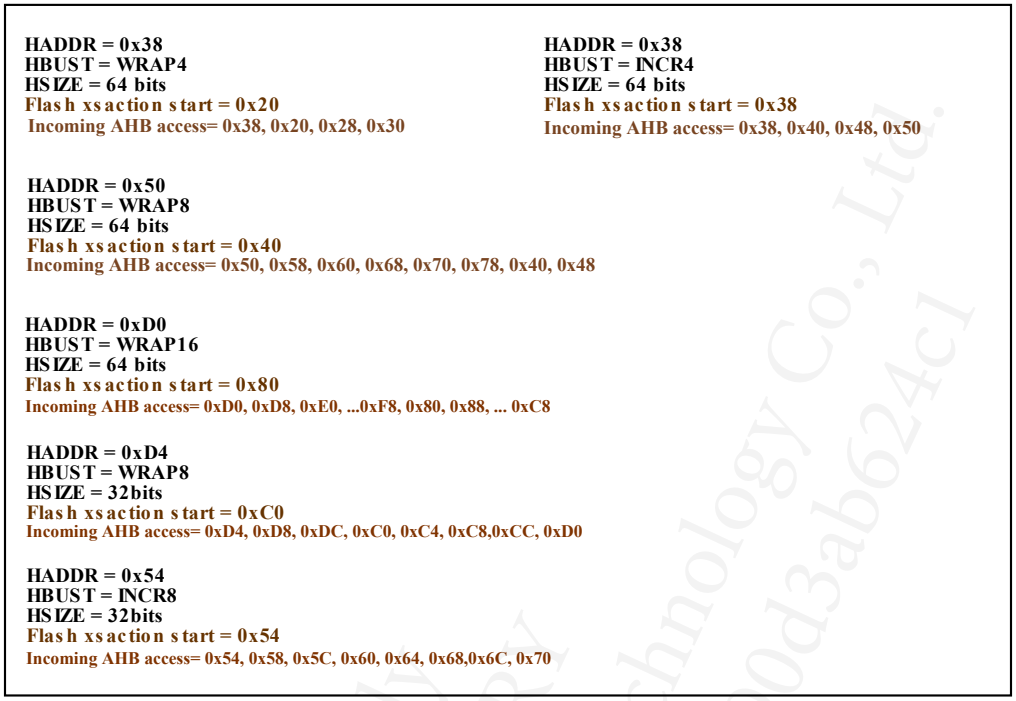

Figure 192. QuadSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

38.6.2.5 LUT

The LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs, which when executed sequentially, generate a valid serial flash memory transaction. Each sequence can have a maximum of 10 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

c8c462e5-4821-4a2c-b251-390d3ab624c1

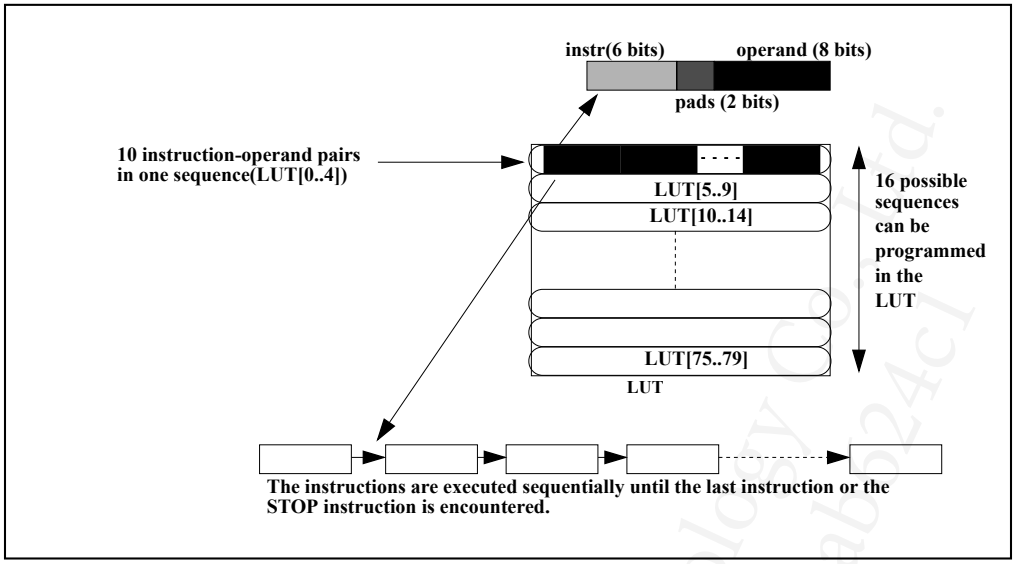

Figure 193. LUT and sequence structure

At reset, the index 0 of the LUT[0..4] is programmed with a basic read sequence as described in Reset sequence. After reset, the complete LUT may be reprogrammed according to the chip connected on board. To protect its contents, during a code runover, the LUT might be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is 5AF05AF0h, and the associated processes are as follows:

Locking the LUT

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued). A successful write to this register locks the LUT.

Unlocking the LUT

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b10 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write to this register unlocks the LUT.

The lock status of the LUT can be read from the LCKCR[UNLOCK] and LCKCR[LOCK] fields.

Some example sequences are defined in Example sequences. The reset sequence at LUT index 0 is shown in the following table.

Table 219. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0h	3h	Read data byte command on one pad
ADDR	0h	18h	24 address bits to be sent on one pad
READ	0h	8h	Read 64 bits
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

38.6.2.6 Issuing SFM commands

Each access to the external device follows this sequence:

1. You must pre-populate the LUT with the serial flash memory command sequences that are required for the flash memory device being used.
2. The module executes the instructions in this sequence one by one. The transaction starts and the module configues the value of SR[BUSY].
3. Communication with the external serial flash memory device starts and the transaction executes.
4. After the transaction is complete (all transmit and receive operations with the external serial flash memory device are complete), the module resets SR[BUSY]. In case of an IP command, FR[TFF] is asserted.

For details, see Flash memory programming and Flash memory read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

Using IP commands

For IP commands, the required components need to be written into the following registers and in this sequence:

1. Write the serial flash memory address to be used as provided in the Serial Flash Address Register (SFAR). For IP commands not related to specific addresses, the base address of the related flash memory needs to be programmed. For example, for an instruction which does not require an address (that is, write enable instruction), the SFAR should be programmed with the base address of the memory the command is to be sent to.
2. Write the sequence ID and data size details in the IP Configuration Register (IPCR).
3. Note that writing a value to IPCR[SEQID] must be the last step of the sequence. It is possible to combine all the fields of the IPCR into one single write. See IP Configuration Register (IPCR) for details.

Using AHB commands

Any AHB memory-mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss," a new serial flash memory transaction is initiated. The transaction is based on the sequence pointed to by BFGENCR[SEQID] as described in Flexible read xAHB buffers.

An AHB access is considered memory mapped when the access is to the memory-mapped serial flash memories, as described in Memory Mapped Serial Flash Data - Individual Flash mode on Flash memory A and Memory Mapped Serial Flash Data - Individual Flash Memory mode on Flash memory B.

38.6.2.7 Flash memory programming

In all cases, the memory sector to be written needs to be erased first. The programming sequence is then initiated in the following way:

1. Check that SR[BUSY] is de-asserted or the value of the BUSY field is 0, also, check that the TX buffer is empty. If you need to discard the data present in the TX buffer (SR[TXNE]) then the TX buffer must be cleared by writing 1 to MCR[CLR_TXF].
2. Program the address related to the command in SFAR. If required, write the desired value to SFACR[CAS], otherwise write 0 to it. Also, write 1 to SFACR[WA] if the serial flash memory is a word addressable flash memory, or write 0 in case serial flash memory is byte addressable.
3. Provide initial data for the program command into the circular buffer through the TBDR. At least one words of data must be written into the TX buffer up to a maximum of 256 entries.
4. Program the IPCR to trigger the command. IPCR[SEQID] should point to an index of the LUT that has the flash memory program sequence pre-programmed. You must write 1 to IPCR[IDATSZ] to denote the size of the write.
5. Repeat step 3, depending on the amount of data required, until all of the required data is written to the TBDR. SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, TBSR[TRCTR] can be read to check how many words have been written into the TX buffer.

After writing to IPCR[SEQID] (see step 4), the module starts executing the programmed sequence. The software ensures that the correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX buffer. It consists of 256 entries of 32-bit sizes and is organized as a circular FIFO, the read pointer for which is incremented after each fetch. When all the data is transmitted, the QuadSPI module returns from the busy state to the idle state.

However, this is not true for the external device because the internal programming is still ongoing. You may monitor the relevant status information available from the serial flash memory device and ensure that the programming is done appropriately.

38.6.2.8 Flash memory read

Host access to the data stored in the external serial flash memory device is performed in two steps. First, the data must be read into the internal buffers and in the second step, these internal buffers can be read by the host.

Reading serial flash memory data into the QuadSPImodule internal buffers

A read access to the external serial flash memory device can be triggered in two different ways:

- IP command read: For reading flash memory data into the RX buffer, you must provide the correct sequence ID in IPCR[SEQID]. The sequence ID points to a sequence in the LUT. The software needs to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. You must program the SFAR , SFACR[CAS], and IPCRs. All available read commands supported by the external serial flash memory are possible.

  Optionally, it is possible to clear the RX buffer pointer prior to triggering the IP command by writing a 1 to MCR[CLR_RXF].

  Using these inputs, the complete transaction is built when IPCR[SEQID] is written to. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash memory device into the RX buffer. As the read access is triggered by an IP command, the value of both SR[IP_ACC] and SR[BUSY] is set to 1.. A count of the number of entries currently in the Rx buffer can be obtained from RBSR[RDBFL].

  Communication with the external serial flash memory stops if the specified number of bytes are read (on successful completion of the transaction).

  NOTE

  In case of external DQS strobe based sampling, read data size (IDATSZ or LUT size) must be in multiples of 8 bytes.

- AHB command read: For reading flash memory data into the AHB buffer, you must:
  - Set up a read access by a master to the address range in the system memory map, which the external serial flash memory devices are mapped to.
  - Write a desired value to SFACR[CAS], if required, or write 0 to the field.
  - Program the buffer registers corresponding to the AHB master initiating the request, and this depends on the configuration of RBCT[RXBRD].
  - Provide the correct sequence ID in the BFGENCR. The software ensures that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. Flash memory device selection and access mode are determined by the address accessed in the AHB address space associated with the QuadSPI module (see Memory-mapped serial flash memory data—individual flash memory mode on flash memory A , Memory-mapped serial flash memory data—individual flash memory mode on flash memory B and Parallel flash memory mode.)

  On each AHB read access to the memory mapped area, the valid data in the AHB buffer is checked against the address requested in the actual read. When the AHB read request cannot be served from the content of the AHB buffer, the buffer is flushed and the controller executes the sequence pointed to by the sequence ID. The requested number of buffer entries defined in BUFxCR[ADATSZ] is then fetched from the external serial flash memory device into the internal AHB buffer. As the read access is triggered through the AHB bus, the value of SR[AHB_ACC] is set, driving SR[BUSY] in turn, until the transaction is complete. Communication with the external serial flash memory stops when the specified number of entries is filled.

Data transfer from the QuadSPI module internal buffers

The data read out from the external serial flash memory device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data is loaded to. See Block diagram for details on the two available buffers, the RX buffer and the AHB buffer, in this module. The buffer appears transparent to you and is non-memory mapped. See the "Flexible AHB Buffer" section for details.

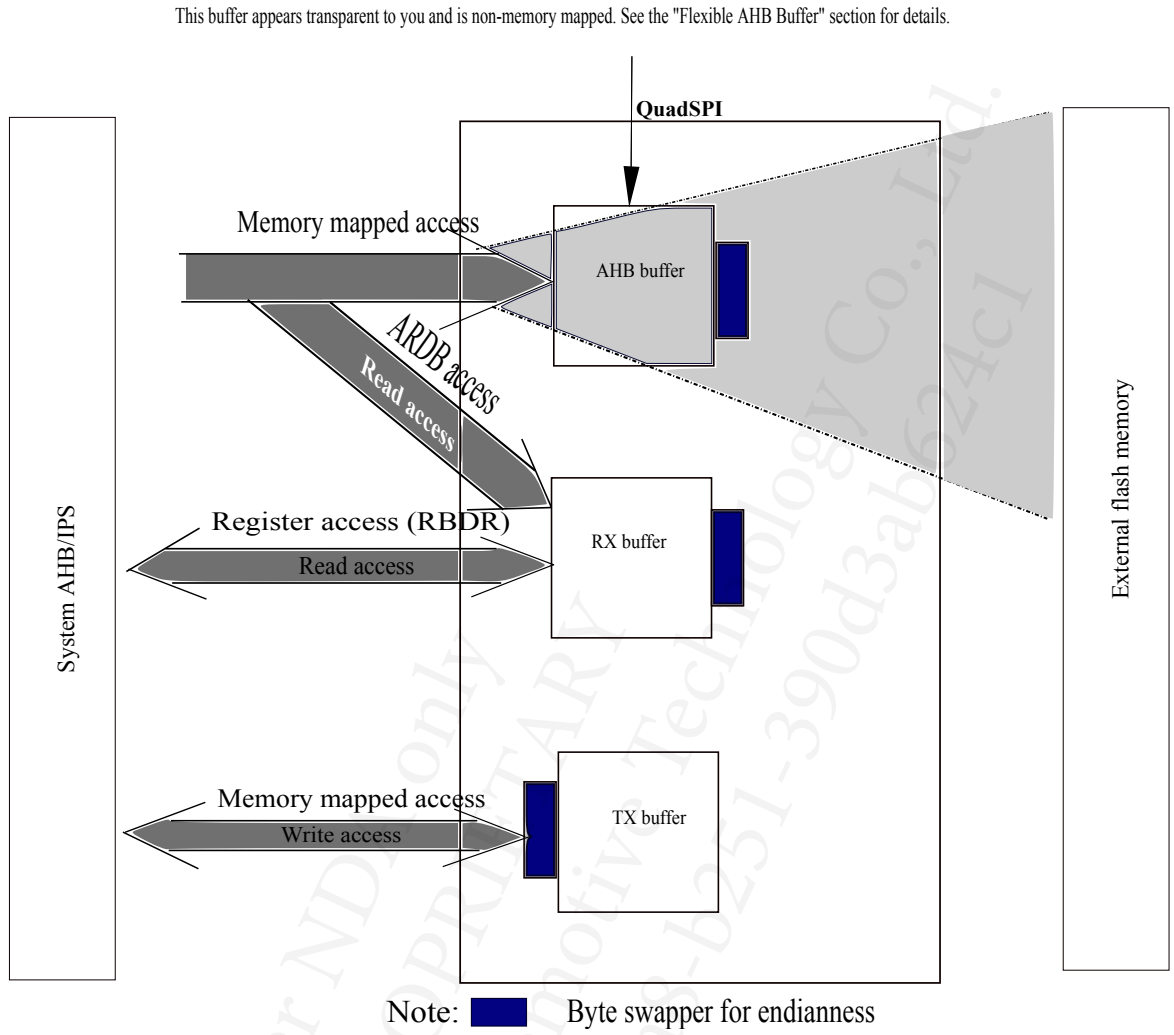

Figure 194. QuadSPI memory map

The RX buffer is implemented as FIFO of depth entries of 4 bytes. Its content is accessible in two different address areas, both referring to identical data and the same physical memory:

- In the IPS address space in the area associated with RX Buffer Data Register (RBDR0 - RBDR63).
- In the AHB address space in the area associated with AHB RX Data Buffer Register (ARDB0 - ARDB127).Two successive entries are accessed with one single 64-bit AHB read operation.

The RX buffer operation can be summarized as follows:

- RBCT[WMRK] determines at which fill level SR[RXWE] is asserted and how many entries are removed from the RX buffer on each buffer POP operation.
- SR[RXWE] indicates that the configured number of data entries is available in the RX buffer and RBSR[RDBFL] indicates how many valid entries are available in total.
- The first entry (RBDR0 or ARDB0) always corresponds to the first valid entry in the RX buffer.

For details, see RX Buffer Data Register (RBDR0 - RBDR63) and AHB RX Data Buffer Register (ARDB0 - ARDB127).

- Flag-based data read of the RX buffer is performed by polling SR[RXWE]. When it is asserted, the valid entries can be read either via the IPS address space (RBDRn) or the AHB address space (ARDBn). A buffer POP operation must be

triggered by the application by writing a 1 to FR[RBDF]. This automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer discards 16 bytes of data.

- DMA-controlled data read of the RX buffer is performed by using the DMA module. The application must ensure that the DMA controller of the related chip is programmed appropriately, as described in DMA usage.
- DMA-controlled read out is triggered fully automatically by the assertion of SR[RXWE]. The related buffer POP operation is also handled completely inside the QuadSPI module. As in the case explained here, accessing the RX buffer content either on RBDRn or ARDBn related addresses is equivalent.
- AHB buffer data read via memory-mapped access: This kind of access is performed by reading one of the addresses assigned to the external serial flash memory device(s) within the range specified in Table 213. If this is not the case, a memory-mapped AHB command read is triggered as described above. If the requested data is already available in the AHB buffer, it is provided directly to the host.

When an AHB access is made to the flash memory mapped address, the data is fetched and returned to the AHB interface. The AHB interface is stalled until the data is fetched. As soon as the data from the requested address is read by the QuadSPI module, the AHB read access is served. Therefore, it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless, this access scheme stalls the AHB bus for the time required to read the data from the serial flash memory device. If you know that the access is sequential, a better way is to have a prefetch enabled by programming the value of BUFxCR[ADATSZ] so that the data is fetched into the buffer before the next sequential AHB access.

As long as the host restricts its accesses to the data present in the buffer and to the data currently fetched from the serial flash memory, it is possible to run the host read from the AHB buffer simultaneously with the serial flash memory read into the AHB buffer.

38.6.2.9 AHB write

This module supports a single master AHB write with these burst types — INCR4, INCR8, INCR16, and INCR unspecified 4n bytes and single 4n bytes — and these burst types are supported with all Hsizes. An AHB write transaction size can be expressed in multiples of 4 bytes, and a single transaction must have a minimum of 4 bytes.

The following restrictions apply to the QuadSPI module with respect to AHB write transactions:

- AHB transactions of WRAP* types are not supported. For these unsupported access types, the controller returns an error response and does not initiate any flash memory transaction.
- Back to back, fixed address AHB write is not supported.
- Early burst termination is not supported for AHB transactions.

The QuadSPI controller queues back-to-back AHB writes with continuous address and sends them in a single flash memory transaction. However, in case the AHB address of a burst is not in continuous addressing sequence to previous write burst, a new flash memory transaction is initiated.

Following is the programming sequence for an AHB write:

1. Check that SR[BUSY] is deasserted or is 0 and check that the TX buffer is empty. If there is any residue data present in the TX buffer (SR[TXNE]), the buffer must be cleared by writing '1'1 to MCR[CLR_TXF].
2. Based on the type of flash memory device that is used for page programming, AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] need to be programmed.

   The default reset value for both the fields is 0 and allows writing to flash memory device assuming a very low T_{pp} (page program wait time) period. This period is very high for most of the flash memory devices. After any write to a flash memory device, the module waits for the write to finish before proceeding further.

   This is controlled by the AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] field configurations.
3. Configure trigger level AWRCR[AWTRGLVL] to an initial buffering level of the TX FIFO. Whenever this trigger level is reached by the AHB write, the QuadSPI module triggers a write to the flash memory.
4. Program the BFGENCR[SEQID] to point to the LUT where flash memory write sequence is stored.

5. AHB write master can now enable the transactions to be written to the flash memory. The AHB master must ensure data throughout to avoid underflow.
6. When a flash memory write completes and flash memory CS is deasserted, the software must poll SR[BUSY] for the deasserted value, which is 0. This indicates that the AHB write is complete. In case an underflow has occurred, flash memory CS is deasserted with SR[TXNE] to know that an AHB write is pending with some residue data in the TX buffer.
7. Whenever flash memory CS is deasserted after an AHB write sequence, FR[PPWF] is set if any of AWRCR[PPW_RD/WR_DIS] is enabled. FR[PPWF] disables any further flash memory read/write based on AWRCR[PPW_RD]/AWRCR[WR_DIS]. After FR[PPWF] is set, it returns every incoming AHB transaction with an error response.
8. The software must clear FR[PPWF] to resume AHB transactions after the expiry of T_{pp} period of flash memory. It can also send IPS read command to the flash memory for checking if T_{pp} is over.
9. The software must ensure that the correct read and write LUT sequences are selected corresponding to the AHB read and write transactions. QuadSPI would malfunction if flash memory read sequence is selected during AHB write or vice versa.

38.6.2.10 Byte ordering of serial flash memory read data

The basic scheme is that the first byte read out of the serial flash memory device, which is addressed by SFAR[SFADR], corresponds to RBDR0[31:24] for IP command read. In contrast to that for AHB command read, the bytes are always positioned according to the byte ordering of the AHB bus.

- Byte ordering in individual flash memory mode

  The following table provides the byte ordering scheme of how the byte oriented data space of the serial flash memory device is mapped into one single 32-bit entry of the RX buffer or the AHB buffer. The table is valid within the following context:

  — Flash memory A or Flash memory B in individual flash memory mode

  — All AHB data read commands with 32-bit access size

Table 220. Byte ordering in individual flash memory mode

Serial flash memory byte numbering	3	2	1	0
Buffer entry bit position [31:0] (32-bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

NOTE

For IP commands, the read size can be specified as number of bytes. If this number is not a multiple of four, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

  For AHB commands and reads, starting from an address not aligned to 32-bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- Byte ordering in parallel flash memory mode

  In the parallel flash memory mode, each byte is combined out of two- half bytes that are read or written in parallel from the two serial flash memory devices. The following tables show how the flash memory content is separated into the half-bytes and how the half-bytes are included with the RBDR0 register.

Table 221. Serial flash memory device half-byte ordering

Serial flash memory device byte #	Flash memory A bit position		Flash memory B bit position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbl0
1	fah1	fal1	fbh1	fbl1
2	fah2	fal2	fbh2	fbl2
3	fah3	fal3	fbh3	fbl3
4	fah4	fal4	fbh4	fbl4
5	fah5	fal5	fbh5	fbl5
6	fah6	fal6	fbh6	fbl6
7	fah7	fal7	fbh7	fbl7
8	fah8	fal8	fbh8	fbl8

The table entry naming reflects the half-byte positioning in the serial flash memory devices:

- <fa> h0 means Flash memory A, <fb>h0 means Flash memory B.
- fa<h>0 means half byte in high position, fa<l>o means half-byte in low position.
- fah<0> means physical byte address 0 in the serial flash memory device and fal<1> means physical byte address 1 in the serial flash memory device.

Table 222. Byte ordering in parallel flash memory mode - RX buffer

SFAR[SFADR] set to 0h								
RBDR0 ARDB0	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
RBDR1 ARDB1	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
SFAR[SFADR] set to 1h								
RBDR0 ARDB0	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
RBDR1 ARDB1	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHA Automotive Technology Co., Ltd.
c8c0265-4821-48a8-b251-390a3ab624c1

NOTE

For IP commands, the read size can be specified as number of bytes. If this number is not a multiple of four, the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

Table 223. Byte ordering in parallel flash memory mode - TX buffer*

SFAR[SFADR] set to 0h								
TBDR0	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
TBDR1	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

* Applicable only for single I/O mode

Table 224. Byte ordering in parallel flash memory mode - AHB buffer

AHB address (32-bit access)	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
AHB address 800_0004h (32-bit access)	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

NOTE

For an AHB command read starting from an address not aligned to 32-bit boundaries or an AHB access size smaller than 32-bit, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- Buffer entry ordering for 64-bit read access

  For read access via the AHB interface, a 64-bit access is possible. Each 64-bit access reads two 32-bit entries, simultaneously. The ordering of these 32-bit entries within the 64-bit word is provided in the following table.

Table 225. 64-bit read access buffer entry ordering

AHB read data bit position [63:0]	**[63:32]**	**[31:0]**
Buffer entry #	**Odd (1, 3, 5, ...)**	**Even (0, 2, 4, ...)**

38.6.2.11 Normal mode interrupt and DMA requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate an interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are associated with the Flag Register (FR).

Table 226. Interrupt and DMA request conditions

Condition	Flag (FR)	DMA
Data learn pattern failure	DLPFF	-
TX buffer fill	TBFF	-
TX buffer underrun	TBUF	-
Illegal instruction error	ILLINE	-

Table continues on the next page...

Table 226. Interrupt and DMA request conditions (continued)

Condition	Flag (FR)	DMA
RX buffer drain	RBDF	X
RX buffer overflow	RBOF	-
AHB buffer overflow	ABOF	-
AHB sequence error	ABSEF	-
AHB illegal transaction error	AITEF	-
IP command usage error	IUEF	-
IP command trigger during AHB access error	IPAEF	-
IP command trigger could not be executed error	IPIEF	-
IP command related transaction finished	TFF	-

Each condition has a corresponsing field in the Flag Register (FR) and a request enable field in the DMA Request Select and Enable Register (RSER). The FR[RBDF] has separate enable fields for generating IRQ and DMA requests. Note that not all the fields have an individual IRQ line. See the chip's Interrupt Vector table for details.

- Transmit buffer fill interrupt request

  This indicates that the TX buffer can accept new data. The buffer is asserted if FR[TBFF] is asserted and if the value of the corresponding enable field, RSER[TBFIE], is 1. See TX buffer Operation for details on the assertion of FR[TBFF].

  Apart from IRQ, it is possible to handle the TX buffer fill by using the DMA. If the value of RSER[TBFDE] is 1, a DMA request is triggered when the number of available space in the TX buffer is more than the TBCT[WMRK] valid entries and the value of SR[TXWA] is set. The application must configure the environment appropriately (for example, the DMA controller) for the DMA transfer.

- Receive buffer drain interrupt or DMA request

  This is derived from FR[RBDF], indicating that the RX buffer of the QuadSPI module has data available from the serial flash memory device to be read by the host. It remains set as long as RBSR[RXWE] is configured. Also, RSER[RBDIE] enables the related IRQ.

  Apart from the IRQ, it is possible to handle the RX buffer drain by using the DMA. If the value of RSER[RBDDE] is 1, a DMA request is triggered when the RX buffer contains more than RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer overflow/underrun interrupt request

  This is a combination of the following fields (all located in the Flag Register (FR) with the related enable bits in the DMA Request Select and Enable Register (RSER)):

  — TBUF - TX buffer underrun, enabled by TBUIE

  — RBOF - RX buffer overflow, enabled by RBOIE

  — ABOF - AHB buffer overflow, enabled by ABOIE

  — The transmit buffer underrun indicates that an underrun condition in the TX buffer has occurred. It is generated when a write instruction is triggered whilst the TX buffer is empty and the the value of RSER[TBUIE] is 1.

  — The receive buffer overflow indicates that an overflow condition in the RX buffer has occurred. It is generated when the RX buffer is full, an additional read transfer attempts to write into the RX buffer, and the value of RSER[RBOIE] is 1.

  — The AHB buffer overflow indicates that an overflow condition in the AHB buffer has occurred. It is generated when the AHB buffer is full, an additional read transfer attempts to write into the AHB buffer and the value of RSER[ABOIE] is 1.

— The data from the transfers that generated the individual overflow conditions is ignored.

- Serial flash memory command error interrupt request

  If the IPAEF, IPIEF, or IUEF fields in the FR are set, and the related interrupt enable bits in the RSER are also set, then an interrupt is requested.

- Transaction finished interrupt request

  The IP command transaction finished IRQ indicates the completion of the current IP command. It is triggered by FR[TFF] and is masked by RSER[TFIE].

38.6.2.12 TX buffer operation

The TX buffer provides the data used for page programming. For proper operation, it is required to provide at least one entry in the TX buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX buffer fast enough as long as the command is executed without a TX buffer overflow or underrun.

The QuadSPI module sets the FR[TBFF] field as long as the TX buffer is not full and can accept more data. At the end of write through TX buffer, you must clear FR[TBFF] to avoid unnecessary last TX buffer fill interrupt. However, there would always be a pending request asserted from QuadSPI controller at the end of any DMA transfer. When external DMA finishes transfer iteration, this request from QuadSPI is kept asserted for the next iteration loop.

NOTE

Even if the generation of DMA requests for filling the TX buffer is disabled by using RSER[TBFDE], the TX buffer still accepts a DMA transfer because of the last asserted pending request.

Disabling of DMA transfer should be controlled by an external DMA master.

When the QuadSPI module tries to pull data out of an empty TX buffer, FR[TBUB] signals the TX buffer underrun. The TX buffer underrun flag is also asserted when the TX buffer contains less than 32-bits of data and the QuadSPI module tries to pull out data from it. The current IP command leading to the underrun condition is continued until the specified number of bytes is sent to the serial flash memory device. Also, the data that is transferred is in the Fs format. This means, after the underrun flag is set under this condition, it returns Fs until the required number of bytes are not sent. This has been done to ensure that the software does not erase the whole sector after underrun and just reprogramming from failure point serves the purpose. When this sequence command is complete, FR[TBFF] is asserted, indicating that the TX buffer is ready to be written again.

The TX buffer overflow is not signaled explicitly, but TBSR[TRBFL] can monitor the TX buffer fill level.

For more information, see TX Buffer Status Register (TBSR) and Flag Register (FR).

38.6.2.13 Address scheme

Earlier, serial flash memories supported only a 24-bit address space, restricting the maximum memory size of the serial flash memory to 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to the legacy 24-bit address mode. It also supports segregation of address programmed into Row address and Column address of the flash memory, as per the requirement.

Extended address mode

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for the 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR commands should be programmed with 32d as the operand value, with SFACR[CAS] programmed to 0. If a flash memory needs some bits of the address as its column address, then it must be considered that a total of 12 bits are required by the flash memory; however, the number of bits should not exceed 32, because the maximum address supported by QuadSPI is 32 bits. Each of the memory vendors have a different way of enabling this mode (see the memory specification from memory vendors). For example, the command B7h sent to the Macronix flash memory enables it for the 32-bit address mode.

Extended address register

In this mode, the upper 8 bits of the 32-bit register are provided by the Extended address register in the memory, which provides a specific register that is updated according to the address to be accessed. This effectively converts the legacy 24-bit address

command into 32-bit address commands. The memories greater in size than 16 MB consist of banks of 16 MB each. The 8 bits occupied in the extended address register effectively enable a bank. For example, in Spansion memory, when the extended address register is updated with a value of 1h, with the help of the 17h command, it opens Bank1 of the memory. The consequent 24-bit address commands lead to Bank1. The extended address register needs to be updated with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

Separation of address into rows and columns

This mode has been introduced for flash memories that need addresses segregated into rows and columns. The value in SFACR[CAS] defines the width of the column address required by a flash memory. The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions, if the value of SFACR[CAS] is 0. Otherwise, the actual address takes CAS into consideration. If the value of SFACR[CAS] is 3, then bits 26-3 of the programmed address are sent to the flash memory as its page address. This is in case the flash memory is operating in a 24-bit mode and bits 2-0 are sent as its column address. If a flash memory requirement for column address is less than the number of pads in which address has to be sent, then QuadSPI appends the remaining bits by 0. You must program the operand value in CADDR and CADDR_DDR command accordingly. It must be ensured that the total number of address bits requested by flash memory as its page and column address must not be more than 32 bits.

Word addressable mode for flash memory

This mode has been introduced for flash memories, which have a word-addressable memory. This means, each address of the flash memory contains one word (two bytes) of data. The value of SFACR [WA] is configured to 1 to enter this mode. QuadSPI internally divides the incoming address in the AHB bus or the address in the SFAR to map it to a valid flash memory location. For example, if the incoming address is 2004h, the controller re-maps this address to access the flash memory location 1002h. If not in this mode, the incoming address 2004h is mapped to flash memory location 2004h.

38.6.2.14 OTFAD support

If OTFAD is enabled in the system, any reads from the QuadSPI are first decrypted by the OTFAD engine and then returned to the AHB bus. If OTFAD is enabled, the prefetch never crosses the 1 KB boundary.

38.6.3 Module Disable mode

Module Disable mode is a block-specific mode that the QuadSPI can enter to disable serial flash memory clock and AHB command. This mode can be entered by:

- The host software: by writing a '1' to MCR[MDIS]

Below are the condition that must be fulfilled to enter the Module Disable mode:

- SR[BUSY] = 0
- SR[AHBTRN] = 0
- RBSR[RDBFL] = 0
- SR[RXDMA] = 0
- SR[TXDMA] = 0
- None of the flags in FR are enabled as interrupts is set

The conditions mentioned above ensures the following:

- There is no SFM command currently being executed.
- All the data read into the RX buffer from the serial flash memory have been fetched by the application.
- There is no current AHB access.
- There is no active DMA request.
- There is no enabled interrupt that is pending.

Certain read or write operations have a different effect when the QuadSPI is in the Module Disable mode. In the Module Disable mode, not all of the status and flag bits of the QuadSPI module are updated, and writing to them has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

NOTE

It is illegal to issue a new SFM command starting two clock cycles prior to raising the request of entering the Module Disable mode until the QuadSPI stays in this mode.

38.6.4 Leaving Module Disable mode

In the Module Disable mode, the serial flash memory clock and AHB command to the QuadSPI module are switched off.

After the QuadSPI has left this mode and has returned to Normal mode, the execution of the first SFM command is deferred until the clock to drive that part of the module related to the serial flash memory device is available. Depending upon the point in time when the first SFM command is triggered, the actual execution of the command starts with a delay, respective with the re-enabling of the flash memory clock signal.

38.7 Initialization/application information

This section provides the initialization and application information of the QuadSPI module.

38.7.1 Power up and reset

The serial flash memory devices connected to the QuadSPI module might require special voltage characteristics of their inputs during power up or reset. The application must ensure this.

38.7.2 Available status/flag information

This section provides an overview of the different flags and statuses available, and their interdependencies for different use cases. The SR and FR are the related registers.

38.7.2.1 IP commands

See IP Configuration Register (IPCR) for additional details not explicitly covered in this paragraph.

- IP commands—normal operation

  Writing to IPCR[SEQID] triggers the execution of a new IP command. Given that this is a legal command, SR[IPACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts.

  After the instruction on the serial flash memory device is complete, these field deassert and FR[TFF] is configured.

- IP commands—error situations

  See Overview_of_Error_Flags for details.

38.7.2.2 AHB commands

See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic in theFlash Memory Read section for details.

- AHB commands—normal operation

  Memory-mapped read access to a serial flash memory address not contained in the AHB buffer triggers the execution of an AHB command. Given that this is a legal command, SR[AHB_ACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts. After the instruction on the serial flash memory device is complete, these fields are deasserted.

- IP commands—error situations

  See Overview of FR error flags for details.

38.7.2.3 SFM commands

An SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash memory or results in an error. See Table 227 for details on errors.

38.7.2.4 Overview of error flags

The following table provides an overview of the different error flags in the FR and additional error-related details.

Table 227. Overview of FR error flags

Error category	Error flag in FR	Command execution on serial flash memory device TFF behavior (in case of IP commands only)	Description
AHB error flag	ABOF	Flash memory transaction continues until it finishes	Set when the module tries to push data into the AHB buffer that exceeds the size of the AHB buffer. Occurs only because of the wrong programming of BUFxCR[ADATSZ].
AHB error flag	AITEF	Flash memory transaction is aborted	No response is generated from QuadSPI to AHB bus in case of illegal transaction. Also, the watchdog timer expires.
Miscellaneous error flag	DLPFF	Flash memory transaction continues until it finishes	Set when the DATA_LEARN instruction is encountered in a sequence but no sampling point is found for the data learning pattern.
Miscellaneous error flag	ILLINE	Flash memory transaction aborted	Illegal instruction error flag - set when an illegal instruction is encountered by the controller in any of the sequences.
Command arbitration error	IPIEF	TFF not asserted in conjunction with that command	IP command error - caused when IP access is currently in progress (IP_ACC is set) and during: • Write attempt to IPCR register • Write attempt to SFAR register • Write attempt to RBCT register
Command arbitration error	IPAEF	TFF not asserted in conjunction with that command	• AHB command already running, another IP command could not be executed • AHB command already running, write attempt to IPCR[SEQID]
IP command error	IUEF	–	• IP command usage error
Buffer-related error	RBOF	TFF is asserted on completion	• RX buffer overrun

Table continues on the next page...

Table 227. Overview of FR error flags (continued)

Error category	Error flag in FR	Command execution on serial flash memory device TFF behavior (in case of IP commands only)	Description
Buffer-related error	TBUF	TFF is asserted on completion	• TX buffer underrun

Note that only the buffer-related errors are associated with a transaction on the external serial flash memory. All the other errors do not trigger an actual transaction.

38.7.2.5 IP bus and AHB access command collisions

There are two flags related to this topic, FR[IPAEF] and FR[IPIEF]. See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic of the Flash Memory read section for a description of the flags.

38.7.3 Flash memory device selection

Regardless of the SFM command (IP or AHB), the access mode is selected by specifying the 32-bit address value for the following SFM command.

For IP commands, the access mode is selected with the address programmed into the SFAR register. See Serial Flash Address Register (SFAR) for details.

For AHB commands, the access mode is determined by the memory-mapped address. See AMBA Bus Register Memory Map for details.

38.7.4 DMA usage

For a complete description of the DMA module, see the related DMA Controller chapter. This section only provides QuadSPI-specific DMA usage details.

38.7.4.1 DMA usage in normal mode

38.7.4.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash memory -> AHB bus / IP bus -> DMA controller) involved in the read/write data process is essential for a proper operation. Such analysis must take into account not only the data rate provided by the serial flash memory but also the data rate of the AHB bus and the performance of the DMA controller in reading/writing data from/to the RX/TX buffer.

Two figures must match for a proper operation, which means that the data rate provided by the serial flash memory device must not exceed the average RX buffer readout data rate. Otherwise, the longer this state persists, it results into an RX buffer overflow. Similarly, the data consumed by the serial flash memory device must not exceed the average TX buffer fill rate. If this persists, it leads to an underrun.

AHB bus side (data read)

The total number of bus cycles for each DMA minor loop completion is added from the following components:

The following table provides certain examples for typical use cases:

Case 1: DMA needs to read 4 bytes from SRAM and provide to QuadSPI. It costs total four bus clock cycles. Then, DMA handshake adds additional six bus clock cycles, resulting in a total of [6 + 4 * (32/4) = 38] bus clock cycles.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CUBIC Automotive Technology Co., Ltd.
c8c6e5-4e23-48a8-b251-390c3ab624c1

Table 228. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 60 MHz bus clock frequency
3	16	6+(16/4)*4 = 22	~366ns
7	32	6+(32/4)*4 = 38	~633ns
11	48	6+(48/4)*4 = 54	~900ns
15	64	6+(64/4)*4 = 70	~1166ns

Case 2: DMA needs to read 32 bytes from SRAM and provide to QuadSPI. DMA handshake takes an additional six bus cycles, with 32 bytes DMA read from SRAM costs (8 + 3) core clock cycles. DMA writes 32 bytes to QuadSPI, takes 2 * (32/4) = 16 bus cycles with one additional CPU access to QuadSPI, costing two bus clock cycles. This results in a total 6 + (8+3)/2 + 2 * (32/4) +2 = 30 bus clock cycles.

Table 229. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop >	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 80 MHz bus clock frequency
3	16	6 + (4+3) /2 + (16/4)*2 + 2 = 20	~333ns
7	32	6 + (8+3) /2 + (32/4)*2 + 2 = 30	~500ns
11	48	6 + (4+3)/2*3 + (48/4)*2 + 2 = 44	~733ns
15	64	6 + (8+3) + (64/4)*2 + 2 = 51	~810ns

NOTE

This table figure represents an ideal scenario; actual performance depends on how the chip integrates DMA and QuadSPI modules.

Serial flash memory device side (data read)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles is required to read 4 bytes, corresponding to one RX buffer entry (setup of command and address not considered): two cycles for quad DDR mode instructions in the parallel flash memory mode, two cycles for the Octal DDR mode (Hyperflash) in the individual flash memory mode, four cycles for quad (SDR) mode instruction in the parallel flash memory mode, or dual IO DDR mode instruction in the parallel flash memory mode, eight cycles for quad mode (SDR) instructions in individual flash memory mode, and so on.
- Overhead because of clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of RBCT[WMRK]:

Table 230. Access duration examples for serial flash memory side

RBCT[WMRK] setting	Num bytes per DMA loop [1]	Num SCKFx for 80 MHz SCKFx			Time duration of flash memory data readout for 80 MHz SCKFx (~12.5ns period)		
		IFM [2] quad	IFM quad DDR	PFM [3] quad DDR/ IFM octal DDR	IFM quad	IFM quad DDR	PFM quad DDR
0	4	8	4	2	~100ns	~50ns	~25ns
1	8	16	8	4	~200ns	~100ns	~50ns
3	16	32	16	8	~400ns	~200ns	~100ns
7	32	64	32	16	~800ns	~400ns	~200ns

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Individual flash memory mode
3. Parallel flash memory mode

NOTE

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

From the examples given in the two tables above, it can be seen that depending on the relationship between the bus clock and serial flash memory clock frequencies, you could perform certain settings where the serial flash memory provides the read data faster than the AHB bus can read out the RX buffer. In the tables provided above, it is the case of PFM quad DDR mode with watermark up to three and other cases. In these cases, the RX buffer data keeps accumulating over time and eventually overflows. To avoid RX buffer overflow, the data transaction size should be small enough.

A complementary example is when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be lesser than the time taken by the controller to push in the remaining entries in the buffer.

IPS bus side (data write)

The total number of bus cycles for each DMA minor loop completion are added from the following components:

- Overhead for each minor loop, given by DMA controller: assume 10 cycles
- Overhead because to clock domain crossing: assume two cycles
- Number of bus clock cycles required for 16 bytes (128-bit write size): assume four cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of TBCT[WMRK]; therefore, the overhead specified above distributes among (TBCT[WMRK]+1) write accesses of 32-bit each.

The following table provides some examples for typical use cases:

Table 231. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop [1]	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 80 MHz bus clock frequency
3	16	12+4 = 16	~200ns
7	32	12+8 = 20	~250ns

1. DMA loop refers to one minor loop completion that is equivalent to one.

NOTE

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

Serial flash memory device side (data write)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles required to write 16 bytes, corresponding to four TX buffer entry (setup of command and address not considered): Eight cycles for Octal DDR mode (Hyperflash memory) instructions in individual flash memory mode, 32 cycles for quad SDR writes in individual flash memory mode and 64 cycles in single IO SDR writes in parallel flash memory mode.
- Overhead due to clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of TBCT[WMRK]:

Table 232. Access duration examples for serial flash memory side

TBCT[WMRK] setting	Num bytes per DMA loop [1]	Num SCKFx			Time duration for consuming data at flash memory interface 100 MHz SCKFx (10ns period)[2]			Time for fifo to get empty[3]		
		IFM [4] quad	IFM octal DDR	[5] single IO SDR mode	IFM quad	IFM octal DDR	PFM single IO SDR	IFM quad	IFM octal DDR	PFM Single IO SDR
3	16	32	8	64	320ns	80ns	640ns	2240ns	560ns	4480ns
7	32	64	16	128	640ns	160ns	1280ns	1920ns	480ns	3840ns

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Not all flash memory devices support writes at 100 MHz. See the flash memory data sheet for the actual page program frequency supported.
3. The assumption for these timings is that the TX Fifo is full when the transaction is initiated.
4. Individual flash memory mode
5. Parallel flash memory mode

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

Considering the examples provided in the two tables above for TX FIFO, it is evident that depending on the relationship between the bus clock and serial flash memory clock frequencies, there are settings possible where the serial flash memory consumes data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation occurs. To avoid TX buffer underrun, the data transaction size should be large enough.

38.7.5 Flash memory devices address mapping

You can configure QuadSPI in following modes for the supported flash memory ports A and B:

- Single mode
- Serial mode
- Parallel mode

The sizes of the flash memory devices are mapped with the system memory space based on the configurations of the following registers:

- SFA1AD
- SFA2AD

- SFB1AD
- SFB2AD

The total memory region for the flash memory devices is mapped between QuadSPI_AMBA_BASE and TOP_ADDR_MEMB2 such that the corresponding CS is asserted based on SFA1AD, SFA2AD and SFB1AD register configurations.

38.7.5.1 Single mode

For single mode configuration, you must write the same value to SFB1AD and SFB2AD registers that you write to the SFA2AD register.

For dual-die flash memories, the values you write to SFB1AD and SFB2AD registers corresponds to the mapped top addresses of each die.

For single-die flash memories, you must write the same value to SFA2AD register that you write to the SFA1AD register.

Following is a programming example for single mode single-die flash memory:

- QuadSPI_AMBA_BASE - 1000_0000h
- SFA1AD[TPADA1] - 2000_0000h
- SFA2AD[TPADA2] - 2000_0000h
- SFB1AD[TPADB1] - 2000_0000h
- SFB2AD[TPADB2] - 2000_0000h

The following figure illustrates the memory mapping for single mode QuadSPI configuration.

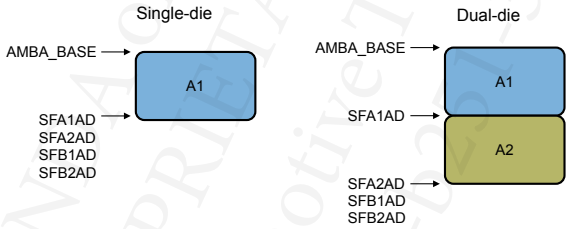

Figure 195. Memory map for Single mode

38.7.5.2 Serial mode

For serial mode configuration, you must write the same value to SFB1AD and SFB2AD registers that you write to the SFA2AD register.

For dual-die flash memories, the values you write to SFA1AD and SFA2AD registers corresponds to the mapped top addresses of each die.

For single-die flash memories, you must write the same value to SFA2AD register that you write to the SFA1AD register.

Following is a programming example for single mode single-die flash memory:

- QuadSPI_AMBA_BASE - 1000_0000h
- SFA1AD[TPADA1] - 2000_0000h
- SFA2AD[TPADA2] - 3000_0000h
- SFB1AD[TPADB1] - 5000_0000h
- SFB2AD[TPADB2] - 7000_0000h

The following figure illustrates the memory mapping for serial mode QuadSPI configuration.

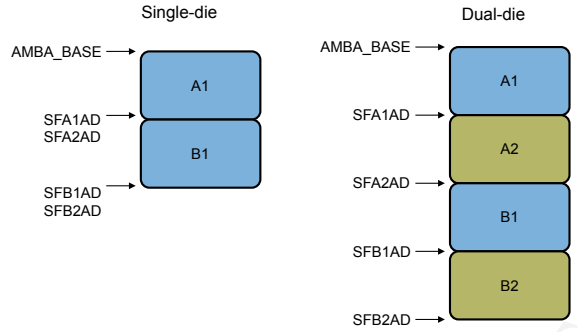

Figure 196. Memory map for Serial mode

38.7.5.3 Parallel mode

QuadSPI can access two flash memories in parallel. This increases the throughput of the QuadSPI by two times. Only read operations and x1 mode write are allowed in this mode. In case a write transaction is initiated in with more than one pad in the Parallel mode, the value of FR[IUEF] is set. When dual-die flash memories are accessed in the Parallel mode, it is mandatory for flash memory A1 to be the same size as B1 and A2 to be the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flash memories connected on board.

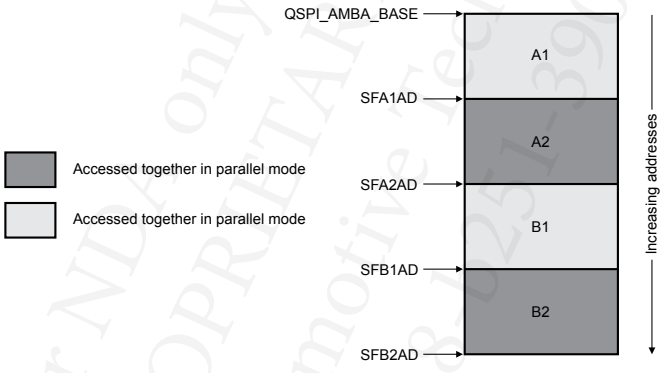

Figure 197. Flash memory addressing

Following is a programming example for parallel mode access (flash memory sizes are assumed to be 256 MB):

- QuadSPI_AMBA_BASE - 1h
- SFA1AD[TPADA1] - 2h
- SFA2AD[TPADA2] - 3h
- SFB1AD[TPADB1] - 4h
- SFB2AD[TPADB2] - 5h

To access the first location of the A1/B1 pair, the incoming address should be 1h. QuadSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, addresses are provided to flash memories A1 and B1.

Flash memory address = memory mapped address - QuadSPI_AMBA_BASE/2

For memory-mapped address:

- 1000_0000h, flash memory address: 0h (or, the first address of flash memories A1 and B1)
- 1000_0004h, flash memory address: 2h
- 1000_0008h, flash memory address: 4h, and so on.

Similarly, to access the first location of the A2/B2 pair, the incoming address should be 3h.

Flash memory address = memory mapped address - SFA2AD/2

For memory-mapped address:

- 0h, flash memory address: 0h (or, the first address of flash memories A2 and B2)
- 4h, flash memory address: 2h
- 8h, flash memory address: 4h, and so on.

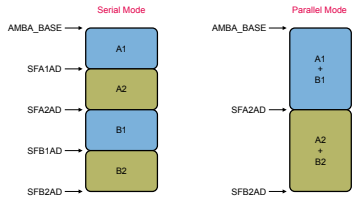

Figure 198. Memory map for Serial and Parallel modes

The software must ensure that when multiple flash memories are used, accesses should never cross a boundary between separate flash memory devices. For example, in the figure provided above, for Serial mode, accesses must not cross the A1 to A2, A2 to B1, or B1 to B2 boundaries. For Parallel mode, accesses must not cross the A1+B1 to A2+B2 boundaries. The software can manage this using the following methods:

- Reduce the data fetch amount of the AHB buffers to 64 bit so that no prefetch occurs. This prevents any legal access from crossing the boundary.
- Reserve a memory region, if prefetch is enabled, to the maximum size of the prefetch, prior to the boundary. As long as no accesses are made to this region of the memory, no access crosses the boundary.
- Ensure that cache does not prefetch across the boundary.

38.8 Byte ordering – endianness

The following topics show the byte ordering in 64-bit LE configuration for AHB buffer and 32-bit LE for TX/RX buffer.

38.8.1 Programming flash memory data

CPU writes instructions to the TBDR register, such as:

- Write TBDR: 4_03_02_01h
- Write TBDR: 8_07_06_05h

The following table shows the content against each TX buffer entry.

Table 233. Example of QuadSPI TX buffer

TX buffer entry	Content
0	4_03_02_01h
1	8_07_06_05h

Programming the TX buffer into the external serial flash memory device results in the following byte order to be sent to the serial flash memory:

- 01...02...03...04...05...06...07...08

38.8.2 Reading flash memory data into the RX buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

Table 234. Resulting RX buffer content

RX buffer entry	Content
0	4_03_02_01h
1	8_07_06_05h

38.8.2.1 Readout of the RX buffer through RBDRn

The RX buffer content appears at CPU read access through the peripheral bus interface in the following order:

- Read RBDR0: 4_03_02_01h
- Read RBDR1: 8_07_06_05h

38.8.2.2 Readout of the RX buffer through ARDBn

The RX buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit access: Read ARDB0: 4_03_02_01h
- 32-bit access: Read ARDB1: 8_07_06_05h
- 64-bit access: Read ARDB0: 8_07_06_05_04_03_02_01h

38.8.3 Reading flash memory data into the AHB buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

Table 235. Resulting AHB buffer content

AHB buffer entry	Content
0	8_07_06_05_04_03_02_01h

38.8.3.1 Readout of the AHB buffer through memory-mapped read

The AHB buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit read access: 4_03_02_01h
- 32-bit read access: 8_07_06_05h
- 64-bit read access: 8_07_06_05_04_03_02_01h

38.9 Driving flash memory control signals in single and dual modes

In single and dual modes, the serial flash memory devices that can connect to the QuadSPI module expect additional control signals on the inputs, which are connected to IOFA[3], IOFA[2], IOFB[3], and IOFB[2] in the quad mode. For easy interfacing, the

outputs IOFA[3:2] for flash memory A and the IOFB[3:2] for flash memory B are driven to the logic state given by the configuration fields MCR[ISD3FA], MCR[ISD2FA], MCR[ISD3FB], and MCR[ISD2FB].

These outputs are driven all the time to the logic level programmed in the MCR except the time when quad commands of the serial flash memory are executed. See the specifications of the related serial flash memory device for details about the inactive level.

38.10 Serial flash memory devices

Several different vendors make flash memory devices with a QuadSPI interface. At present, there is no set standard for the QuadSPI instruction set. The most common commands currently have the same instruction code for all vendors; however, some commands are unique to specific vendors. Some of the example sequences are provided in the following sections.

38.10.1 Example sequences

This section provides the example sequences of the QuadSPI module.

Table 236. Exit 4 x I/O read enhance performance mode (XIP) (Macronix) and read status

Instruction	Pad	Operand	Description
CMD	0h	EBh	4xIO read command
ADDR	2h	18h	24-bit address to be sent on four pads
MODE	2h	0h	2 mode cycles (exit XIP)
DUMMY	0h	4h	4 dummy cycles
READ	2h	8h	Read 64 bits
CMD	0h	5h	Read Status register
READ	0h	1h	Status register data
STOP	0h	0h	Stop, instruction over

38.10.1.1 Read command (Spansion hyperflash memory)

This section provides the read command sequences (Spansion hyperflash memory) of the QuadSPI module.

Table 237. Read command (Spansion hyperflash memory)

Instruction	Pad	Operand	Comment
CMD_DDR	3h	A0h	Read command with continuous burst type
ADDR_DDR	3h	18h	24-bit row address
CADDR_DDR	3h	10h	16-bit column address with lower 3 bits valid and rest 0
Dummy	3h	0hF	15 dummy cycles
READ_DDR	3h	4h	32-bit data read on 8 pads
STOP	3h	0h	Stop, instruction over

Hyperflash memory is a word addressable flash memory. This means that each address accesses a word-wide (two-byte) data value. The software should ensure that when Hyperflash memory is connected to the controller, the value of SFACR[WA] must be 1. With this value, the controller remaps a byte addressable access to a word addressable access.

38.10.1.2 Read status register (Spansion hyperflash memory)

This section provides details related to the read status register of the QuadSPI module.

Table 238. Read status register (Spansion hyperflash memory)

Instruction	Instruction sequence	Pad	Operand	Description
CMD_DDR	Read Pre Command	3h	0h	Write command with wrapped burst type
ADDR_DDR		3h	18h	24-bit row address (0000AAh)
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits valid and rest 0(0005h) treated as command
CMD_DDR		3h	0h	Write command with wrapped burst type
CMD_DDR		3h	70h	Write data to be sent to flash memory as pre-command
CMD_DDR	Command phase (fourth/final chip select phase)	3h	A0h	Read command with continuous burst type
ADDR_DDR		3h	18h	24-bit row address
CADDR_DDR		3h	10h	16-bit column address with lower 3 bits as valid and rest 0
DUMMY		3h	0hF	15 dummy cycles
READ_DDR		3h	4h	32-bit data read on 8 pads
STOP		3h	0h	Stop, instruction over

38.10.1.3 Word program (Spansion hyperflash memory)

This section provides the word program (Spansion hyperflash memory) of the QuadSPI module.

Table 239. Word program (Spansion hyperflash memory)

Instruction	Instruction sequence	Pad	Operand	Description
CMD_DDR	Unlock sequence 1 (first chip select phase)	3h	0h	Write command with wrapped burst type
CMD_DDR		3h	0h	8-bit address 00h treated as command

38.10.2 Dual-die flash memories

Certain serial flash memory vendors provide dual-die packages that are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual chip selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The following figure shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

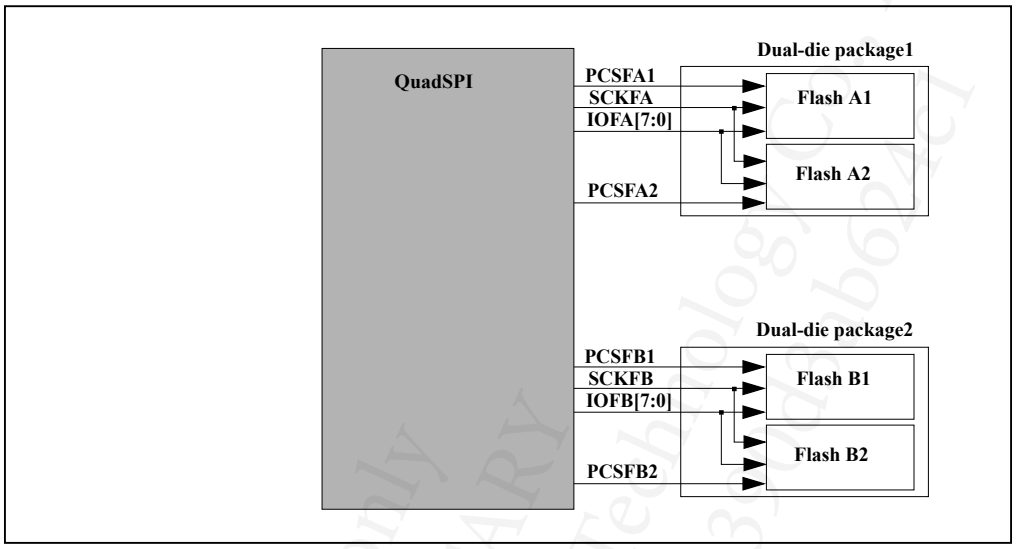

Figure 199. Generic configuration for dual-die support

Because the two devices within a package share the same I/O pads, they cannot function in the parallel mode. The software should ensure that when QuadSPI is configured in the parallel mode, the two selected flash memory devices belong to different dual-die packages.

38.10.3 Boot initialization sequence

The following is the recommended sequence of steps for booting from QuadSPI:

NOTE

Before you start, you must ensure that the system is out of reset and flash memory is available. Corresponding clocks and I/O pins must be configured.

1. Request is sent to QuadSPI for address 0h of flash memory.

   The reset command sequence in QuadSPI has 3h (basic read command) that is applicable to the flash memories.
2. The first few bytes of data are read from the flash memory. These bytes contain the following information:
   - The total sizes of all the flash memories connected on board
   - Support of the DDR mode
   - Frequency of the DDR operation
   - Mode entry sequence
   - 24-bit or 32-bit addressing (assuming 2- to 4-bit for the first accesses)
3. All the serial flash memories are configured:
   - Quad mode is enabled
   - Dummy reads to enter XIP

4. QuadSPI is configured:
   - Parallel enable set
   - LUT is configured for the highest performance reads
   - DDR mode is enabled (if applicable)
   - Buffers are configured
5. Serial flash memory clock frequency increases.
6. Boot reads happen in the parallel, DDR enabled, quad output mode.

38.11 Sampling of serial flash memory input data

38.11.1 Basic description

QuadSPI is used to read data from the serial flash memory device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash memory device. See the following figure for an overview of this scheme.

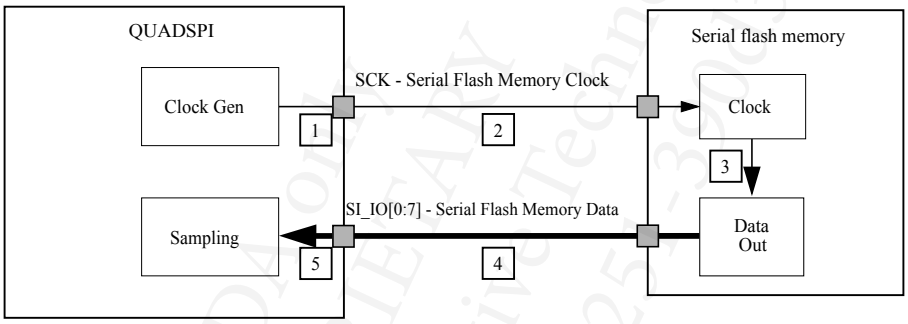

Figure 200. Serial flash memory sampling clock overview

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash memory. After a time of $t_{Del,total}$ the data arrives at the internal sampling stage of the QuadSPI module. Considering the figure provided here, the following parts of the delay chain contribute to $t_{Del,total}$:

- Output delay of the serial flash memory clock output of the device containing the QuadSPI module
- Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash memory device
- Clock to data out delay of the external serial flash memory device, including input and output delays
- Wire delay of application/PCB from the external serial flash memory device to the device containing the QuadSPI module
- Device delay corresponding to the input data

NOTE

The $t_{Del,total}$ is specific to the characteristics of the actual implementation.

38.11.2 DQS sampling method

38.11.2.1 Basic description

In the DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash memory move in the same direction; therefore, it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on the rising edge of the strobe signal.

The next figure shows the sampling read data in the SDR mode using the DQS.

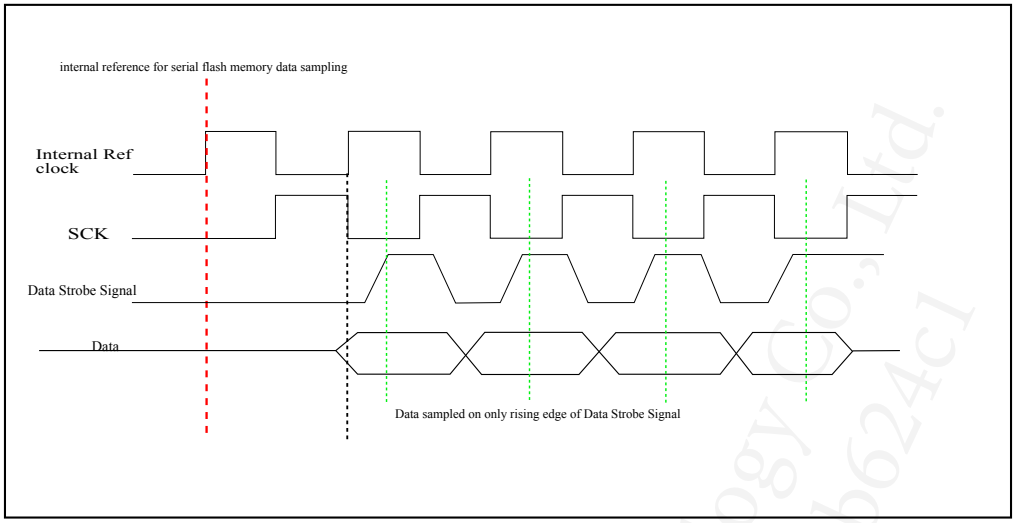

Figure 201. Data strobe functionality in SDR mode

When using the DQS for DDR reads, QuadSPI internally samples the incoming data on both the edges of the strobe signal. See the next figure for details.

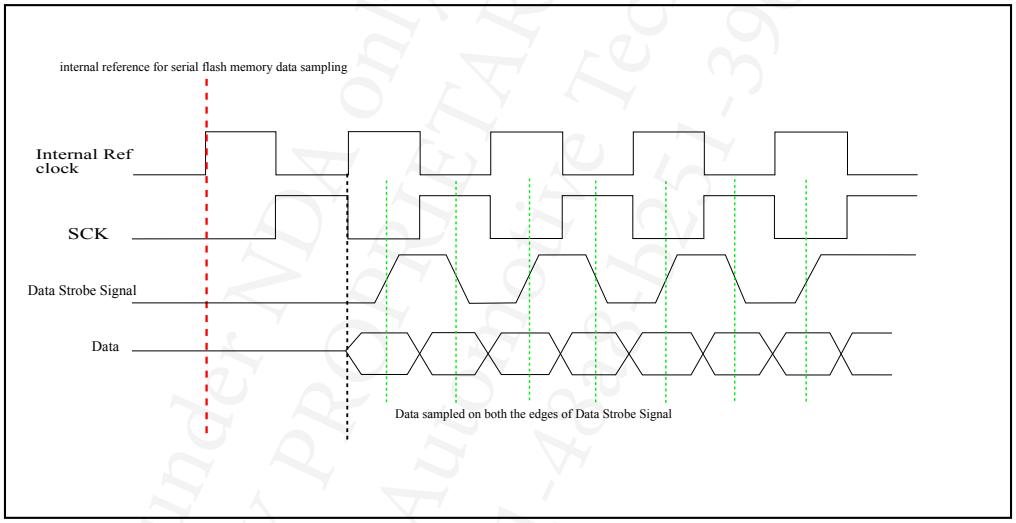

Figure 202. Data strobe functionality in DDR mode

38.11.2.2 External DQS

In serial flash memories supporting DQS, the data strobe signal is an output from the flash memory device that indicates when data is being transferred from the flash memory to the host controller. The data is then captured by the controller on:

- Only one edge (either rising or falling edge) of DQS signal in the SDR mode
- Both rising/falling edges of the DQS signal in the DDR mode

Some serial flash memories (for example, HyperFlash) provide the data strobe output (RWDS) with latency cycles included in between the ongoing read transactions. The data is sampled on both the edges of this signal taking into consideration that when no signal is provided by the flash memory between ongoing transactions, data is not sampled then, and at the end of the transaction, the required number of data to be fetched remains the same. See the next figure for details.

Serial: 4821-4a81b251-390c3ab624c1

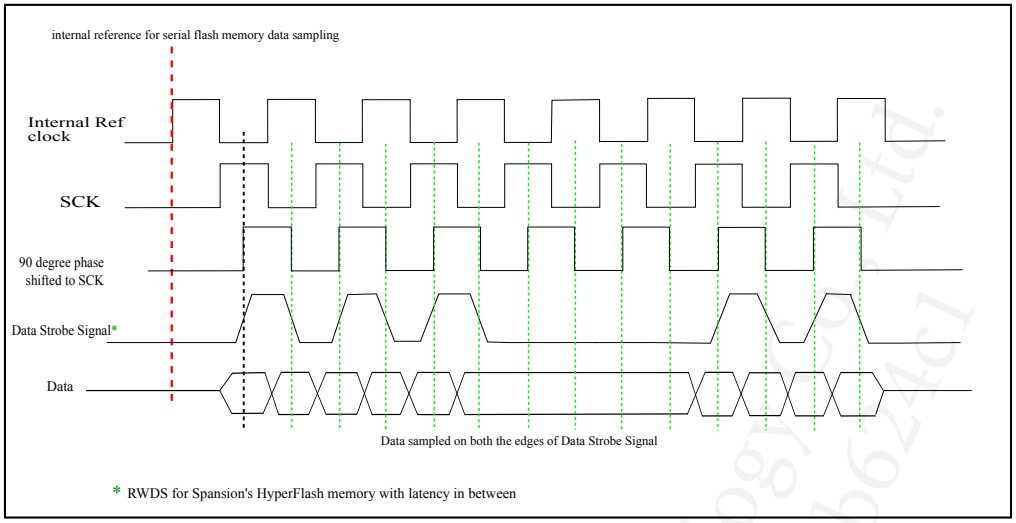

Figure 203. Data strobe functionality with latency included

This can be enabled by programming MCR[DQS_FA_SEL] = "11" for flash memory A and MCR[DQS_FB_SEL] = "11" for flash memory B. This mode supports the following configuration:

- Both high/low frequency delay chain manual programming using DLLCRA[SLV_DLY_COARSE] or DLLCRB[SLV_DLY_COARSE]
- DLL-assisted sampling only using DLLCRA[DLLEN] and DLLCRB[DLLEN]
- DLL-assisted auto data learning using DLLCRA[DLLEN] and DLLCRB[DLLEN] along with MCR{DLPEN]
- MCR[CK2_DCARS_FB] and MCR[CK2_DCARS_FA] should be disabled as DLL is used

NOTE

This mode may not be available on the chip. See the "Supported read modes" section in the chip-specific QuadSPI information for the read modes that this chip supports.

38.11.2.3 Pad loopback

The internal clock is loop-backed from the dummy internal pad to compensate data pad delays. This can be enabled by configuring the value of MCR[DQS_FA_SEL] as "01" for flash memory A and the value of MCR[DQS_FB_SEL] as "01" for flash memory B. This mode can be used with the following configuration:

- High/low frequency delay chain manual programming using DLLCRA[SLV_DLY_COARSE] or DLLCRB[SLV_DLY_COARSE]
- DLL-assisted sampling only using DLLCRA[DLLEN] and DLLCRL[DLLEN]
- DLL-assisted auto data learning using DLLCRA[DLLEN] and QuadPI_DLLCRB[DLLEN] along with MCR[DLPEN]

NOTE

This mode may not be available on the chip. See the "Supported read modes" section in the chip-specific QuadSPI information for the read modes that this chip supports.

38.11.2.4 External center-aligned read strobe

QuadSPI supports serial flash memories using the CRS protocol. Using this protocol, in addition to the SCK, the host controller provides a 90° phase shifted SCK that allows the flash memory to generate valid data timed off SCK edges and a DQS signal output that is timed off the 90° phase shifted SCK edges that is centered within the valid read data window. This allows the host controller to easily capture read data from the flash memory by using the data read strobe transitions and thereby allows

for a higher performance operation. As the flash memory is the originator of the center-aligned data read strobe as well as the read data, the temporal timing phase alignment between these signals is easier to guarantee across PVT (process, voltage, and temperature) corners.

The following figure shows data strobe functionality using CRS protocol.

NOTE

This mode might not be available on the chip. See the "Supported read modes" section in the chip-specific QuadSPI information for the read modes that this chip supports.

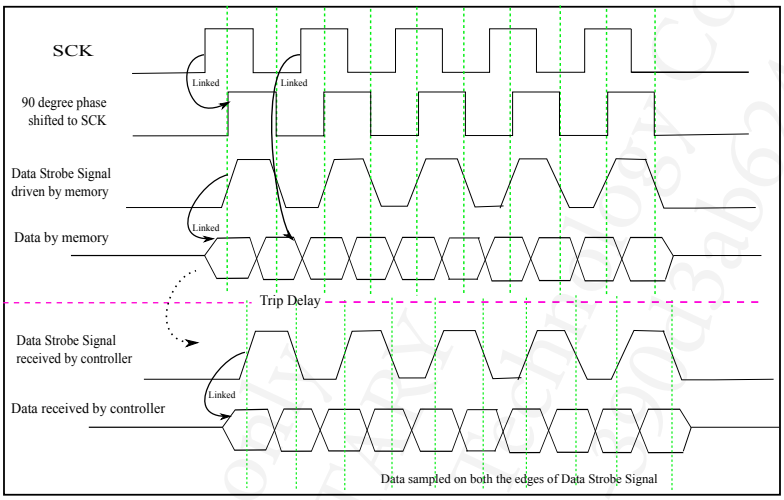

Figure 204. Data strobe functionality using the CRS protocol

38.12 Data learning

38.12.1 Basic description

Data learning is used to manage varying data valid windows from the flash memory as well as any variations in the chip based on PVT conditions in the DDR mode. QuadSPI provides this feature via the DATA_LEARN instruction for all flash memories, irrespective of whether the flash memory supports it. The DATA_LEARN instruction accepts an operand that defines the number of bits of the known pattern for which the data learning has to be done. The known pattern is provided in the DLPR register.

QuadSPI supports the following data learning:

- DQS

The following sections explain data learning in detail.

38.12.2 DQS sampling method

The semi-automatic data learning is supported in the DQS sampling method. To start data learning:

1. Configure a known pattern in the Data Learn register inside flash memories that support data learning. The pattern should be selected to have multiple low and high transitions in the data bus.

   NOTE

   Certain flash memories provide data learning as a feature for DDR data reads.

2. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash memory returns the data learning pattern in between dummy cycles in every read command. Each I/O gives the same DLP value for every clock edge.

NOTE

For flash memories that *do not* support data learning, configure a known location in flash memory with a known pattern. The pattern should not have 0h or FFh included. The pattern should be selected to have multiple low and high transitions in the data bus. Set up a QuadSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The address in the SFAR register should point to the known location within the pattern. Configure the known pattern in DLPR[DLPV]. See Programming the data learning pattern in flash memory for details on how the data has to be ordered in memory for correct operation.

3. Select a sampling point. See chip-specific QuadSPI information for selection of the sampling point.
4. Initiate the read via a peripheral transaction.
5. QuadSPI reads the data from the flash memory. It then encounters the DATA_LEARN instruction and samples the incoming data on both edges (rising and falling) of the DQS.

NOTE

If the data from the flash memory does not match the data learning pattern, the FR[DLPFF] flag is set. The QuadSPI module reports no sampling point automatically.

6. Repeat steps 2-7 with varying VT conditions for a particular process until FR[DLPFF] is set. The sampling points where no FR[DLPFF] is set signify a valid setting.

In the case of multiple valid settings, the software should select the middle point. The sampling point should be fixed within the above selected point for the next READ transactions.

NOTE

Ensure that QuadSPI is not accessed during calibration.

NOTE

Ensure that there is no latency between DQS edges while performing data learning using the DQS sampling method.

This feature might be used to auto-calibrate the sampling point for DDR reads, and auto-calibration might be triggered at fixed intervals, or depending on a change in PVT conditions.

In case the sampling point needs to be changed based on initiating options (such as, DLL lock status, time period, or software forced interrupt), data learn instruction has to be re-initiated.

The following figure shows data learning in DQS mode.

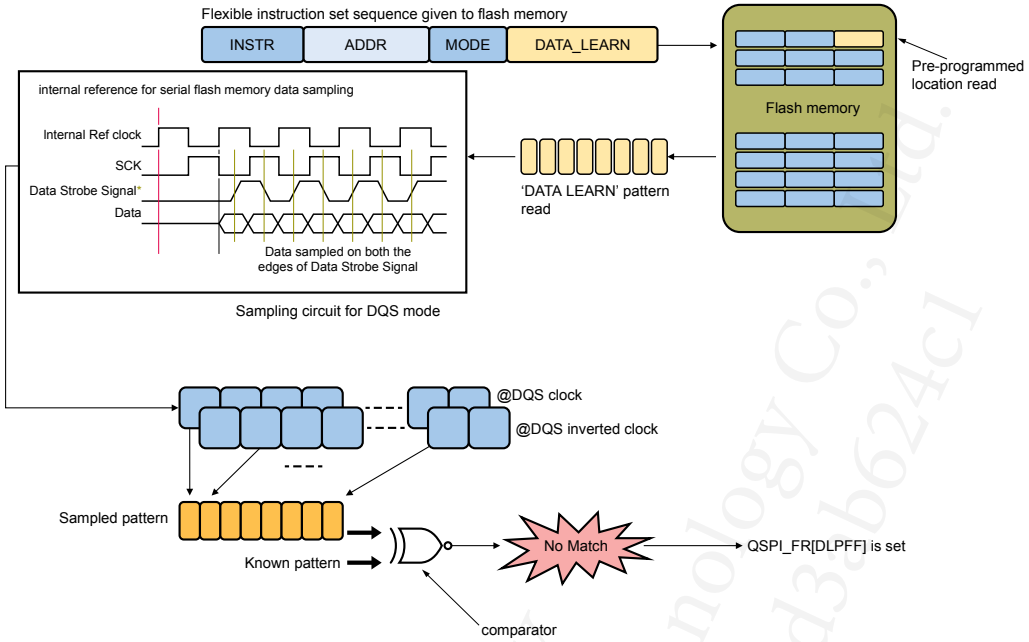

Figure 205. Data learning with DQS sampling method

NOTE

This mode might not be available on the chip. See the chip-specific QuadSPI information for the read modes that this chip supports.

38.12.3 Programming the data learning pattern in flash memory

Exmaple scnerio: If the value of DLPR[DLPV] is 43h, QuadSPI tries to match this sample on every incoming data line for single, dual, quad, or octal configurations. The following table shows the data programmed in flash memory with endianness taken into consideration.

Table 251. Programming the data learning pattern in flash memory

Endianness	Single IO	Dual IO	Quad IO	Octal IO
BE	43h	300Fh	0F0000FFh	00FF00000000FFFFh
LE	43h	0F30h	FF00000Fh	FFFF0000000000FFh

38.13 DLL and delay chain usage

The DLL is a general-purpose, dynamically adaptive clock delay module. It provides the ability to select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT). The DLL is suitable for applications where accurate delay adjustment is required, such as in case of DDR interfaces.

DLL working concept

The DLL control loop consists of a counter, reference delay line, and phase detector which operate on the ref_clock reference clock input. The reference clock (clk_ref) is fed into the reference delay line. After reset, a single delay tap is selected. A phase detector is used to detect the condition where a half shift has occurred. In addition to this, signals are generated to either increment or decrement the counter, which controls the delay line (if the half-phase detect condition is not met). Any changes in the delay of the individual elements of the delay chain (because of PVT) automatically cause the phase detector logic to determine if a change in the counter value is required. After the half-phase shift is detected, an internal lock signal is generated, and after a lock event occurs, the slave delay chain is ready to be updated based on a triggering event.

Slave delay chain programming sequence—

Following is the programming sequence for DLL bypass mode.

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=1, and DLLCRA[SLAVE_AUTO_UPDT]=0.
2. Program the following fields to provide the desired DQS delay for sampling: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_COARSE], and DLLCR[FREQEN]. See the chip-specific QuadSPI information for the supported programming settings.
3. Program DLLCRA[SLV_UPD]=1 to load these values in the slave delay chain.
4. Check the slave delay chain update status by polling DLLSR[SLVA_LOCK]=1 and clear DLLCRA[SLV_UPD] after confirming the update state.

NOTE

This programming sequence corresponds to flash memory A. Similar steps apply for flash memory B.

Following is the programming sequence for DLL auto update mode.

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=0, and DLLCRA[SLAVE_AUTO_UPDT]=1.
2. Program the DLL configuration by using DLLCRA[DLL_REFCNTR] and DLLCRA[DLLRES]. See the chip-specific QuadSPI information for the supported DLL configuration settings.
3. Program the slave settings to delay DQS by using these fields: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_OFFSET], and DLLCR[FREQEN]. See the chip-specific QuadSPI information for the supported settings.
4. If offset delay needs to be updated on the slave chain, program DLLCRA[SLV_UPD]=1.
5. Enable DLL by programming DLLCRA[DLLEN]=1 and reset DLLCRA[SLV_UPD]=0. Slave delay chain is updated automatically and can be checked by polling DLLSR[SLVA_LOCK]==1

NOTE

This programming sequence corresponds to flash memory A. Similar steps apply for the flash memory B.

38.14 Data input hold requirement of flash memory

In the DDR mode, the data is valid only for half clock cycle. It is difficult to meet the data input hold time requirement for flash memory. QuadSPI internally delays the data sent to flash memory so that it becomes easy to meet the hold requirement. The FLSHCR[TDH] is used for this purpose. If FLSHCR[TDH] is configured to 0, then the data sent to flash memory is aligned with the internal reference clock of QuadSPI. If it is 1, then the data is aligned to 2x internal reference half clock.

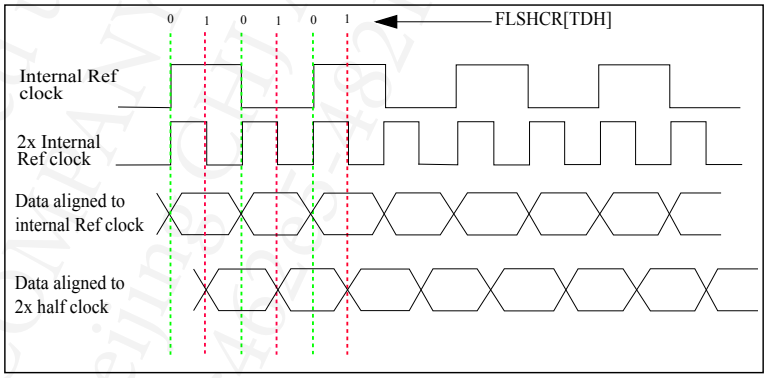

Figure 206. Data hold

Chapter 39
Ultra Secured Digital Host Controller (uSDHC)

39.1 Chip-specific uSDHC information

39.1.1 Chip-specific uSDHC information

uSDHC on this chip does not implement DLL_CTRL (60h) or DLL_STATUS (64h). Disregard their references in this document.

39.2 Introduction

uSDHC provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 207. The module acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by uSDHC:

- The Multi Media Card (MMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.
- The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC (with some additions).
- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low-power consumption for mobile electronic devices. For the sake of simplicity, the next figure does not show cards with reduced size or mini cards.

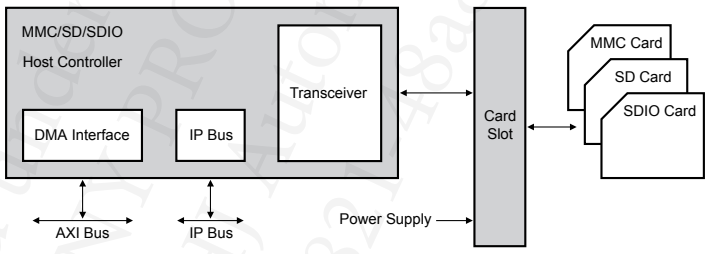

Figure 207. System connection of uSDHC

39.2.1 Features

Here are some of the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for MMC cards using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for MMC cards using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports a single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer

- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies two fully configurable 256x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access
- support Command queue mechanism

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

39.2.2 Modes and operations

39.2.2.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification mode (up to 400 kHz)
- MMC full-speed mode (up to 26 MHz)
- MMC high-speed mode (up to 52 MHz)
- MMC HS200 mode(up to 200 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full-speed mode (up to 25 MHz)
- SD/SDIO high-speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode(up to 208 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

39.3 External signals

The following table describes the uSDHC external signals:

Table 252. uSDHC external signals

Signal	Description	Direction
CLK	Clock for MMC/SD/SDIO card	O

Table continues on the next page...

Table 252. uSDHC external signals (continued)

Signal	Description	Direction
CMD	CMD line connect to card	I/O
DATA7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DATA6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DATA5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DATA4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
DATA3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DATA2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DATA0	DAT0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection pin If not used (for the embedded memory), tie low to indicate that there is a card attached.	I
WP	Card write protect detect If not used (for the embedded memory), tie low to indicate that it is not write protected.	I
RESET_B	Card hardware reset signal, active low	O
VSELECT	IO power voltage selection signal	O
STROBE	Input clock for eMMC HS400 mode	I

39.3.1 Signals overview

uSDHC has 15 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, and SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC module and the card.

Provided under NDA ONLY
COMPANY PROPRIETARY
Beijing Qianxin Technology Co., Ltd
c0462e21-4821-4aa8-b251-390d3ab624c1

- The CD is card detection signal directly routed from the socket. This signal is active low (0). A low on CD# means that a card is inserted. It is optional for system implementation.
- The WP is write protection signals directly routed from the socket. This signal is active low (0). A high on WP means that the write protect switch is active. It is optional for system implementation.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier. It is optional for system implementation.
- STROBE is input clock signal for eMMC HS400 mode.

If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high. If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.

39.4 uSDHC memory map/register definition

39.4.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

39.4.1.1 uSDHC memory map

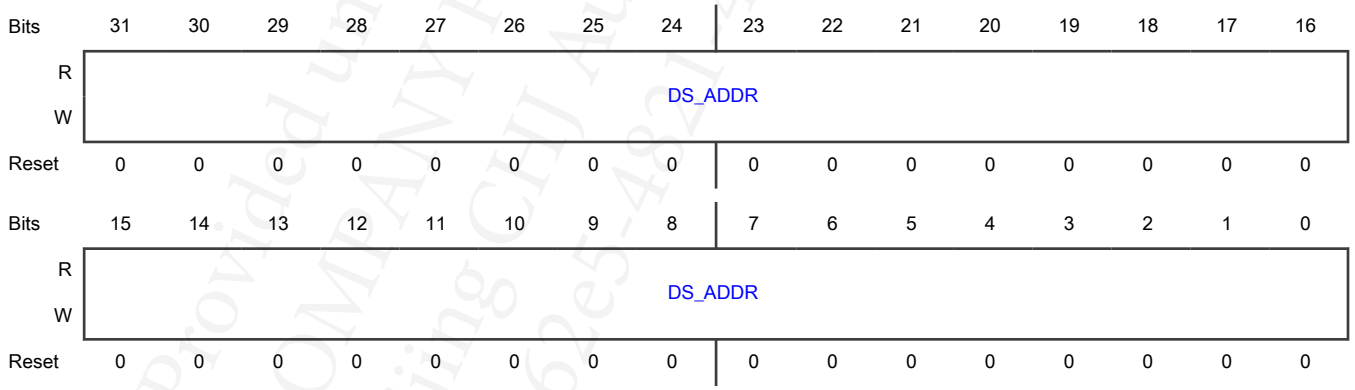
39.4.1.2 DMA System Address (DS_ADDR)



Offset

Register	Offset
DS_ADDR	0h

Function

This register contains the physical system memory address used for DMA transfers.

Diagram

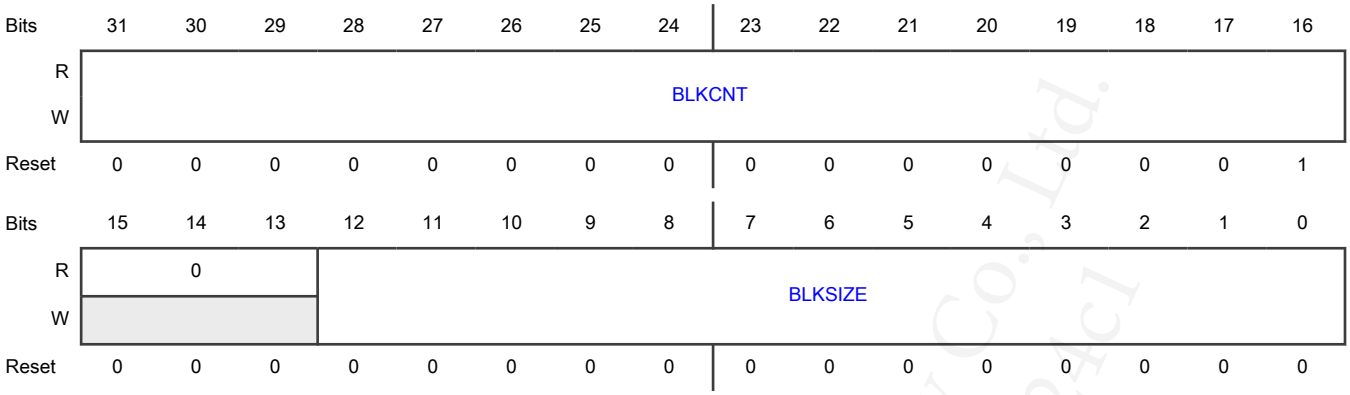
Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
c8c462e54821748a-b251-3900a6a62a61

Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

39.4.1.3 Block Attributes (BLK_ATT)

Offset



Register	Offset
BLK_ATT	4h

Function

This register is used to configure the number of data blocks and the number of bytes in each block.

Beijing CHJ Automotive Technology Co.,Ltd.
c8c46225-4821-4a38-b2f1-590e5e24c0e

Diagram

Fields

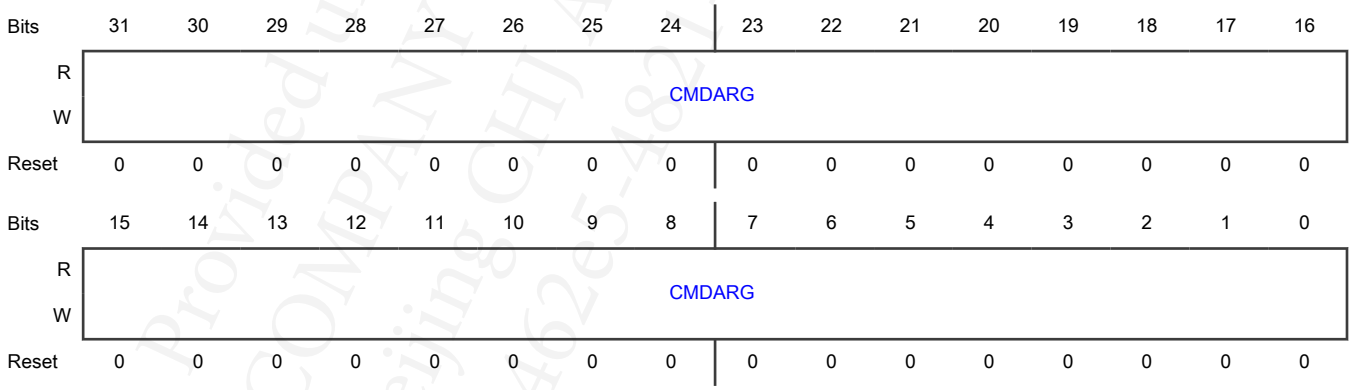
Field	Function
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000000000000000b - Stop count 0000000000000001b - 1 block 0000000000000010b - 2 blocks 1111111111111111b - 65535 blocks
15-13 —	Reserved
12-0	Transfer block size

Table continues on the next page...

Table continued from the previous page...

Field	Function
BLKSIZE	This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0000000000000b - No data transfer 0000000000001b - 1 byte 0000000000010b - 2 bytes 0000000000011b - 3 bytes 0000000000100b - 4 bytes 0000111111111b - 511 bytes 0001000000000b - 512 bytes 0100000000000b - 2048 bytes 1000000000000b - 4096 bytes

39.4.1.4 Command Argument (CMD_ARG)



Offset

Register	Offset
CMD_ARG	8h

Function

This register contains the SD/MMC command argument.

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-482a-48a8-b251-390d3ab624c1

Fields

Field	Function
31-0 CMDARG	Command argument The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

39.4.1.5 Command Transfer Type (CMD_XFR_TYP)

Offset

Register	Offset
CMD_XFR_TYP	Ch

Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

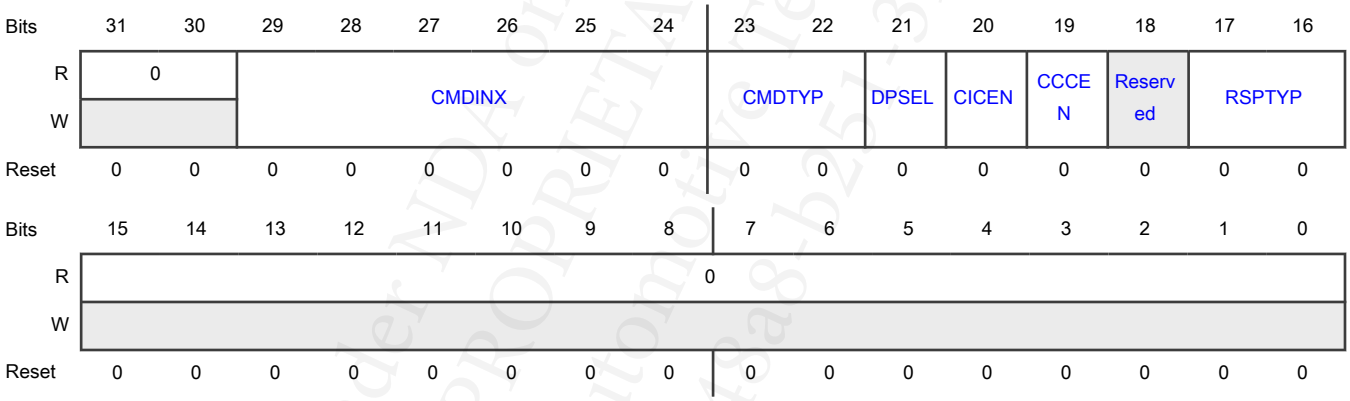
On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 253. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer



The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 254. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

Diagram

Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command type

Table continues on the next page...

Table continued from the previous page...

Field	Function
	There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0b - No data present 1b - Data present
20 CICEN	Command index check enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-0 —	Reserved

39.4.1.6 Command Response0 (CMD_RSP0)

Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 255. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

39.4.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

Function

The Buffer Data Port register is for 32-bit data access by the Arm platform. When the internal DMA is enabled, any write to this field is ignored, and any read from this field always yields 0s.

Diagram

39.4.1.11 Present State (PRES_STATE)

Offset

Register	Offset
PRES_STATE	24h

Function

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level

Table continues on the next page...

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.
c8c462e5-4f0f-4f82-b251-37d3ab624c1

Table continued from the previous page...

Field	Function
	This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 00000000b - Data 0 line signal level 00000001b - Data 1 line signal level 00000010b - Data 2 line signal level 00000011b - Data 3 line signal level 00000100b - Data 4 line signal level 00000101b - Data 5 line signal level 00000110b - Data 6 line signal level 00000111b - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19 WPSPL	Write protect switch pin level The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0b - Write protected (WP = 1) 1b - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)
17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tape select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode,and EMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable 1b - Read enable
10 BWEN	Buffer write enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data 1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No valid data 1b - Transferring data
7 SDOFF	SD clock gated off internally This status field indicates that the SD clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON field is 0 to stop the SD clock in idle status. This field is for the host driver to debug data transaction on the SD bus. 0b - SD clock is active. 1b - SD clock is gated off.
6 PEROFF	IPG_PERCLK gated off internally This status field indicates that the IPG_PERCLK is internally gated off. This field is for the host driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK is gated off, otherwise IPG_PERCLK is always active. 0b - IPG_PERCLK is active. 1b - IPG_PERCLK is gated off.
5 HCKOFF	HCLK gated off internally This status field indicates that the HCLK is internally gated off. This field is for the host driver to debug during a data transfer. 0b - HCLK is active. 1b - HCLK is gated off.
4 IPGOFF	Peripheral clock gated off internally This status field indicates that the peripheral clock is internally gated off. This field is for the host driver to debug. 0b - Peripheral clock is active. 1b - Peripheral clock is gated off.
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / MMC Command. Commands with a busy signal

Table continues on the next page...

Table continued from the previous page...

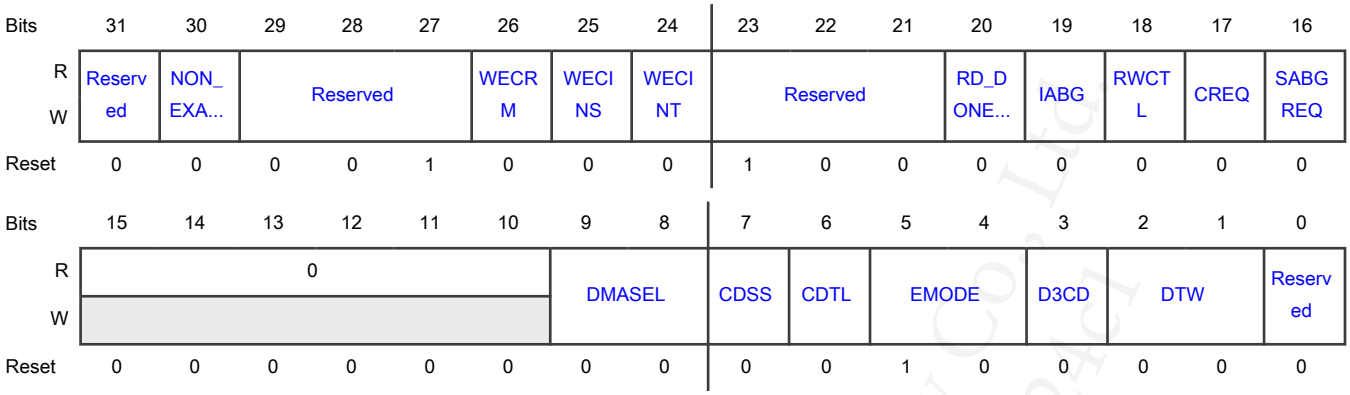
Field	Function
	belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / MMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

39.4.1.12 Protocol Control (PROT_CTRL)

Offset

Register	Offset
PROT_CTRL	28h

Function



This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Diagram

Fields

Field	Function
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO cards. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set

Table continues on the next page...

Table continued from the previous page...

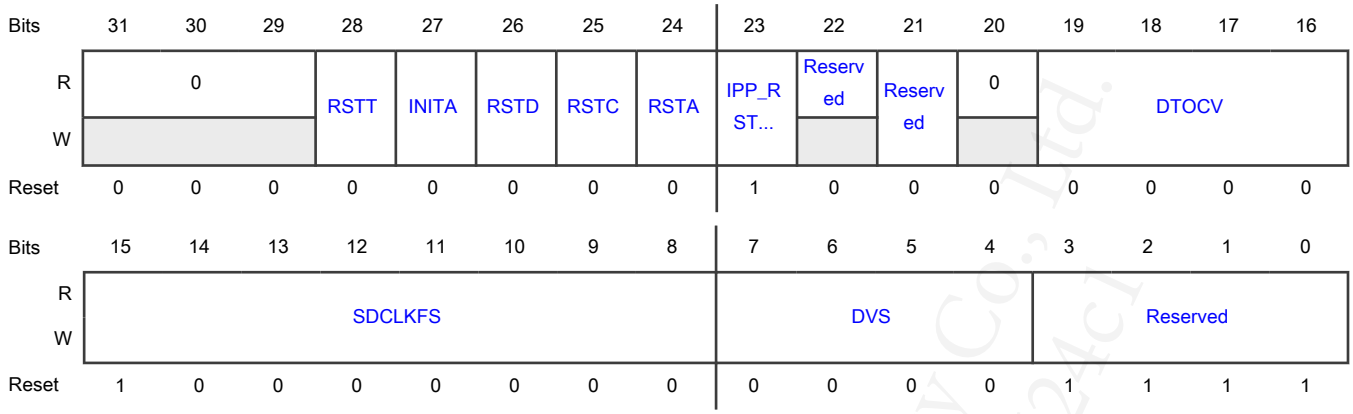
Field	Function
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that the SDIO card support read wait. Therefore, the host driver does not set this field during read transfers unless the SDIO card supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected. 10b - ADMA2 is selected. 11b - Reserved
7 CDSS	Card detect signal selection This field selects the source for the card detection. 0b - Card detection level is selected (for normal purpose). 1b - Card detection test level is selected (for test purpose).

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 CDTL	Card detect test level This field is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0b - Card detect test level is 0, no card inserted 1b - Card detect test level is 1, card inserted
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode 11b - Reserved
0 —	Reserved

39.4.1.13 System Control (SYS_CTRL)



Offset

Register	Offset
SYS_CTRL	2Ch

Function

This register provides control of the system. See detail in the field description.

Diagram

Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26 RSTD	Software reset for data line Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0b - No reset 1b - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This field's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 —	Reserved
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000b - SDCLK x 2^{32} 0001b - SDCLK x 2^{33} 0010b - SDCLK x 2^{18} 0011b - SDCLK x 2^{19} 1101b - SDCLK x 2^{29} recommend to use for other speed mode except HS400/HS200/SDR104 mode 1110b - SDCLK x 2^{30} recommend to use for HS200/SDR104 mode 1111b - SDCLK x 2^{31} recommend to use for HS400 mode
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0')

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and is never exceed this limit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

39.4.1.14 Interrupt Status (INT_STATUS)

Offset

Register	Offset
INT_STATUS	30h

Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 256. uSDHC status for command timeout error/command complete bit combinations

Command CRC Error	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 257. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 258. uSDHC status for command CRC error/command timeout error bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Fields

Field	Function
31-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any

Table continues on the next page...

Table continued from the previous page...

Field	Function
	error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20	Data timeout error

Table continues on the next page...

Table continued from the previous page...

Field	Function
DTOE	Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Time out
15 —	Reserved
14 CQI	Command queuing interrupt This interrupt is asserted when at least one of the bits in CQIS register is set. This interrupt is cleared only by clearing the source interrupt in CQIS register.
13 TP	Tuning pass:(only for SD3.0 SDR104 mode and EMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from the SDIO card does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field

Table continues on the next page...

Table continued from the previous page...

Field	Function
	and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete 1b - Command complete

39.4.1.15 Interrupt Status Enable (INT_STATUS_EN)

Offset

Register	Offset
INT_STATUS_EN	34h

Function

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

39.4.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

Offset

Register	Offset
INT_SIGNAL_EN	38h

Function

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

Diagram

39.4.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

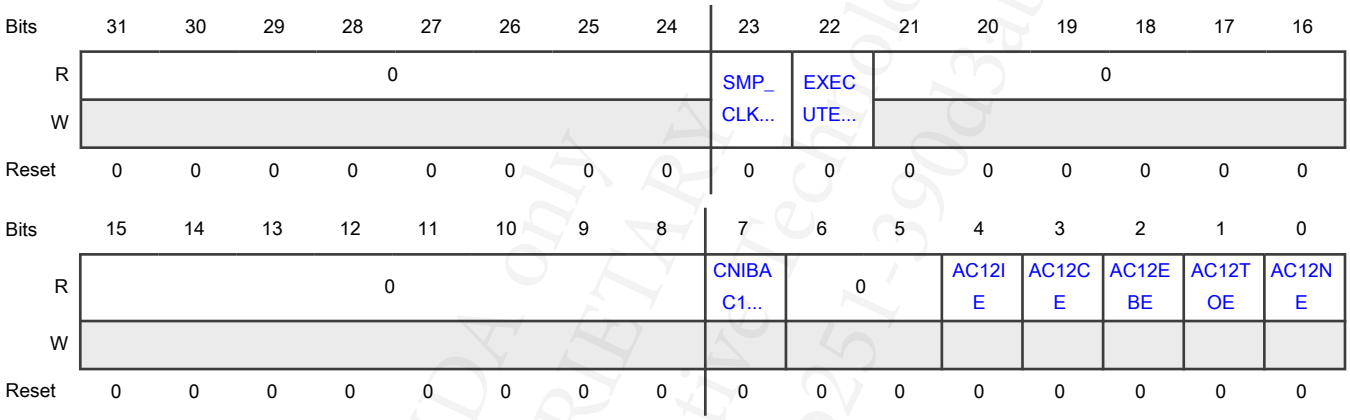
Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 259. Relationship between command CRC error and command timeout error for auto CMD12

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict



Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued

- At the end field of an Auto CMD12 response
  - — Check errors correspond to fields 1-4
  - — Set fields 1-4 corresponding to detected errors
  - — Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - — Set field 7 to 1 if there is a command that can't be issued
  - — Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Diagram

Fields

Field	Function
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data

Table continues on the next page...

Table continued from the previous page...

Field	Function
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0b - Tuning procedure is aborted 1b - Start tuning procedure
21-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
2 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

39.4.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

Offset

Register	Offset
HOST_CTRL_CAP	40h

Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

Diagram

28-24 —	Reserved
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum

Table continues on the next page...

Table continued from the previous page...

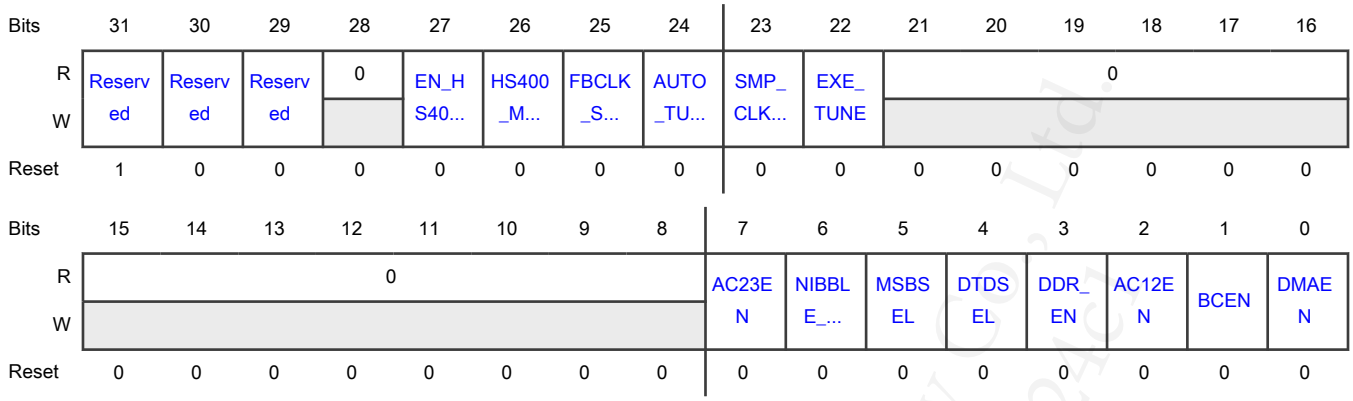
Field	Function
	legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

39.4.1.20 Mixer Control (MIX_CTRL)

Offset

Register	Offset
MIX_CTRL	48h

Function



This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 260. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Provided under NDA only

Diagram

Fields

Field	Function
31 —	Reserved Always write as 1.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 0.
28 —	Reserved
27 EN_HS400_MODE	Enable enhance HS400 mode Enhance HS400 enable
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and and EMMC HS200 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and EMMC HS200 mode)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 0b - Not tuned or tuning completed 1b - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Single block 1b - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. If a CMD with the response data size cannot be divided by 64 bytes, is given without a STOP CMD, and is followed by a software reset, then you must write a 0 to DTDSEL before inserting a software reset. This is necessary to avoid any issue during the SD card reinitialization. Read multiple blocks will not be affected as it is required to have a STOP CMD. 0b - Write (Host to card) 1b - Read (Card to host)
3 DDR_EN	Dual data rate mode selection
2	Auto CMD12 enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
AC12EN	Multiple block transfers for memory require a CMD12 to stop the transaction. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

39.4.1.21 Force Event (FORCE_EVENT)

Offset

Register	Offset
FORCE_EVENT	50h

Function

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding field of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

39.4.1.22 ADMA Error Status (ADMA_ERR_STATUS)

Offset

Register	Offset
ADMA_ERR_STATUS	54h

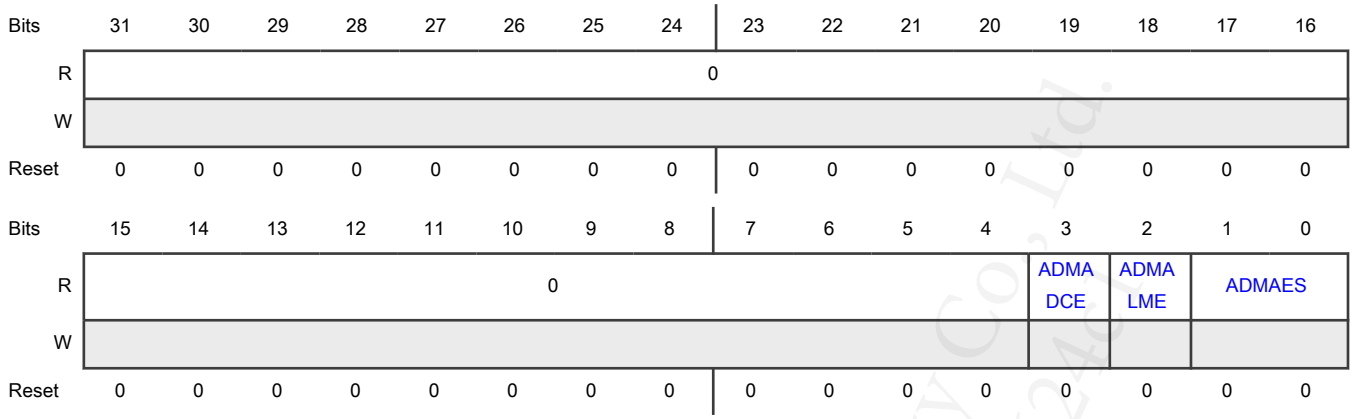
Function

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.



The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 261. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

Provided under NDA

c8c462e5-4821-43a8-b251-39013ac24d1

Diagram

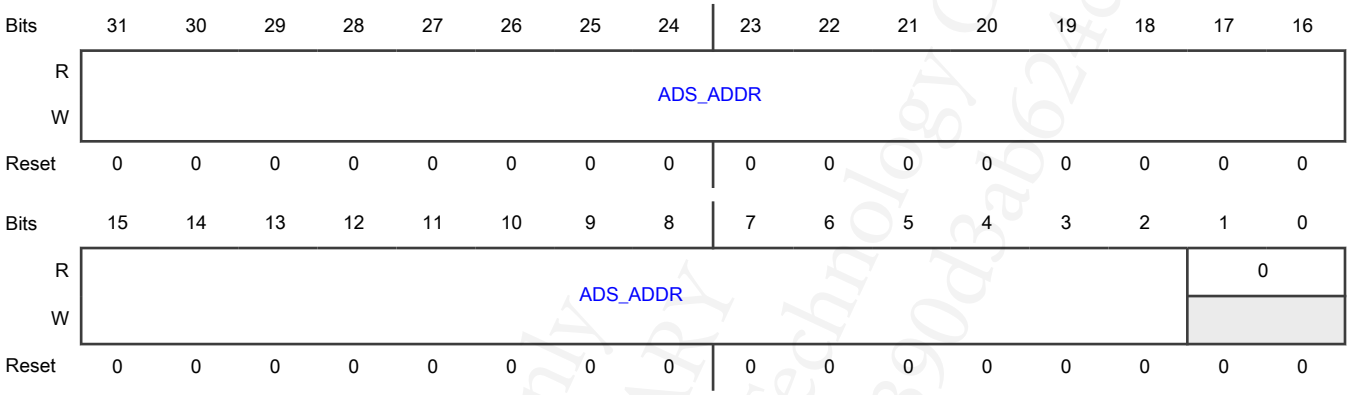
Fields

Field	Function
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

39.4.1.23 ADMA System Address (ADMA_SYS_ADDR)

Offset

Register	Offset
ADMA_SYS_ADDR	58h



Preliminary NDA only
COMPANY PROPRIETARY
Beijing C&A Automotive Technology Co., Ltd.
c8c46255-8921-4518-b251-390a3ab624c4

Function

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Diagram

Fields

Field	Function
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.

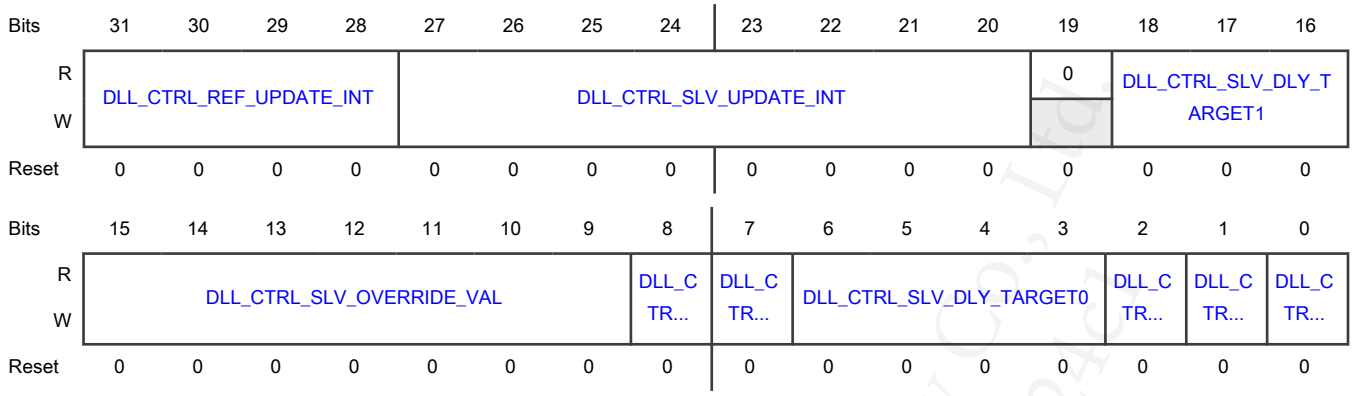
39.4.1.24 DLL (Delay Line) Control (DLL_CTRL)

Offset



Register	Offset
DLL_CTRL	60h

Function

This register contains control fields for DLL.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

Diagram

Fields

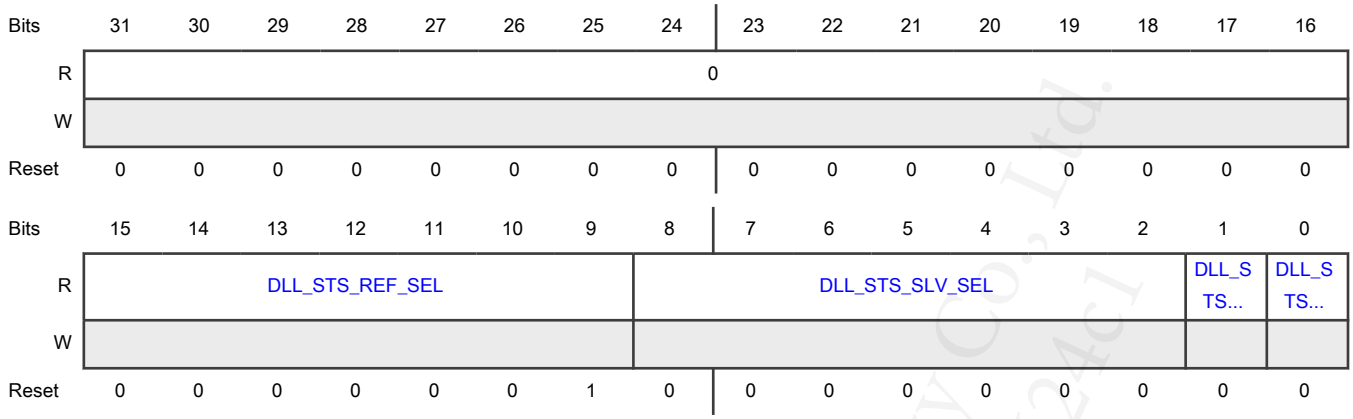
Field	Function
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7	DLL gate update

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLL_CTRL_GATE_UPDATE	Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4. **NOTE** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

39.4.1.25 DLL Status (DLL_STATUS)



Offset

Register	Offset
DLL_STATUS	64h

Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

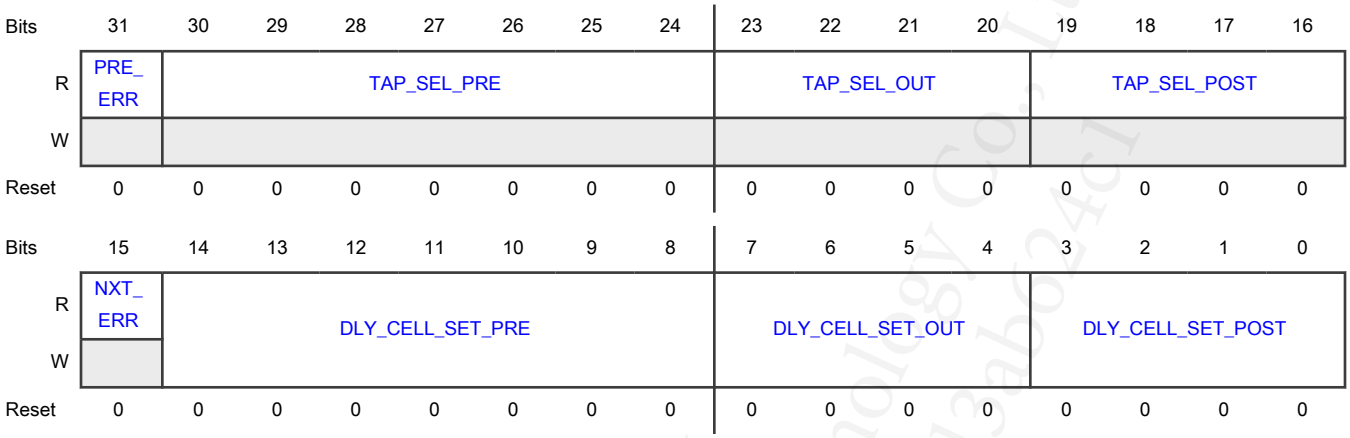
Diagram

Fields

Field	Function
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

39.4.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

Offset



Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Provided under NDA only
COMPANY PROPRIETARY
Beijing CEC Automotive Technology Co., Ltd.
c8c462e5-4621-4a8-251-390a3ab624c1

Function

This register contains the Clock Tuning Control status information. All fields are read only and reads the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode and EMMC HS200 mode.

Diagram

Fields

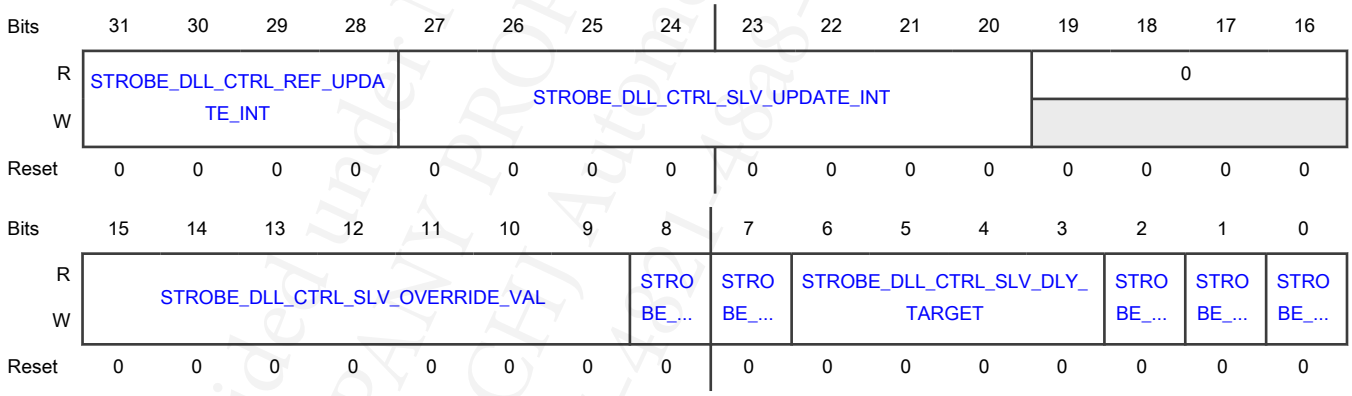
Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLY_CELL_SET_PRE	
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

39.4.1.27 Strobe DLL control (STROBE_DLL_CTRL)



Offset

Register	Offset
STROBE_DLL_CTRL	70h

Function

This register contains the strobe DLL control information.

Diagram

Fields

Field	Function

Table continues on the next page...

Table continued from the previous page...

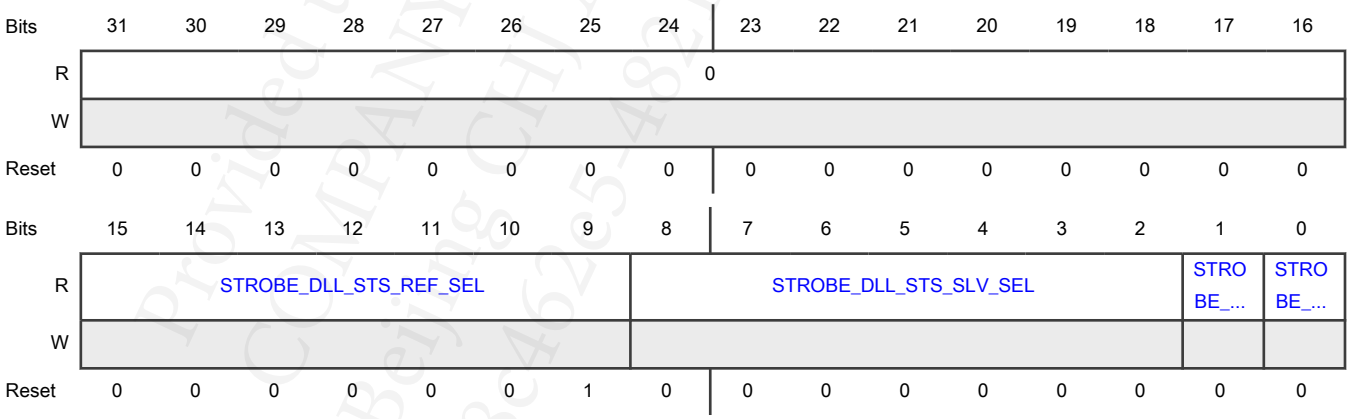
Field	Function
STROBE_DLL_CTRL_REF_UPDATE_INT	The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 STROBE_DLL_CTRL_SLV_UPDATE_INT	Strobe DLL control slave update interval Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE** software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control slave Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control slave override Set this field to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK / 2) / 16, So the input read-clock can be delayed relative input data from (STROBE_REF_CLOCK / 2) / 16 to (STROBE_REF_CLOCK *4)/16. **NOTE** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK/16.
2	Strobe DLL control slave force updated

Table continues on the next page...

Table continued from the previous page...

Field	Function
STROBE_DLL_CTRL_SLV_FORCE_UPD	Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL control reset Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE** Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

39.4.1.28 Strobe DLL status (STROBE_DLL_STATUS)



Offset

Register	Offset
STROBE_DLL_STATUS	74h

Function

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

Diagram

c8462525-4821-48a8-b251-39033b62fc1

Fields

Field	Function
31-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_STS_REF_SEL	Strobe DLL status reference select Reference delay line select taps. This is encoded by 7 fields for 127 taps.
8-2 STROBE_DLL_STS_SLV_SEL	Strobe DLL status slave select Slave delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status slave lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

Table continued from the previous page...

Field	Function
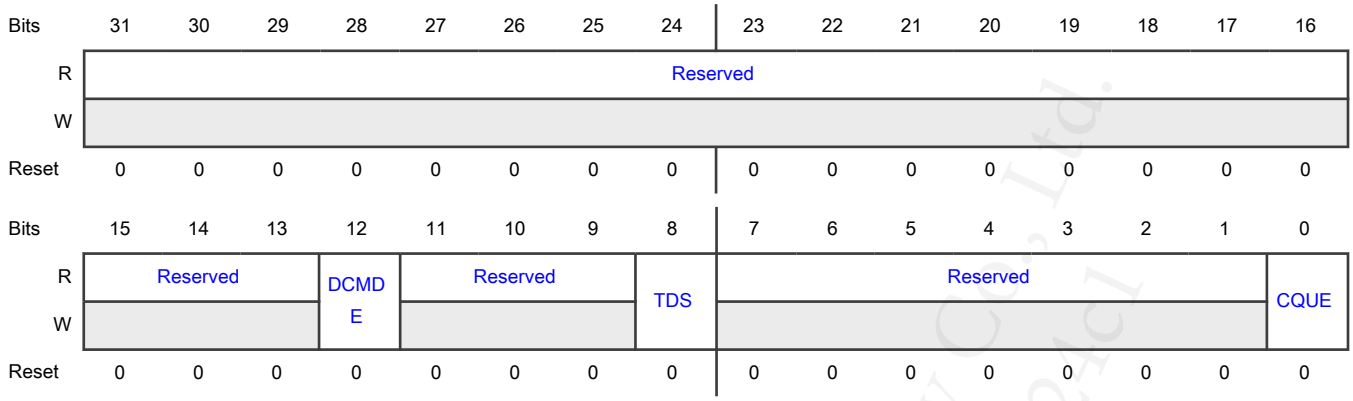
—	
15-12 ITCFMUL	Internal timer clock frequency multiplier ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See ITCFVAL definition for details. 0001b - 0.001 MHz 0010b - 0.01 MHz 0011b - 0.1 MHz 0100b - 1 MHz 0101b - 10 MHz 0110-1001b - Reserved
11-10 —	Reserved
9-0 ITCFVAL	Internal timer clock frequency value ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the polling period when using periodic SEND_QUEUE_ STATUS (CMD13) polling. The clock frequency is calculated as ITCFVAL* ITCFMUL. For example, to encode 19.2 MHz, ITCFVAL is C0h (= 192 decimal) and ITCFMUL is 2h (0.1 MHz): 192 * 0.1 MHz = 19.2 MHz.

39.4.1.35 Command Queuing Configuration (CQCFG)

Offset



Register	Offset
CQCFG	108h

Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

Diagram

Fields

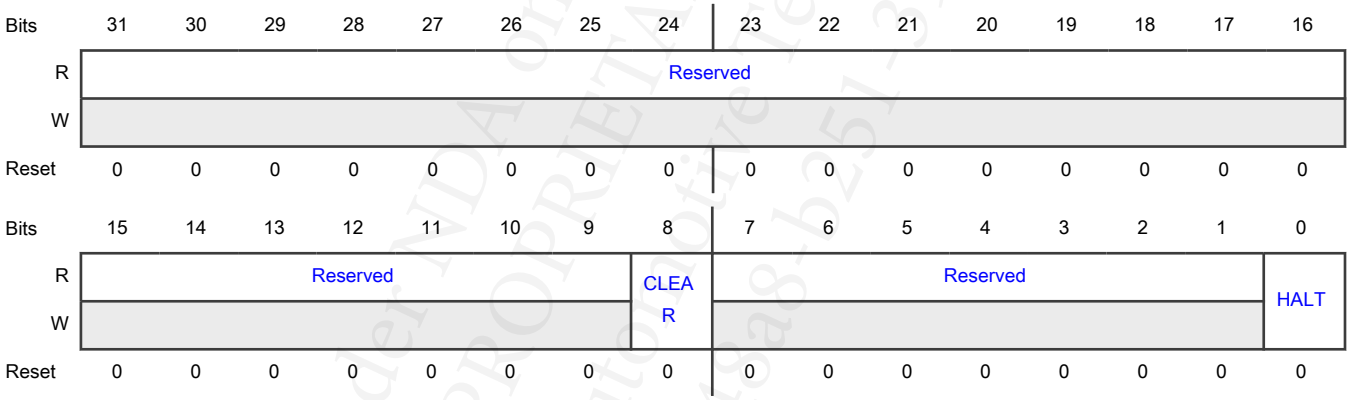
Field	Function
31-13 —	Reserved
12 DCMDE	Direct command (DCMD) enable This bit indicates to the hardware whether the Task Descriptor in slot #31 of the TDL is a Data Transfer Task Descriptor, or a Direct Command Task Descriptor. CQE uses this bit when a task is issued in slot #31, to determine how to decode the Task Descriptor. 0b - Task descriptor in slot #31 is a Data Transfer Task Descriptor 1b - Task descriptor in slot #31 is a DCMD Task Descriptor
11-9 —	Reserved
8 TDS	Task descriptor size This bit indicates whether the task descriptor size is 128 bits or 64 bits as detailed in Data Structures section. This bit can only be configured when Command Queuing Enable bit is ‘0’ (command queuing is disabled) 0b - Task descriptor size is 64 bits 1b - Task descriptor size is 128 bits
7-1 —	Reserved
0 CQUE	Command queuing enable Software shall write '1' this bit when in order to enable command queuing mode (for example, enable CQE). When this bit is 0, CQE is disabled and software controls the e•MMC bus using the legacy e•MMC host controller. Before software writes '1' to this bit, software shall verify that the e•MMC host controller is in idle state and there are no commands or data transfers ongoing.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When software wants to exit command queuing mode, it shall clear all previous tasks if such exist before setting this bit to 0.

39.4.1.36 Command Queuing Control (CQCTL)



Offset

Register	Offset
CQCTL	10Ch

Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Diagram

Fields

Field	Function
31-9 —	Reserved
8 CLEAR	Clear all tasks Software shall write '1' this bit when it wants to clear all the tasks sent to the chip. This bit can only be written when CQE is in halt state (for example, Halt bit is 1). When software writes 1, the value of the register is updated to '1', and CQE shall reset CQTDBR register and all other context information for all unfinished tasks. Then CQE will clear this bit.

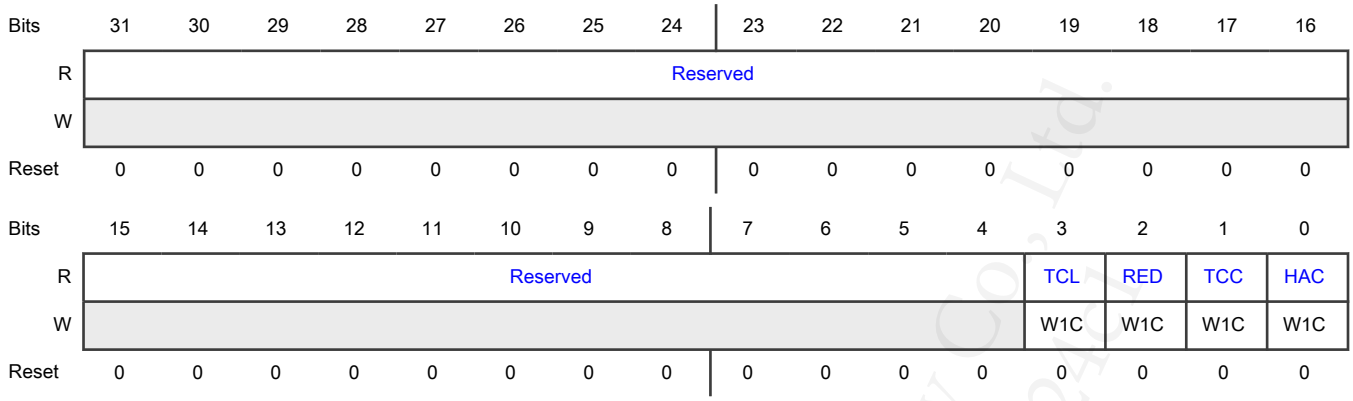
Table continues on the next page...

Table continued from the previous page...

Field	Function
	Software should poll on this bit until it is set to back 0 and may then resume normal operation, by clearing the Halt bit. CQE does not communicate to the chip that the tasks were cleared. It is software's responsibility to order the chip to discard the tasks in its queue using CMDQ_TASK_MGMT command. Writing '0' to this register shall have no effect.
7-1 —	Reserved
0 HALT	Halt Host software shall write '1' to the bit when it wants to acquire software control over the e•MMC bus and disable CQE from issuing commands on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT) When software writes '1', CQE shall complete the ongoing task if such a task is in progress. Once the task is completed and CQE is in idle state, CQE shall not issue new commands and shall indicate so to software by setting this bit to 1. Software may poll on this bit until it is set to 1, and may only then send commands on the e•MMC bus. In order to exit halt state (for example, resume CQE activity), software shall clear this bit (write '0'). Writing '0' when the value is already '0' shall have no effect.

39.4.1.37 Command Queuing Interrupt Status (CQIS)

Offset



Register	Offset
CQIS	110h

Function

This register indicates pending interrupts that require service. Each bit in this registers is asserted in response a specific event, only if the respective bit is set in CQISTE register.

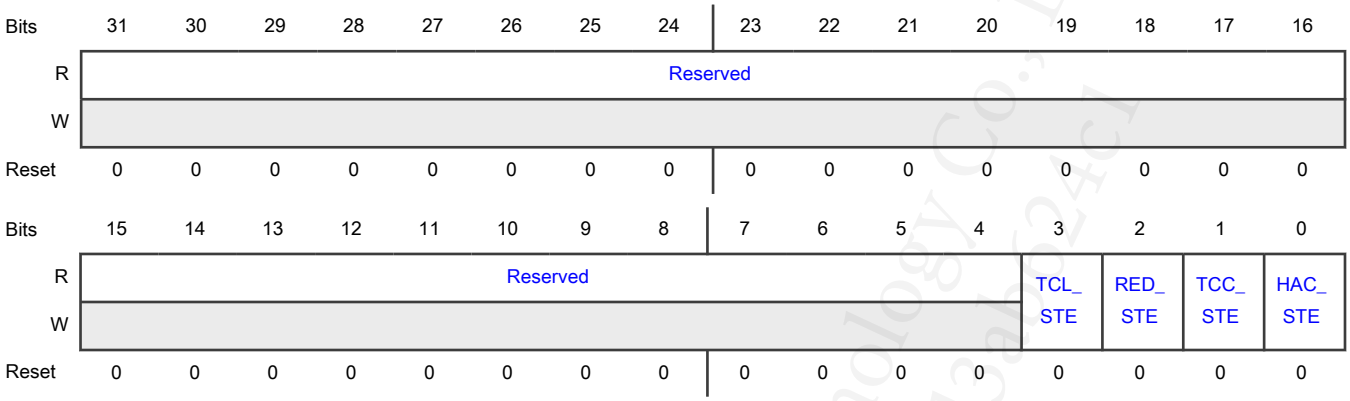
Provided under NDA
COMPANY PROPRIETARY
Beijing CTI Automotive Technology Co.,Ltd.
c8c462e5-4821-48a8-b251-390f3a6624c1

Diagram

Fields

Field	Function
31-4 —	Reserved
3 TCL	Task cleared This status bit is asserted (if CQISTE[TCL_STE]=1) when a task clear operation is completed by CQE. The completed task clear operation is either an individual task clear (CQTCLR) or clearing of all tasks (CQCTL).
2 RED	Response error detected interrupt This status bit is asserted (if CQISTE[RED_STE]=1) when a response is received with an error bit set in the device status field. The contents of the device status field are listed in 6.13. Software uses CQRMEM register to configure which device status bit fields may trigger an interrupt, and which are masked.
1 TCC	Task complete interrupt This status bit is asserted (if CQISTE[TCC_STE]=1) when at least one of the following two conditions are met: • A task is completed and the INT bit is set in its Task Descriptor • Interrupt caused by Interrupt Coalescing logic (see 0)
0 HAC	Halt complete interrupt This status bit is asserted (if CQISTE[HAC_STE]=1) when halt bit in CQCTL register transitions from 0 to 1 indicating that host controller has completed its current ongoing task and has entered halt state.

39.4.1.38 Command Queuing Interrupt Status Enable (CQISTE)



Offset

Register	Offset
CQISTE	114h

Function

This register enables and disables the reporting of the corresponding interrupt to host software in CQIS register. When a bit is set ('1') and the corresponding interrupt condition is active, then the bit is CQIS is asserted. Interrupt sources that are disabled (‘0’) are not indicated in the CQIS register. This register is bit-index matched to CQIS register.

Diagram

Fields

Field	Function
31-4 —	Reserved
3 TCL_STE	Task cleared status enable 0b - CQIS[TCL] is disabled 1b - CQIS[TCL] is set when its interrupt condition is active
2 RED_STE	Response error detected status enable 0b - CQIS[RED] is disabled 1b - CQIS[RED] is set when its interrupt condition is active
1 TCC_STE	Task complete status enable 0b - CQIS[TCC] is disabled 1b - CQIS[TCC] is set when its interrupt condition is active
0 HAC_STE	Halt complete status enable 0b - CQIS[HAC] is disabled 1b - CQIS[HAC] is set when its interrupt condition is active

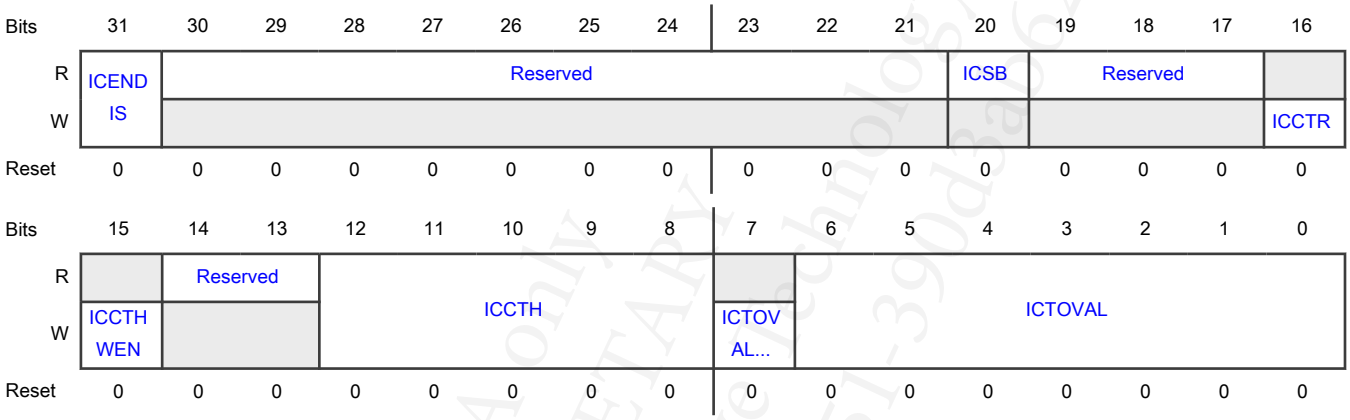
39.4.1.40 Command Queuing Interrupt Coalescing (CQIC)



Offset

Register	Offset
CQIC	11Ch

Function

This register controls the interrupt coalescing feature.

Diagram

Fields

Field	Function
31 ICENDIS	Interrupt coalescing enable/disable When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
30-21 —	Reserved
20 ICSB	Interrupt coalescing status This bit indicates to software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (for example, ICSB is set if and only if IC counter > 0). 0b - No task completions have occurred since last counter reset (IC counter =0) 1b - At least one task completion has been counted (IC counter >0)
19-17 —	Reserved
16 ICCTR	Counter and timer reset When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.

Table continues on the next page...

Table continued from the previous page...

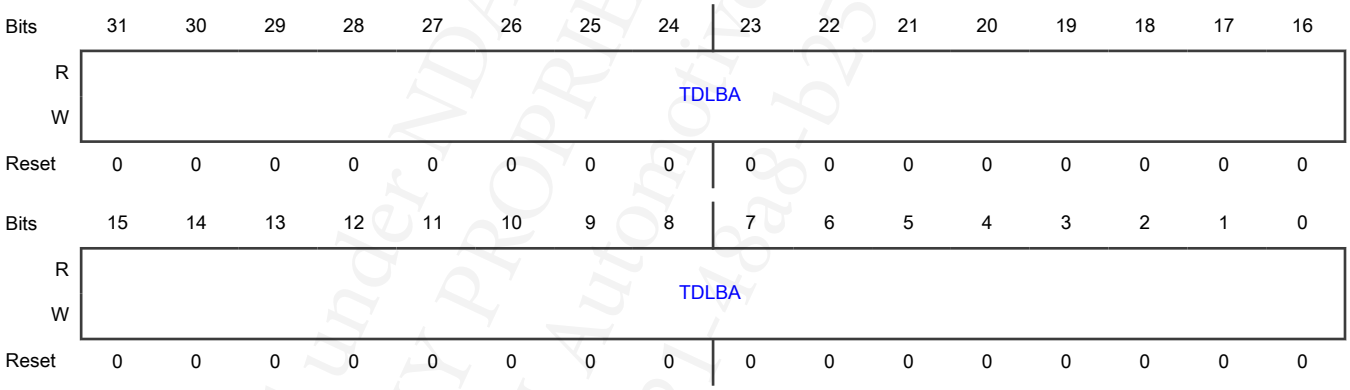
Field	Function
15 ICCTHWEN	Interrupt coalescing counter threshold write enable When software writes ‘1’, the value ICCTH is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICCTH is not updated. **NOTE** Write operations to ICCTH are only allowed when the task queue is empty.
14-13 —	Reserved
12-8 ICCTH	Interrupt coalescing counter threshold Software uses this field to configure the number of task completions (only tasks with INT=0 in the Task Descriptor) which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in ICCTH. The maximum allowed value is 31. **NOTE** When ICCTH is 0, task completions are not counted, and counting-based interrupts are not generated. In order to write to this field, the ICCTHWEN field must be set at the same write operation.
7 ICTOVALWEN	Interrupt coalescing timeout value write enable When software writes ‘1’, the value ICTOVAL is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICTOVAL is not updated. **NOTE** Write operations to ICTOVAL are only allowed when the task queue is empty.
6-0 ICTOVAL	Interrupt coalescing timeout value Software uses this field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when a data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field it generates an interrupt and stops. The timer’s unit is equal to 1024 clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 01h (1024 clock periods) and the maximum value is 7Fh (127*1024 clock periods).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in ICTOVAL is 10h, the calculated polling period is 16*1024*52.08 ns= 853.33 us **NOTE** When ICTOVAL is 0, the timer is not running, and timer-based interrupts are not generated. In order to write to this field, the ICTOVALWEN bit must be set at the same write operation.

39.4.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)



Offset

Register	Offset
CQTDLBA	120h

Function

This register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Diagram

Fields

Field	Function
31-0 TDLBA	Task descriptor list base address This register stores the LSB bits (bits 31:0) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This address shall be set on 1 KByte boundary: The lower 10 bits of this register shall be set to 0 by software and shall be ignored by CQE.

Register	Offset
CQTDLBAU	124h

Function

This register is used for configuring the upper 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

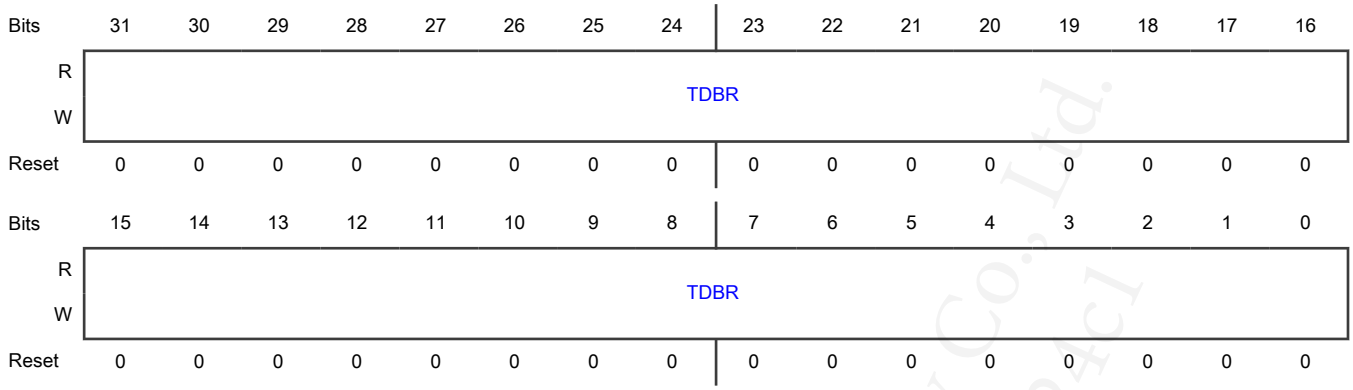
Diagram

Fields

Field	Function
31-0 TDLBAU	Task descriptor list base address This register stores the MSB bits (bits 63:32) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This register is reserved when using 32-bit addressing mode.

39.4.1.43 Command Queuing Task Doorbell (CQTDBR)

Offset



Register	Offset
CQTDBR	128h

Function

Using this register, software triggers CQE to process a new task.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-482-4888-b251-390d3ab6240d

Diagram

Fields

Field	Function
31-0 TDBR	Task doorbell Software configures TDLBA and TDLBAU, and enable CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers CQE to start processing the task encoded in slot n of the TDL. CQE always processes tasks in-order according to the order submitted to the list by CQTDBR write transactions. CQE processes Data Transfer tasks by reading the Task Descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device. CQE processes DCMD tasks (in slot #31, when enabled) by reading the Task Descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to '0' by CQE in one of the following events: 1. When a task execution is completed (with success or error) 2. The task is cleared using CQTCLR register 3. All tasks are cleared using CQCTL register 4. CQE is disabled using CQCFG register Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission: CQE shall process the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution will be based on said processing order. Writing 0 by software shall have no impact on the hardware, and will not change the value of the register bit.

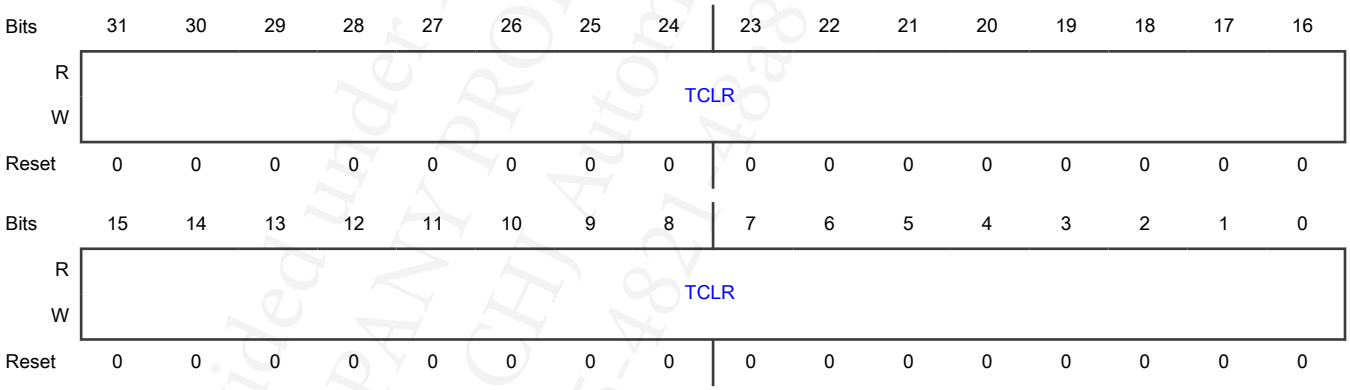
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e54-821-48a8-b251-39d3ab624c1

Fields

Field	Function
31-0 DPT	Device pending tasks Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task hasn't been executed yet. CQE shall set this bit after receiving a successful response for CMD45. CQE shall clear this bit after the task has completed execution. Software needs to read this register in the task-discard procedure, when the controller is halted, to determine if the task is queued in the device. If the task is queued, the driver sends a CMDQ_TASK_MGMT (CMD48) to the device ordering it to discard the task. Then software clears the task in the CQE. Only then the software orders CQE to resume its operation using CQCTL register.

39.4.1.47 Command Queuing Task Clear (CQTCLR)



Offset

Register	Offset
CQTCLR	138h

Function

This register is used for removing an outstanding task in the CQE. The register should be used only when CQE is in Halt state.

Diagram

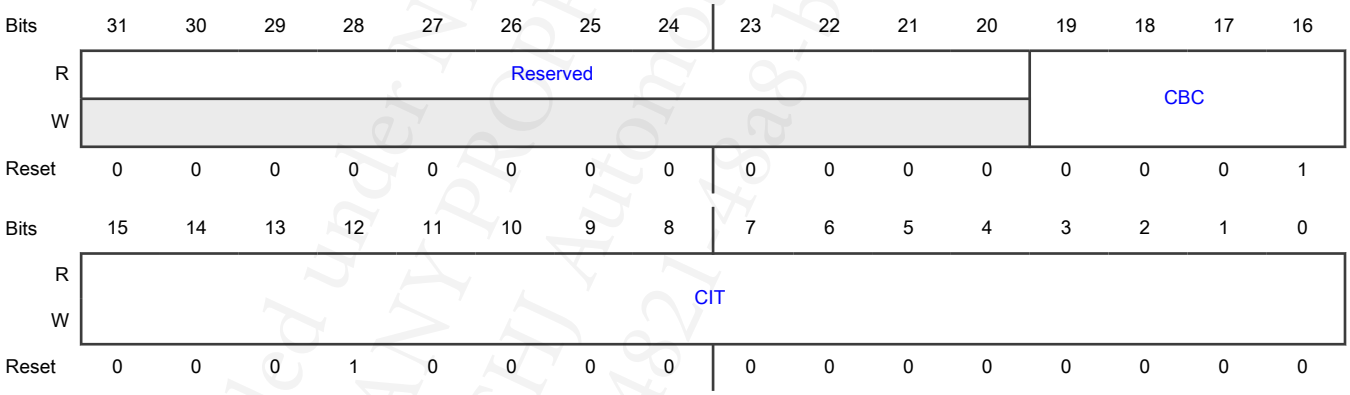
Fields

Field	Function
31-0 TCLR	Task clear Writing 1 to bit n of this register orders CQE to clear a task which software has previously issued. This bit can only be written when CQE is in Halt state as indicated in CQCFG register Halt bit.

Table continues on the next page...

Field	Function
	When software writes '1' to a bit in this register, CQE updates the value to '1', and starts clearing the data structures related to the task. CQE clears the bit fields (sets a value of 0) in CQTCLR and in CQTDBR once clear operation is complete. Software should poll on the CQTCLR until it is cleared to verify clear operation was complete. Writing to this register only clears the task in the CQE and does not have impact on the device. In order to discard the task in the device, host software shall send CMDQ_TASK _MGMT while CQE is still in Halt state. Host driver is not allowed to use this register to clear multiple tasks at the same time. Clearing multiple tasks can be done using CQCTL register. Writing 0 to a register bit shall have no impact.

39.4.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)



Offset

Register	Offset
CQSSC1	140h

Function

The register controls the when SEND_QUEUE_STATUS commands are sent.

Diagram

Fields

Field	Function
31-20 —	Reserved
19-16	Send status command block counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
CBC	This field indicates to CQE when to send SEND_QUEUE_STATUS (CMD13) command to inquire the status of the device's task queue. A value of *n* means CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. A value of 0 means that SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead it will be sent only when the data lines are idle. A value of 1 means that STATUS command is to be sent during the last block of the transaction.
15-0 CIT	Send status command idle timer This field indicates to CQE the polling period to use when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicating that no task is ready for execution, CQE counts the configured time until it issues the next SEND_QUEUE_STATUS. Timer units are clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). Default interval is: 4096 clock periods. For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in CQSSC1.CIT is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 us

39.4.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)

The reset value of this register is set to trigger an interrupt on all “Error” type bits in the device status, as defined in 6.13. **NOTE** Responses to CMD13 (SQS) encode the QSR, so they are ignored by this logic. 00000000000000000000000000000000b - When a R1/R1b response is received, bit i in the device status is ignored 00000000000000000000000000000001b - When a R1/R1b response is received, with bit i in the device status set, a RED interrupt is generated

39.4.1.52 Command Queuing Task Error Information (CQTERRI)

Offset

Register	Offset
CQTERRI	154h

Function

This register is updated by CQE when an error occurs on data or command related to a task activity.

When such error is detected by CQE or indicated by the e•MMC controller CQE stores in CQTERRI the task IDs and the command indices of the commands which were executed on the command line and data lines when the error occurred.

Software is expected to use this information in the error recovery procedure. See B.2.8 for more details.

39.5 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

39.5.1 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme.

NXP Semiconductors NDA only
BLUE CHIP COMPANY PROPRIETARY
c8c6e5-4a21-4848-b251-390da3ab624c1
Beijing Automotive Technology Co., Ltd.

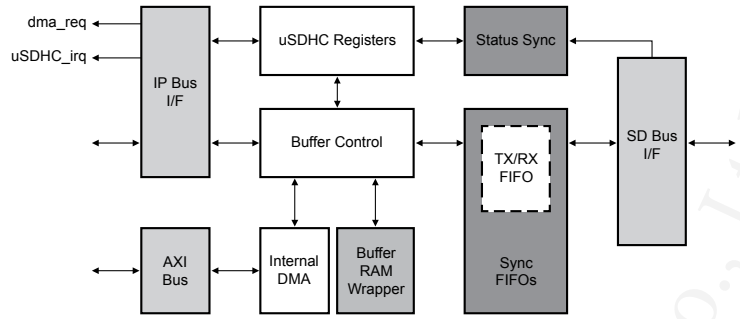

Figure 209. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

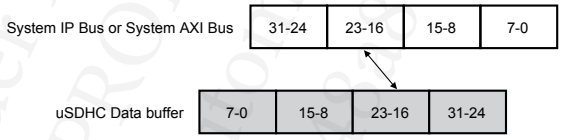

Figure 210. Data swap between system bus and uSDHC data buffer in the byte little endian mode

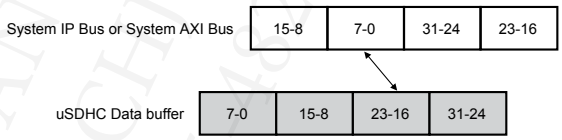

Figure 211. Data swap between system bus and uSDHC data buffer in half word big endian mode

39.5.1.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

Provided under NDA ONLY
COMPANY PROPRIETARY
Leijin CHEN (leijin.chen@nxp.com) - 5d3e624c1
c8-162540-1 Thursday, 1 October 2020 Technology Co., Ltd.

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

39.5.1.2 Read operation sequence

There are 2 ways to read data from the buffer when the user transfers data to the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted.

For any write transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

39.5.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC module, the only data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The host driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

39.5.1.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length cannot be divided evenly into a multiple of the block size, then there are two ways to transfer the data. These two ways depend on the function and the card design. Option

1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the division of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

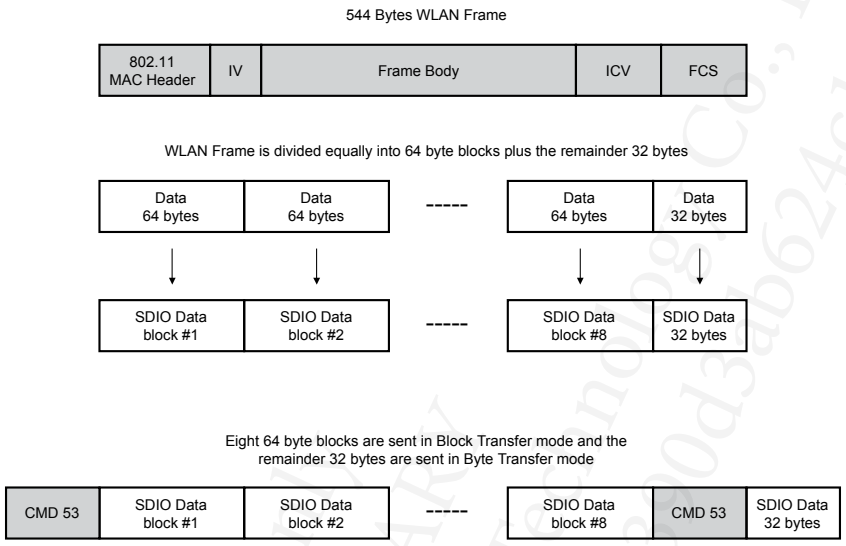

Figure 212. Example for dividing large data transfers

39.5.2 DMA AXI interface

The internal DMA implements a DMA engine and the AXI master. When the internal DMA is enabled, the uSDHC_dreq_b is not asserted during the transfer, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See the figure below for an illustration of the DMA AXI interface block.

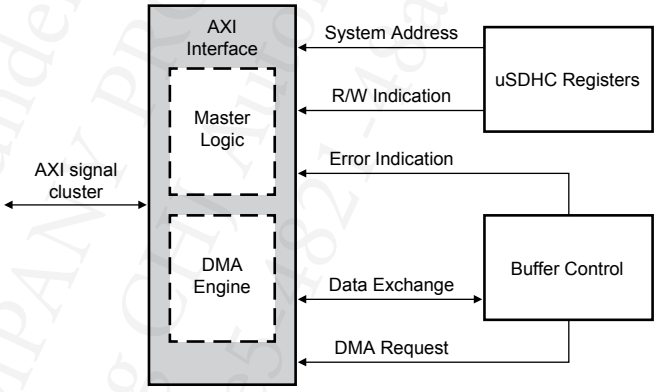

Figure 213. DMA AXI interface block

39.5.2.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface. The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts

the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words. After the first burst transfer, if there are more than two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

39.5.2.2 AXI master interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block. DMA operation resumes when the interrupt is serviced by the software.

39.5.2.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 improves the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

39.5.2.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor
- Set data length and address descriptor
- Link descriptor

- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so only a tran type descriptor can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 214. Format of the ADMA1 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA1.

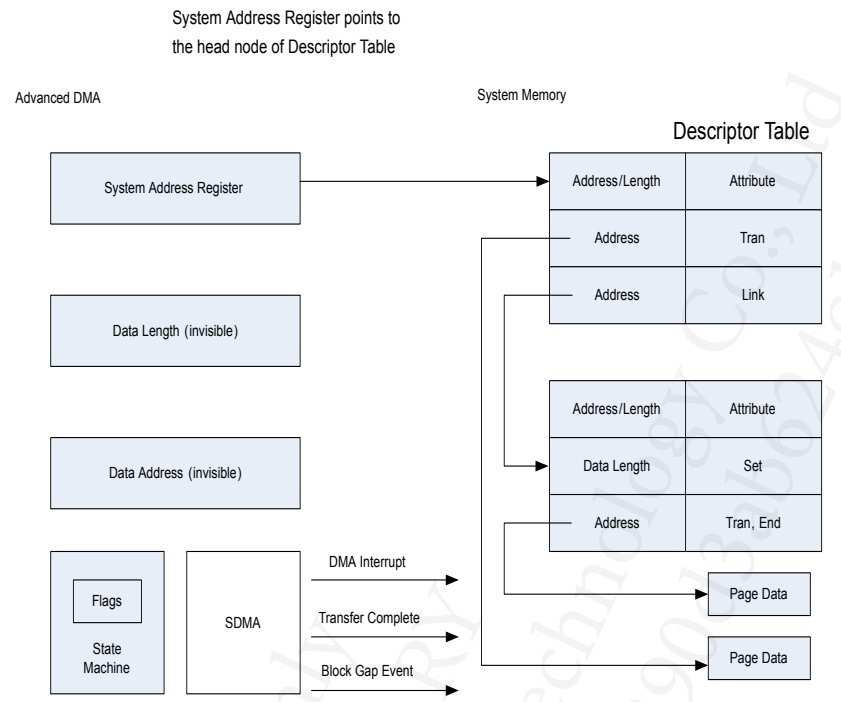

Figure 215. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 216. Format of the ADMA2 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA2.

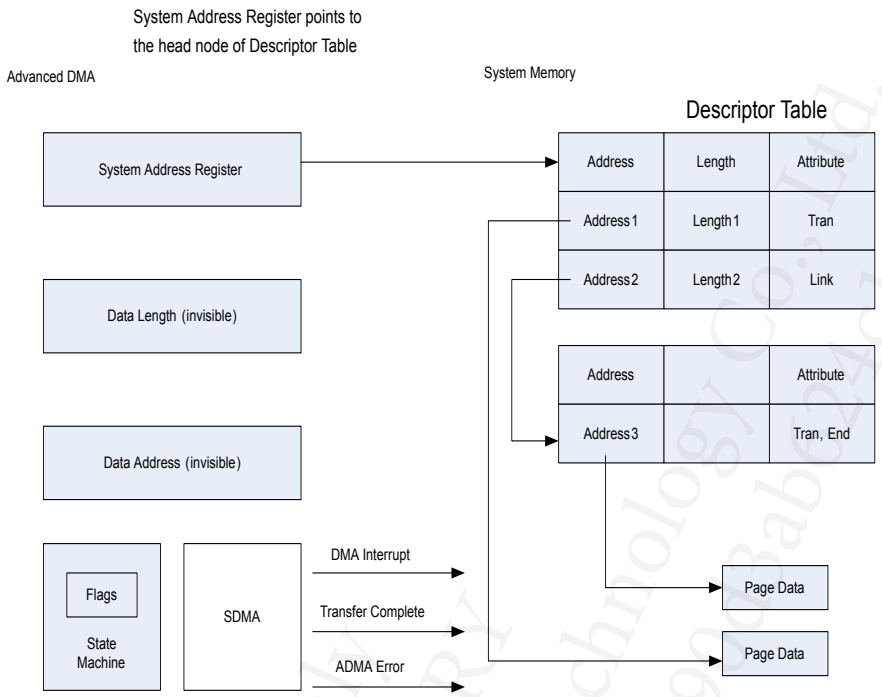

Figure 217. Concept and access method of the ADMA2 descriptor table

39.5.2.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

39.5.2.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

39.5.3 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See the figure below for the block diagram.

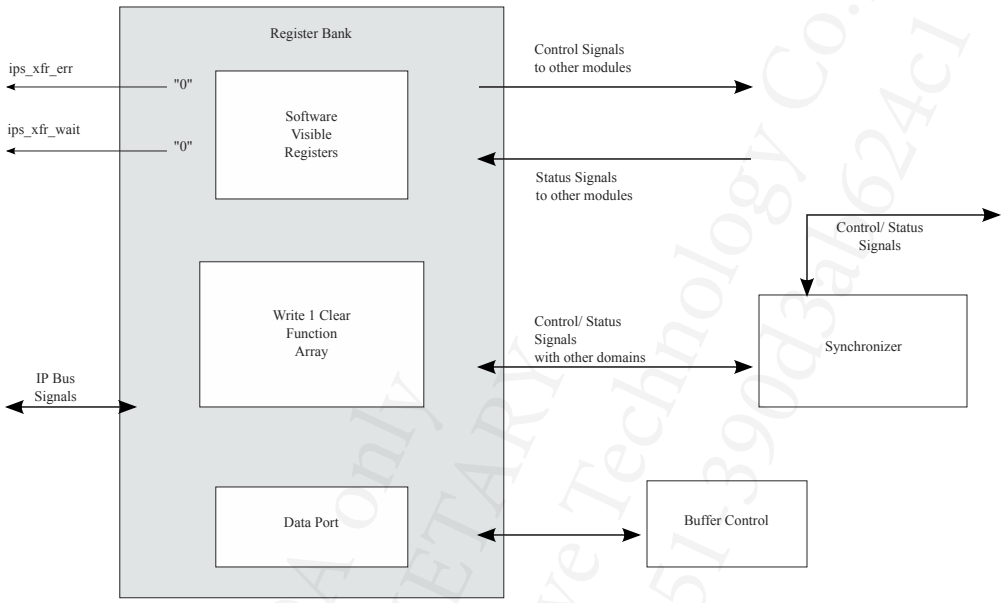

Figure 218. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

39.5.3.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD control misc
- Command control

- Data control
- Clock control

39.5.3.2 SD control misc

In the SD control misc unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is active, writes to the register bank are ignored.

39.5.3.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

39.5.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC shift register.

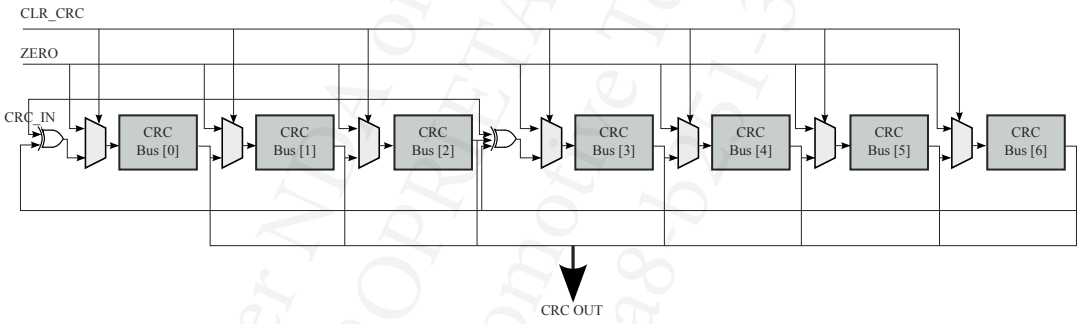

Figure 219. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

39.5.3.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

39.5.4 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

39.5.5 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] is for prescaler configuration while the [DVS] is for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

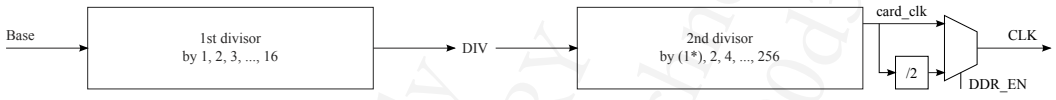

Figure 220. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 209) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

- In the DDR mode, CLK is equal to card_clk/2.

39.5.6 SDIO card interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

39.5.6.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

39.5.6.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides sample the level on pin 8 during the interrupt period. At all other times, the host ignores the level on pin 8 and treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10 for further information about the SDIO card interrupt.

39.5.6.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

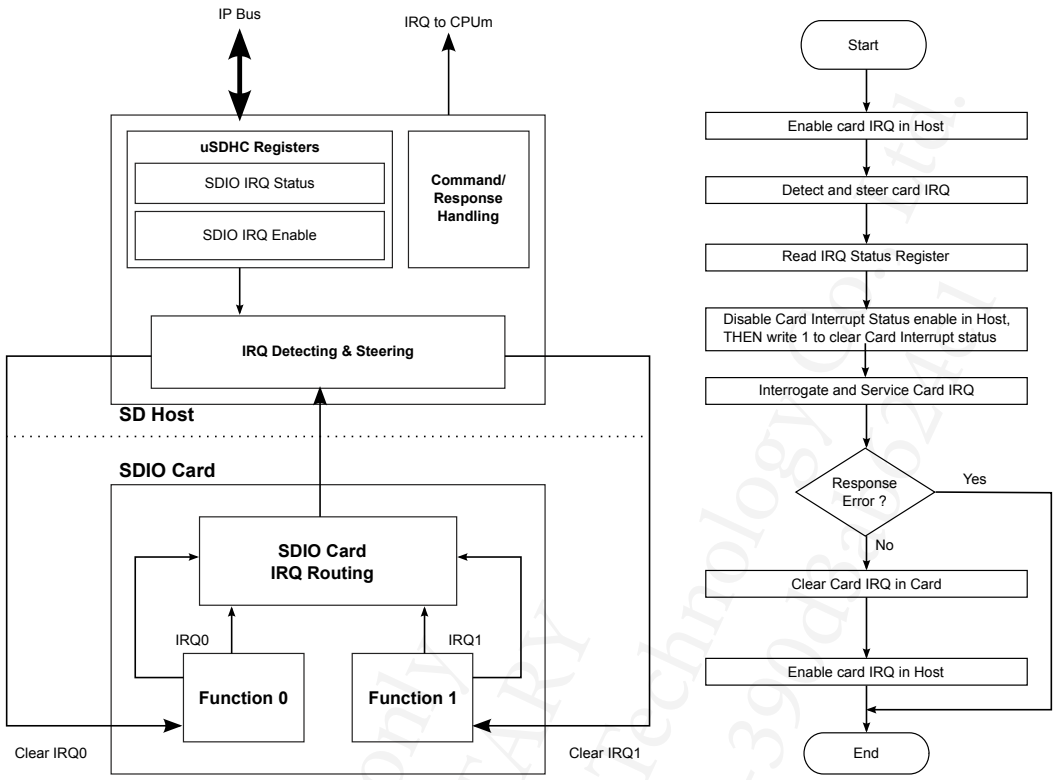

Figure 221. Card interrupt scheme, card interrupt detection, and handling procedure

39.5.7 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

39.5.8 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The uSDHC module offers a power management feature. By clearing the clock enabled bits in the System Control register, the clocks are gated in the low position to uSDHC. For maximum power saving, the user can disable all the clocks to uSDHC when there is no operation in progress.

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

39.5.8.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

39.5.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 specification: boot operation and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

39.5.9.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

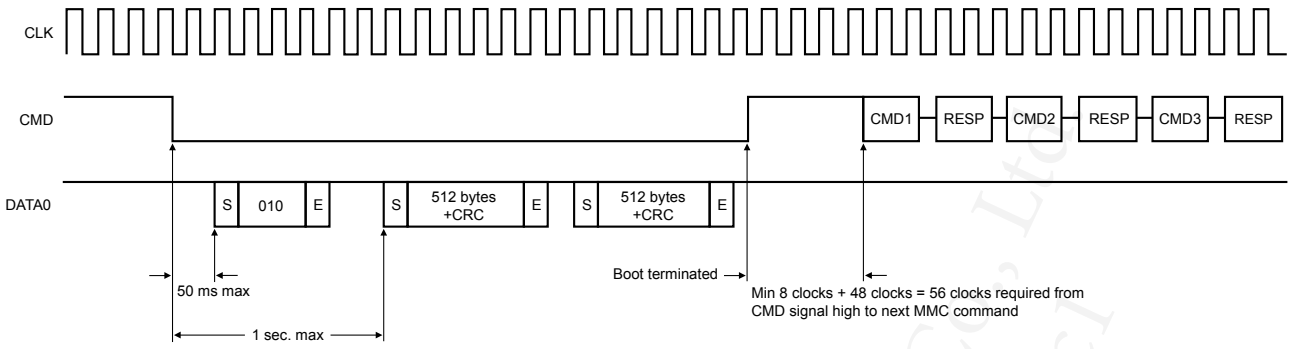

Figure 222. MultiMediaCard state diagram (normal boot mode)

39.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave must send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

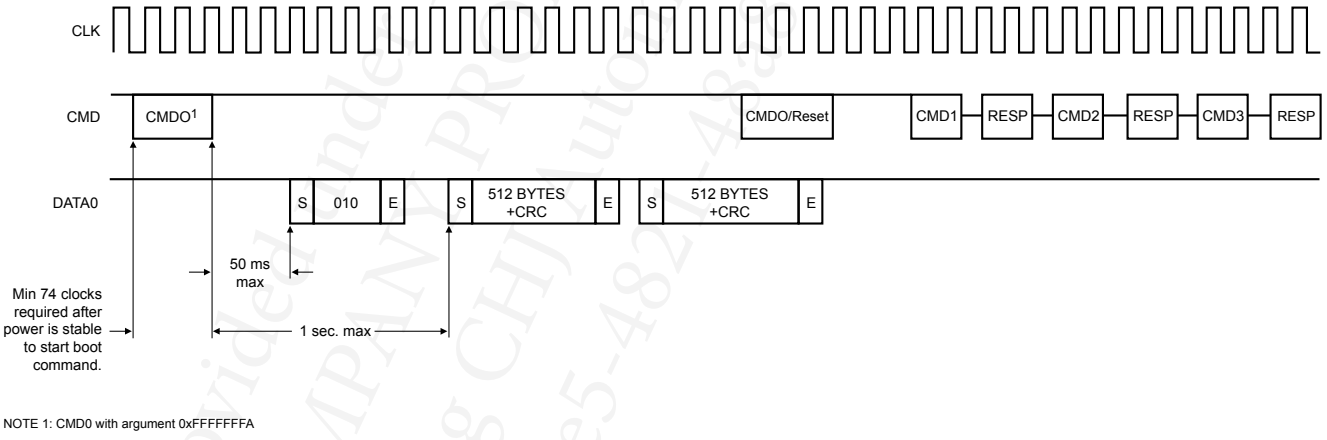

Figure 223. MultiMediaCard state diagram (alternative boot mode)

39.6 Initialization/application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

A uSDHC FIFO control problem exists with a software reset for a single block read. See MIX_CTRL[DTDSEL] for more information.

39.6.1 Command send & response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

39.6.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for MMC cards.

39.6.2.1 Card detect

See the figure below for a flow diagram showing the detection of MMC, SD, and SDIO cards using uSDHC.

Beijing CU Automotive Technology Co., Ltd
c84625-832c-4848-b251-390daa6241c1
Preliminary Information
COMPANY CONFIDENTIAL

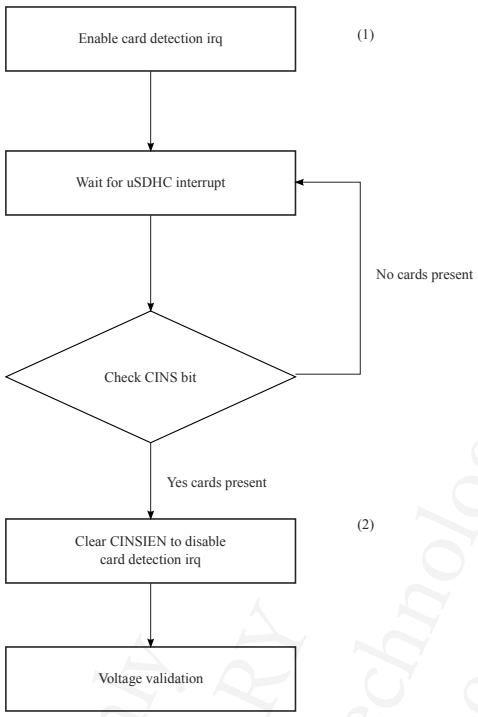

Figure 224. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

39.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O card, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

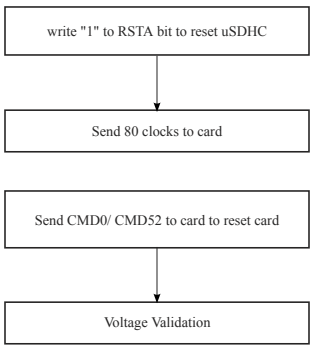

Figure 225. Flow chart for resetting uSDHC and SD I/O card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

39.6.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
```

```
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card  if (card is already labelled as SDCombo) { //
change label
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
} // of else
}
```

39.6.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For MMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for

their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC) {
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

39.6.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

39.6.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

39.6.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

39.6.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC card, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC card to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC card bus with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

39.6.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol

Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for the SDIO card. This is because when such a command is sent, uSDHC interprets the system that switches to another function on the SDIO card and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

39.6.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

39.6.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

39.6.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status ans wait until the card is ready for data.

NOTE

For eMMC card, block length can be set to only 512 bytes.

2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC card to high-speed mode and use SWITCH (CMD6).
4. Set the eMMC card bus with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

39.6.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.

3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

39.6.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the SD/MMC DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As the user may change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set the DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET bit

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

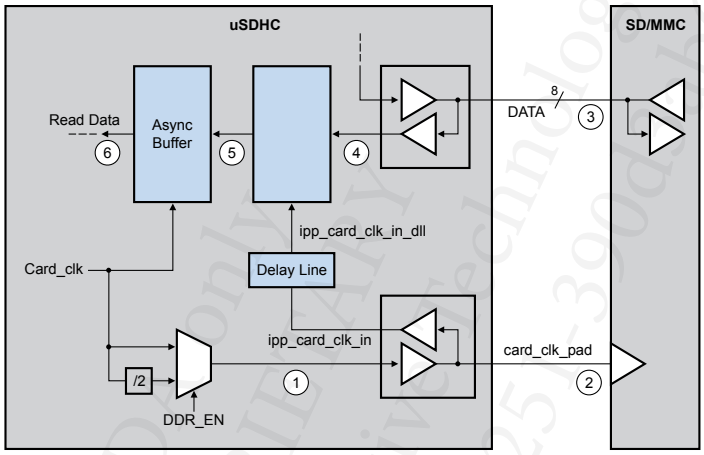

Figure 226. DLL in read path

39.6.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

39.6.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.

5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

39.6.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

39.6.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

39.6.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

39.6.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

39.6.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register do not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

39.6.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

39.6.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

39.6.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to Card interrupt handling for the card interrupt handling flow.

39.6.4 Switch function

A switch command is issued by the host driver to enable new features added to the SD/MMC spec. The SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO cards, the high-speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with

the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high-speed mode/HS200/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

39.6.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

39.6.4.2 Query, enable, and disable SD high-speed mode/DDR50/SDR50/SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;(high
speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
```

```
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

39.6.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

39.6.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

39.6.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

```
Set the 'Valid' bit to '1';
}
```

39.6.6 Fast boot operation

39.6.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the init_active bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

39.6.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the

default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.

7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

39.6.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.

10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

39.7 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 262. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.

Table continues on the next page...

Table 262. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.

Table continues on the next page...

Table 262. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.

Table continues on the next page...

Table 262. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.

Table continues on the next page...

Table 262. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.

Table continues on the next page...

Table 262. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block

Table continues on the next page...

Table 262. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
					WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 263.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 263. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

39.8 Software restrictions

39.8.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

39.8.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each

block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

39.8.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

39.8.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

39.8.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

39.8.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

39.8.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

39.8.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

Chapter 40
System Timer Module (STM)

40.1 Chip-specific STM information

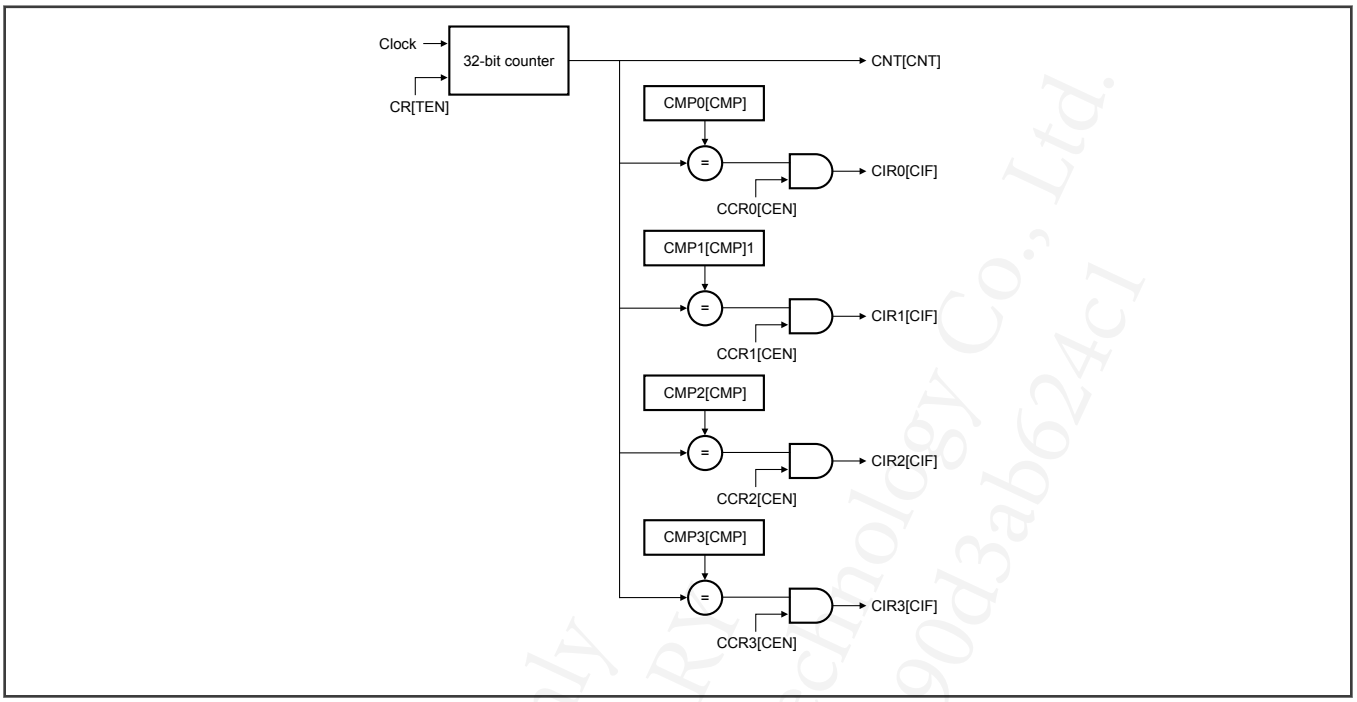
40.1.1 STM instances

This chip implements these STMs. All instances have the same configuration.

- STM_0
- STM_1
- STM_2
- STM_3
- STM_4
- STM_5
- STM_6
- STM_7

40.2 Introduction

The System Timer Module (STM) supports commonly required system and application software timing functions. STM includes a 32-bit count-up timer and four 32-bit compare channels with a separate interrupt source for each channel. The timer is driven by the STM module clock divided by an 8-bit prescale value (1 to 256).



40.3 Features

STM has the following features:

- One 32-bit count-up timer with an 8-bit prescaler
- Four 32-bit compare channels
- An independent interrupt source for each channel
- Ability to stop the timer in Debug mode

Fields

Field	Function
31-0 CMP	Channel Compare If the channel is enabled (CCR0[CEN]), when the timer count (CNT) matches this value, STM asserts the channel IRQ and sets the channel interrupt flag (CIR0[CIF]).

40.7 Configure the timer

1. Set the initial timer count (CNT[CNT]).
2. Specify STM behavior in chip Debug mode (CR[FRZ]).
3. Set the counter prescaler (CR[CPS]).
4. Start the timer (CR[TEN]).

40.8 Configure the compare channels

For each compare channel:

1. Set the channel compare value (CMP0[CMP]).
2. Enable the compare channel (CCR0[CEN]).

40.9 Respond to compare channel events

For each compare channel:

1. Check the channel interrupt flag (CIR0[CIF]).
2. If the channel interrupt flag is set, respond to the interrupt request.
3. When the channel interrupt has been handled, clear the channel interrupt flag (CIR0[CIF]).

40.10 Functional description

40.10.1 Count-up timer

STM has one 32-bit count-up timer that serves as the time base for four compare channels. When enabled, the counter increments at the module clock frequency divided by a prescaler value in the range from 1 to 256. When enabled in Normal mode, the timer increments continuously. The counter rolls over at FFFF_FFFFh to 0000_0000h with no restrictions at this boundary.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462c_4821-48a8-b251-390d3ab624c1

40.10.2 Compare channels

STM has four identical compare channels. Each channel includes a channel control register (CCR0), a channel interrupt register (CIR0), and a channel compare register (CMP0). When the channel is enabled and its channel compare value matches the timer count, STM sets the channel interrupt flag and generates an IRQ on that channel.

40.10.3 Behavior in different chip modes

STM supports the chip modes of operation as follows:

Chip mode	STM behavior
Normal	When the timer is enabled (CR[TEN] = 1), the timer counts up continuously.
Debug	If CR[FRZ] = 1, STM stops the timer. Otherwise, when the timer is enabled (CR[TEN] = 1), the timer counts up continuously.

Chapter 41
Software Watchdog Timer (SWT)

41.1 Chip-specific SWT information

41.1.1 SWT instances

This chip implements these SWTs. Each instance supports the indicated core.

- SWT_0: Cortex-M7 – core 0
- SWT_1: Cortex-M7 – core 1
- SWT_2: Cortex-M7 – core 2
- SWT_3: Cortex-A53 – core 0
- SWT_4: Cortex-A53 – core 1
- SWT_5: Cortex-A53 – core 2
- SWT_6: Cortex-A53 – core 3

NOTE

Stop mode in context to SWT refers to sleeping / WFI mode of core to which it is attached.

NOTE

For any operation to be performed on an SWT instance, its respective core must be enabled.

41.1.2 SWT time-out events: configuring reset and interrupt requests

For each SWT instance, configure the outcomes of SWT time-out events, as well as reactions to SWT reset and interrupt requests, using the Interrupt Then Reset Request field of the SWT Control Register (CR[ITR]). See related information in:

- "SWT0 timeout" section
- Interrupt Map file attached to this document
- Fault Map file attached to this document

41.1.3 Reset SWT only when a timeout triggers a reset request

The chapter describes that SWT has a feature that when a timeout triggers a reset request and the application does not require a chip reset, then you can make the SWT instance reset itself rather than the whole system.

In this chip, this feature is only available for SWT_1-SWT_6 when the corresponding reset is configured as interrupt in FCCU at the chip level. For SWT_0, this feature is not supported as it cannot be demoted to interrupt in MC_RGM.

41.2 Introduction

The Software Watchdog Timer (SWT) is a 32-bit window watchdog timer that enables the system to recover from situations such as:

- Software trapped in a loop
- A bus transaction failing to terminate

In regular operation, SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified timeout period. If this servicing action does not occur before the timer expires, SWT generates an interrupt or a hardware reset request.

You can configure SWT to generate a reset request or an interrupt on the initial timeout. SWT always generates a reset request on a second consecutive timeout.

41.2.1 Features

SWT has the following features:

- 32-bit countdown timer
- Selection of regular or window servicing
- Selection of reset request or interrupt on an initial timeout
- Selection of fixed or keyed service sequence
- Master access protection
- Hard and soft configuration lock bits

41.3 Initialize the SWT

To initialize the SWT, you must do the following:

- Select the clock source (if there are more than one possible sources).
- Set the timeout period.
- Control timeout behavior. There are two options:
  - Select reset request on timeout, or
  - Select interrupt on initial timeout.

You must intialize all registers before enabling SWT (CR[WEN]). You can initialize the registers in any sequence.

41.3.1 Select the clock source

See the chip-specific SWT information to find the clock source that drives the countdown timer.

41.3.2 Set the timeout period

When you enable SWT, it loads the greater of the specified watchdog timeout period or the minimum timeout period into an internal 32-bit countdown timer every time you perform a valid service operation.

To set the watchdog timeout period:

- Write the desired timeout period to TO[WTO].

The minimum timeout period is 256 clock cycles.

41.3.3 Control timeout behavior

SWT can respond to a timeout in one of two ways:

- Generate an immediate reset request on any timeout.
- Generate an interrupt and load the countdown timer on an inital timeout, then generate a reset request on a subsequent timeout.

41.3.3.1 Select reset request on timeout

To configure SWT to generate an immediate reset request on any timeout:

- Write 0 to CR[ITR].

pre-release NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c84625-4821-4588-9251-390d3ab624c1

41.3.3.2 Select interrupt on initial timeout

To configure SWT to generate an interrupt on an initial timeout:

- Write 1 to CR[ITR].

In this configuration, on the initial timeout:

- SWT loads the countdown timer with the timeout period (TO[WTO]).
- SWT indicates the interrupt with the timeout interrupt flag (IR[TIF]).
- If a second consecutive timeout occurs before writing the service sequence for the first timeout, SWT generates a reset request.

You clear the interrupt flag by writing 1 to IR[TIF].

41.3.4 Configure locking and unlocking

You can lock the SWT configuration with either a hard lock or a soft lock. When either lock is in effect, CR, TO, WN, and SK are read-only.

41.3.4.1 Enable the hard lock

To enable the hard lock:

- Write 1 to CR[HLK].

Hard lock is disabled only by a reset.

41.3.4.2 Enable the soft lock

To enable the soft lock:

- Write 1 to CR[SLK].

41.3.4.3 Unlock the soft lock

To unlock the soft lock:

1. Write C520h to SR[WSC].
2. Write D928h to SR[WSC].

This unlock sequence:

- Ignores service sequence writes.
- Recognizes the unlock sequence regardless of previous writes.
- Recognizes the unlock sequence regardless of the time between writes.
- Does not require CR[WEN] to be 1.

You can write this unlock sequence at any time.

NOTE

It is possible for a keyed service sequence to unlock soft lock. See Avoid accidental soft unlock for the procedure to handle this situation.

41.3.4.4 Avoid accidental soft unlock

When SWT operates in keyed sequence service, the sequence of service keys generated by the pseudorandom generator includes the unlock keys for soft lock. If one or more service routines use both unlock keys in the proper order, 0xC520 followed at any future time by 0xD928, SWT clears soft lock (CR[SLK] = 0). The unlock sequence logic ignores any service keys other than

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c462e5-4d21-48a8-b251-390d3ab624c1

the unlock keys, so the unlock keys don't have to be inserted consecutively. If the second unlock key is also the second key of a service operation, unlock occurs before the service operation completes.

To avoid accidental unlock:

If the service routine writes a key value of C520h to SR[WSC] as a key of the service operation, then do the following:

1. Complete the service operation.
2. Complete the unlock sequence by writing the second unlock key, D928h, to SR[WSC].
3. Reinitiate the soft lock (CR[SLK] = 1).

41.3.5 Select behavior on an invalid access

SWT can respond to an invalid access one of two ways:

- Generate a bus error.
- Generate a bus error and, if SWT is enabled, a reset request.

To select how SWT responds to an invalid access:

- Write the appropriate value to CR[RIA].

41.4 Enable the SWT

To enable the SWT:

- Write 1 to CR[WEN].

41.5 Initiate service operations

When enabled, SWT requires periodic execution of a servicing operation.

SWT can operate in one of the following service sequence modes:

- Fixed service sequence
- Keyed service sequence

41.5.1 Initiate a fixed service sequence

To initiate the fixed service sequence:

1. Select the fixed servicing mode (write 00b to CR[SMD]).
2. Write A602h to SR[WSC].
3. Write B480h to SR[WSC].

There is no timing requirement between the two writes. The service sequence logic ignores unlock-sequence writes.

41.5.2 Initiate a keyed service sequence

To initiate the keyed service sequence:

1. Select the keyed servicing mode (write 01b to CR[SMD]).
2. Read the next service key from SK[SK].
3. Write that service key to SR[WSC].
4. Repeat steps 2 and 3 one time.

See Service key generation for information about service keys.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-4821-48a8-b251-390d3ab624c1

41.5.3 Select window service mode

In window service mode, you must write the service sequence only when the watchdog timer is less than the window start value (WN[WST]). If you write the service sequence outside of this window, the access is invalid and generates a bus error or reset request depending on the Reset on Invalid Access setting (CR[RIA]).

For example, if the timeout period is 5000 and the window start value is 1000, you must write the service sequence during the last 20% of the timeout period.

Synchronization logic in SWT causes a slight delay in the opening of the window. This delay can be up to three system clock cycles plus four counter clock cycles.

To select window service mode:

- Write 1 to (CR[WND].

41.6 Reset only the SWT

When a timeout triggers a reset request and the application does not require a system reset, you can make the SWT instance reset itself rather than the whole system.

To make a timeout reset request trigger only an SWT reset (rather than the whole system), write 1 to the Reset Request Flag (RRR[RRF]).

This action causes SWT to:

- Clear the reset request.
- If an interrupt request also occurred, clear the interrupt request (IR[TIF]).
- Reset and restart the SWT.

For systems with multiple SWT instances, this feature allows you to reset an individual SWT instance, avoiding the widespread impact of a system reset.

41.7 Test SWT operation

When you disable SWT, it loads the current countdown timer into CO[CNT]. When you enable SWT, it clears this register. You can use CO[CNT] to perform a software self-test of SWT.

To test SWT operation:

1. Enable the SWT (CR[WEN] = 1).
2. Do not service SWT for a fixed period of time that is less than the timeout value.
3. Disable the SWT (CR[WEN] = 0).
4. Read the value in CO[CNT] to determine whether the internal countdown timer is working properly.

NOTE

The value shown in CO[CNT] can lag behind the actual internal timer up to six system clock cycles plus eight counter clock cycles.

41.8 Functional description

41.8.1 Behavior in different chip modes

SWT supports the chip modes of operation as follows:

provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e5-4821-48a8-b251-390d3ab624c1

Chip mode	SWT behavior
Normal	When SWT is enabled (CR[WEN] = 1), the SWT timer counts down continuously.
Debug	If CR[FRZ] = 1, SWT stops the timer; otherwise, the timer continues to run.
Stop or Standby	If CR[STP] = 1, SWT stops the timer; otherwise, the timer continues to run.

41.8.2 Register access latency

Accesses to SWT registers occur with no peripheral bus wait states. The switch fabric may add one or more system wait states. However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system clock cycles plus seven counter clock cycles.

41.8.3 Service key generation

SWT generates service keys with the pseudorandom key generator defined by the following equation.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 227. Pseudorandom key generator

This algorithm generates a sequence of 2^{16} different key values before repeating. In keyed service sequence mode, each time you write a valid key to SR[WSC], SWT updates SK[SK] with the next key.

For example, if the previous service key (SK[SK]) is 100h, then the next service sequence keys are 1103h followed by 2136h.

41.9 SWT register descriptions

The SWT programming model allows only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- Non-32-bit accesses
- Writes to read-only registers
- Writes of incorrect values to SR when SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

You control how SWT responds to an invalid access with CR[RIA].

41.9.1 SWT memory map

SWT_0 base address: 4010_0000h

SWT_1 base address: 4010_4000h

SWT_2 base address: 4010_8000h

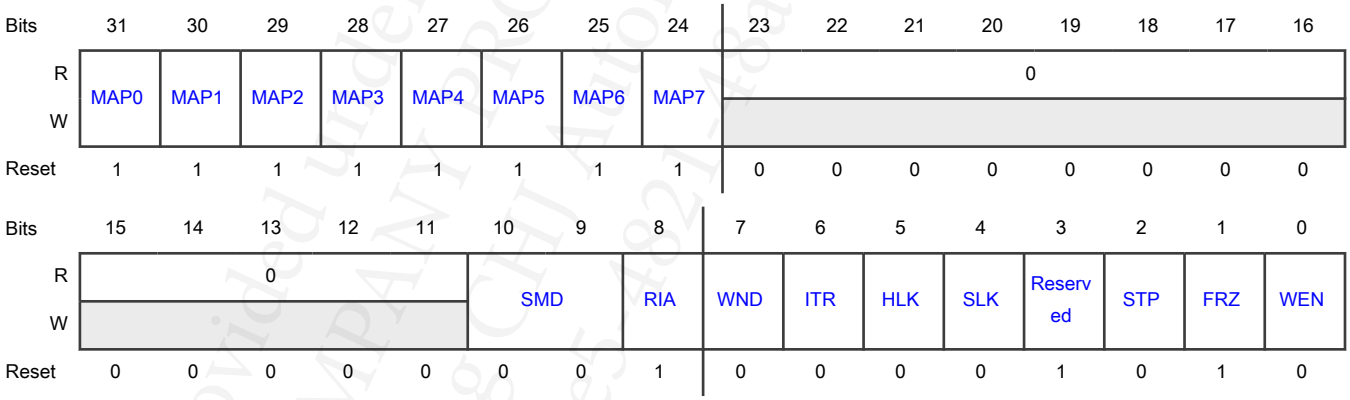
41.9.2 Control (CR)



Offset

Register	Offset
CR	0h

Function

Contains fields for configuring and controlling SWT. The register is read-only if either hard lock or soft lock is enabled (either HLK or SLK is 1).

Diagram

Fields

Field	Function
31	Master Access Protection 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
MAP0	The platform bus master assignments are chip-specific. The number of this field corresponds to the XRDC DIDs of the bus master. MAP0 corresponds to XRDC DIDs 0 and 8. 0b - Access disabled 1b - Access enabled
30 MAP1	Master Access Protection 1 See the description for MAP0. MAP1 corresponds to XRDC DIDs 1 and 9. 0b - Access disabled 1b - Access enabled
29 MAP2	Master Access Protection 2 See the description for MAP0. MAP2 corresponds to XRDC DIDs 2 and 10. 0b - Access disabled 1b - Access enabled
28 MAP3	Master Access Protection 3 See the description for MAP0. MAP3 corresponds to XRDC DIDs 3 and 11. 0b - Access disabled 1b - Access enabled
27 MAP4	Master Access Protection 4 See the description for MAP0. MAP4 corresponds to XRDC DIDs 4 and 12. 0b - Access disabled 1b - Access enabled
26 MAP5	Master Access Protection 5 See the description for MAP0. MAP5 corresponds to XRDC DIDs 5 and 13. 0b - Access disabled 1b - Access enabled
25 MAP6	Master Access Protection 6 See the description for MAP0. MAP6 corresponds to XRDC DIDs 6 and 14. 0b - Access disabled 1b - Access enabled
24 MAP7	Master Access Protection 7 See the description for MAP0. MAP7 corresponds to XRDC DIDs 7 and 15.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Access disabled 1b - Access enabled
23-11 —	Reserved
10-9 SMD	Service Mode 00b - To service the watchdog, write the fixed sequence 0xA602, 0xB480 to SR. 01b - To service the watchdog, write two pseudorandom key values to SR. 10b - Do not use this value. Writing this value can cause the watchdog to not be serviced. 11b - Do not use this value. Writing this value can cause the watchdog not to be serviced.
8 RIA	Reset on Invalid Access Controls how SWT responds to an invalid access. **NOTE** For a description of how this chip implements SWT reset requests resulting from SWT invalid accesses, see the chip-specific SWT information. 0b - Generate a bus error 1b - If SWT is enabled (WEN = 1), generate a bus error and a reset request; otherwise, generate a bus error.
7 WND	Window Mode Specify regular or window mode operation. 0b - Can execute service sequence at any time 1b - Can execute service sequence only when the timeout counter is less than the value in WN
6 ITR	Interrupt Then Reset Request **NOTE** For a description of how this chip implements SWT reset requests and interrupt requests resulting from SWT timeouts, see the chip-specific SWT information. 0b - Generate a reset request on a timeout 1b - Generate an interrupt on an initial timeout; generate a reset request on a second consecutive timeout
5 HLK	Hard Lock Indicates that the hard lock is enabled. You cannot directly write 0 to this field. This field becomes 0 only after a reset. 0b - CR, TO, WN, and SK are read/write registers if SLK is also 0 1b - CR, TO, WN, and SK are read-only registers

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 SLK	Soft Lock Indicates that the soft lock is enabled. You cannot directly write 0 to this field. Clear this field by writing the unlock sequence to the service register. 0b - CR, TO, WN, and SK are read/write registers if HLK is also 0 1b - CR, TO, WN, and SK are read-only registers
3 —	Reserved
2 STP	Stop Mode Control Controls the watchdog timer when the chip enters Stop or Standby mode. 0b - Timer continues 1b - Timer stops
1 FRZ	Debug Mode Control Controls the watchdog timer when the chip enters Debug mode. 0b - Timer continues 1b - Timer stops
0 WEN	Watchdog Enable Enables or disables SWT. The reset value is 0. Therefore, after reset, you must enable SWT to start the countdown timer. 0b - Disabled 1b - Enabled

41.9.3 Interrupt (IR)

Offset

Register	Offset
IR	4h

Function

The timeout interrupt flag.

Provided under NDA only
COMPANY PROPRIETARY

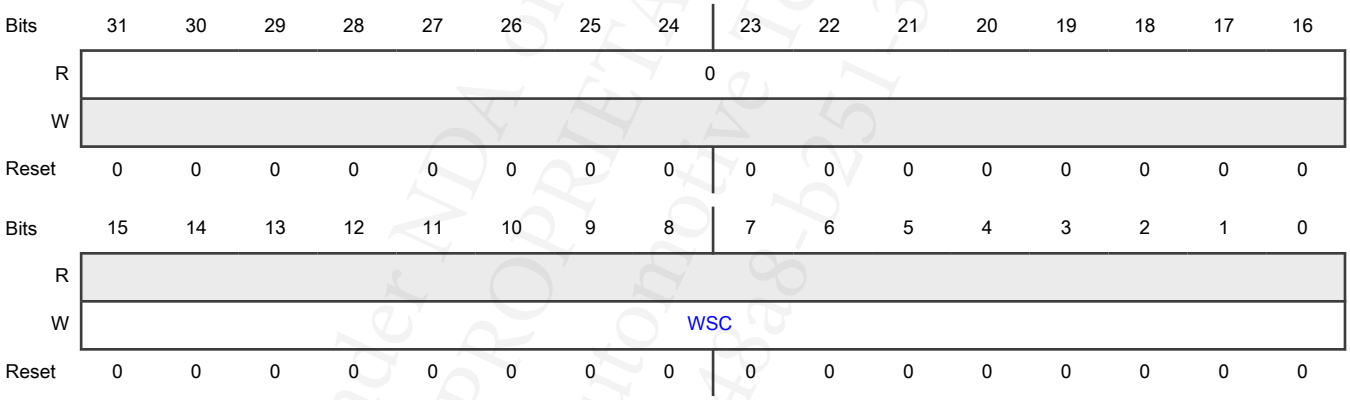
c8462e5-4821-48a8-b251-39d3ab624c1

Fields

Field	Function
31-0 WST	Window Start Value When you enable window mode (CR[WND]), you can write the service sequence only when the internal timer is less than this value.

41.9.6 Service (SR)



Offset

Register	Offset
SR	10h

Function

Initiates the service operation and resets the watchdog timer.

Diagram

Fields

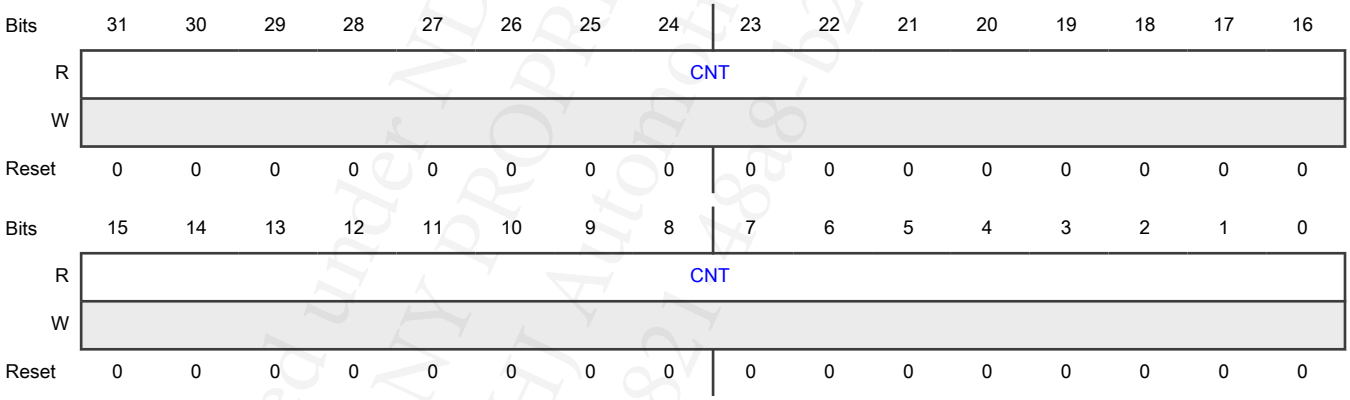
Field	Function
31-16 —	Reserved
15-0 WSC	Watchdog Service Code Use this field to service the watchdog and to unlock the Soft Lock (CR[SLK]). To service the watchdog: If SWT is in keyed service mode (CR[SMD]), write two pseudorandom key values to WSC (see Service key generation for details). Otherwise, write the following values to WSC, in the order shown:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. A602h 2. B480h To unlock the Soft Lock (CR[SLK]), write the following values to WSC, in the order shown: 1. C520h 2. D928h When read, WSC always returns zero.

41.9.7 Counter Output (CO)



Offset

Register	Offset
CO	14h

Function

Shows the value of the internal timer when SWT is disabled.

Diagram

Fields

Field	Function
31-0 CNT	Watchdog Count When SWT is disabled (CR[WEN] is 0), CNT shows the value of the internal timer. When SWT is enabled (CR[WEN] is 1), it writes 0 to CNT. Values in this field can lag behind the internal timer value up to six system clock cycles plus eight counter clock cycles. Therefore, the CNT value that is read immediately after disabling SWT may be higher than the actual value of the internal timer.

Chapter 42
Periodic Interrupt Timer (PIT)

42.1 Chip-specific PIT information

42.1.1 PIT module instance details

In this chip, in addition to timer channels for raising interrupts and triggering DMA channels, the PIT module is the source of:

- The external time tick for the FlexCAN free-running timer
- The external OS tick for the FlexRay stopwatch counter

42.1.2 PIT triggers

The following table shows the connections between the outputs of the PIT modules and other peripherals.

The PIT modules are connected to separate peripheral interface modules.

Timer	Channel	Peripheral	Function
PIT_0	0	DMAMUX_0	Periodic trigger input 0
PIT_0	1	DMAMUX_0	Periodic trigger input 1
PIT_0	2	DMAMUX_1	Periodic trigger input 0
PIT_0	3	DMAMUX_1	Periodic trigger input 1
PIT_0	4	FlexRay	External OS tick for stopwatch counter (configured by SRC_0 FLEXRAY_OS_TICK_INPUT_SELECT_REG)
PIT_0	5	FlexCAN_0, FlexCAN_1	External time tick for free-running timer
PIT_0	6	CTU	Trigger of CTU PWM
PIT_1	0	DMAMUX_2	Periodic trigger input 0
PIT_1	1	DMAMUX_2	Periodic trigger input 1
PIT_1	2	DMAMUX_3	Periodic trigger input 0
PIT_1	3	DMAMUX_3	Periodic trigger input 1
PIT_1	4	FlexCAN_2, FlexCAN_3	External time tick for free-running timer
PIT_1	5	—	—

42.2 Introduction

The following sections show the PIT's:

- Block diagram
- Features

42.2.1 Block diagram

The following figure shows the block diagram of PIT module.

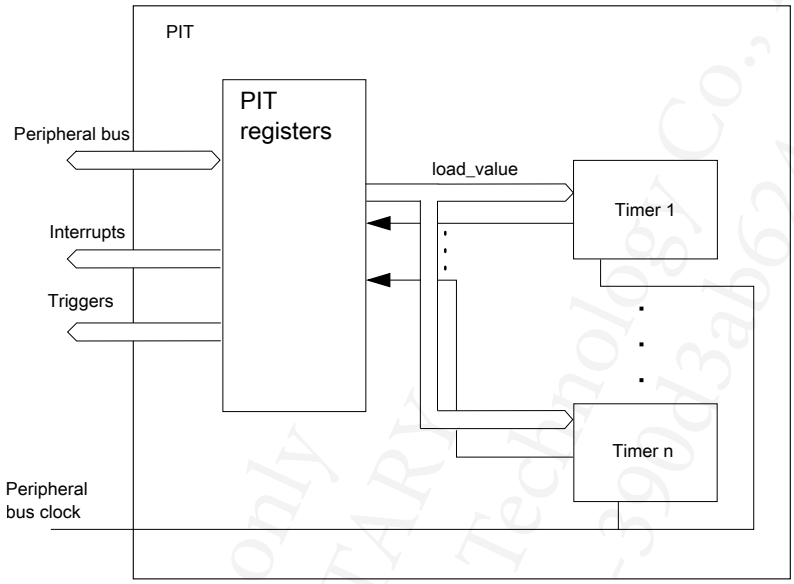

Figure 228. Block diagram of PIT

42.2.2 Features

The key features of the module are these:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer
- All the timers use a downcounter

42.3 Modes of operation

This subsection briefly describes all operating modes supported by PIT.

- Run mode

  All functional parts of the PIT are running during normal Run mode.

42.4 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.

NOTE

When a chip has more than one instance of the PIT, the different instances might have different feature and register sets. Please see the configuration information.

42.4.1 PIT memory map

PIT_0 base address: 4018_8000h

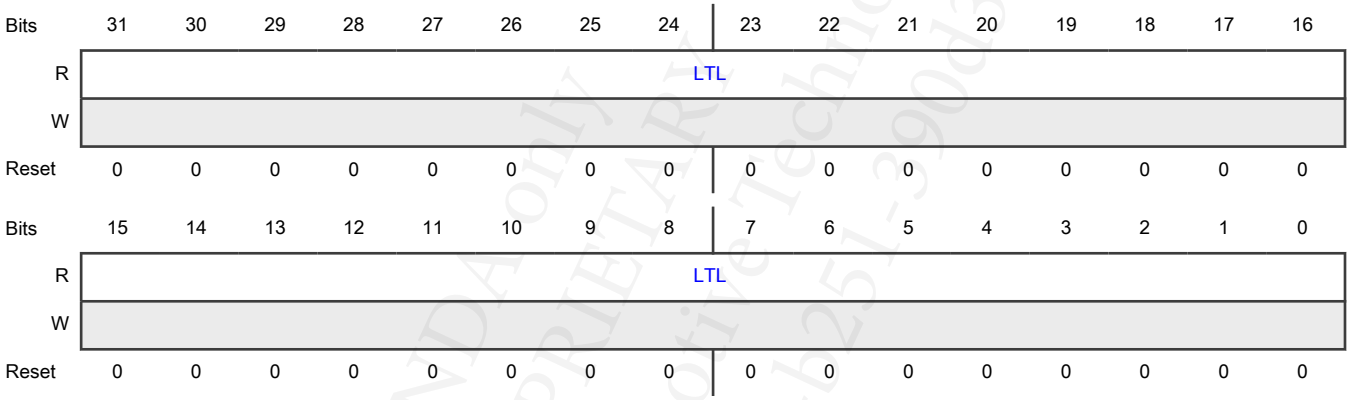
c8c4625-4821-48a8-1251-390d3ab624c1

42.4.4 PIT Lower Lifetime Timer Register (LTMR64L)

Offset



Register	Offset
LTMR64L	E4h

Function

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. The value for the LTMR64H register is set to CVAL1 register at the time of the first access and the value of the LTMR64L register is set to CVAL0 register at first access. Therefore, the application is not affected by the carry-over effects of the running counter.

Diagram

Fields

Field	Function
31-0 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

42.4.5 Timer Load Value Register (LDVAL0 - LDVAL6)

Offset

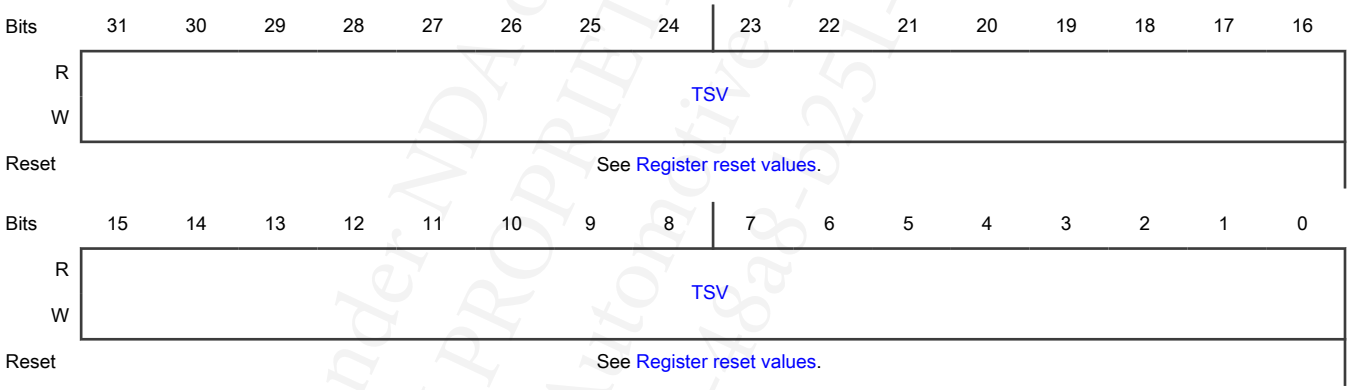
Register	Offset
LDVAL0	100h
LDVAL1	110h
LDVAL2	120h
LDVAL3	130h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
LDVAL4	140h
LDVAL5	150h
LDVAL6	160h

Function



These registers select the timeout period for the timer interrupts.

NOTE

Each module instance supports a different number of registers.

Register supported	Register not supported

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c46225-4821-48a8-9251-390d3b624c1

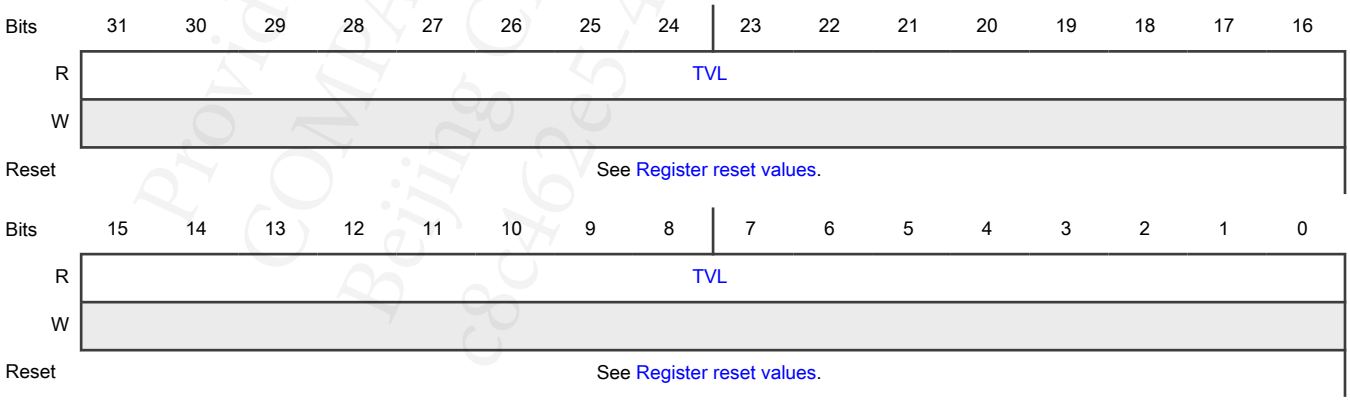
Field	Function
TSV	Sets the timer start value. The timer counts down until it reaches 0, then generates an interrupt and loads this register value again. Writing a new value to this register does not restart the timer; instead the value is loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

42.4.6 Current Timer Value Register (CVAL0 - CVAL6)

Offset

Register	Offset
CVAL0	104h
CVAL1	114h
CVAL2	124h
CVAL3	134h
CVAL4	144h
CVAL5	154h
CVAL6	164h

Function



These registers indicate the current timer position.

NOTE

Each module instance supports a different number of registers.

Register supported	Register not supported
PIT_0_CVAL0–CVAL6	—
PIT_1_CVAL0–CVAL5	PIT_1_CVAL6

Diagram

Register reset values

Register	Reset value
CVAL0–CVAL5	PIT_0,PIT_1: 0000_0000h
CVAL6	0000_0000h

Fields

Field	Function
31-0 TVL	Current Timer Value Represents the current timer value, if the timer is enabled. **NOTE** • If the timer is disabled, do not use this field because its value is unreliable. • The timer uses a downcounter. The timer values are frozen in the Debug mode if MCR[FRZ] is set.

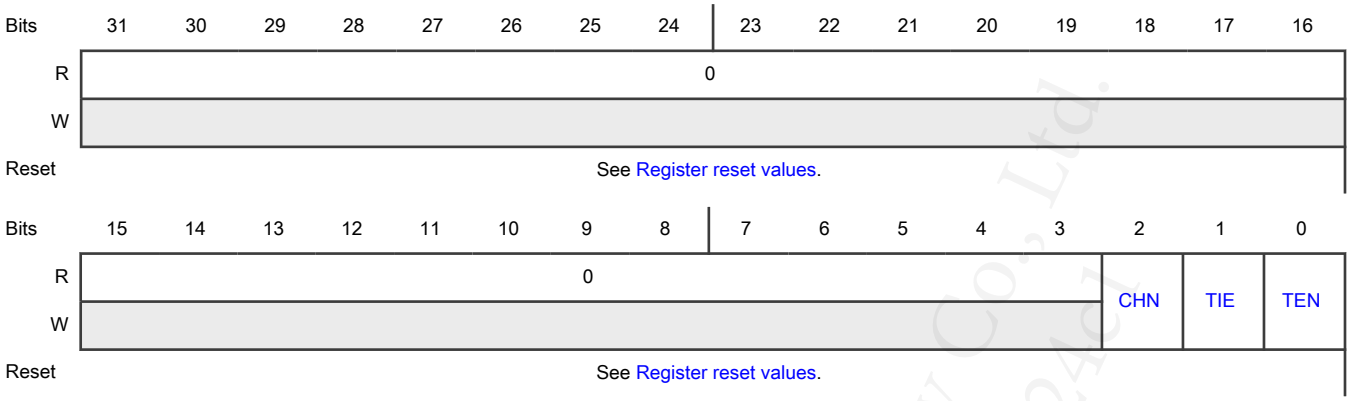
42.4.7 Timer Control Register (TCTRL0 - TCTRL6)

Offset

Register	Offset
TCTRL0	108h
TCTRL1	118h
TCTRL2	128h
TCTRL3	138h
TCTRL4	148h
TCTRL5	158h
TCTRL6	168h

Function

These registers contain the control bits for each timer.



NOTE

Each module instance supports a different number of registers.

Register supported	Register not supported
PIT_0_TCTRL0–TCTRL6	—
PIT_1_TCTRL0–TCTRL5	PIT_1_TCTRL6

Fields

Field	Function
31-1 —	Reserved
0 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it and writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0b - Timeout has not yet occurred. 1b - Timeout has occurred.

42.5 Functional description

This section provides the functional description of the module.

42.5.1 General operation

This section provides detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts, and each interrupt is available on a separate interrupt line.

42.5.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start values again. Each time a timer reaches 0, it generates a trigger pulse and sets the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted by first disabling and then enabling the timer with TCTRLn[TEN]. See the following figure.

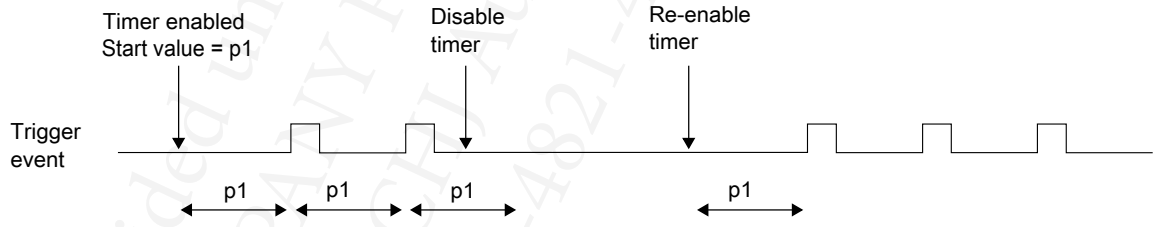

Figure 229. Stopping and starting a timer

The counter period of a running timer can be modified by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

Provided under IHS only
COMPANY PROPRIETARY
Beijing BCR Automotive Technology Co., Ltd.
c8c46285-4821-4b8-b621-390d3ab6240

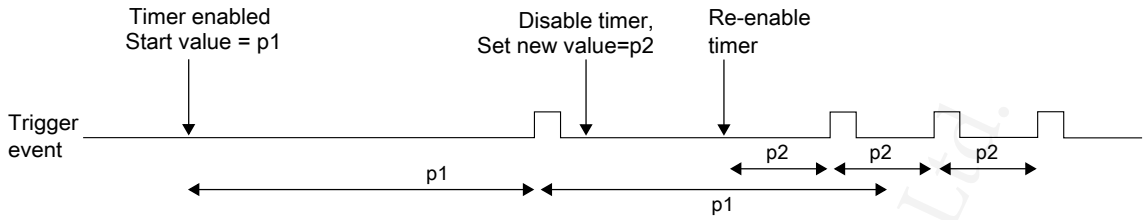

Figure 230. Modifying running timer period

It is also possible to change the counter period without restarting the timer, by writing LDVAL with the new load value. This value then loads after the next trigger event. See the following figure.

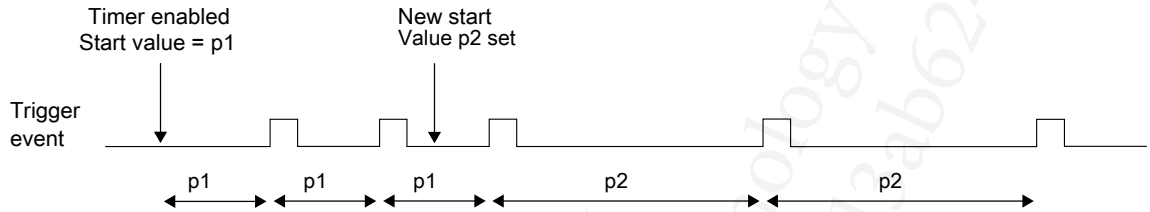

Figure 231. Dynamically setting a new load value

NOTE

- If MCR[FRZ] is written as 1 and when the timer is nearing 0 (CVALn =0x0), the debug mode command may not make it to the IP before the timer expires and generates a trigger.
- Debug Mode will be ignored if CVALn =0x0, but the trigger will remain asserted until the mode is removed. The user is recommended to exit Debug mode and then clear the interrupt TFLGn[TIF].
- If the timers are to be freezed for debug, sufficient time must be ensured for the IP to react.

42.5.1.2 Debug mode

In the Debug mode, the timers are frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

42.5.2 Interrupts

All the timers support interrupt generation.

Timer interrupts can be enabled by setting TCTRLn[TIE].

TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

42.5.3 Chained timers

When a timer has chain mode enabled, it counts after the previous timer has expired. So if timer n-1 counts down to 0, counter n decrements the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

42.6 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.

- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F, respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. Also, TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

42.7 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt is raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

Freescale NXP Confidential Proprietary
COMPANY PROPRIETARY
Beijing C.T. Automotive Technology Co., Ltd.
c8c62e3-4421-48a8-b251-390d3ab624

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

42.8 Example configuration for the Lifetime Timer

To configure the Lifetime Timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the Lifetime Timer, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 43
FlexTimer (FTM)

43.1 Chip-specific FTM information

43.1.1 FTM instances

The chip contains two FTM instances: FTM_0 and FTM_1.

The following table summarizes the features for each instance.

Table 264. FTM instance features

Feature	FTM_0	FTM_1
Number of channels	6	6
Input filter on channel 0	Yes	Yes
Input filter on channel 1	Yes	Yes
Input filter on channel 2	Yes	Yes
Input filter on channel 3	Yes	Yes
Number of fault inputs	0	0
Quadrature decoder	Yes	Yes
DMA support	Yes	Yes
Output Buffer Enable active value	1	1
Half-cycle reload	Yes	Yes
Dithering	Yes	Yes

43.1.2 FTM global time base

This chip provides the optional FTM global time base feature. For more details, see the Global time base (GTB) section of this chapter. FTM0 provides the only source for the FTM global time base. The FTM1 module can share the same time base as shown in the following figure.

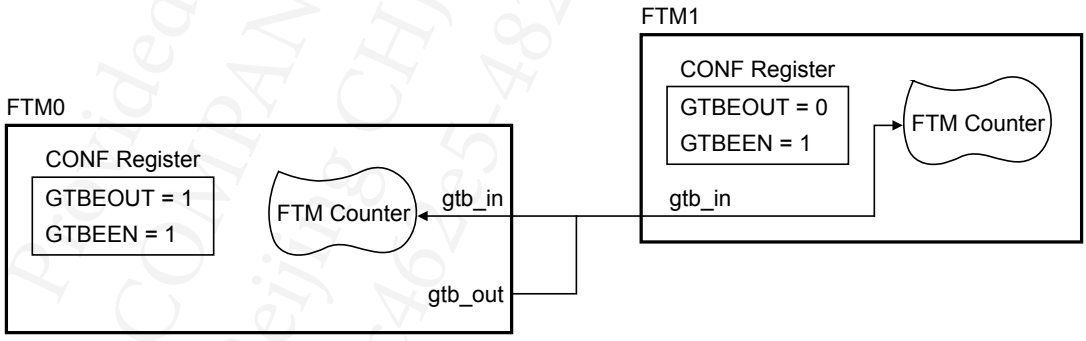

Figure 232. FTM global time base configuration

43.1.3 Initialization triggers and external triggers

The following table shows FlexTimer trigger connections.

Table 265. FTM trigger connections

Timer	Trigger or channel	Connection
FTM_0	Trigger_0 input	GMAC_0
FTM_0	Trigger_1 input	Reserved
FTM_0	Trigger_2 input	Reserved
FTM_1	Trigger_0 input	GMAC_0
FTM_1	Trigger_1 input	Reserved
FTM_1	Trigger_2 input	Reserved
FTM_0	Channel_0 output	CTU trigger 0
FTM_0	Channel_1 output	CTU trigger 1
FTM_0	Channel_2 output	CTU trigger 2
FTM_0	Channel_5 output	GMAC_0
FTM_1	Channel_0 output	CTU trigger 3
FTM_1	Channel_1 output	CTU trigger 4
FTM_1	Channel_2 output	CTU trigger 5
FTM_1	Channel_5 output	GMAC_0

43.2 Introduction

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

43.2.1 Features

The FTM features include:

- FTM source clock is selectable
  - Source clock can be the FTM input clock, the fixed frequency clock, or an external clock
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the FTM input clock
  - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter
  - It can be a free-running counter or a counter with initial and final value
  - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:

  - The capture can occur on rising edges, falling edges or both edges
  - An input filter can be selected for some channels. One unique prescaler is available for all filters
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Software control of PWM outputs
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when a register reload point occurs
- Synchronized loading of write buffered FTM registers
- Half cycle and Full cycle register reload capacity
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input capture mode
- Direct access to input pin states
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event
- The FTM channels can be selected to generate a trigger pulse on channel output instead of a PWM
- Dithering capability to simulate fine edge control for both PWM period or PWM duty cycle

43.2.2 Modes of operation

When the chip is in an active Debug mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

43.2.3 Block Diagram

The FTM uses one input/output (I/O) pin per channel, CHn (FTM channel (n)) where n is the channel number (0–7).

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

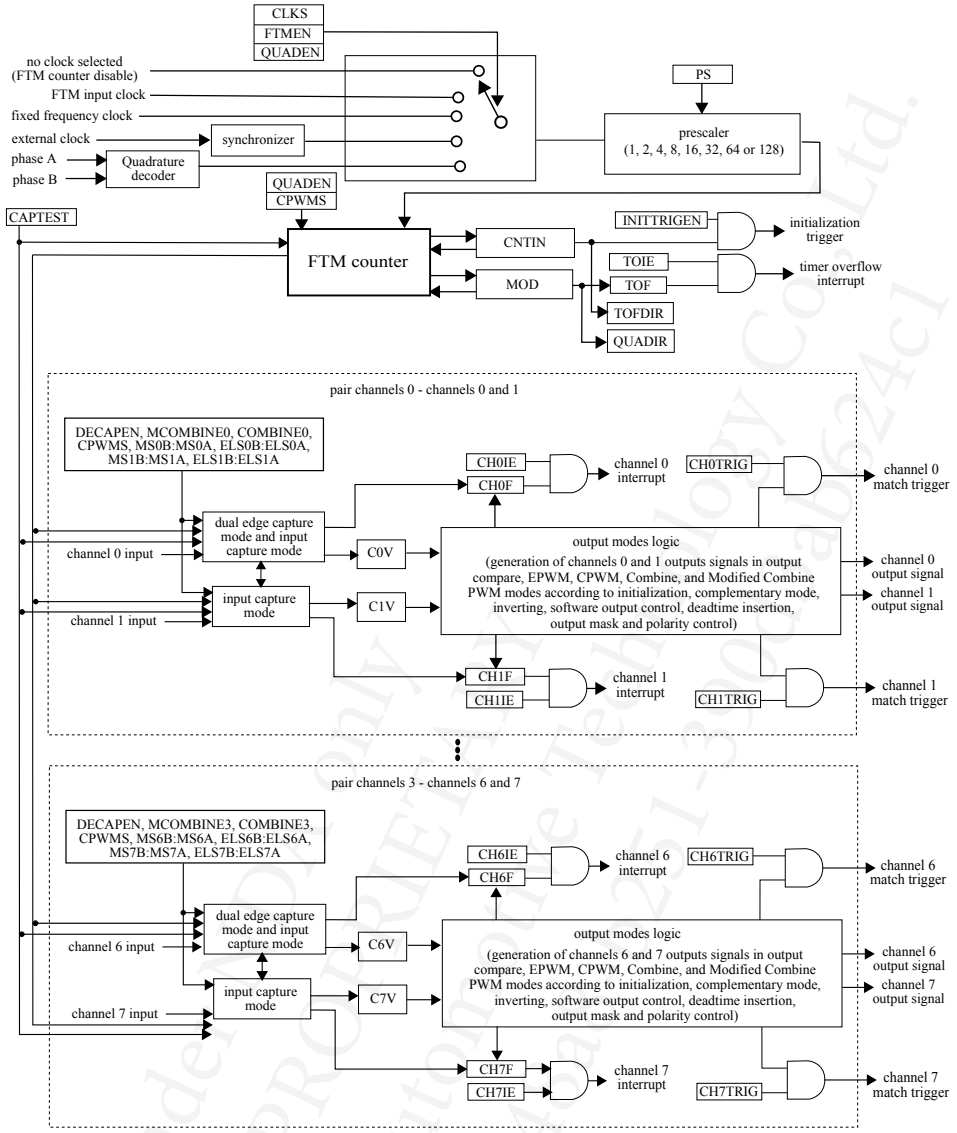

Figure 233. FTM Block Diagram

43.3 FTM signal descriptions

Table 266 shows the user-accessible signals for the FTM.

Table 266. FTM signal descriptions

Signal	Description	I/O	Function
EXTCLK	External clock. FTM external clock can be selected to drive the FTM counter.	I	The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of FTM input clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.

Table continues on the next page...

Table 266. FTM signal descriptions (continued)

Signal	Description	I/O	Function
CHn	FTM channel (n), where n can be 7-0	I/O	Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.
PHA	Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A.	I	The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder Mode.
PHB	Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B.	I	The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder Mode.

43.4 Memory map and register definition

43.4.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance.

43.4.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved. Double buffered register writes must be done using 32-bit operations.

43.4.3 FTM register descriptions

43.4.3.1 FTM memory map

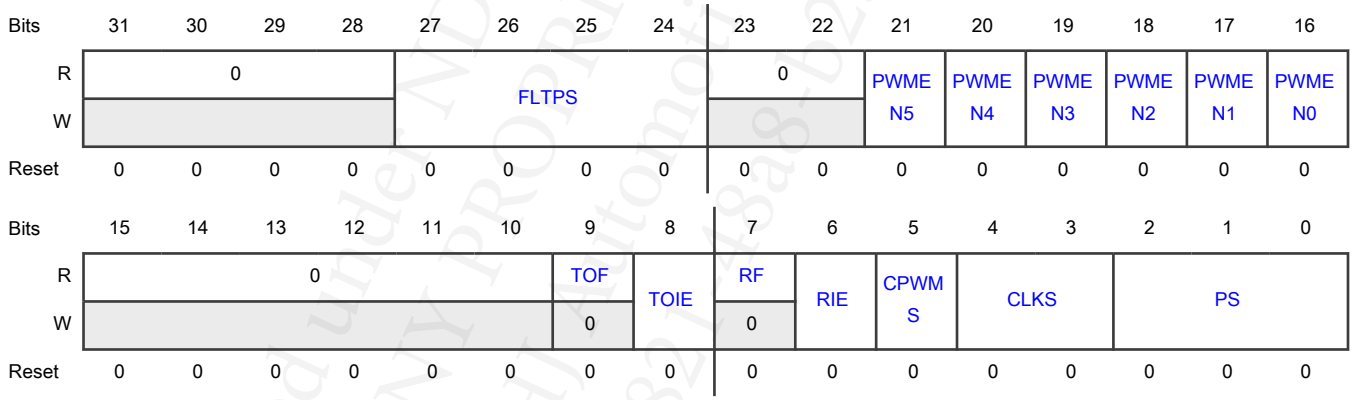
43.4.3.2 Status And Control (SC)

Offset

Register	Offset
SC	0h



Function

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, filter prescaler, and prescaler factor.

This register also contains the output enable control bits and the reload opportunity flag control.

These controls relate to all channels within this module.

Table continued from the previous page...

Field	Function
	If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case, a TOF interrupt request is not lost due to the clearing sequence for a previous TOF. 0b - FTM counter has not overflowed. 1b - FTM counter has overflowed.
8 TOIE	Timer Overflow Interrupt Enable Enables FTM overflow interrupts. 0b - Disable TOF interrupts. Use software polling. 1b - Enable TOF interrupts. An interrupt is generated when TOF equals one.
7 RF	Reload Flag The RF bit is set at each selected reload point. See Reload Points. The RF bit is cleared by reading the SC register while RF is set and then writing a 0 to RF bit. Writing 1 to RF has no effect. If another selected reload point happens between the read and write operations, the write operation has no effect; therefore, RF remains set. 0b - A selected reload point did not happen. 1b - A selected reload point happened.
6 RIE	Reload Point Interrupt Enable Enables the reload point interrupt. 0b - Reload point interrupt is disabled. 1b - Reload point interrupt is enabled.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the FTM to operate in Up-Down Counting mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0b - FTM counter operates in Up Counting mode. 1b - FTM counter operates in Up-Down Counting mode.
4-3 CLKS	Clock Source Selection Selects one of the three FTM counter clock sources. This field is write protected. It can be written only when MODE[WPDIS] = 1. 00b - No clock selected. This in effect disables the FTM counter. 01b - FTM input clock 10b - Fixed frequency clock 11b - External clock
2-0	Prescale Factor Selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
PS	Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next FTM input clock cycle after the new value is updated into the register bits. This field is write protected. It can be written only when MODE[WPDIS] = 1. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

43.4.3.3 Counter (CNT)

Offset

Register	Offset
CNT	4h

Function

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

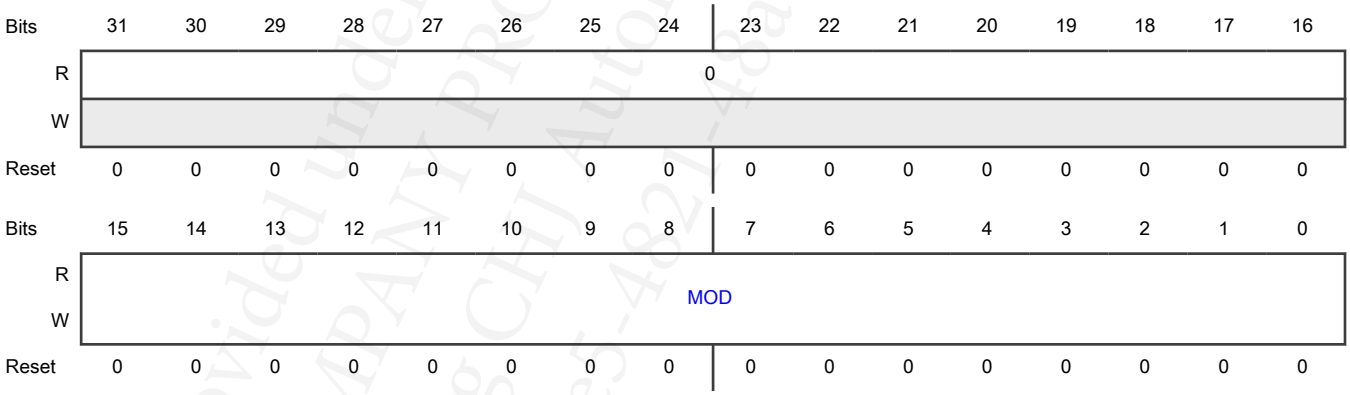
15-0 COUNT	Counter Value

43.4.3.4 Modulo (MOD)

Offset

Register	Offset
MOD	8h



Function

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock cycle, and the next value of FTM counter depends on the selected counting method; see Counter.

Writes to the MOD register are done on its write buffer. The MOD register is updated with its write buffer value according to Registers updated from write buffers. If FTMEN = 0, a write to SC register resets manually this write coherency mechanism.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Table continued from the previous page...

Field	Function
10 CHOV	Channel (n) Output Value The CHOV bit has the final value of the channel (n) output. **NOTE** The CHOV bit should be ignored when the channel (n) is not in an output mode. 0b - The channel (n) output is zero. 1b - The channel (n) output is one.
9 CHIS	Channel (n) Input State The CHIS bit has the value of the channel (n) input after the double-sampling or the filtering (if the channel (n) filter is enabled) both them are inside the FTM. **NOTE** The CHIS bit should be ignored when the channel (n) is not in an input mode. **NOTE** When the pair channels is on dual edge mode, the channel (n+1) CHIS bit is the channel (n+1) input value and not the channel (n) input value (this signal is the input signal used by the dual edge mode). 0b - The channel (n) input is zero. 1b - The channel (n) input is one.
8 TRIGMODE	Trigger mode control This bit controls the trigger generation on FTM channel outputs. This mode is allowed only if when FTM channel is configured to EPWM or CPWM modes. If a match in the channel occurs, a trigger pulse with one FTM clock cycle width will be generated in the channel output. See Channel trigger output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0b - Channel outputs will generate the normal PWM outputs without generating a pulse. 1b - If a match in the channel occurs, a trigger generation on channel output will happen. The trigger pulse width has one FTM clock cycle.
7 CHF	Channel (n) Flag Set by hardware when an event occurs on the channel (n). CHF is cleared by reading the CnSC register while CHF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect. If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF. 0b - No channel (n) event has occurred. 1b - A channel (n) event has occurred.
6	Channel (n) Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
CHIE	Enables channel (n) interrupt. 0b - Disable channel (n) interrupt. Use software polling. 1b - Enable channel (n) interrupt.
5 MSB	Channel (n) Mode Select Used on the selection of the channel (n) mode. See Channel Modes. This field is write protected. It can be written only when MODE[WPDIS] = 1.
4 MSA	Channel (n) Mode Select Used on the selection of the channel (n) mode. See Channel Modes. This field is write protected. It can be written only when MODE[WPDIS] = 1.
3 ELSB	Channel (n) Edge or Level Select Used on the selection of the channel (n) mode. See Channel Modes. This field is write protected. It can be written only when MODE[WPDIS] = 1.
2 ELSA	Channel (n) Edge or Level Select Used on the selection of the channel (n) mode. See Channel Modes. This field is write protected. It can be written only when MODE[WPDIS] = 1.
1 ICRST	FTM counter reset by the selected input capture event. FTM counter reset is driven by the selected event of the channel (n) in the Input Capture mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0b - FTM counter is not reset when the selected channel (n) input event is detected. 1b - FTM counter is reset when the selected channel (n) input event is detected.
0 DMA	DMA Enable Enables DMA transfers for the channel. 0b - Disable DMA transfers. 1b - Enable DMA transfers.

43.4.3.6 Channel (n) Value (C0V - C5V)

Offset

Register	Offset
C0V	10h
C1V	18h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
C2V	20h
C3V	28h
C4V	30h
C5V	38h

Function

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture , Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writes to the CnV register are done on its write buffer. The CnV register is updated with its write buffer value according to Registers updated from write buffers. If FTMEN = 0, a write to CnSC register resets manually this write coherency mechanism.

Diagram

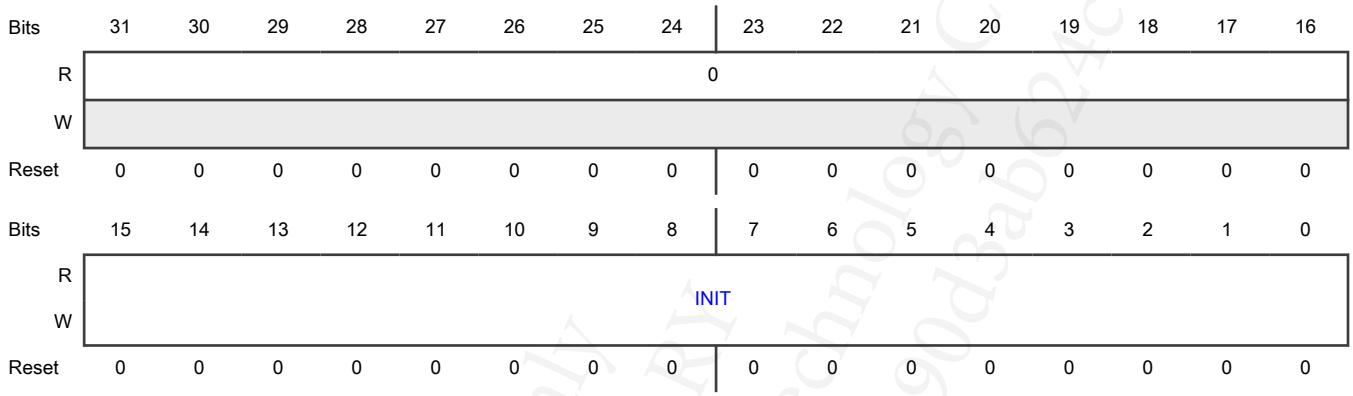
Fields

Field	Function
31-16 —	Reserved
15-0 VAL	Channel Value Captured FTM counter value of the input modes or the match value for the output modes

43.4.3.7 Counter Initial Value (CNTIN)

Offset

Register	Offset
CNTIN	4Ch



Function

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to Registers updated from write buffers.

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 INIT	INIT Initial Value Of The FTM Counter

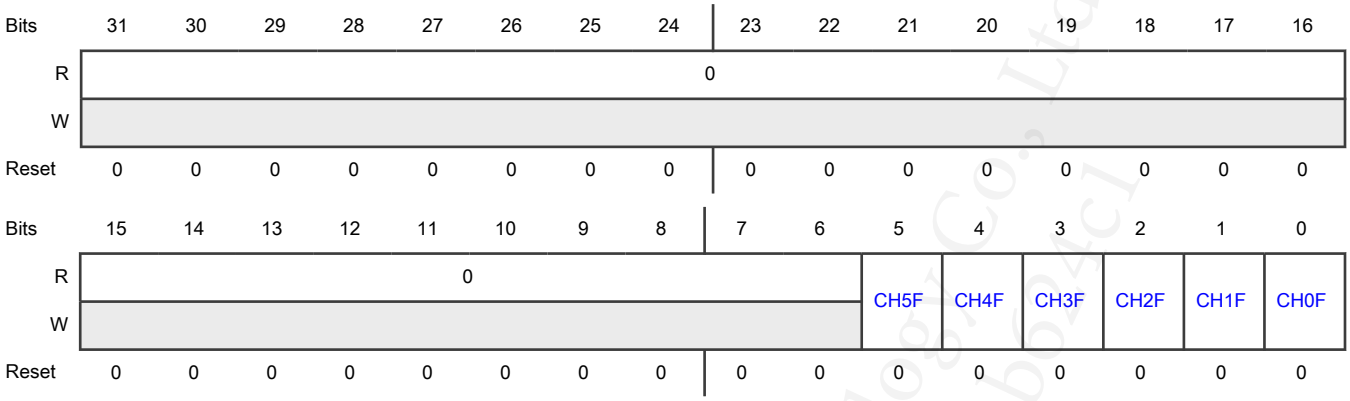
43.4.3.8 Capture And Compare Status (STATUS)

Offset

Register	Offset
STATUS	50h

Function

The STATUS register contains a copy of the status flag CHF bit in CnSC for each FTM channel for software convenience.



Each CHF bit in STATUS is a mirror of CHF bit in CnSC. All CHF bits can be checked using only one read of STATUS. All CHF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHF is cleared by reading STATUS while CHF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
ec02e5-4821-48a8-b251-390d8ab624c1

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case, a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

Diagram

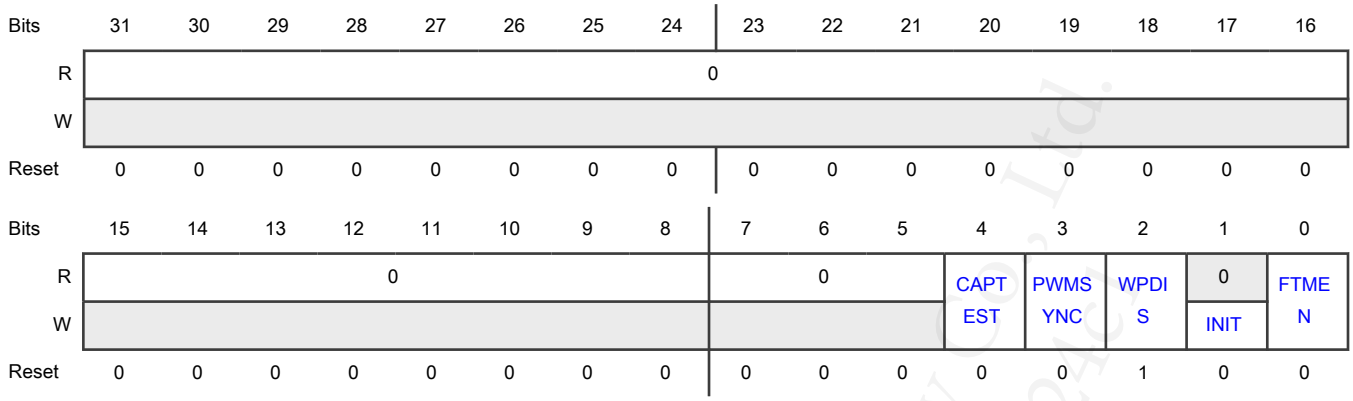
Fields

Field	Function
31-6 —	Reserved
5-0 CHnF	Channel n Flag See the register description. 0b - No channel event has occurred. 1b - A channel event has occurred.

43.4.3.9 Features Mode Selection (MODE)

Offset

Register	Offset
MODE	54h



Function

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-5 —	Reserved
4 CAPTEST	Capture Test Mode Enable Enables the capture test mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0b - Capture test mode is disabled. 1b - Capture test mode is enabled.
3 PWMSYNC	PWM Synchronization Mode Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See PWM synchronization. The PWMSYNC bit configures the synchronization when SYNCMODE is 0. 0b - No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. 1b - Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.
2 WPDIS	Write Protection Disable When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect. 0b - Write protection is enabled. 1b - Write protection is disabled.
1	Initialize The Channels Output

Table continues on the next page...

Table continued from the previous page...

Field	Function
INIT	When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect. The INIT bit is always read as 0.
0 FTMEN	FTM Enable This field is write protected. It can be written only when MODE[WPDIS] = 1. 0b - TPM compatibility. Free running counter and synchronization compatible with TPM. 1b - Free running counter and synchronization are different from TPM behavior.

43.4.3.10 Synchronization (SYNC)

Offset

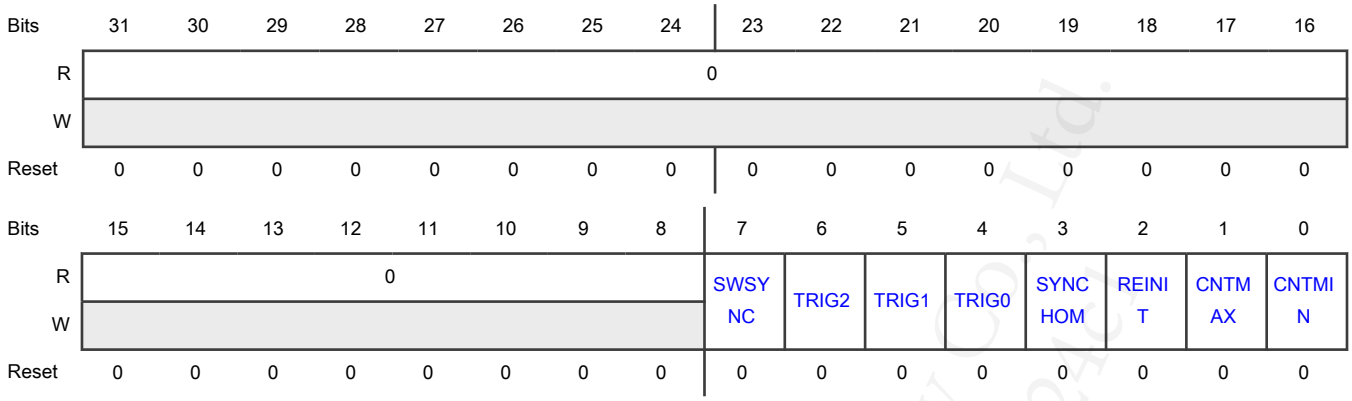
Register	Offset
SYNC	58h

Function

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CnV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

NOTE



The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See PWM synchronization.

Provided under NDA only
COMPANY PROPRIETARY

Diagram

Fields

Field	Function
31-8 —	Reserved
7 SWSYNC	PWM Synchronization Software Trigger Selects the software trigger as the PWM synchronization trigger. The software trigger happens when a 1 is written to SWSYNC bit. 0b - Software trigger is not selected. 1b - Software trigger is selected.
6 TRIG2	PWM Synchronization Hardware Trigger 2 Enables hardware trigger 2 to the PWM synchronization. Hardware trigger 2 happens when a rising edge is detected at the trigger 2 input signal. 0b - Trigger is disabled. 1b - Trigger is enabled.
5 TRIG1	PWM Synchronization Hardware Trigger 1 Enables hardware trigger 1 to the PWM synchronization. Hardware trigger 1 happens when a rising edge is detected at the trigger 1 input signal. 0b - Trigger is disabled. 1b - Trigger is enabled.
4 TRIG0	PWM Synchronization Hardware Trigger 0 Enables hardware trigger 0 to the PWM synchronization. Hardware trigger 0 occurs when a rising edge is detected at the trigger 0 input signal. 0b - Trigger is disabled. 1b - Trigger is enabled.
3	Output Mask Synchronization

Table continues on the next page...

Table continued from the previous page...

Field	Function
SYNCHOM	Selects when the OUTMASK register is updated with the value of its buffer. 0b - OUTMASK register is updated with the value of its buffer in all rising edges of the FTM input clock. 1b - OUTMASK register is updated with the value of its buffer only by the PWM synchronization.
2 REINIT	FTM Counter Reinitialization by Synchronization Determines if the FTM counter is reinitialized when the selected trigger for the synchronization is detected (FTM counter synchronization). The REINIT bit configures the synchronization when SYNCMODE is zero. 0b - FTM counter continues to count normally. 1b - FTM counter is updated with its initial value when the selected trigger is detected.
1 CNTMAX	Maximum Loading Point Enable Selects the maximum loading point to PWM synchronization (Synchronization Points). If CNTMAX is 1, the selected loading point is when the FTM counter reaches its maximum value (MOD register). 0b - The maximum loading point is disabled. 1b - The maximum loading point is enabled.
0 CNTMIN	Minimum Loading Point Enable Selects the minimum loading point to PWM synchronization (Synchronization Points). If CNTMIN is 1, the selected loading point is when the FTM counter reaches its minimum value (CNTIN register). 0b - The minimum loading point is disabled. 1b - The minimum loading point is enabled.

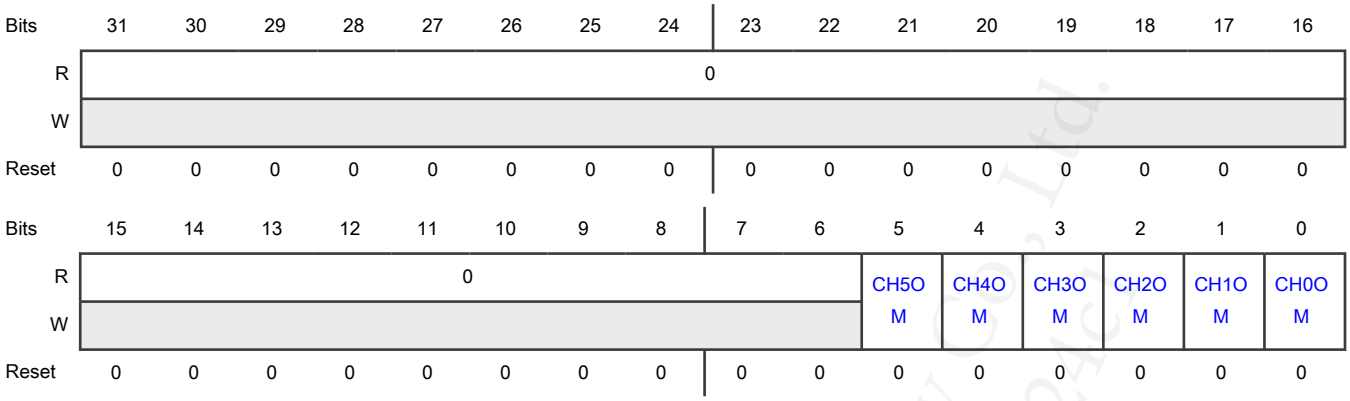
5-0 CHnOI	Channel n Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0b - The initialization value is 0. 1b - The initialization value is 1.

43.4.3.12 Output Mask (OUTMASK)

Offset

Register	Offset
OUTMASK	60h

Function



This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to PWM synchronization.

Output Mask bits must not be set for trigger mode.

43.4.3.18 Input Capture Filter Control (FILTER)

Offset

Register	Offset
FILTER	78h

Function

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

NOTE

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

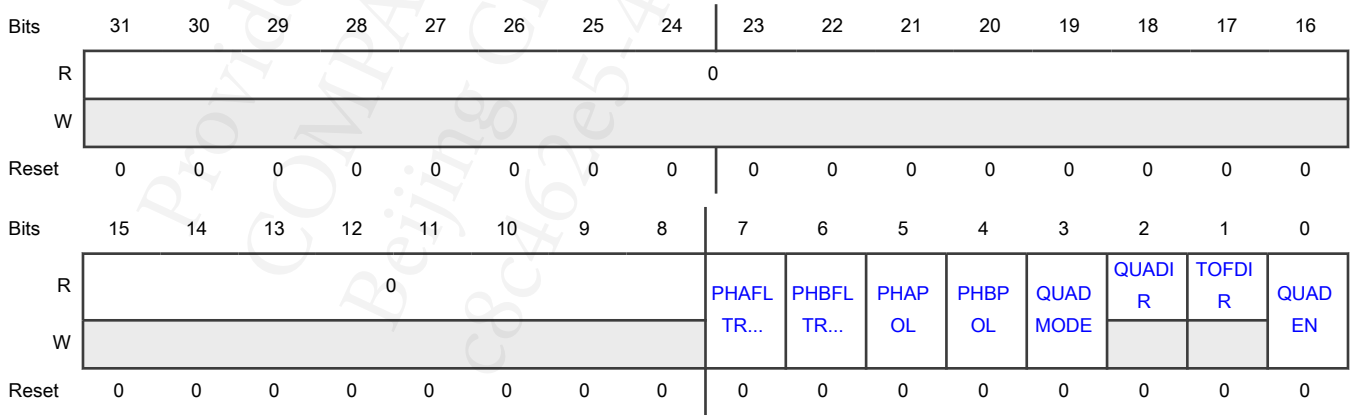
15-12 CH3FVAL	Channel 3 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
11-8 CH2FVAL	Channel 2 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
7-4 CH1FVAL	Channel 1 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
3-0 CH0FVAL	Channel 0 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.

43.4.3.19 Quadrature Decoder Control And Status (QDCTRL)



Offset

Register	Offset
QDCTRL	80h

Function

This register has the control and status bits for the Quadrature Decoder mode.

Diagram

Fields

Field	Function
31-8 —	Reserved
7 PHAFLTREN	Phase A Input Filter Enable Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero. 0b - Phase A input filter is disabled. 1b - Phase A input filter is enabled.
6 PHBFLTREN	Phase B Input Filter Enable Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero. 0b - Phase B input filter is disabled. 1b - Phase B input filter is enabled.
5 PHAPOL	Phase A Input Polarity Selects the polarity for the quadrature decoder phase A input. 0b - Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal. 1b - Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.
4 PHBPOL	Phase B Input Polarity Selects the polarity for the quadrature decoder phase B input. 0b - Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal. 1b - Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.
3 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in the Quadrature Decoder mode. 0b - Phase A and phase B encoding mode. 1b - Count and direction encoding mode.
2 QUADIR	FTM Counter Direction In Quadrature Decoder Mode Indicates the counting direction. 0b - Counting direction is decreasing (FTM counter decrement). 1b - Counting direction is increasing (FTM counter increment).
1	Timer Overflow Direction In Quadrature Decoder Mode

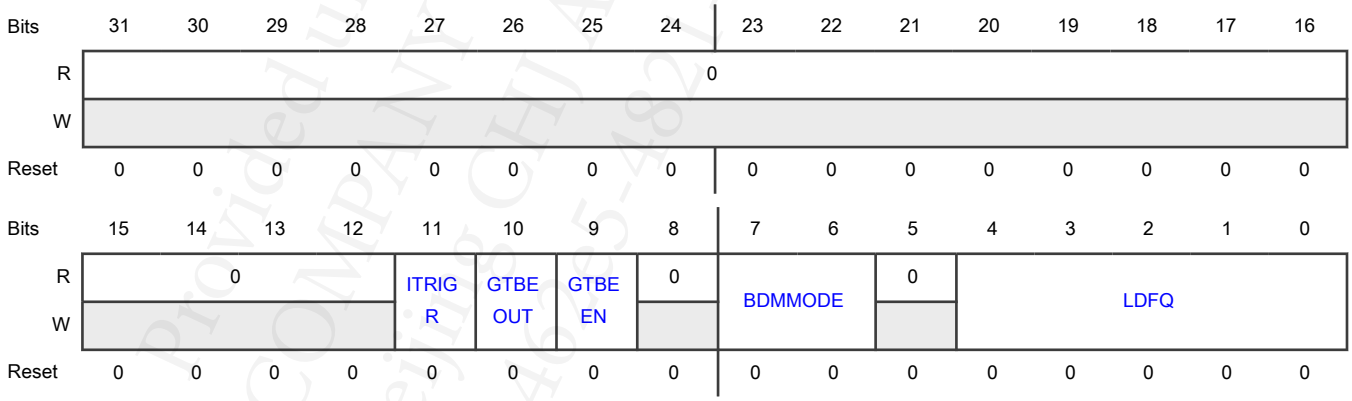
Table continues on the next page...

Table continued from the previous page...

Field	Function
TOFDIR	Indicates if the TOF bit was set on the top or the bottom of counting. 0b - TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register). 1b - TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).
0 QUADEN	Quadrature Decoder Mode Enable Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0b - Quadrature Decoder mode is disabled. 1b - Quadrature Decoder mode is enabled.

43.4.3.20 Configuration (CONF)

Offset



Register	Offset
CONF	84h

Function

This register selects the frequency of the reload opportunities, the FTM behavior in Debug mode, the use of an external global time base, and the global time base signal generation.

This register also controls if initialization trigger should be generated when a reload point is reached.

Diagram

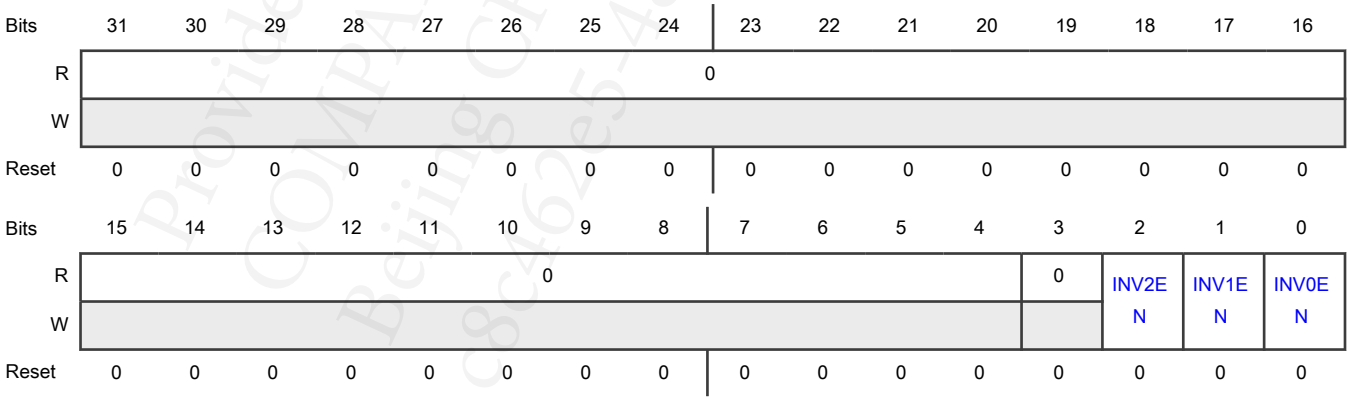
43.4.3.22 FTM Inverting Control (INVCTRL)

Offset



Register	Offset
INVCTRL	90h

Function

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

Diagram

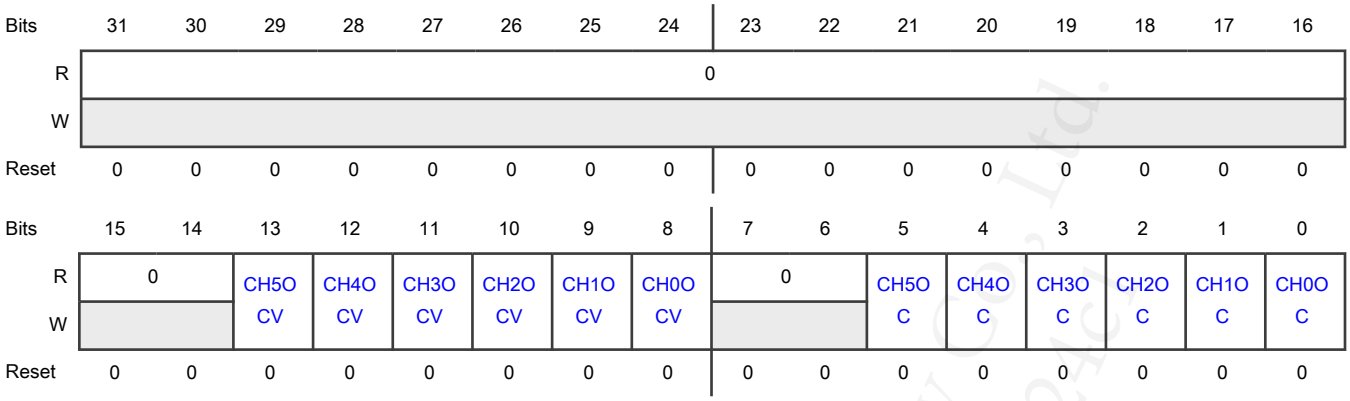
0 INV0EN	Pair Channels 0 Inverting Enable 0b - Inverting is disabled. 1b - Inverting is enabled.

43.4.3.23 FTM Software Output Control (SWOCTRL)

Offset

Register	Offset
SWOCTRL	94h

Function



This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CH(n)OC bits enable the control of the corresponding channel (n) output by software.
- The CH(n)OCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

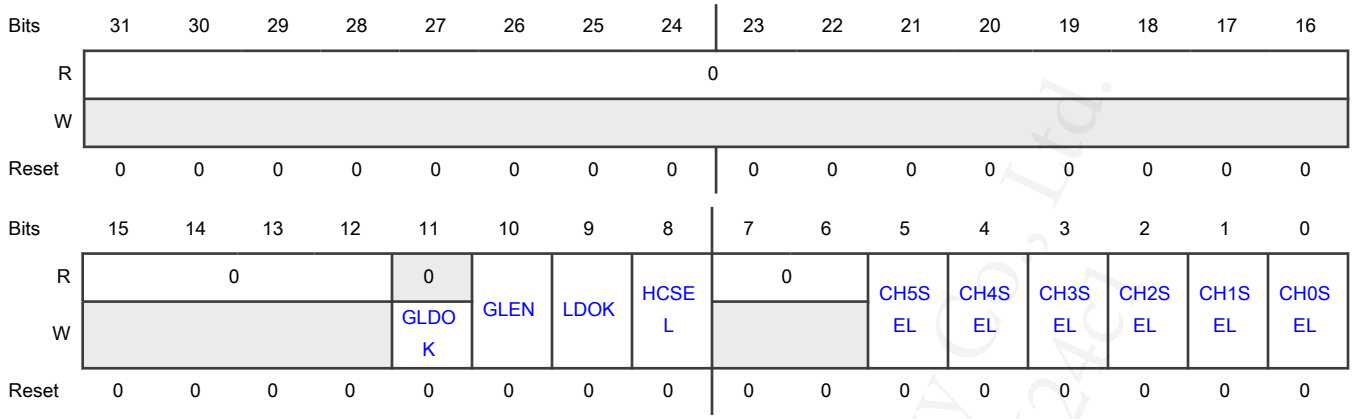
43.4.3.24 FTM PWM Load (PWMLOAD)



Offset

Register	Offset
PWMLOAD	98h

Function

Enables the reload of the MOD, HCR, CNTIN, C(n)V, and C(n+1)V registers with the values of their write buffers when the FTM counter changes from the MOD register value to its next value or when a channel (j) match occurs. A match occurs for channel (j) when FTM counter = C(j)V. A reload can also occurs when FTM counter = HCR register at a half cycle match. This register also controls the local and global load mechanisms.

Diagram

Fields

Field	Function
31-12 —	Reserved
11 GLDOK	Global Load OK This bit controls the global load mechanism. It generates a pulse at FTM module global load output with one FTM clock cycle width, which is used to set LDOK bits of FTM and other modules (including other FTMs). This bit is self-cleared and read value is always zero. The global load mechanism depends on SoC specific information. Refer to FTM SoC specific information to more details. 0b - No action. 1b - LDOK bit is set.
10 GLEN	Global Load Enable This bit enables the global load mechanism implemented by GLDOK. If GLEN bit is set, then an external event on the FTM global load input sets the LDOK bit. The clear of the LDOK bit is done by CPU writes '0' to the bit. 0b - Global Load Ok disabled. 1b - Global Load OK enabled. A pulse event on the module global load input sets the LDOK bit.
9 LDOK	Load Enable Enables the loading of the MOD, CNTIN, HCR and CV registers with the values of their buffers. The LDOK bit can also be set by the Global Load mechanism if GLEN bit is enabled. 0b - Loading updated values is disabled. 1b - Loading updated values is enabled.
8 HCSEL	Half Cycle Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit enables the half cycle match as a reload oportunity. A half cycle is defined by when the FTM counter matches the HCR register. 0b - Half cycle reload is disabled and it is not considered as a reload opportunity. 1b - Half cycle reload is enabled and it is considered as a reload opportunity.
7-6 —	Reserved
5-0 CHnSEL	Channel n Select 0b - Channel match is not included as a reload opportunity. 1b - Channel match is included as a reload opportunity.

43.4.3.25 Half Cycle Register (HCR)

Offset

Register	Offset
HCR	9Ch

Function

The Half Cycle Register contains the match value for FTM half cycle reload feature. After FTM counter reaches this value, a reload opportunity is generated if FTM_PWMLOAD[HCSEL] is enabled.

Writing to the HCR register latches the value into a buffer. The HCR register is updated with the value of its write buffer according to Registers updated from write buffers.

43.5 Functional Description

43.5.1 Clock source

The FTM has only one clock domain: the FTM input clock.

43.5.1.1 Counter clock source

The CLKS[1:0] bits select one of three possible clock sources for the FTM counter or disable the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the FTM input clock or an external clock. This clock input is defined by chip integration. Refer to the chip specific documentation for further information. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the FTM input clock frequency.

The external clock passes through a synchronizer clocked by the FTM input clock to assure that counter transitions are properly aligned to FTM input clock transitions.Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the FTM input clock frequency.

43.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

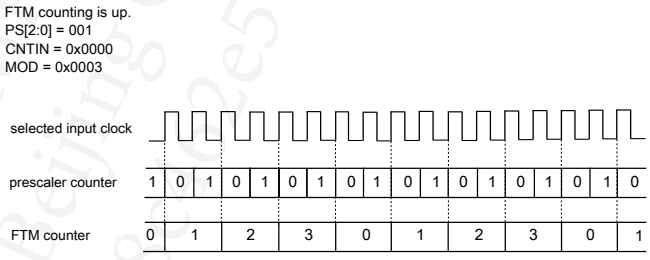

Figure 234. Example of the prescaler counter

43.5.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- Up counting
- Up-down counting
- Quadrature Decoder Mode

43.5.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is (MOD – CNTIN + 0x0001) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

A counter event happens at the same time of TOF bit set when the FTM counter changes from MOD to CNTIN. See Counter events for more details.

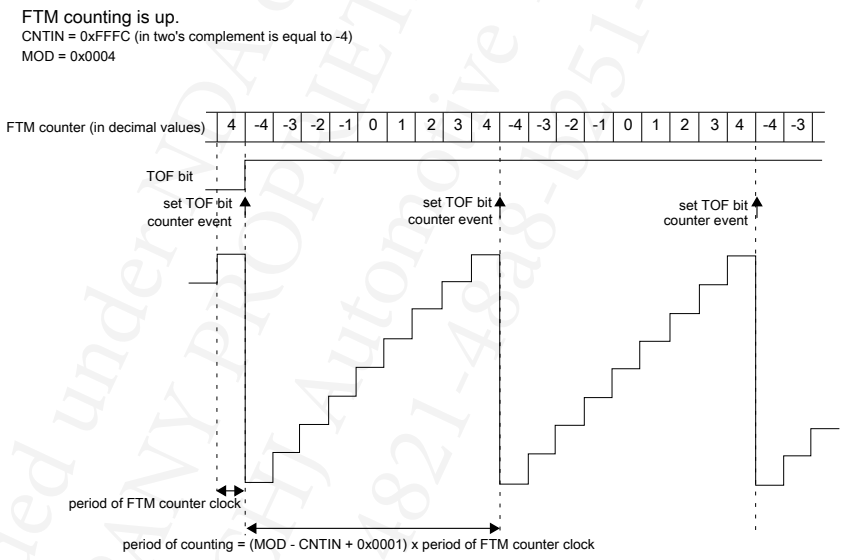

Figure 235. Example of FTM up and signed counting

Table 267. FTM counting based on CNTIN value

When	Then
CNTIN = 0x0000	The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.
CNTIN[15] = 1	The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed.

Table continues on the next page...

Table 267. FTM counting based on CNTIN value (continued)

When	Then
CNTIN[15] = 0 and CNTIN ≠ 0x0000	The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.

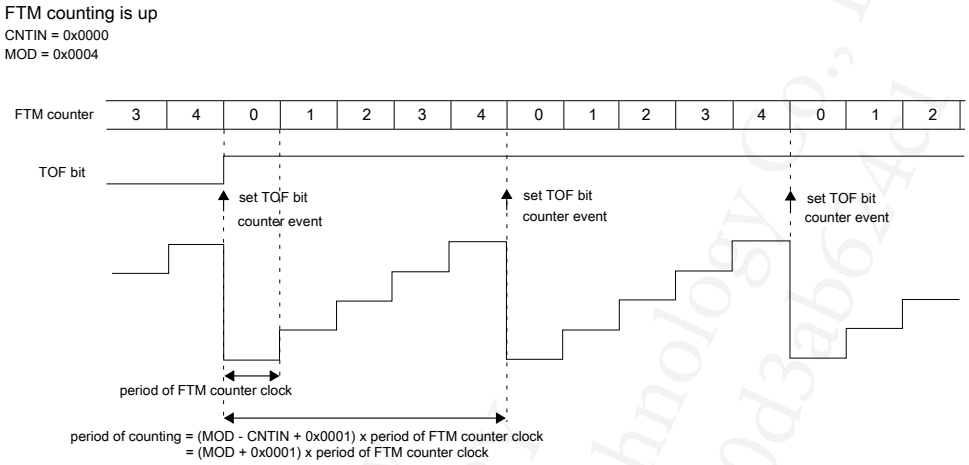

Figure 236. Example of FTM up counting with CNTIN = 0x0000

NOTE

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

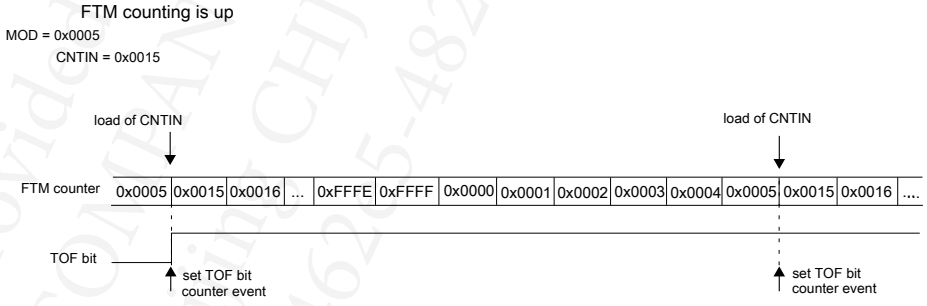

Figure 237. Example of up counting when the value of CNTIN is greater than the value of MOD

43.5.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is 2 × (MOD – CNTIN) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

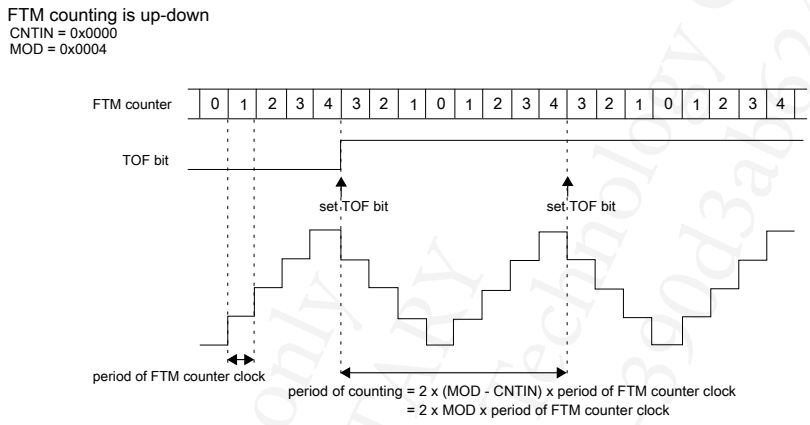

Figure 238. Example of up-down counting when CNTIN = 0x0000

NOTE

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if CnV > CNTIN, or
- if CnV = 0 or if CnV[15] = 1. In this case, 0% CPWM is generated.

The figure below shows the possible counter events when in up-down counting mode. See Counter events for more details.

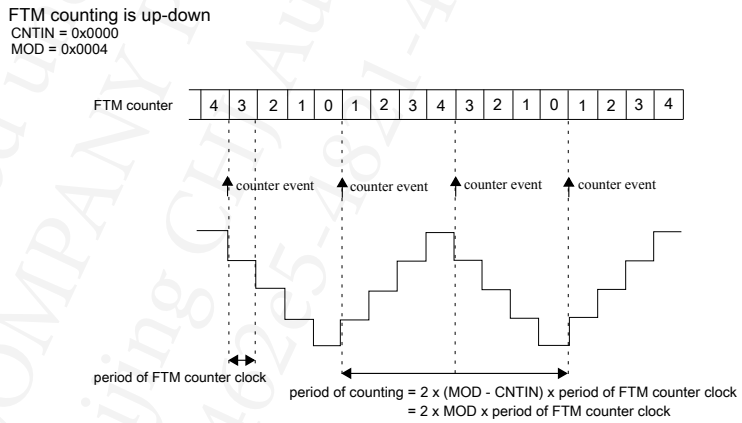

Figure 239. Example of counter events in up-down counting mode when CNTIN = 0x0000

43.5.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

A counter event occurs at the same time of TOF bit set when the FTM counter changes from 0xFFFF to 0x0000. See Counter events for more details.

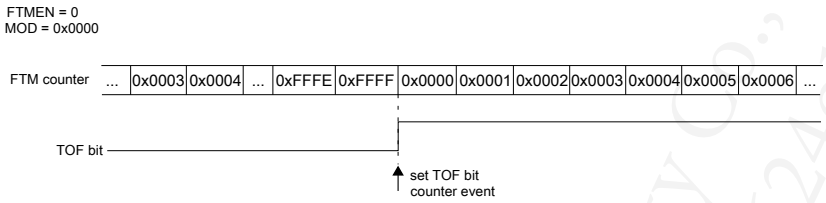

Figure 240. Example when the FTM counter is free running

The FTM counter is also a free running counter when:

- FTMEN = 1
- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

43.5.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- FTM counter synchronization.
- A channel in Input Capture mode with ICRST = 1 (FTM Counter Reset in Input Capture Mode).

Note that reseting the counter also generates a counter event. See Counter events for more details.

43.5.3.5 Counter events

Counter events can be used as reload opportunities to FTM register sychronization mechanism. See Reload Points for more details. There are some possible counter events depending on the counter mode. Please see the table below for more details.

Table 268. FTM counter events

When	Then
FTM counter is in up counting mode or freerunning	• A counter event happens at the same time of TOF bit set when the FTM counter changes from MOD to CNTIN (counter wrap). Figure at Up counting shows the counter event generation. • When in freerunning, there is a counter event when FTM counter changes from 0xFFFF to 0x0000. Figure at Free running counter shows the counter event generation.

Table continues on the next page...

Table 268. FTM counter events (continued)

When	Then
FTM counter is in up-down counting mode	• In up-down counting mode, there are two possible counter events when FTM counter turns from down to up counting and when counter turns from up to down counting. User can select which point will be used to generate the counter event. Figure at Up-down counting shows the possible counter events.
FTM counter is reseted (see Counter reset) or a value different from zero is written at CLKS field	• In up-counting mode, all counter reset events or a write in the CLKS with a value different from zero generates a counter event. • In up-down counting mode, counter reset events only generates a counter event if the minimum load point when FTM counter turns from down to up counting is configured. A write in the CLKS with a value different from zero always generates a counter event in up-down counting mode.

43.5.4 Channel Modes

The following table shows the channel modes selection.

Table 269. Channel Modes Selection

DECAPEN	MCOMBINE	COMBINE	CPWMS	MSB:MSA	ELSB:ELSA	Mode	Configuration
X	X	X	X	XX	00	Pin not used for FTM—revert the channel pin to general purpose I/O or other peripheral control

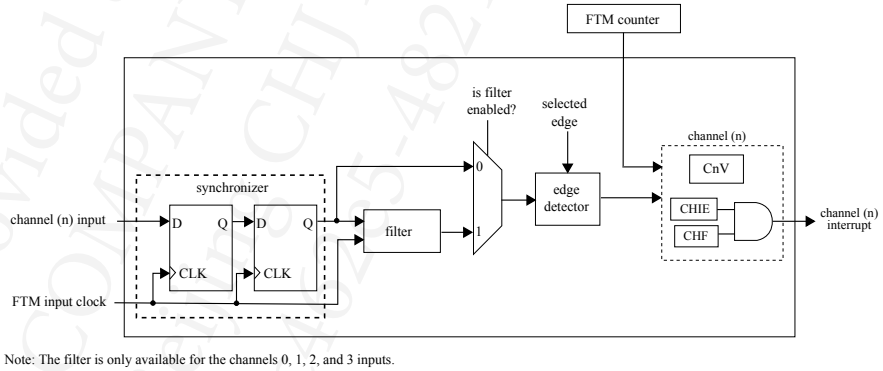
Table 270. Dual Edge Capture Mode — Edge Polarity Selection

ELSB	ELSA	Channel Port Enable	Detected Edges
0	0	Disabled	No edge
0	1	Enabled	Rising edge
1	0	Enabled	Falling edge
1	1	Enabled	Rising and falling edges

43.5.5 Input Capture Mode

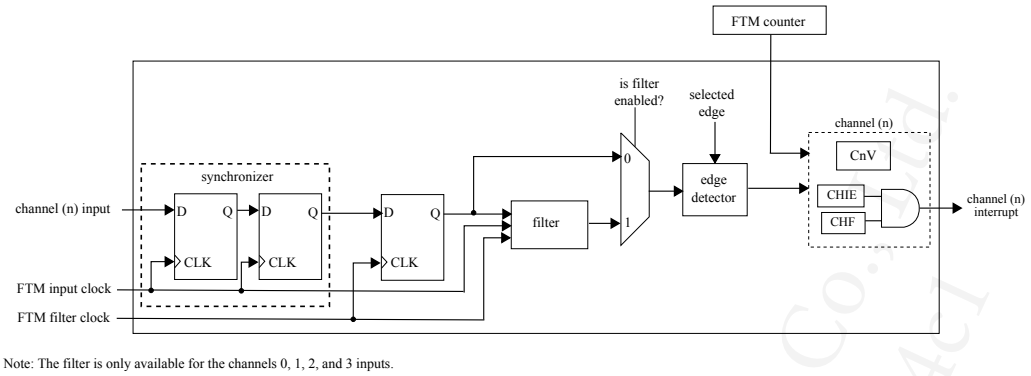
The Input Capture mode is selected when:



- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0
- CPWMS = 0
- MSB:MSA = 0:0, and
- ELSB:ELSA ≠ 0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHF bit is set and the channel interrupt is generated if enabled by CHIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSB:ELSA bits determine which edge, falling or rising, triggers input-capture event.



Writes to the CnV register are ignored in input capture mode.

While in Debug mode, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of Debug, is captured into the CnV register and the CHF bit is set.

Note: The filter is only available for the channels 0, 1, 2, and 3 inputs.

Figure 241. Diagram for Input Capture Mode when FLTPS[3:0] = 0

Note: The filter is only available for the channels 0, 1, 2, and 3 inputs.

Figure 242. Diagram for Input Capture Mode when FLTPS[3:0] ≠ 0

43.5.5.1 Filter for Input Capture Mode

The filter is only available on channels 0, 1, 2, and 3.

If FLTPS[3:0] = 0, the channel input after being synchronized by FTM input clock (Figure 241) is the filter input.

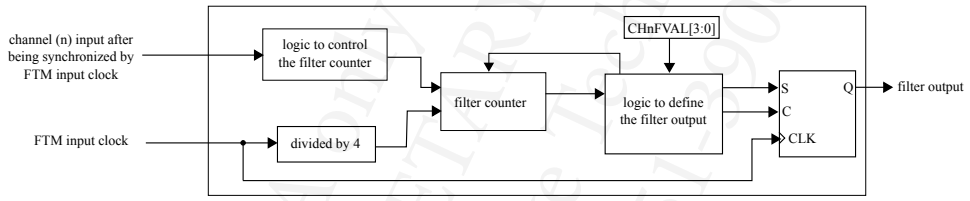


Figure 243. Channel Input Filter when FLTPS[3:0] = 0

If FLTPS[3:0] ≠ 0, the channel input after being synchronized by FTM input clock and being sampled by FTM filter clock (Figure 242) is the filter input.

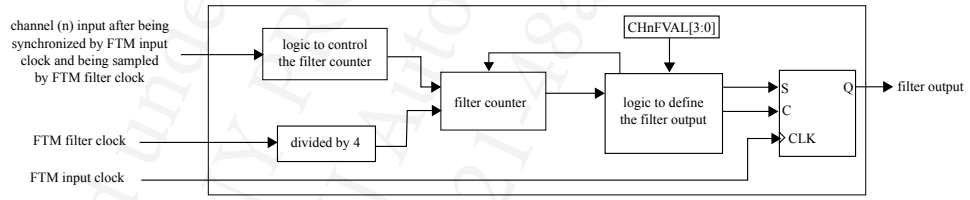

Figure 244. Channel Input Filter when FLTPS[3:0] ≠ 0

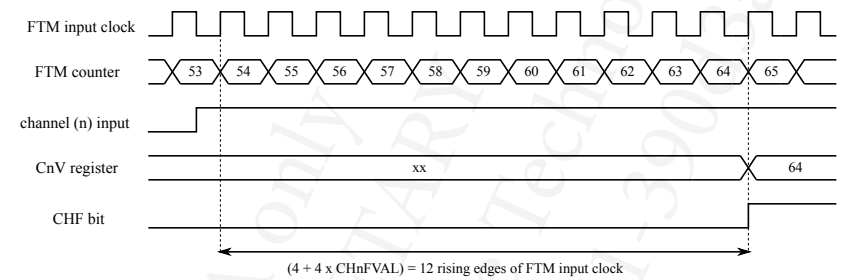
NOTE

The maximum frequency for the channel input to be detected correctly is FTM filter clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

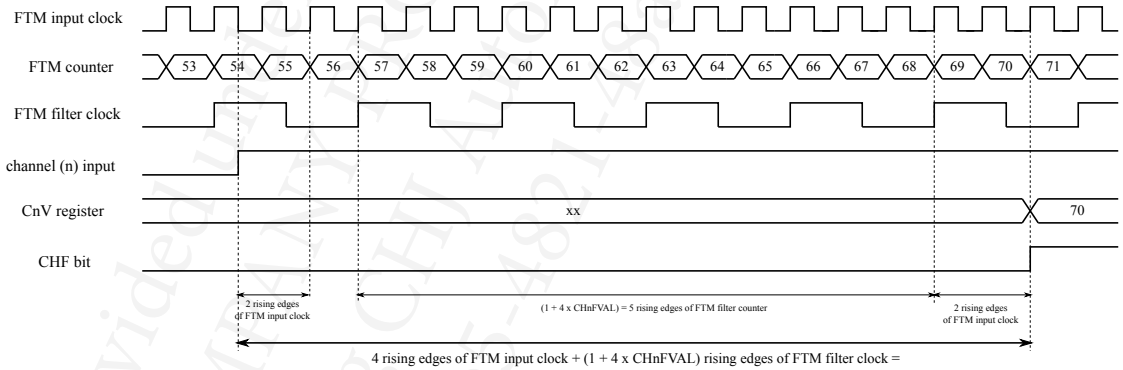
When there is a state change in the channel input, the counter is reset and starts counting up. As long as the new state is stable on the channel input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the new channel input signal value is validated. It is then transmitted as a pulse to the edge detector.



If the opposite edge appears on the channel input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. If a pulse is sampled as a value less than (CHnFVAL[3:0] x 4) consecutive rising edges of FTM filter clock, it is regarded as a glitch and is not passed on to the edge detector.

The table below shows the delay that is added by the FTM channel input filter according to its configuration.

Table 271. FTM Channel Input Filter Delay



FTM channel input filter	FLTPS[3:0] bits	Number of rising edges between the selected edge on channel input and setting CHF bit
• channel does not have the input filter, or • channel input filter is disabled (CHnFVAL[3:0] = 0)	FLTPS[3:0] = 0	• 3 rising edges of FTM input clock
	FLTPS[3:0] ≠ 0	• 3 rising edges of FTM input clock, plus • 1 rising edge of FTM filter clock
• channel has the input filter, and • channel input filter is enabled (CHnFVAL[3:0] ≠ 0)	FLTPS[3:0] = 0	• (4 + 4 × CHnFVAL[3:0]) rising edges of FTM input clock
	FLTPS[3:0] ≠ 0	• 4 rising edges of FTM input clock, plus • (1 + 4 × CHnFVAL[3:0]) rising edges of FTM filter clock

The following figures illustrate two examples of channel input filter.

Note:
PS[2:0] = 3'b000
channel (n) in input capture mode with capture only on rising edges
CHnFVAL[3:0] = 4'h2 (channel (n) input filter is enabled)

Figure 245. Example of Channel Input Filter when FLTPS[3:0] = 0

Note:
PS[2:0] = 3'b000
channel (n) in input capture mode with capture only on rising edges
CHnFVAL[3:0] = 4'h1 (channel (n) input filter is enabled)
FLTPS[3:0] = 4'h2 (divide by 3)

Figure 246. Example of Channel Input Filter when FLTPS[3:0] ≠ 0

43.5.5.2 FTM Counter Reset in Input Capture Mode

If the channel (n) is in input capture mode and CnSC[ICRST = 1], then when the selected input capture event occurs in the channel (n) input signal, the current value of the FTM counter is captured into the CnV register, the CHF bit is set, the channel (n) interrupt is generated (if CHIE = 1) and the FTM counter is reset to the CNTIN register value.

This allows the FTM to measure a period/pulse being applied to the channel (n) input (number of the FTM input clocks) without having to implement a subtraction calculation in software subsequent to the event occurring.

The figure below shows the FTM counter reset when the selected input capture event is detected in a channel in input capture mode with ICRST = 1.

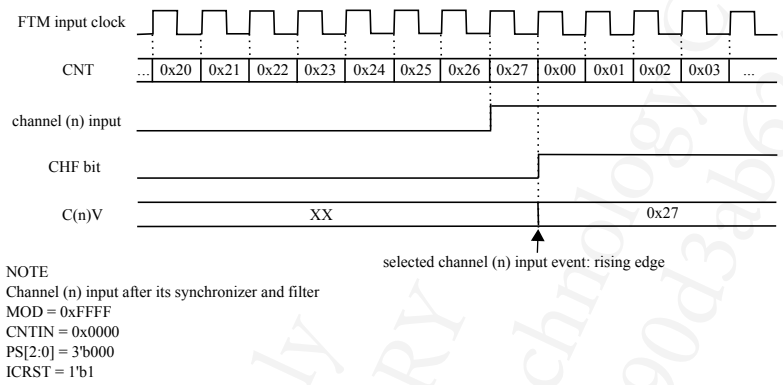


Figure 247. Example of the Input Capture mode with ICRST = 1

NOTE

- It is expected that the ICRST bit be set only when the channel is in input capture mode.
- If the FTM counter is reset because the channel is in input capture mode with ICRST = 1, then the prescaler counter (Prescaler) is also reset.

43.5.6 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0
- CPWMS = 0, and
- MSB:MSA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHF bit is set and the channel (n) interrupt is generated if CHIE = 1 at the channel (n) match (FTM counter = CnV).

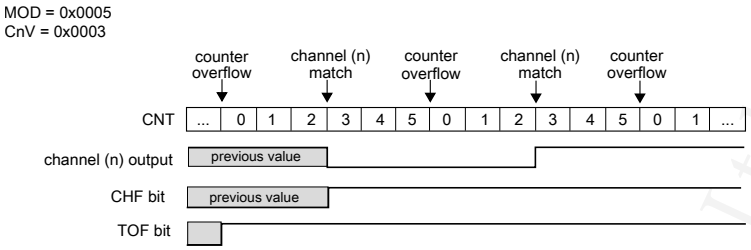

Figure 248. Example of the Output Compare mode when the match toggles the channel output

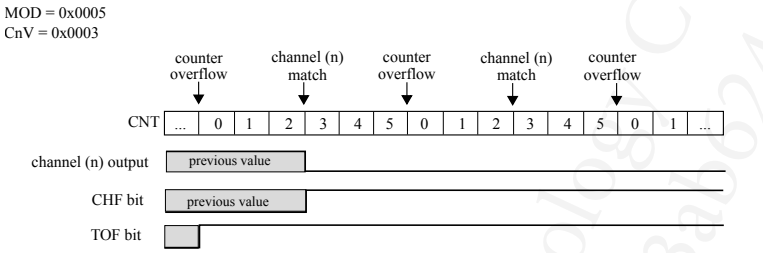

Figure 249. Example of the Output Compare mode when the match clears the channel output

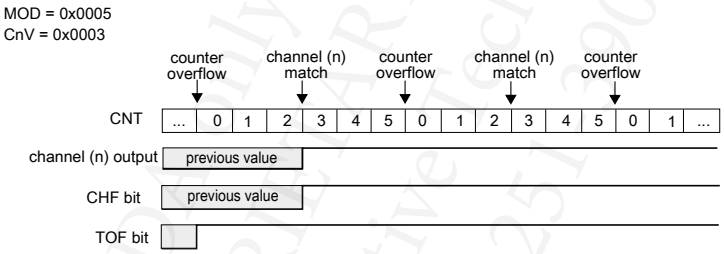

Figure 250. Example of the Output Compare mode when the match sets the channel output

If (ELSB:ELSA = 0:0) when the counter reaches the value in the CnV register, the CHF bit is set and the channel (n) interrupt is generated if CHIE = 1, however the channel (n) output is not modified and controlled by FTM.

43.5.7 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0
- CPWMS = 0, and
- MSB = 1

The EPWM period is determined by (MOD − CNTIN + 0x0001) and the pulse width (duty cycle) is determined by (CnV − CNTIN).

The CHF bit is set and the channel (n) interrupt is generated if CHIE = 1 at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

Provided under NDA ONLY
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
cc42e5-4821-48a2-8251-2903a624c1

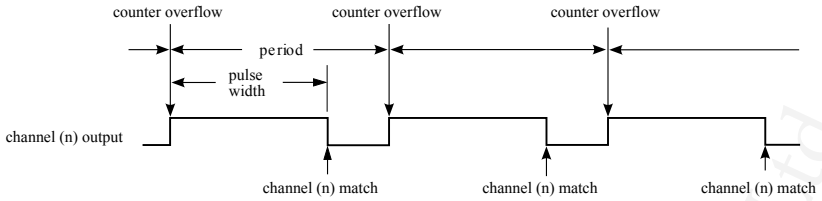

Figure 251. EPWM period and pulse width with ELSB:ELSA = 1:0

If (ELSB:ELSA = 0:0) when the counter reaches the value in the CnV register, the CHF bit is set and the channel (n) interrupt is generated if CHIE = 1, however the channel (n) output is not controlled by FTM.

If (ELSB:ELSA = 1:0), then the channel (n) output is forced high at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

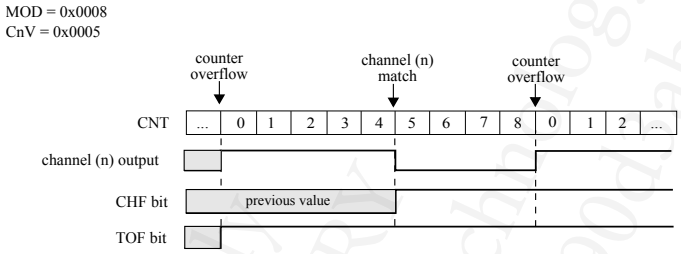

Figure 252. EPWM signal with ELSB:ELSA = 1:0

If (ELSB:ELSA = X:1), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

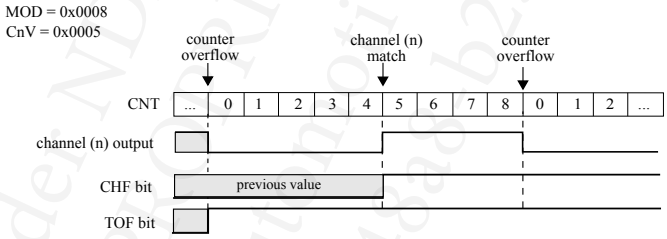

Figure 253. EPWM signal with ELSB:ELSA = X:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHF bit is not set even when there is the channel (n) match.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHF bit is not set. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

NOTE

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if CNTIN < CnV <= MOD,
- 100% EPWM signal when CNTIN > CnV or CnV > MOD.

43.5.8 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by 2 × (CnV − CNTIN) and the period is determined by 2 × (MOD − CNTIN). See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHF bit is set and channel (n) interrupt is generated (if CHIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

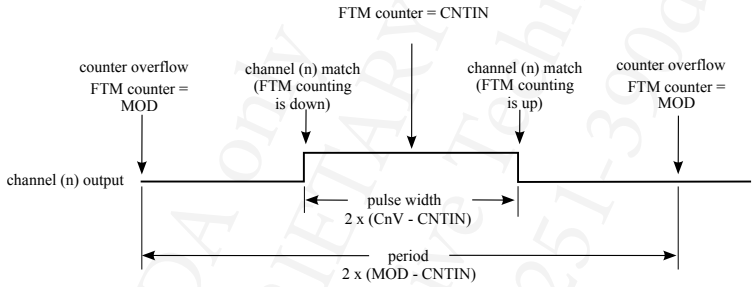

Figure 254. CPWM period and pulse width with ELSB:ELSA = 1:0

If (ELSB:ELSA = 0:0) when the FTM counter reaches the value in the CnV register, the CHF bit is set and the channel (n) interrupt is generated (if CHIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSB:ELSA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

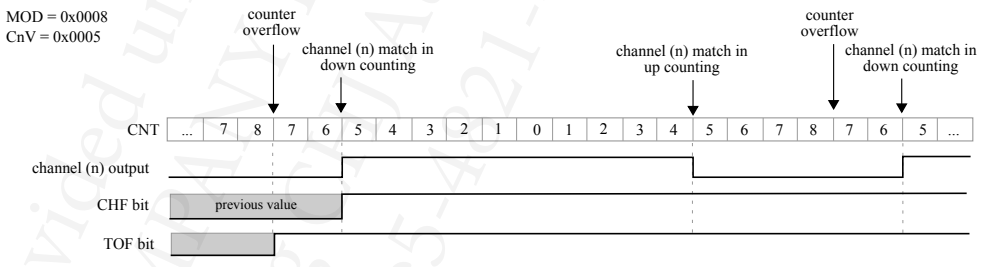

Figure 255. CPWM signal with ELSB:ELSA = 1:0

If (ELSB:ELSA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

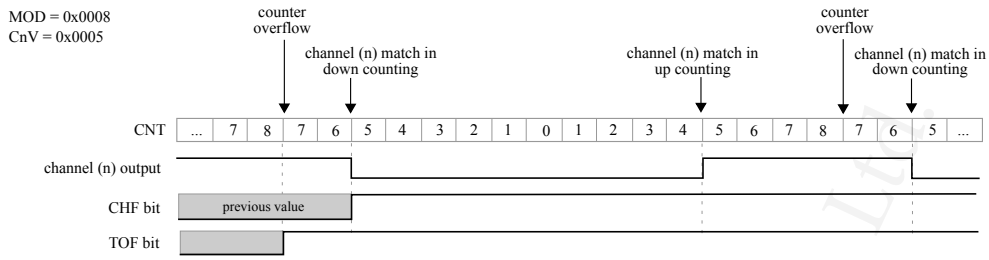

Figure 256. CPWM signal with ELSB:ELSA = X:1

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

43.5.9 Combine mode

The Combine mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 1, and
- CPWMS = 0

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD − CNTIN + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)V − C(n)V|).

The channel (n) CHF bit is set and its interrupt is generated, if channel (n) CHIE = 1, at the channel (n) match (FTM counter = C(n)V). The channel (n+1) CHF bit is set and its interrupt is generated, if channel (n+1) CHIE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If channel (n) ELSB:ELSA = 1:0, then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced high at the channel (n) match (FTM counter = C(n)V). See the following figure.

If channel (n) ELSB:ELSA = X:1, then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced low at the channel (n) match (FTM counter = C(n)V). See the following figure.

In Combine mode, the channel (n+1) ELSB:ELSA bits are not used in the generation of the channels (n) and (n+1) output. However, if channel (n) ELSB:ELSA = 0:0, then the channel (n) output is not controlled by FTM, and if channel (n+1) ELSB:ELSA = 0:0, then the channel (n+1) output is not controlled by FTM.

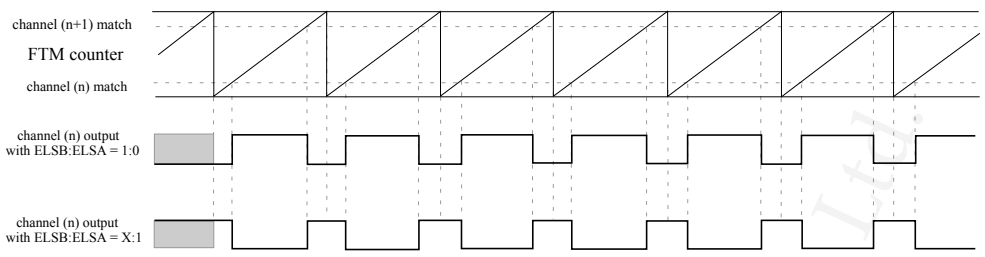

Figure 257. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

43.5.9.1 Asymmetrical PWM

In Combine mode and Modified Combine PWM Mode, the PWM first edge (channel (n) match: FTM counter = C(n)V) is independent of the PWM second edge (channel (n+1) match: FTM counter = C(n+1)V).

43.5.10 Modified Combine PWM Mode

The Modified Combine PWM mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- MCOMBINE = 1
- COMBINE = 1, and
- CPWMS = 0

The Modified Combine PWM mode is intended to support the generation of PWM signals where the period is not modified while the signal is being generated, but the duty cycle will be varied. In this mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output. Thus, the channel (n) match edge is fixed and the channel (n+1) match edge can be varied.

When a pair of channels is in Modified Combine PWM mode, it is recommend that the other pairs also be in Modified Combine PWM mode.

In the Modified Combine PWM mode, assuming that CNTIN ≥ 0, MOD > 0, and CNTIN < MOD:

- The PWM period is determined by (MOD - CNTIN + 0x0001);

- The channel (n) PWM duty cycle is calculated according to the following table.

Table 272. Modified Combine PWM Mode - Duty Cycles

Channel (n) PWM Duty Cycle	Condition
0% duty cycle	For CNTIN ≤ (C(n)V and C(n+1)V) ≤ MOD: C(n)V = C(n+1)V
duty cyle between 0% and 100%	For CNTIN ≤ (C(n)V and C(n+1)V) ≤ MOD: • if (C(n)V < C(n+1)V), then the duty cycle is (C(n+1)V - C(n)V) • if (C(n)V > C(n+1)V), then the duty cycle is [(MOD - C(n)V) + (C(n+1)V - CNTIN) + 1]
100% duty cyle	CNTIN ≤ C(n)V ≤ MOD and C(n+1)V > MOD

The channel (n) CHF bit is set and its interrupt is generated, if channel (n) CHIE = 1, at the channel (n) match (FTM counter = C(n)V). The channel (n+1) CHF bit is set and its interrupt is generated, if channel (n+1) CHIE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If channel (n) ELSB:ELSA = 1:0, then the channel (n) output is forced high at the channel (n) match (FTM counter = C(n)V) and it is forced low at the channel (n+1) match (FTM counter = C(n+1)V).

If channel (n) ELSB:ELSA = X:1, then the channel (n) output is forced low at the channel (n) match (FTM counter = C(n)V) and it is forced high at the channel (n+1) match (FTM counter = C(n+1)V).

In Modified Combine PWM mode, the channel (n+1) ELSB:ELSA bits are not used in the generation of the channels (n) and (n+1) output. However, if channel (n) ELSB:ELSA = 0:0, then the channel (n) output is not controlled by FTM, and if channel (n+1) ELSB:ELSA = 0:0, then the channel (n+1) output is not controlled by FTM.

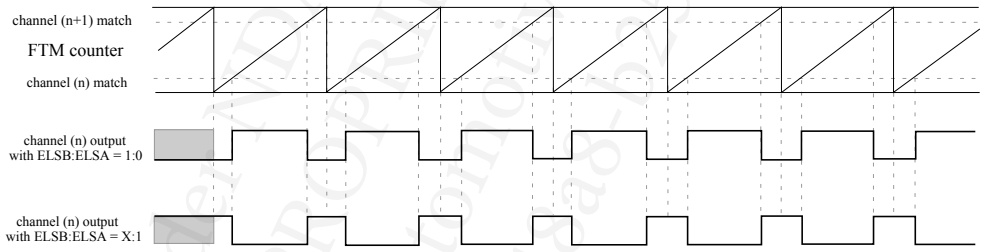

Figure 274. Modified Combine PWM Mode

The Modified Combine PWM mode allows the offset addition of the duty cyle, thus, in some cases, the C(n+1)V match can happen on the next FTM counter period. For CNTIN ≥ 0, MOD > 0, and CNTIN < MOD, this situation happens when C(n)V > C(n+1)V.

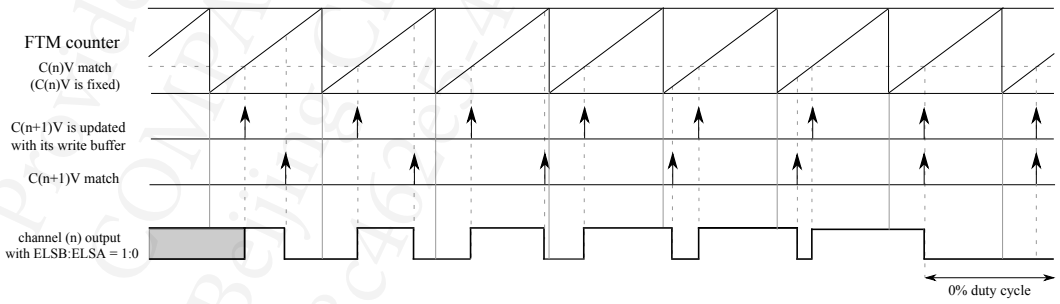

Figure 275. Modified Combine PWM Mode Examples

If more than one pair of channels are configured in Modified Combine PWM Mode, it is possible to fix an offset for the channel (n) match edge of each pair with respect to other pairs. This behavior is useful in the generation of lighting PWM control signals where it is desirable that edges are not coincident with each other pair to help eliminate noise generation. The C(n)V register value is the shift of the PWM pulse with respect to the beginning of FTM counter period (FTM counter = CNTIN).

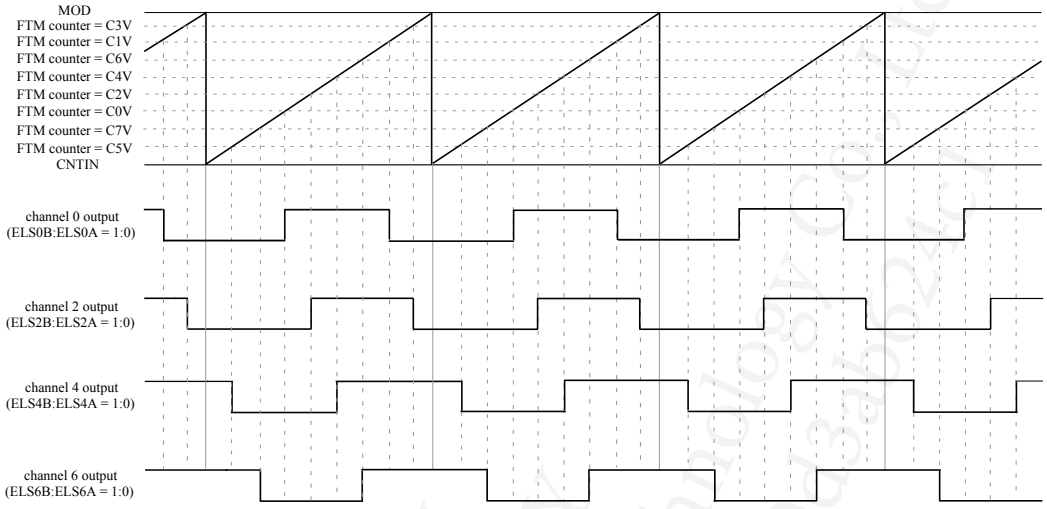

Figure 276. Example of Four Pairs of Channels in Modified Combine PWM Mode

43.5.10.1 Synchronization

In the Modified Combine Mode, the following registers should be updated when the FTM counter clock is disabled (CLKS[1:0] = 0:0).

- CNTIN (CNTIN register update)
- MOD (MOD and HCR registers update)
- C(n)V and C(n+1)V (CnV register update)

In the Modified Combine Mode, if (FTMEN = 1), (CLKS[1:0] ≠ 0:0), and there was a write to the register C(n+1)V, then the register C(n+1)V is updated with its write buffer value on the next channel (n) match (FTM counter = C(n)V). This feature allows to vary the PWM duty cycle value in this mode.

NOTE

In the Modified Combine Mode, the bit SYNCEN(n) should be zero bit for the channels (n) and (n+1). So, the following features are not available for this mode.

- C(n)V and C(n+1)V register synchronization
- Reload Points
- Global Load

43.5.11 Complementary Mode

The Complementary mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

NOTE

The Complementary Mode is not available on Output Compare mode.

The channel (n+1) output is the same as the channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0
- channels (n) and (n+1) are on Combine Mode or Modified Combine PWM Mode

The channel (n+1) output is independent from channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0
- channel (n) is on Output Compare Mode, EPWM or CPWM

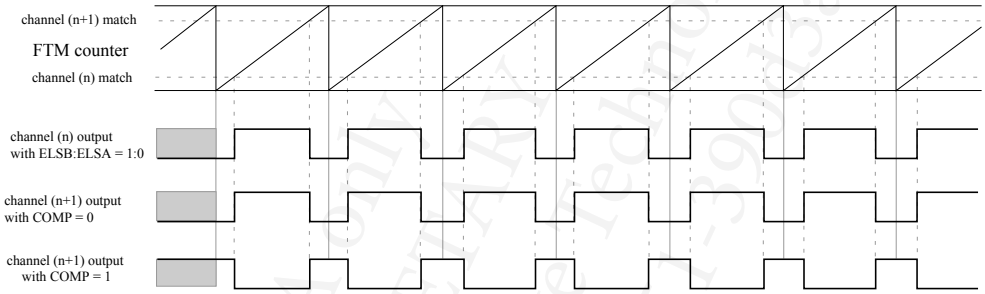

Figure 277. Channel (n+1) output in Complementary mode with (ELSB:ELSA = 1:0)

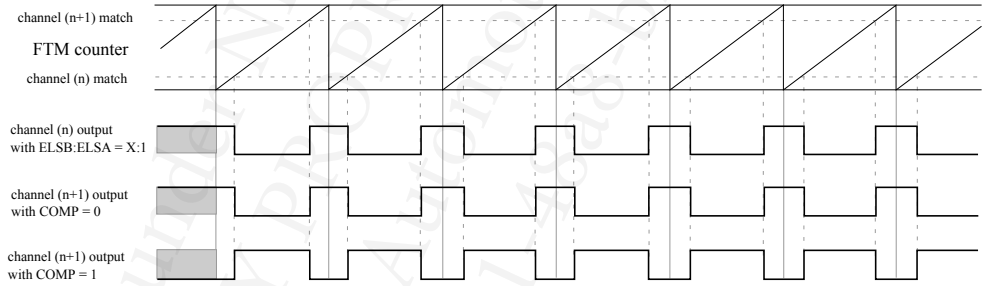

Figure 278. Channel (n+1) output in Complementary mode with (ELSB:ELSA = X:1)

43.5.12 Registers updated from write buffers

43.5.12.1 CNTIN register update

The following table describes when CNTIN register is updated:

Table 273. CNTIN register update

When	Then CNTIN register is updated
CLKS[1:0] = 0:0	When CNTIN register is written, independent of FTMEN bit.
• FTMEN = 0, or	At the next FTM input clock after CNTIN was written.

Table continues on the next page...

Table 273. CNTIN register update (continued)

When	Then CNTIN register is updated
• CNTINC = 0	
• FTMEN = 1, • SYNCMODE = 1, and • CNTINC = 1	By the CNTIN register synchronization.
• CNTINC = 1, and • LDOK = 1	By the Reload Points.

43.5.12.2 MOD and HCR registers update

The following table describes when MOD or HCR registers are updated:

Table 274. MOD and HCR updates

When	Then MOD or HCR is updated
CLKS[1:0] = 0:0	When MOD (or HCR) is written, independent of FTMEN bit.
• CLKS[1:0] ≠ 0:0, and • FTMEN = 0	According to the CPWMS bit, that is: • If the selected mode is not CPWM then MOD (or HCR) is updated after MOD (or HCR) register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. • If the selected mode is CPWM then MOD (or HCR) register is updated after MOD (or HCR) register was written and the FTM counter changes from MOD to (MOD – 0x0001).
• CLKS[1:0] ≠ 0:0, and • FTMEN = 1	By the MOD register synchronization. HCR follows the same procedure of MOD register in this case.
• LDOK = 1	By the Reload Points.

43.5.12.3 CnV register update

The following table describes when CnV register is updated:

Table 275. CnV register update

When	Then CnV register is updated
CLKS[1:0] = 0:0	When CnV register is written, independent of FTMEN bit.
• CLKS[1:0] ≠ 0:0, and • FTMEN = 0	According to the selected mode, that is:

Table continues on the next page...

Table 275. CnV register update (continued)

When	Then CnV register is updated
	• If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written. • If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. • If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).
• CLKS[1:0] ≠ 0:0, and • FTMEN = 1	According to the selected mode, that is: • If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization. • If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization.
• SYNCEN = 1, and • LDOK = 1	By the Reload Points.

43.5.13 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, HCR, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

NOTE

The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

43.5.13.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when TRIGn = 1, where n = 0, 1 or 2 corresponding to each one of the input signals, respectively. The hardware trigger input n is synchronized by the FTM input clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the TRIGn bit is cleared when 0 is written to it or when the trigger n event is detected.

In this case, if two or more hardware triggers are enabled (for example, TRIG0 and TRIG1 = 1) and only trigger 1 event occurs, then only TRIG1 bit is cleared. If a trigger n event occurs together with a write setting TRIGn bit, then the synchronization is initiated, but TRIGn bit remains set due to the write operation.

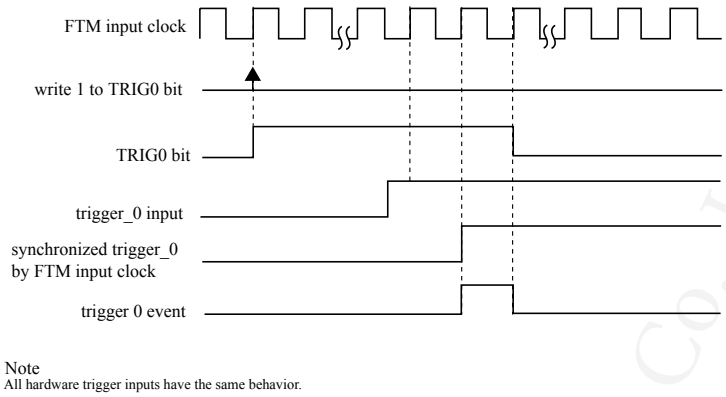

Figure 279. Hardware trigger event with HWTRIGMODE = 0

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

43.5.13.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see Synchronization Points and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

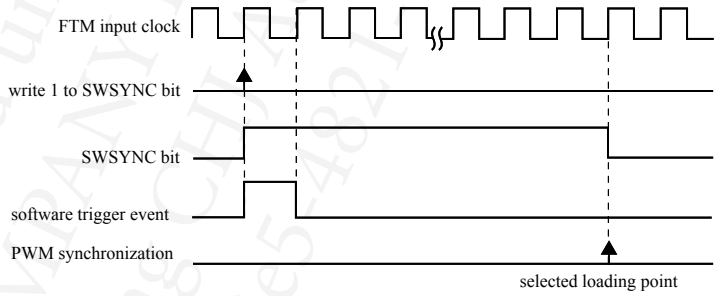

Figure 280. Software trigger event

43.5.13.3 Synchronization Points

The synchronization points are points where the registers can be updated with their write buffer by PWM synchronization. These synchronization points are safe points because guarantee smooth transitions in the generated PWM signals.

In Up counting, the synchronization points are when the FTM counter changes from MOD to CNTIN. In this case, the synchronization points are enabled if (CNTMIN = 1) or (CNTMAX = 1).

In Up-down counting, the synchronization points are:

- if (CNTMAX = 1), when the FTM counter changes from (MOD) to (MOD - 1);
- if (CNTMIN = 1), when the FTM counter changes from (CNTIN) to (CNTIN + 1).

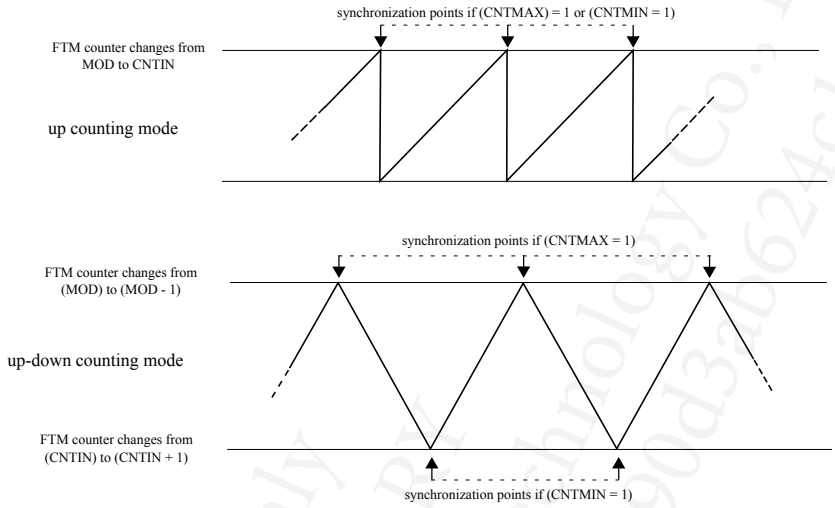

Figure 281. Synchronization Points

43.5.13.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

c8c462e5-4821-48a8-9251-390d3a624c1

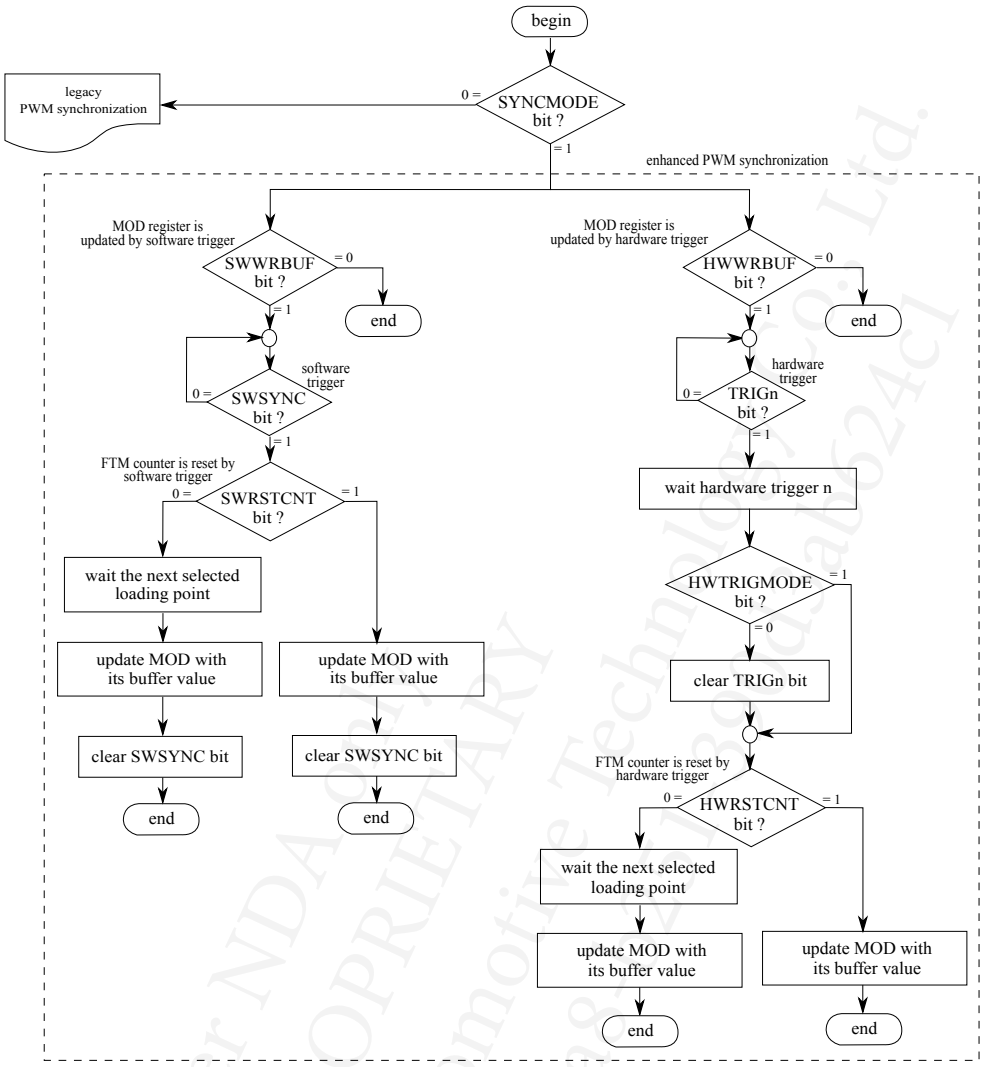

Figure 282. MOD register synchronization flowchart

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 0), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the trigger enable bit (TRIGn) is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

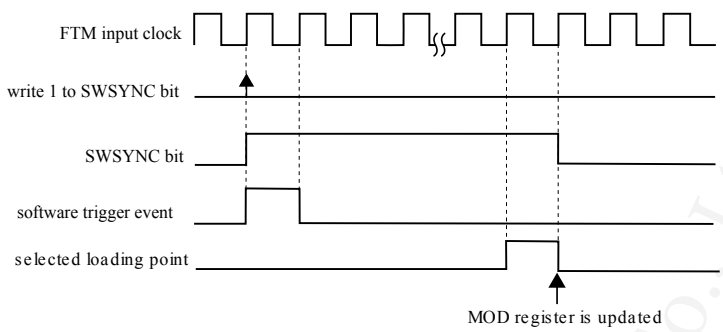

Figure 283. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 0), and software trigger was used

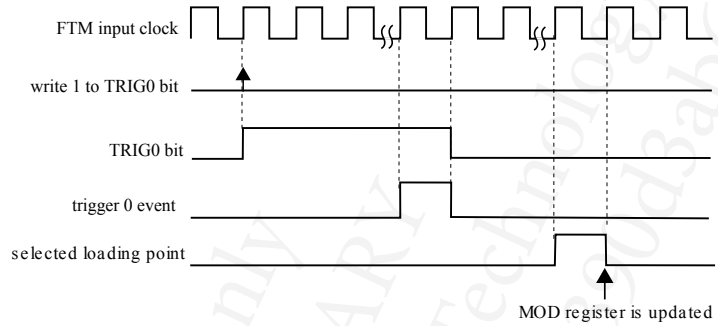

Figure 284. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 1), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

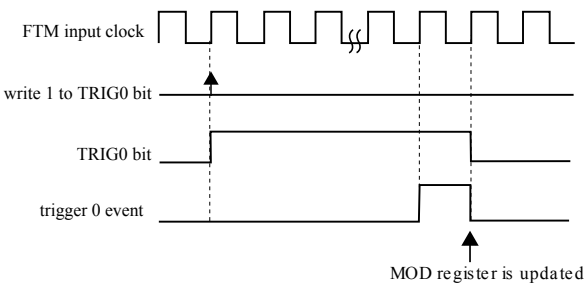

Figure 286. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

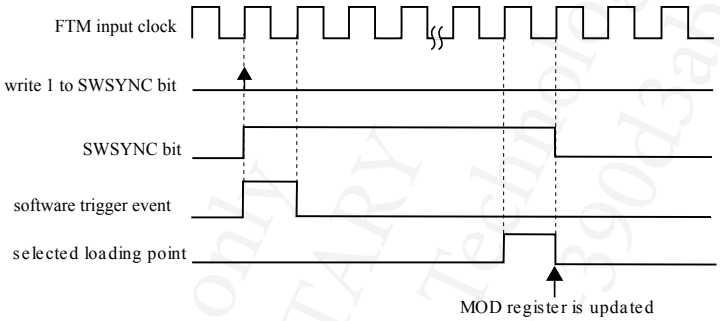

Figure 287. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)

43.5.13.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see MOD register synchronization.

43.5.13.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the MOD register synchronization. However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

43.5.13.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of FTM input clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

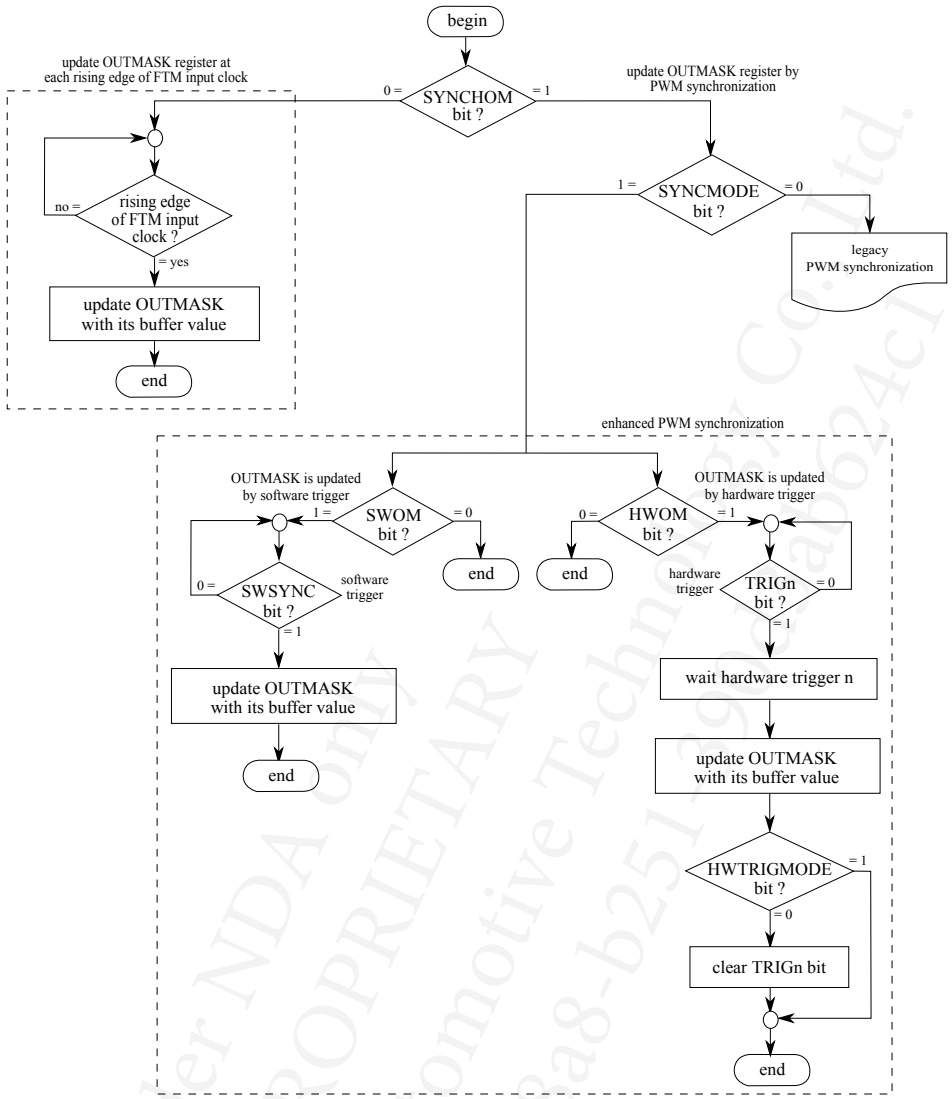

Figure 288. OUTMASK register synchronization flowchart

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

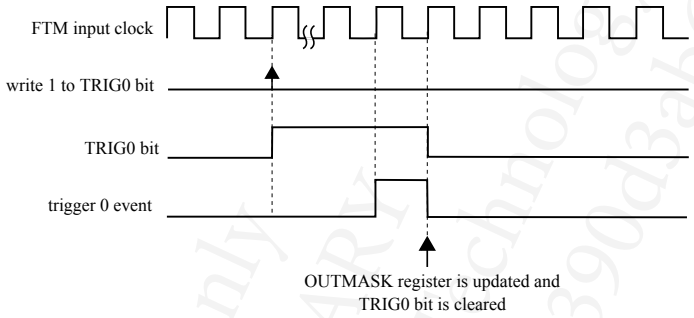

Figure 290. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to Hardware trigger. An example with a hardware trigger follows.

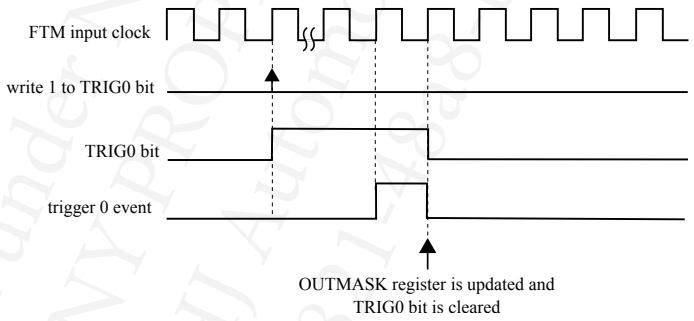

Figure 291. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used

43.5.13.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of FTM input clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

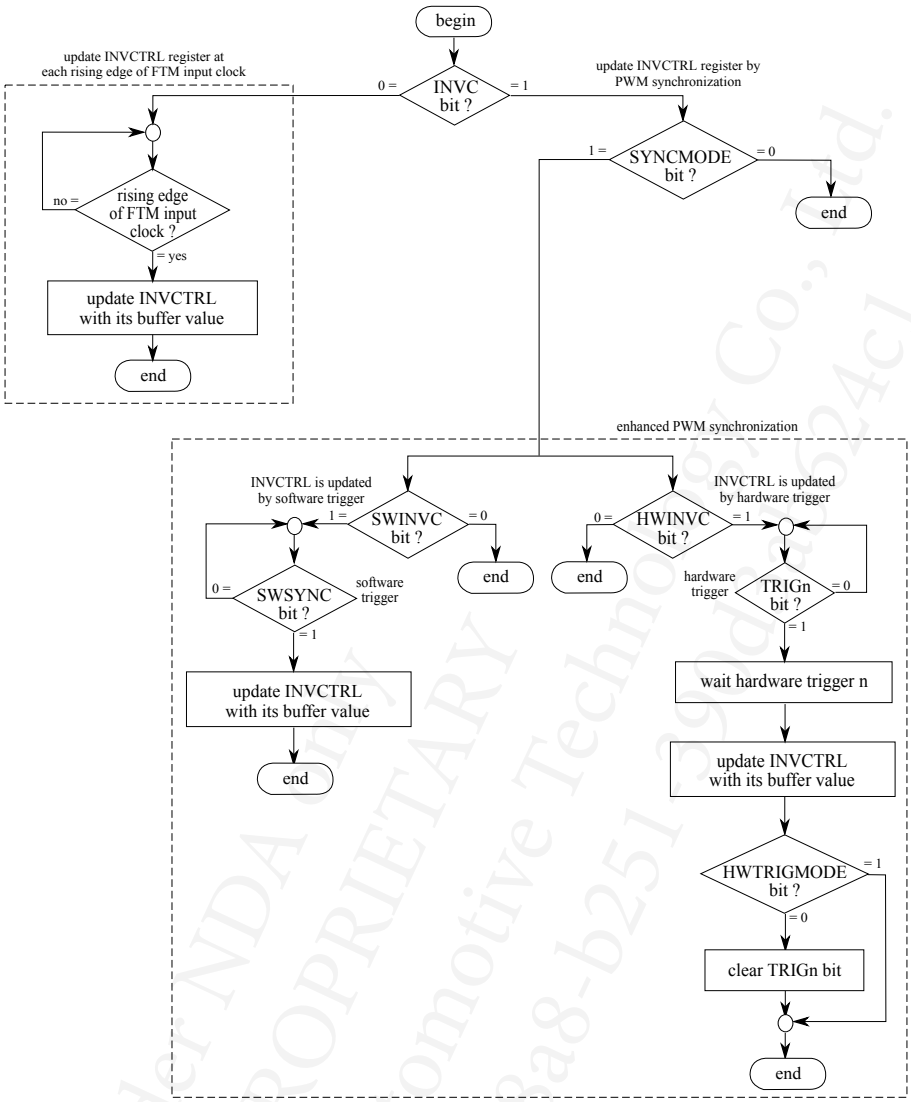

Figure 292. INVCTRL register synchronization flowchart

43.5.13.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of FTM input clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

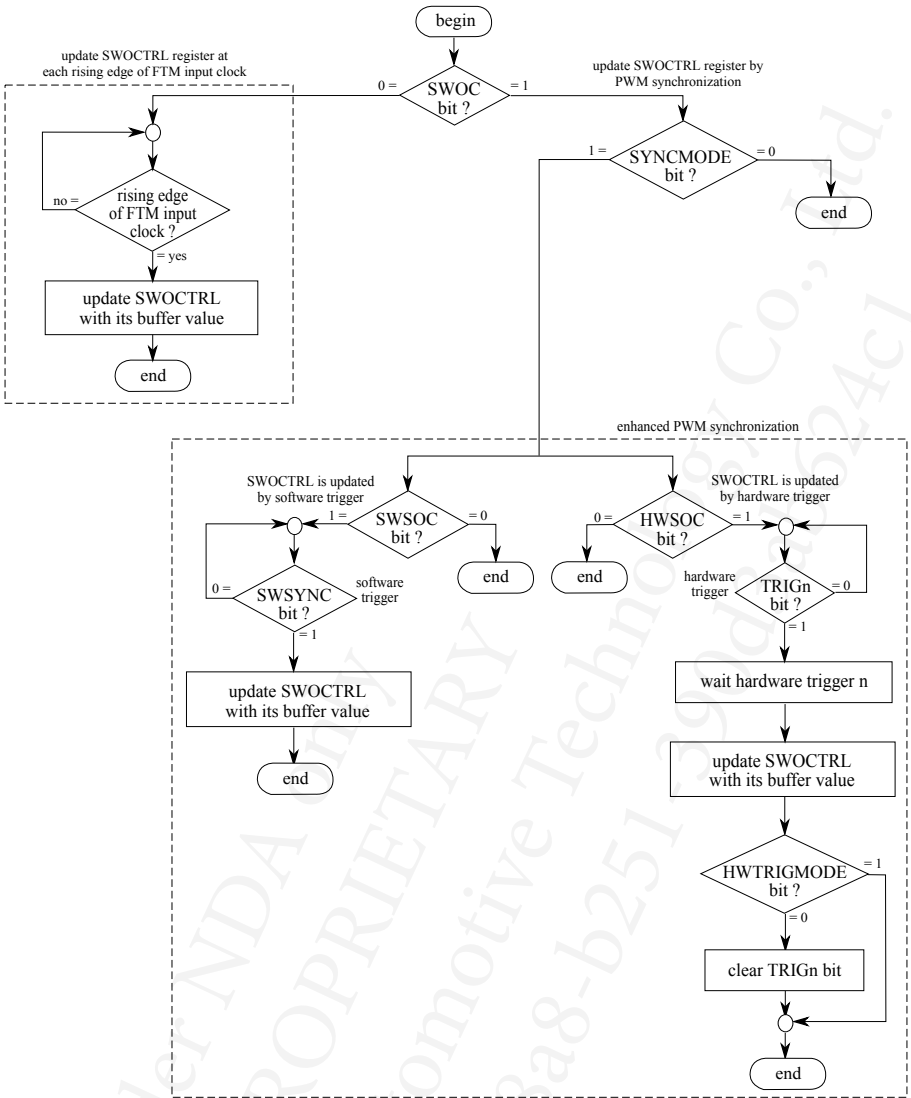

Figure 293. SWOCTRL register synchronization flowchart

43.5.13.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n+1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

Beijing CT Automotive Technology Co., Ltd.
c8c46a21-48a8-b251-1908-6924c1

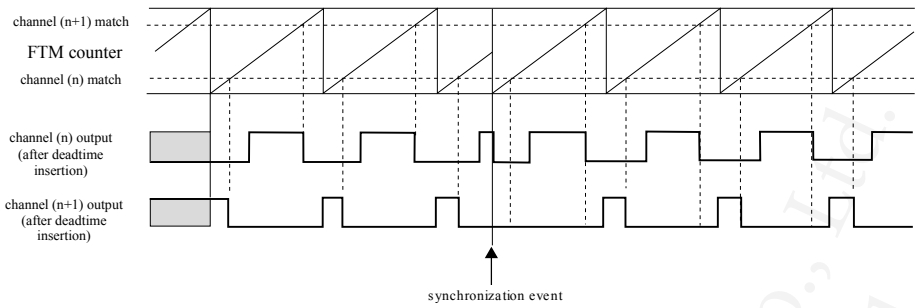

Figure 294. FTM counter synchronization

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

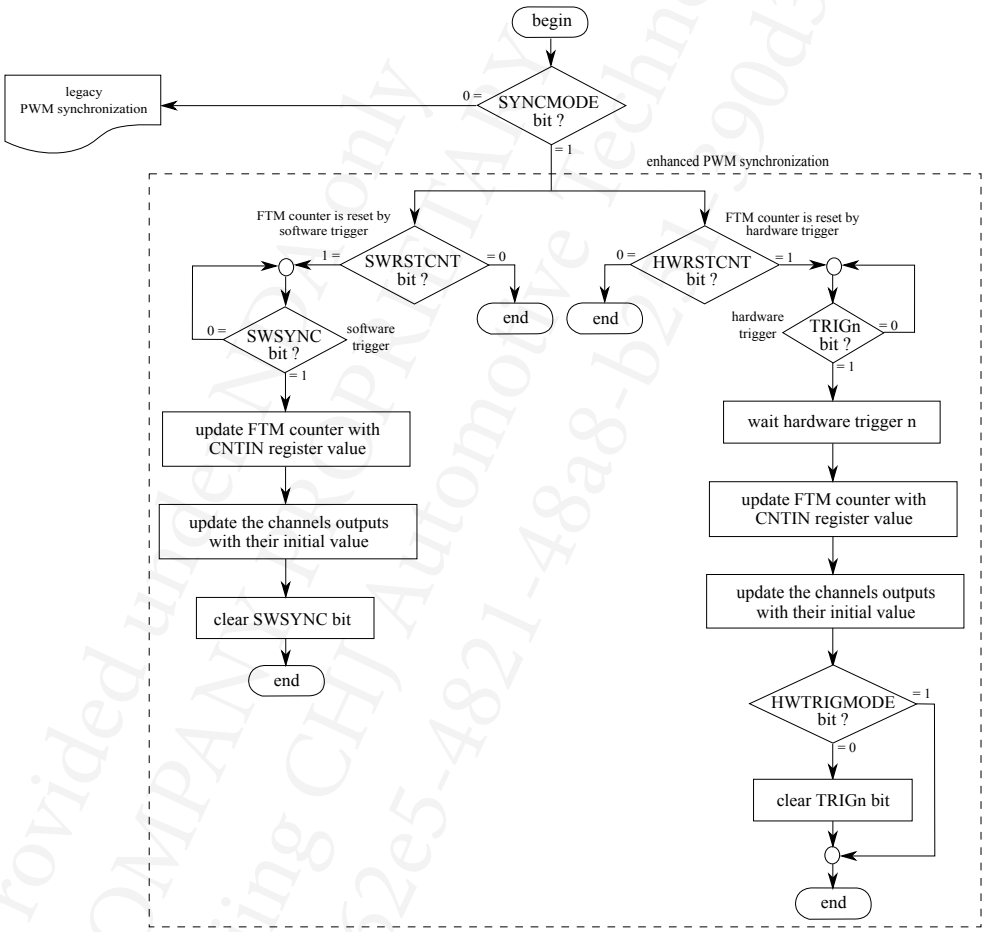

Figure 295. FTM counter synchronization flowchart

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger

event was a hardware trigger then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

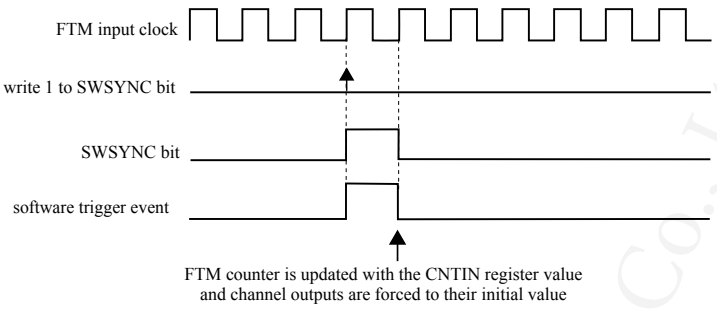

Figure 296. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used

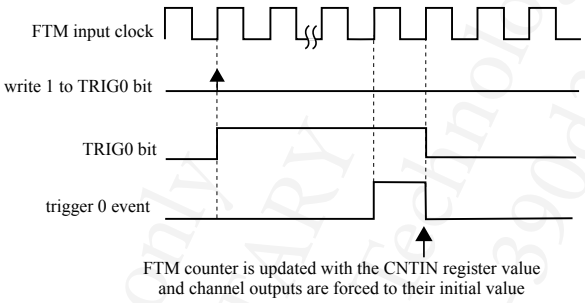

Figure 297. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to Hardware trigger.

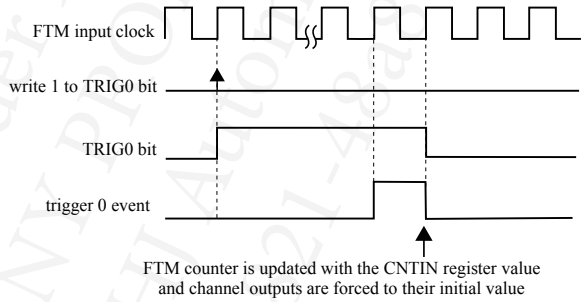

Figure 298. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used

43.5.14 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INVm = 1 (where m represents a channel pair)

The INVm bit in INVCTRL register is updated with its buffer value according to INVCTRL register synchronization.

In combine mode with channel (n) ELSB:ELSA = 1:0, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

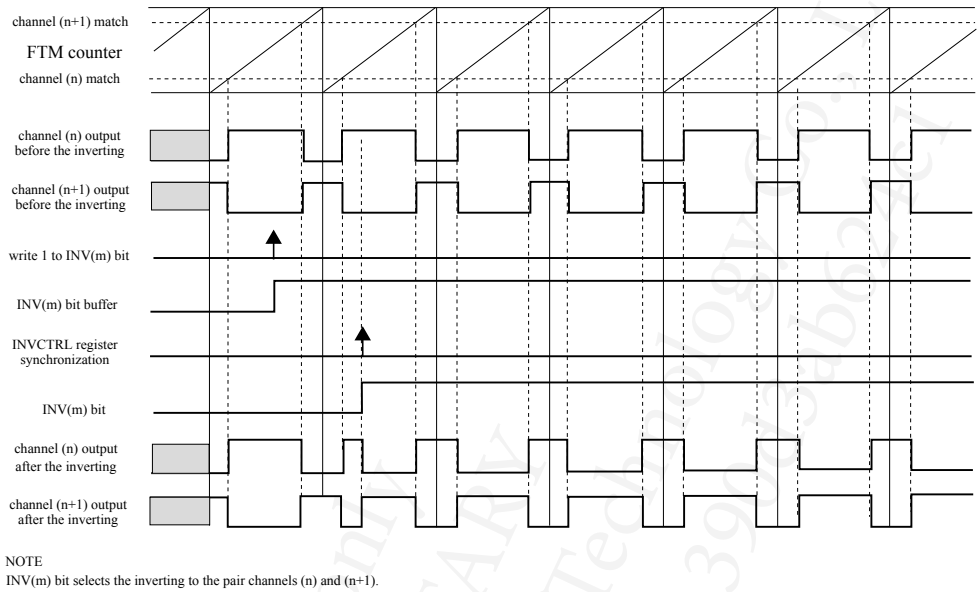

Figure 299. Channels (n) and (n+1) outputs after the inverting in combine mode with channel (n) ELSB:ELSA = 1:0

Note that the channel (n) ELSB:ELSA bits should be considered because they define the active state of the channels outputs. In combine mode with channel (n) ELSB:ELSA = X:1, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

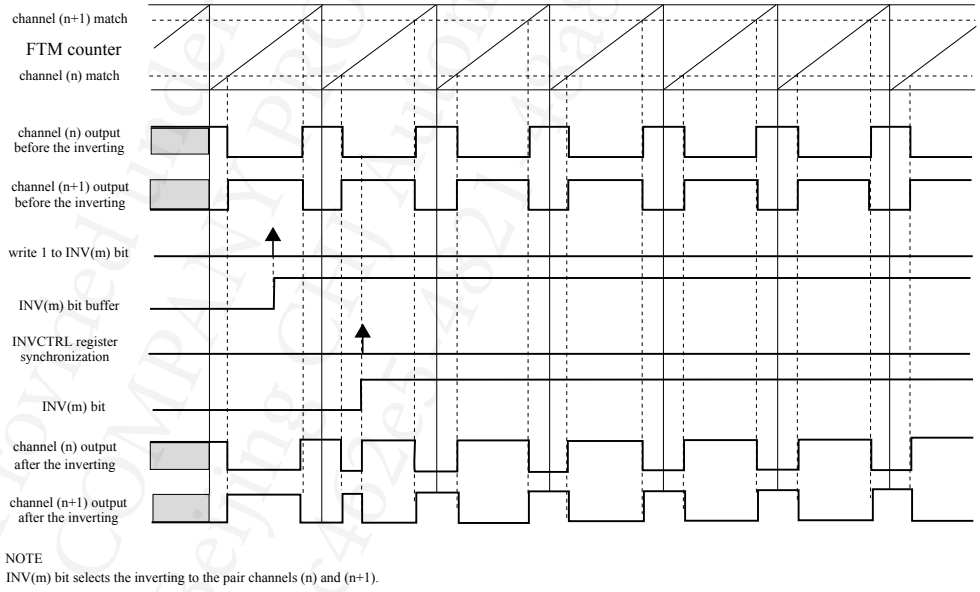

Figure 300. Channels (n) and (n+1) outputs after the inverting in combine mode with channel (n) ELSB:ELSA = X:1

NOTE

The Inverting is not available in Output Compare mode and Modified Combine PWM Mode.

43.5.15 Software Output Control Mode

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CH(n)OC = 1

The CH(n)OC bit enables the software output control for a specific channel output and the CH(n)OCV selects the value that is forced to this channel output.

Both CH(n)OC and CH(n)OCV bits in SWOCTRL register are buffered and updated with their buffer value according to SWOCTRL register synchronization.

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

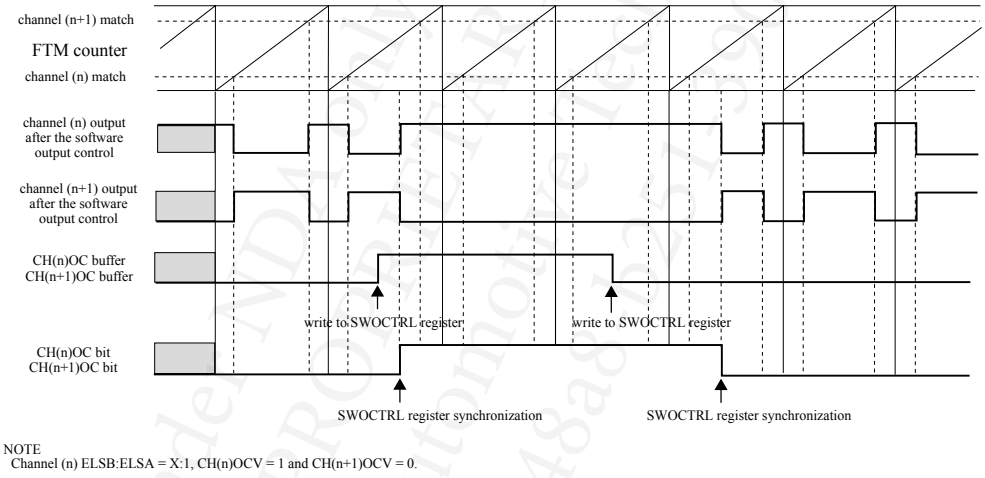

Figure 301. Example of software output control in Combine and Complementary mode

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

Table 276. Software ouput control behavior when (COMP = 0)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to one

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

Table 277. Software ouput control behavior when (COMP = 1)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to zero

NOTE

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

43.5.16 Deadtime insertion

The deadtime insertion is enabled when DTEN is set and the concatenation {DTVALEX[3:0], DTVAL[5:0]} is non-zero.

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The clock for the DEADTIME delay is the FTM input clock divided by DTPS bits, and the {DTVALEX[3:0], DTVAL[5:0]} bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If POL(n) = 0, POL(n+1) = 0, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If POL(n) = 1, POL(n+1) = 1, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n+1) output is cleared.

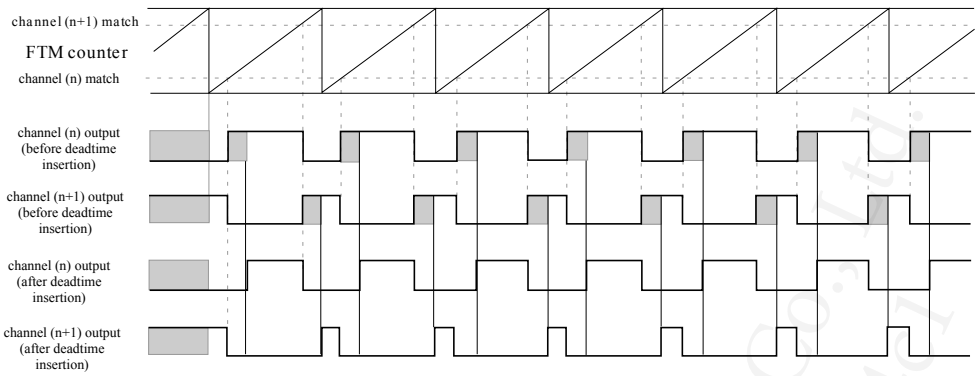

Figure 302. Deadtime insertion with ELSB:ELSA = 1:0, POL(n) = 0, and POL(n+1) = 0

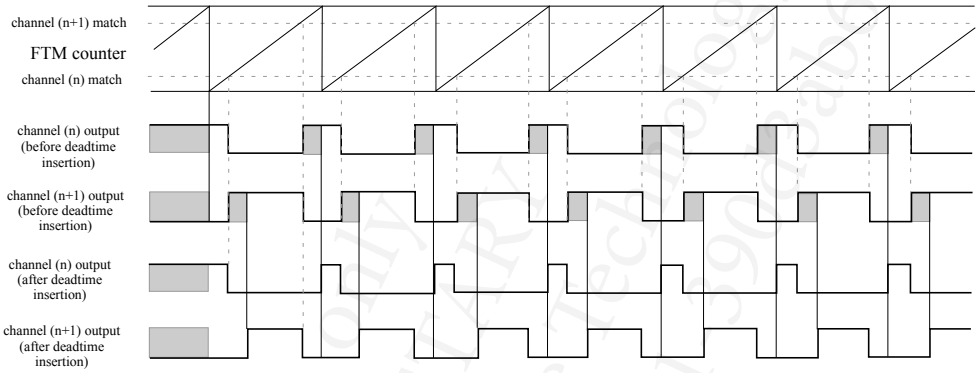

Figure 303. Deadtime insertion with ELSB:ELSA = X:1, POL(n) = 0, and POL(n+1) = 0

NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

43.5.16.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ((C(n+1)V – C(n)V) × FTM input clock), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ((MOD – CNTIN + 1 – (C(n+1)V – C(n)V)) × FTM input clock), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

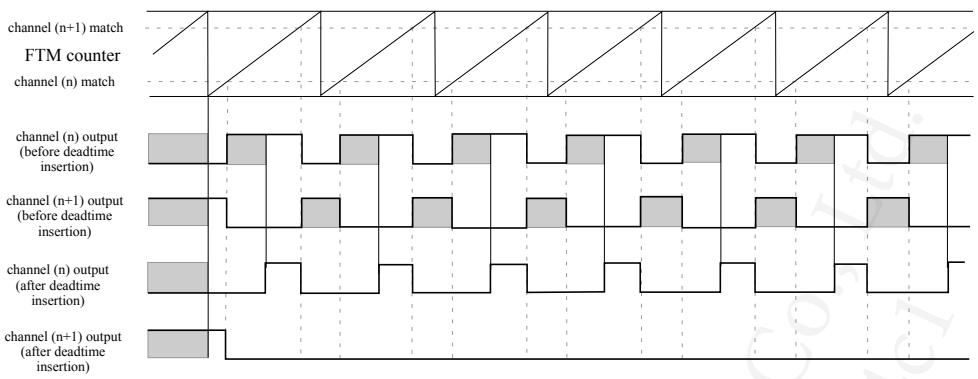

Figure 304. Example of the deadtime insertion (channel (n) ELSB:ELSA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle

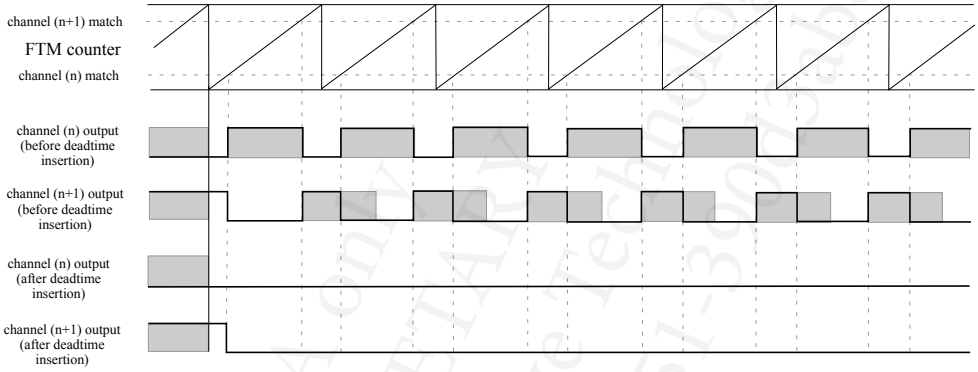

Figure 305. Example of the deadtime insertion (channel (n) ELSB:ELSA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle

43.5.17 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see OUTMASK register synchronization.

If CH(n)OM = 1, then the channel (n) output is forced to its inactive state (POLn bit value). If CH(n)OM = 0, then the channel (n) output is unaffected by the output mask. See the following figure.

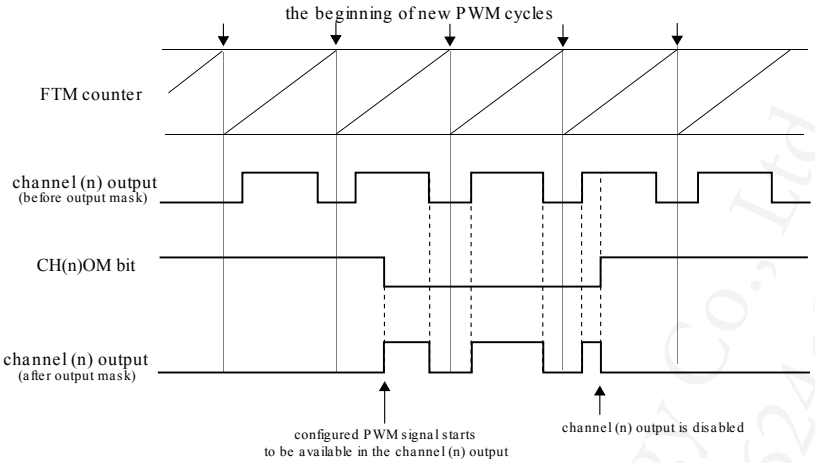

Figure 306. Output mask with POLn = 0

The following table shows the output mask result before the polarity control.

Table 278. Output mask result for channel (n) before the polarity control

CH(n)OM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	

43.5.18 Polarity Control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

43.5.19 Initialization

The initialization forces the CH(n)OI bit value to the channel (n) output when 1 is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

Table 279. Initialization behavior when (COMP = 0 and DTEN = 0)

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	0	is forced to zero	is forced to zero
0	1	is forced to zero	is forced to one
1	0	is forced to one	is forced to zero
1	1	is forced to one	is forced to one

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

Table 280. Initialization behavior when (COMP = 1 or DTEN = 1)

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	X	is forced to zero	is forced to one
1	X	is forced to one	is forced to zero

NOTE

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

43.5.20 Features Priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

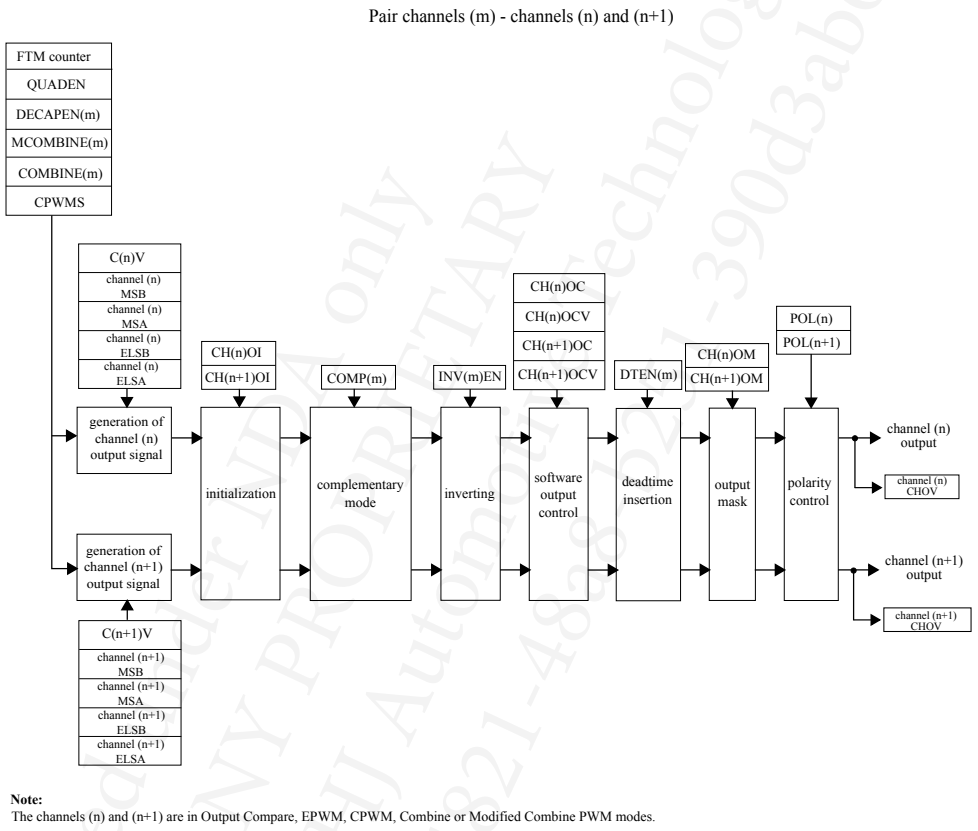

Figure 307. Priority of the features usead at the generation of channels (n) and (n+1) output

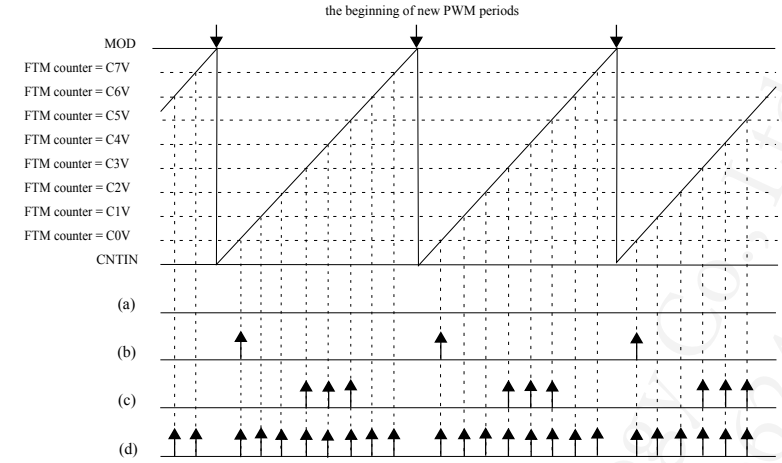

NOTE

The Initialization must not be used with Inverting and Software Output Control Mode.

43.5.21 External Trigger

If the CH(n)TRIG bit (register EXTTRIG) is set, where n = 0, 1, 2, 3, 4, 5, 6 or 7, then the FTM generates a trigger when the channel (n) match occurs (FTM counter = C(n)V) at the FTM external trigger output.

The width of a channel (n) trigger is one FTM input clock and the FTM is able to generate multiple triggers in one PWM period. See the figure below.

Note
(a) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0, CH6TRIG = 0, CH7TRIG = 0
(b) CH0TRIG = 1, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0, CH6TRIG = 0, CH7TRIG = 0
(c) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1, CH6TRIG = 0, CH7TRIG = 0
(d) CH0TRIG = 1, CH1TRIG = 1, CH2TRIG = 1, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1, CH6TRIG = 1, CH7TRIG = 1

Figure 308. External Trigger

43.5.22 Initialization Trigger

Initialization trigger allows FTM to generate a trigger in some specific points of FTM counter cycle. This feature is controlled by the bits INITTRIGEN and ITRIGR. The INITTRIGEN bit enables the initialization trigger generation and the ITRIGR bit selects when the initialization trigger is generated.

If INITTRIGEN = 1 and ITRIGR = 1, then the initialization trigger is generated when FTM counter reaches a reload point according to the frequency of the reload opportunities (Reload Points).

NOTE

For this configuration of initilization trigger and in CPWM mode, the bits CNTMAX and CNTMIN select where the initialization trigger is generated.

If INITTRIGEN = 1 and ITRIGR = 0, then the initialization trigger is generated when FTM counter is updated with the CNTIN register value. See the cases below.

1. When FTM counter is updated with CNTIN register value automatically.

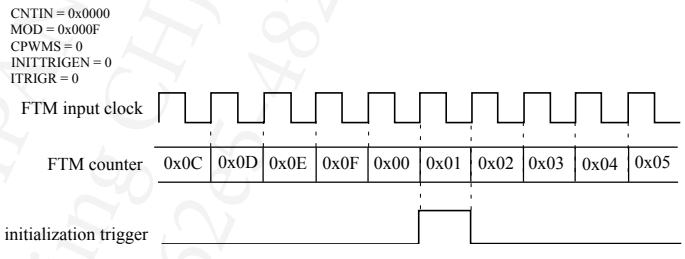

Figure 309. Example of the generation of the initialization trigger in the case 1.

2. When there is a write to CNT register.

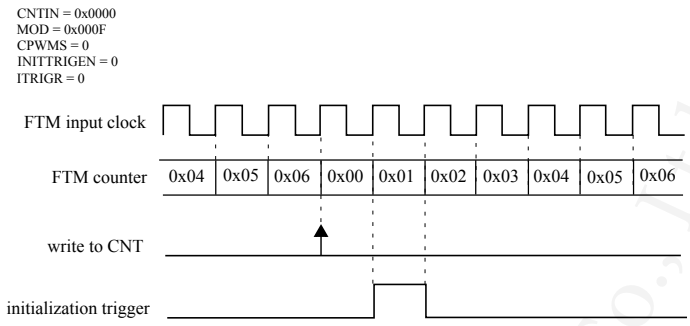

Figure 310. Example of the generation of the initialization trigger in the case 2.

NOTE

This behavior is not available in CPWM mode.

3. When there is the FTM counter synchronization.

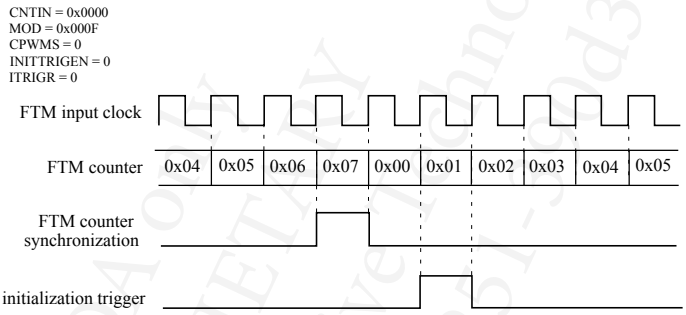

Figure 311. Example of the generation of the initialization trigger in the case 3.

NOTE

This behavior is not available in CPWM mode.

4. If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.

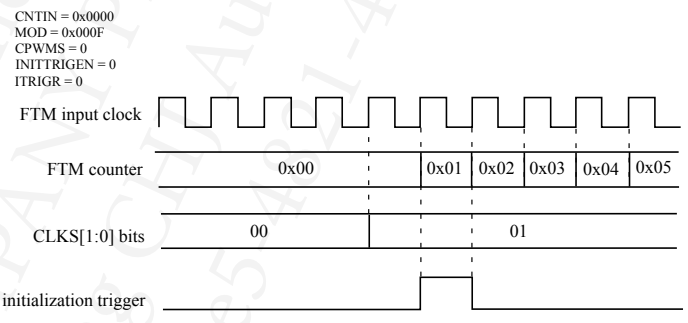

Figure 312. Example of the generation of the initialization trigger in the case 4.

NOTE

This behavior is not available in CPWM mode.

43.5.23 Capture Test Mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for Input Capture Mode and FTM counter must be configured to the Up counting.

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

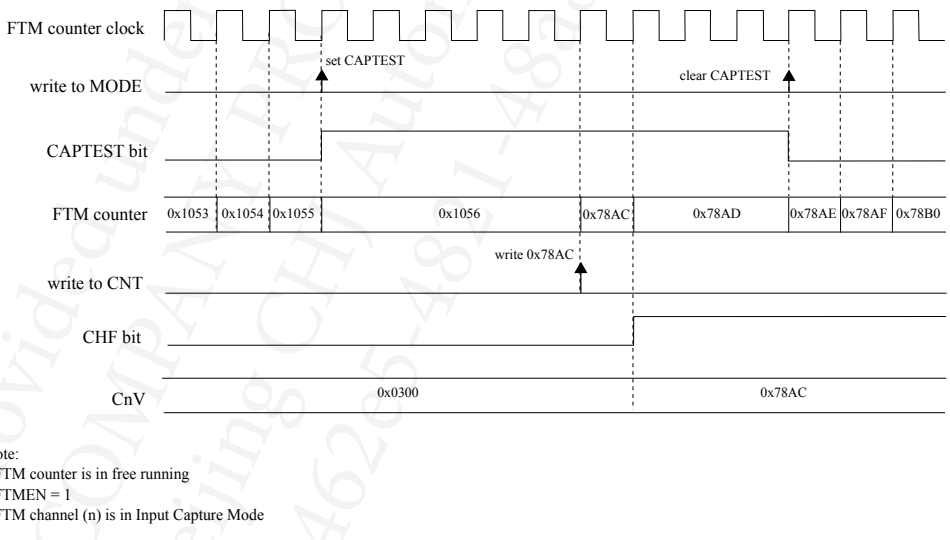

Figure 314. Capture Test Mode

43.5.24 DMA

The channel generates a DMA transfer request according to DMA and CHIE bits. See the following table.

Table 281. Channel DMA transfer request

DMA	CHIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHF = 1).	The channel interrupt is not generated.

If DMA = 1, the CHF bit is cleared either by channel DMA transfer done or reading CnSC while CHF is set and then writing a zero to CHF bit according to CHIE bit. See the following table.

Table 282. Clear CHF bit when DMA = 1

CHIE	How CHF Bit Can Be Cleared
0	CHF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHF is set and then writing a 0 to CHF bit.
1	CHF bit is cleared when the channel DMA transfer is done.

43.5.25 Dual Edge Capture Mode

The dual edge capture mode is enabled if DECAPEN = 1. This mode allows to measure a pulse width or period of the channel (n) input where n = 0, 2, 4 or 6. The channel (n) filter can be enabled for n = 0 or 2.

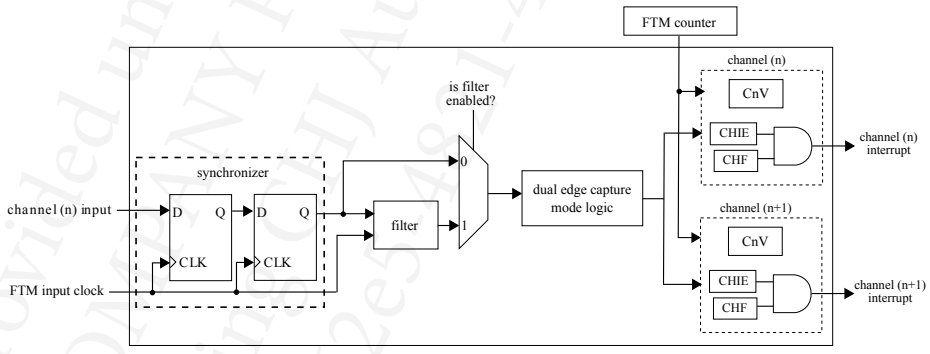

Figure 315. Diagram for Dual Edge Capture Mode when FLTPS[3:0] = 0

COMPANY PROPRIETARY
Beijing eGTJ Automotive Technology Co., Ltd.
c8c62e54821-4848-b25f-590c3a624d

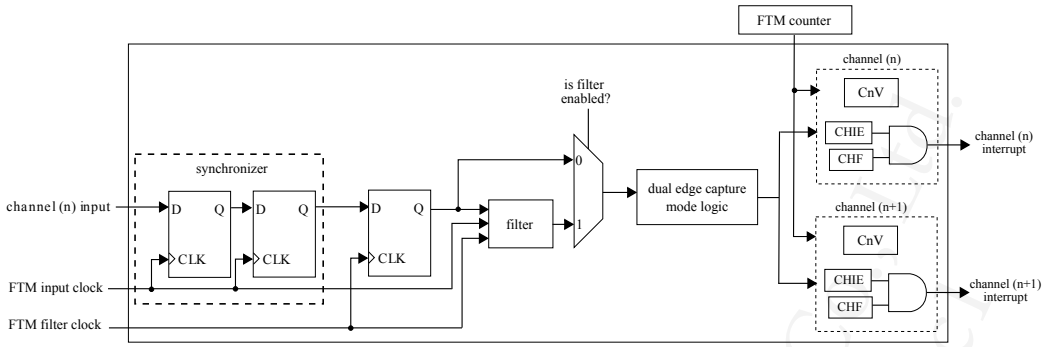

Figure 316. Diagram for Dual Edge Capture Mode when FLTPS[3:0] ≠ 0

The channel (n) MSA bit defines if the dual edge capture mode is one-shot or continuous.

The channel (n) ELSB:ELSA bits select the edge that is captured by channel (n), and channel (n+1) ELSB:ELSA bits select the edge that is captured by channel (n+1). If both channel (n) ELSB:ELSA and channel (n+1) ELSB:ELSA bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the dual edge capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then channel (n) CHF bit is set and the channel (n) interrupt is generated (if channel (n) CHIE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (channel (n) CHF = 1), then channel (n+1) CHF bit is set and the channel (n+1) interrupt is generated (if channel (n+1) CHIE = 1).

The C(n)V register stores the FTM counter value when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the FTM counter value when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism (for channels (n) and (n+1)) ensures coherent data when the C(n)V and C(n+1)V registers are read. The only requirement is that C(n)V must be read before C(n+1)V.

NOTE

- The dual edge capture mode must be used with channel (n) ELSB:ELSA = 0:1 or 1:0, channel (n+1) ELSB:ELSA = 0:1 or 1:0 and the FTM counter in Free running counter.

43.5.25.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (channel (n) MSA = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The channel (n) ELSB:ELSA bits select the first edge to be captured, and channel (n+1) ELSB:ELSA bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the channel (n) CHF and channel (n+1) CHF bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the channel (n+1) CHF bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

43.5.25.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (channel (n) MSA = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The channel (n) ELSB:ELSA bits select the initial edge to be captured, and channel (n+1) ELSB:ELSA bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the channel (n) CHF and channel (n+1) CHF bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the channel (n+1) CHF bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the channel (n+1) CHF bit. Therefore, when the channel (n+1) CHF bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the channel (n) CHF and channel (n+1) CHF bits to start new measurements.

43.5.25.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (channel (n) ELSB:ELSA = 0:1) and the channel (n+1) to capture falling edges (channel (n+1) ELSB:ELSA = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (channel (n) ELSB:ELSA = 1:0) and the channel (n+1) to capture rising edges (channel (n+1) ELSB:ELSA = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in One-Shot Capture mode or Continuous Capture mode.

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The channel (n) CHF bit is set when the first edge of this pulse is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. Both DECAP and channel (n+1) CHF bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

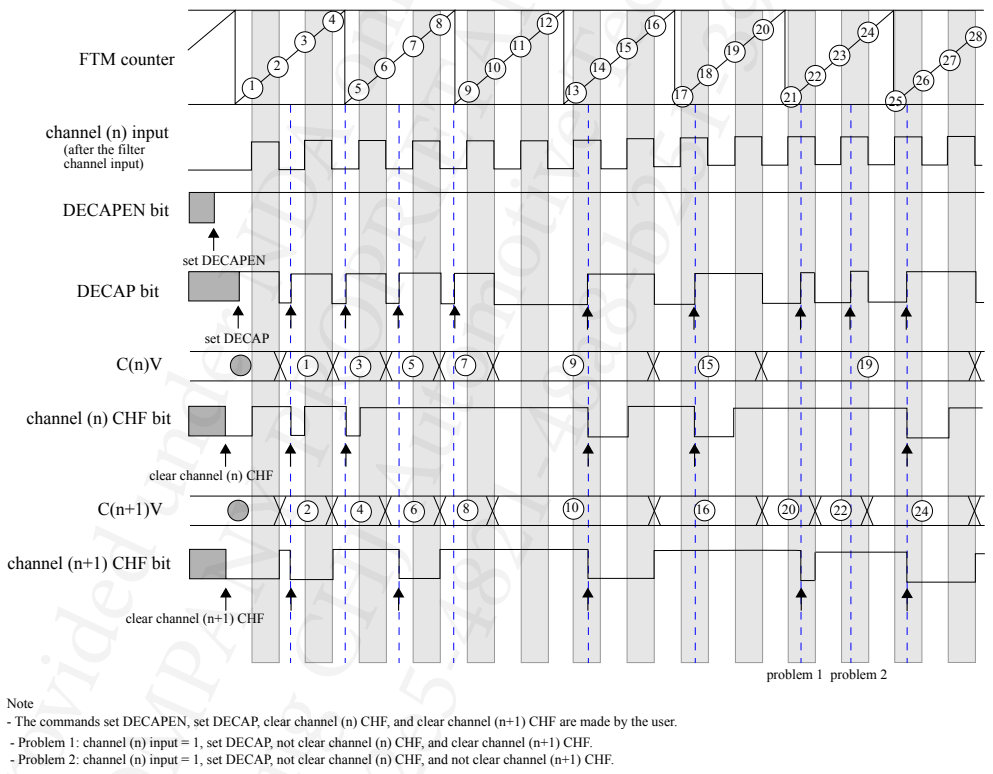

Figure 317. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement

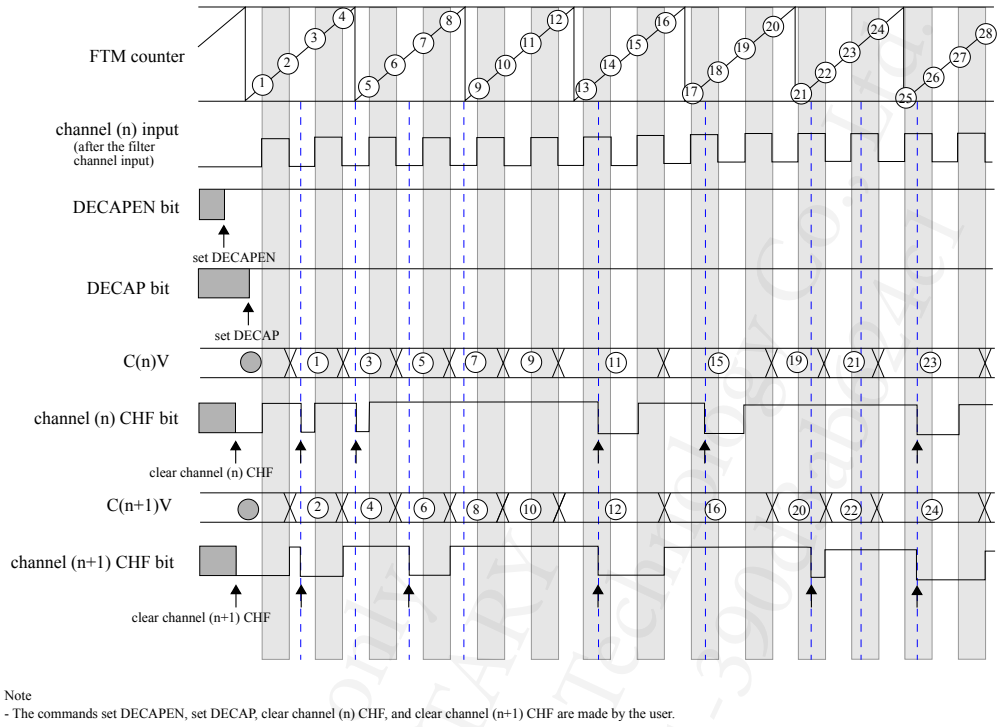
The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The channel (n) CHF bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set when the second edge of this pulse is detected,

that is, the edge selected by channel (n+1) ELSB:ELSA bits. The channel (n+1) CHF bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.



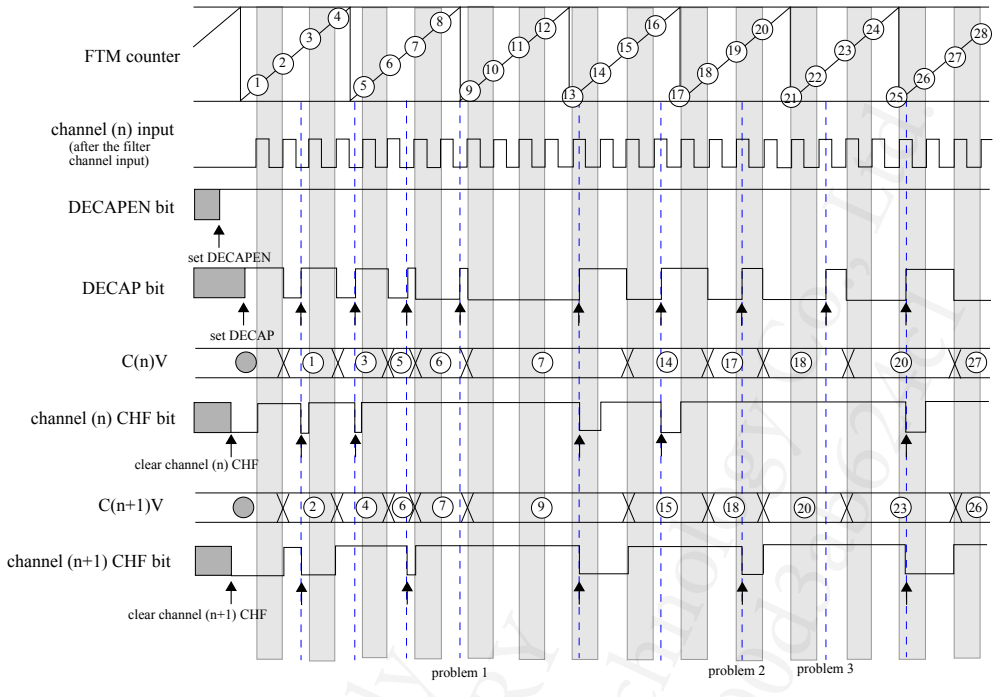


Figure 318. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement

43.5.25.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges (channel (n) ELSB:ELSA = 0:1 and channel (n+1) ELSB:ELSA = 0:1), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges (channel (n) ELSB:ELSA = 1:0 and channel (n+1) ELSB:ELSA = 1:0), then the period between two consecutive falling edges is measured.

The period measurement can be made in One-Shot Capture mode or Continuous Capture mode.

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next period. The channel (n) CHF bit is set when the first rising edge is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. Both DECAP and channel (n+1) CHF bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note
- The commands set DECAPEN, set DECAP, clear channel (n) CHF, and clear channel (n+1) CHF are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear channel (n) CHF, and not clear channel (n+1) CHF.
- Problem 2: channel (n) input = 1, set DECAP, not clear channel (n) CHF, and clear channel (n+1) CHF.
- Problem 3: channel (n) input = 1, set DECAP, not clear channel (n) CHF, and not clear channel (n+1) CHF.

Figure 319. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The channel (n) CHF bit is set when the first rising edge is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set when the second rising edge is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. The channel (n+1) CHF bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.

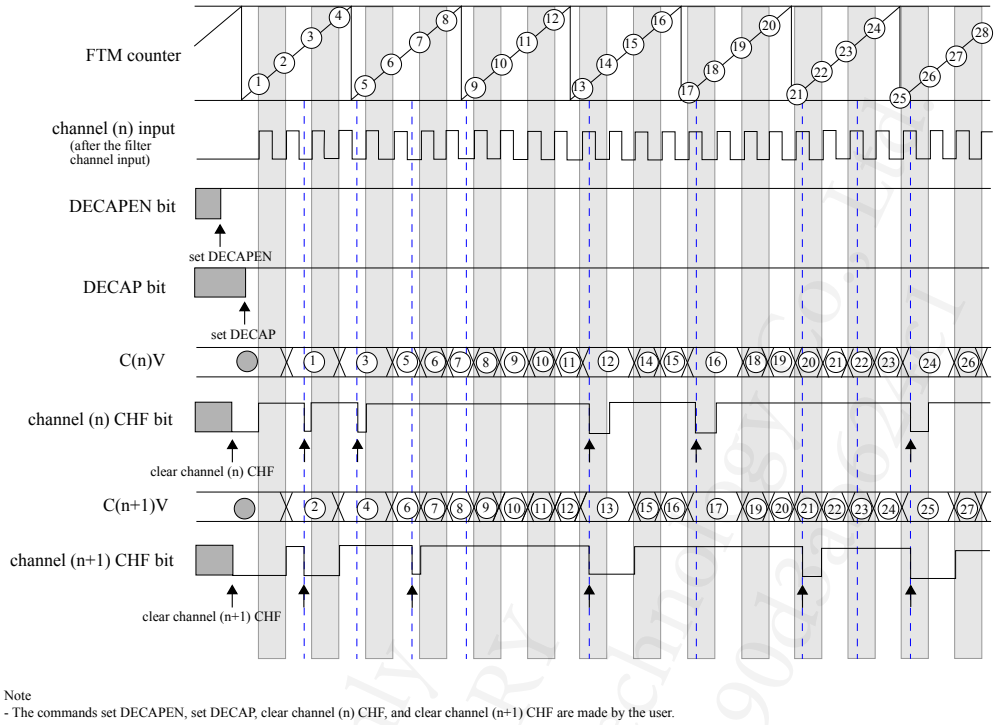

Figure 320. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges

43.5.25.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal. C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

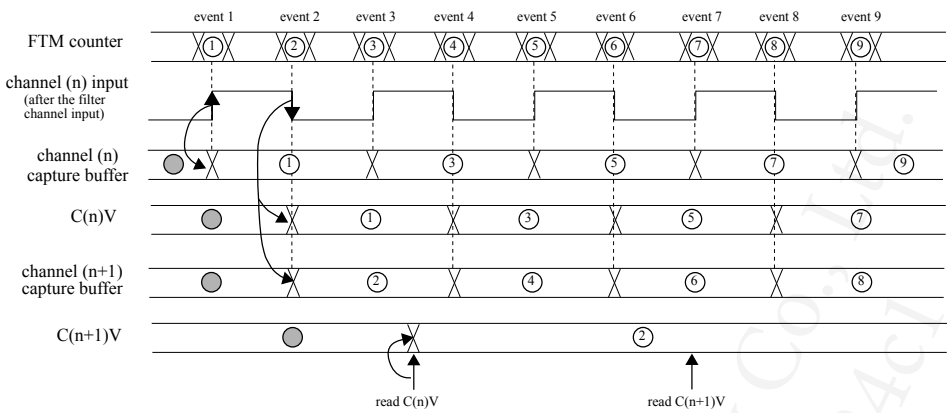

Figure 321. Dual Edge Capture mode read coherency mechanism

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

43.5.26 Quadrature Decoder Mode

The quadrature decoder mode is enabled if QUADEN = 1. The quadrature decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement.

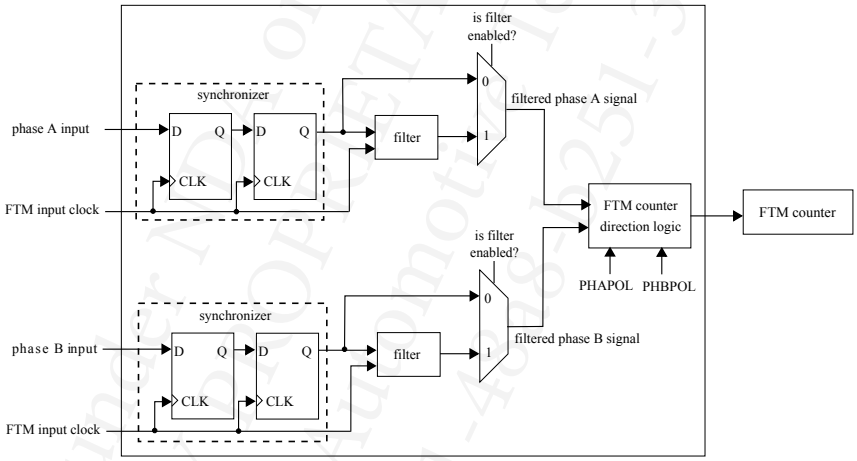

Figure 322. Diagram for Quadrature Decoder when FLTPS[3:0] = 0

Provided under NDA ONLY
COMPANY PROPRIETARY
Beijing CHIPTOP Technology Co., Ltd.
c8c462e5-4821-4819-b251-390d3a1624c1

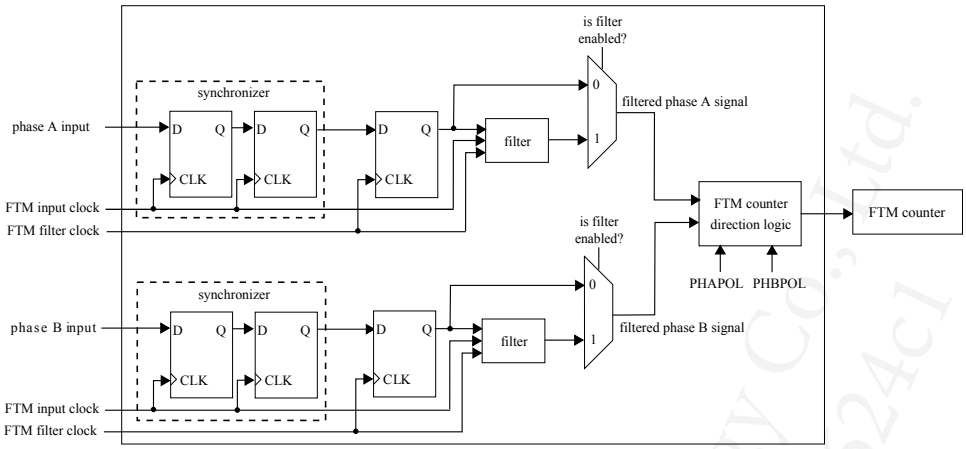

Figure 323. Diagram for Quadrature Decoder when FLTPS[3:0] ≠ 0

Each one of input signals phase A and B has a filter that is equivalent to the channel input filter (Filter for Input Capture Mode). The phase A input filter is enabled by PHAFLTREN bit and its value is defined by CH0FVAL[3:0] bits. The phase B input filter is enabled by PHBFLTREN bit and its value is defined by CH1FVAL[3:0] bits.

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in quadrature decoder mode.

NOTE

The FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is enabled. Therefore it is expected that the quadrature decoder mode be used only with the FTM channels in input capture or output compare modes.

NOTE

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADMODE selects the encoding mode used in the quadrature decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

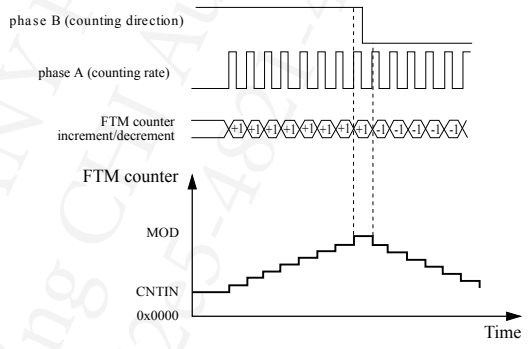

Figure 324. Quadrature Decoder – Count and Direction Encoding mode

If QUADMODE = 0, then the phase A and phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

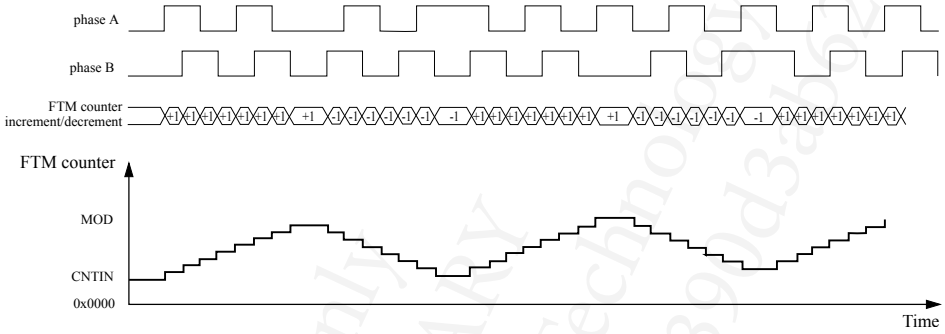

Figure 325. Quadrature Decoder – Phase A and Phase B Encoding Mode

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

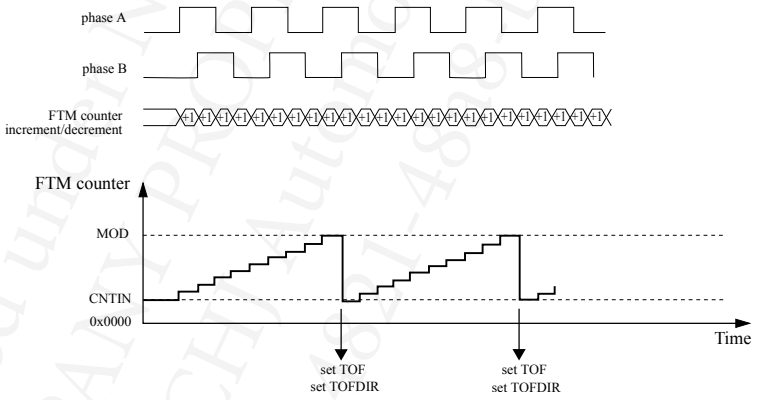

Figure 326. FTM Counter Overflow in Up Counting for Quadrature Decoder Mode

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

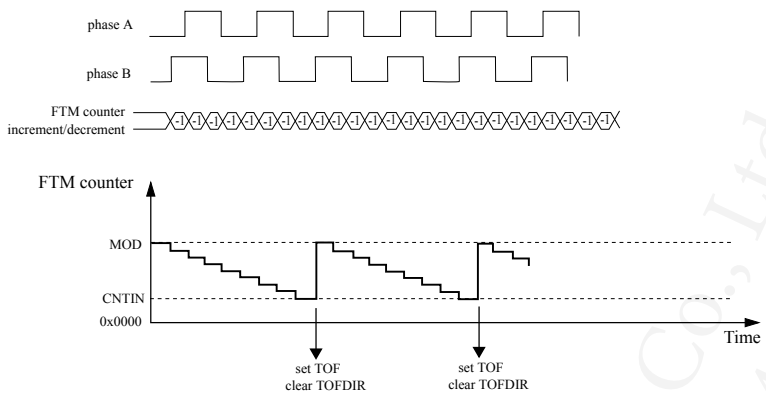

Figure 327. FTM Counter Overflow in Down Counting for Quadrature Decoder Mode

43.5.26.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

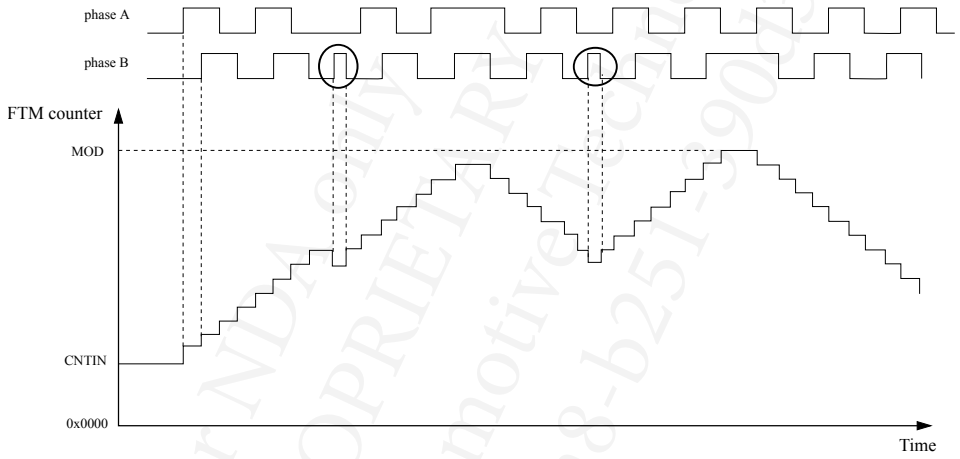

Figure 328. Motor position jittering in a mid count value

The following figure shows motor jittering produced by the phase B and A pulses respectively:

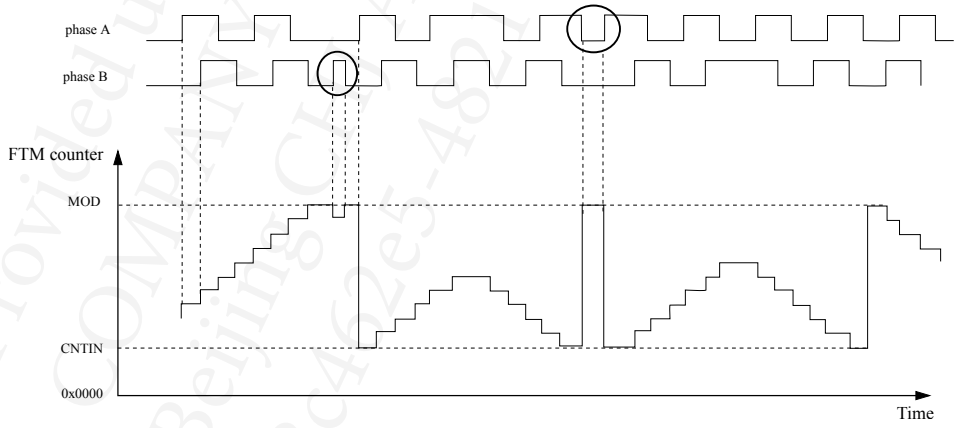

Figure 329. Motor position jittering near maximum and minimum count value

Provided under NDA only
COMPANY PROPRIETARY
Beijing CIAT Automotive Technology Co., Ltd.
8c42e3-482-18a8-b251-90d3b624c1

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

43.5.27 Debug mode

When the chip is in Debug mode, the BDMMODE[1:0] bits select the behavior of the FTM counter, the channel (n) CHF bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

Table 283. FTM behavior when the chip Is in Debug mode

BDMMODE	FTM Counter	channel (n) CHF bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
00	Stopped	can be set	Functional mode	Writes to these registers bypass the registers buffers
01	Stopped	is not set	The channels outputs are forced to their safe value according to POLn bit	Writes to these registers bypass the registers buffers
10	Stopped	is not set	The channels outputs are frozen when the chip enters in Debug mode	Writes to these registers bypass the registers buffers
11	Functional mode	can be set	Functional mode	Functional mode

Note that if BDMMODE[1:0] = 2’b00 then the channels outputs remain at the value when the chip enters in Debug mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this Debug mode.

- Write any value to CNT register; see Counter reset. In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see FTM counter synchronization. In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See Initialization.

NOTE

If CLKS[1:0] = 2'b00 in Debug, a non-zero value is written to CLKS in Debug, and CnV = CNTIN when the Debug is disabled, then the CHF bit is set (since if the channel is a 0% EPWM signal) when the Debug is disabled.

43.5.28 Reload Points

This feature allows to update the registers CNTIN, HCR, MOD and C(n)V with the value of their write buffer at the selected reload point.

NOTE

- This feature is independent of the PWM synchronization.
- At these reload points neither the channels outputs nor the FTM counter are changed. Software must select these reload points at the safe points in time.

43.5.28.1 Reload Opportunities

The reload opportunities are:

1. At the half cycle

   This reload opportunity is enabled if (HCSEL = 1) and it happens at the half cycle (FTM counter = HCR register). The software should calculate the half cycle value according to the FTM counter configuration, then writes this value to the register HCR.

2. At the channel (n) match

   This reload opportunity is enabled if (CH(n)SEL = 1) and it happens at the channel (n) match (FTM counter = C(n)V).

3. When the FTM counter is an up counter

   This reload opportunity is when the FTM counter changes from (MOD) to (CNTIN - 1) and it is always enabled.

   The following figure shows an example of the reload opportunities at the half cycle, at the channels match, and when the FTM counter is an up counter.

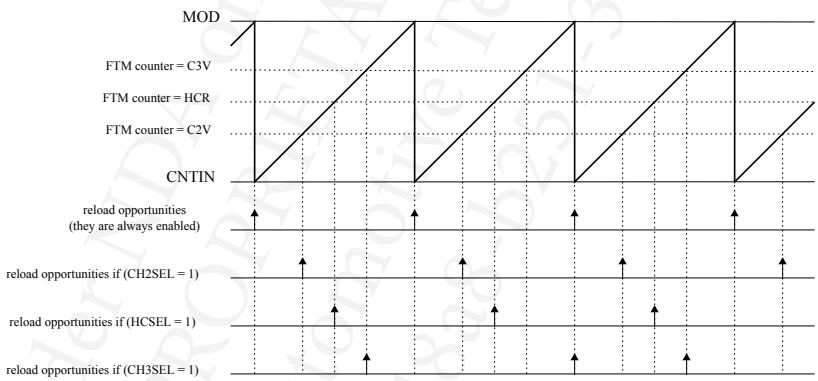

Figure 330. Reload opportunities when the FTM counter is an up counter

4. When the FTM counter is an up-down counter

   In this case, the reload opportunities are enabled by the bits CNTMAX and CNTMIN according to Table 284.

Table 284. Reload opportunities enabled by the bits CNTMAX and CNTMIN when the FTM counter is up-down counter

CNTMAX	CNTMIN	Reload Opportunities
0	0	when the FTM counter changes from (MOD) to (MOD - 1)
0	1	when the FTM counter changes from (CNTMIN) to (CNTMIN + 1)
1	0	when the FTM counter changes from (MOD) to (MOD - 1)
1	1	• when the FTM counter changes from (MOD) to (MOD - 1), and • when the FTM counter changes from (CNTMIN) to (CNTMIN + 1)

The following figure shows an example of the reload opportunities at the half cycle, at the channels match, and when the FTM counter is an up-down counter.

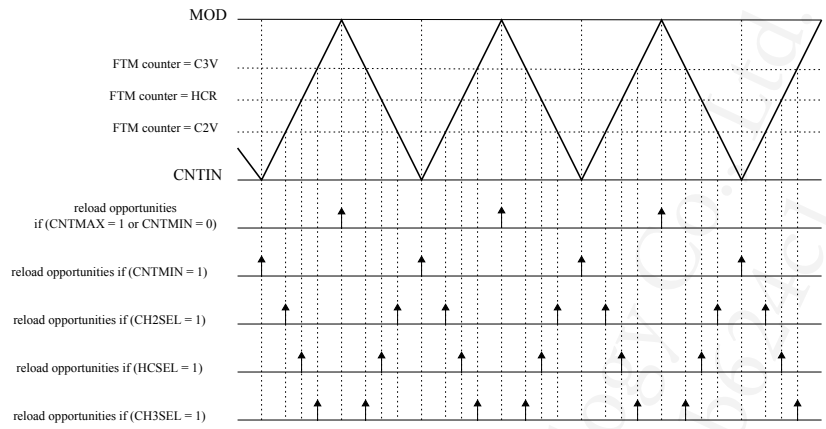

Figure 331. Reload opportunities when the FTM counter is an up-down counter

43.5.28.2 Frequency of Reload Opportunities

The LDFQ[4:0] bits define the number of enabled reload opportunities should happen until an enabled reload opportunity becomes a reload point. The following figure shows an example when the LDFQ[4:0] = 4.

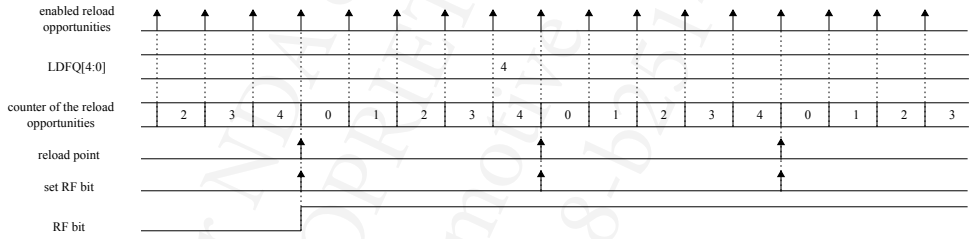

Figure 332. Frequency of Reload Opportunities with LDFQ[4:0] = 4

If LDFQ[4:0] = 0, then all reload opportunities are reload points.

The counter of the reload opportunities is reset when there is a write to the register CNT.

The RF bit is set at each reload point (see the figure above) independent of LDOK bit value. The reload point interrupt is generated when (RF = 1) and (RIE = 1).

43.5.28.3 Update of the Registers

After writing new value to the registers with write buffer, selecting which of them will be updated (according to Table 285), selecting the reload opportunities, selecting the frequency of the reload opportunities, thus the LDOK bit should be set to enable the update of these registers at the next reload point.

Table 285. Additional conditions to update the registers

Register	Additional Condition
CNTIN	CNTINC = 1
HCR	-

Table continues on the next page...

Table 285. Additional conditions to update the registers (continued)

Register	Additional Condition
MOD	-
C(n)V and C(n+1)V	SYNCENm = 1, where m is the pair of the channels (n) and (n+1)

43.5.29 Global Load

The global load mechanism allows several modules to have their double buffered registers synchronously reloaded after a synchronization event if a write to one operation is performed in the global load OK (GLDOK) bit in the PWMLOAD register. Global load may be enabled or disabled configuring the global load enable (GLEN) bit in the PWMLOAD register. Writing one in the GLDOK bit with GLEN enabled has the same effect of writing one in the LDOK bit. Refer to SoC specific information about global load connections.

Global load mechanism allows MOD, HCR, CNTIN, and C(n)V registers to be updated with the content of the register buffer at configurable reload point. The figure below shows an example of connection between FTM global load inputs and outputs considering that GLDOK bit is implemented outside from FTM module.

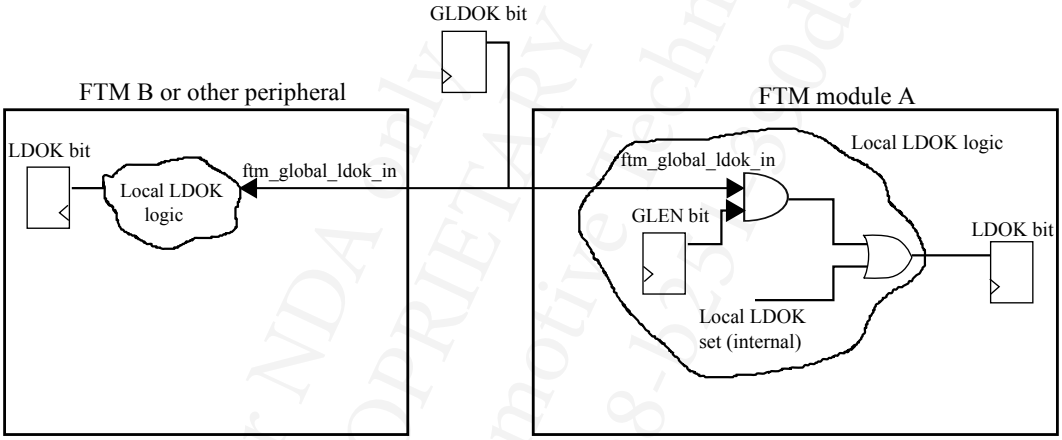

Figure 333. Global load logic

43.5.30 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

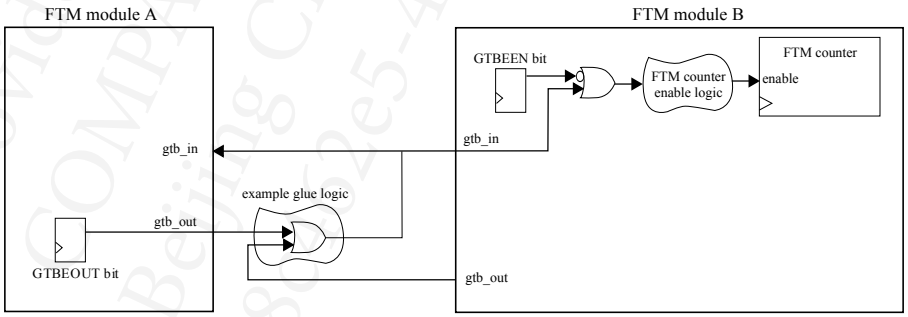

Figure 334. Global time base (GTB) block diagram

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb_in*, and the output signal *gtb_out*. The GTBEEN bit enables gtb_in to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when gtb_in is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the gtb_out signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the gtb_in and gtb_out signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the gtb_in signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

43.5.30.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

43.5.31 Channel trigger output

The channel trigger output provides a trigger signal which has one FTM input clock period width in the channel (n) output.

If the TRIGMODE bit of the CnSC register is set (TRIGMODE = 1), a trigger pulse with one FTM input clock width is generated in the channel (n) output when a match occurs. It is only allowed to use trigger mode when channel (n) is in EPWM or CPWM modes.

The figures below show some cases of channel (n) trigger generation in the channel (n) output.

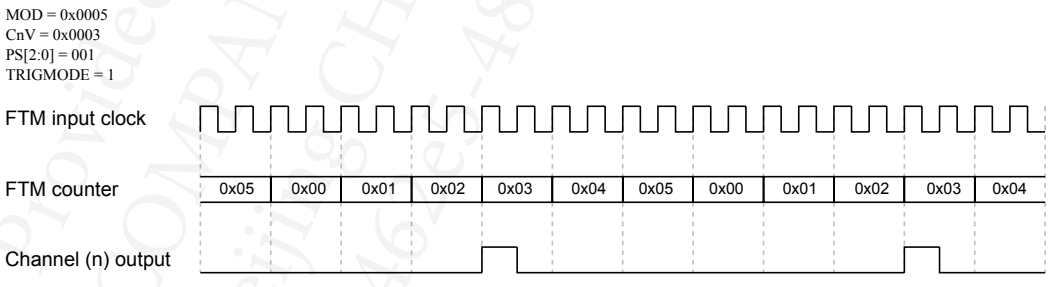

Figure 335. Example of channel (n) trigger at the channel (n) output in EPWM mode

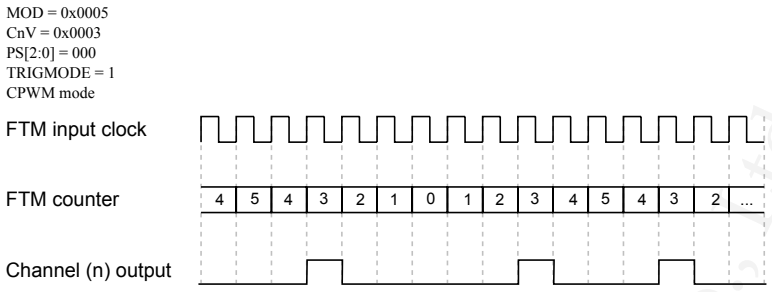

Figure 336. Example of channel (n) trigger at the channel (n) output in CPWM mode

43.5.32 External Control of Channels Output

The channel (n) PWMEN bit can be used in an FTM external logic to control the final value of the channel (n) output. The following figure shows an example of this external logic.

The term "channel (n) output" means the channel (n) output value after the Polarity Control. See Features Priority and Polarity Control for more details.

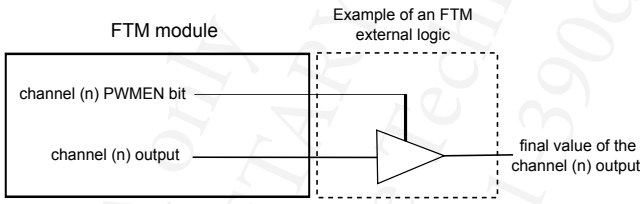

Figure 337. Example of the External Control of the Channel (n) Output

43.5.33 Dithering

FTM implements a fractional delay to achieve fine resolution on the generated PWM signals using dithering. The dithering can be used by applications where more resolution than one unit of the FTM counter is needed.

Two kinds of dithering are available: PWM period dithering and edge dithering.

43.5.33.1 PWM Period Dithering

The PWM period dithering is enabled when a non-zero value is written to FRACMOD.

The internal accumulator used in the PWM period dithering is reset when:

- the field MOD of the register MOD_MIRROR is updated with the value of its write buffer,
- the FRACMOD is updated with the value of its write buffer, or
- the FTM counter is stopped.

NOTE

For the PWM period dithering, the register MOD_MIRROR should be used instead of the register MOD.

To avoid inconsistencies, the field FRACMOD is cleared when the field MOD of the register MOD is updated with the value of its write buffer.

The PWM period dithering is not available:

- when the FTM counter is a free running counter
- when the FTM is in quadrature decoder mode

43.5.33.1.1 Up Counting

When the FTM counter is an up counter and the PWM period dithering is enabled, at the end of each PWM period, the FRACMOD value is added to an internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), then one unit of FTM counter is added to the end of the current PWM period, and the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

Due to one unit of FTM counter that can be added to the PWM period, the largest valid value for MOD is 0xFFFE for PWM period dithering with unsigned counting and 0x7FFE for PWM period dithering with signed counting.

The following figures show some examples of PWM period dithering when the FTM counter is an up counter.

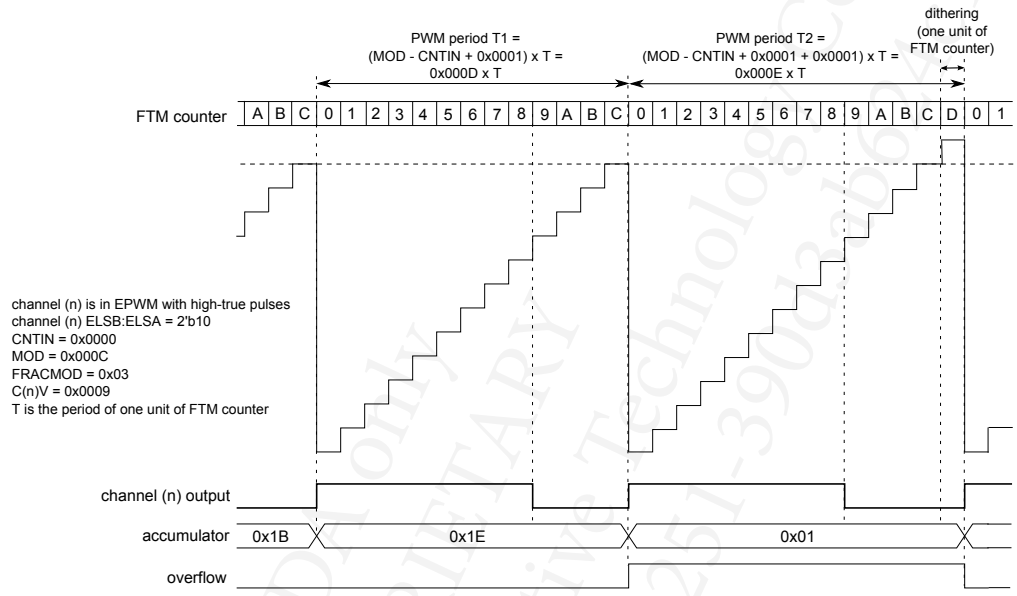

Figure 338. PWM Period Dithering with Up Counting

Assuming:

- the FTM counter is an up counter,
- T is one unit of FTM counter,
- the PWM period without period dithering is [(MOD - CNTIN + 1) x T],
- the number of PWM periods with period dithering is FRACMOD,
- the PWM period with period dithering is [(MOD - CNTIN + 1 + 1) x T],

thus, the average period (in decimal) is [(MOD - CNTIN + 1) + (FRACMOD/32)] x T, where the integer value is (MOD - CNTIN + 1) and the fractional value is (FRACMOD/32). See the example below.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4e24-48a8-b251-390d2ab6b6f1

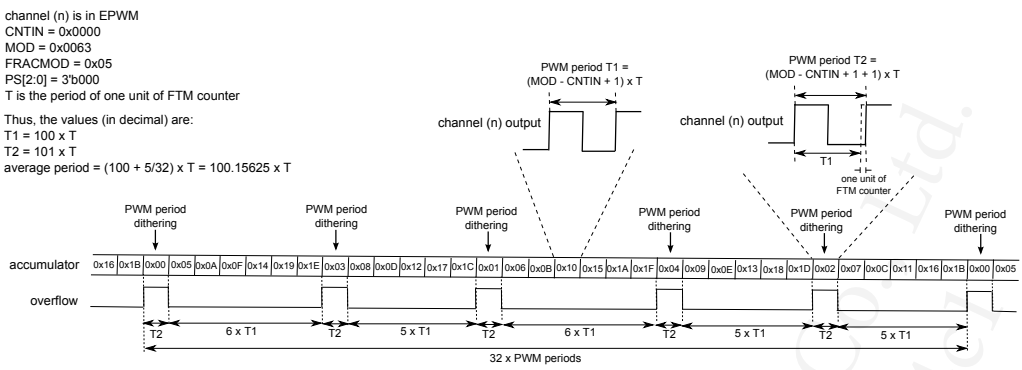

Figure 339. Example of Average Period when the PWM Period Dithering is used with the Up Counting

NOTE

For the generation of 100% PWM signal in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using EPWM mode and PWM Period Dithering, it is recommended to use (C(n) > MOD + 1).

For the generation of PWM signals in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Combine mode and PWM Period Dithering, it is recommended to use:

- For 0% PWM signal: (C(n)V > MOD + 1) and (C(n+1)V > MOD + 1);
- For 100% PWM signal: (C(n)V = CNTIN) and (C(n+1)V > MOD + 1).

For the generation of PWM signals in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Modified Combine PWM mode and PWM Period Dithering, it is recommended to use:

- For 0% PWM signal: (C(n)V > MOD + 1) and (CNTIN ≤ C(n+1)V ≤ MOD);
- For 100% PWM signal: (CNTIN ≤ C(n)V ≤ MOD) and (C(n+1)V > MOD + 1).

43.5.33.1.2 Up-Down Counting

When the FTM counter is an up-down counter and the PWM period dithering is enabled, at the end of each PWM period, the FRACMOD value is added to an internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), then one unit of FTM counter is added to the end of the current PWM period and other unit is added to the begin of the next PWM period (see the figure below). After the accumulator overflows, the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

Due to one unit of FTM counter that can be added to the PWM period, the largest valid value for MOD is 0x7FFE for PWM period dithering in up-down counting (CPWM mode).

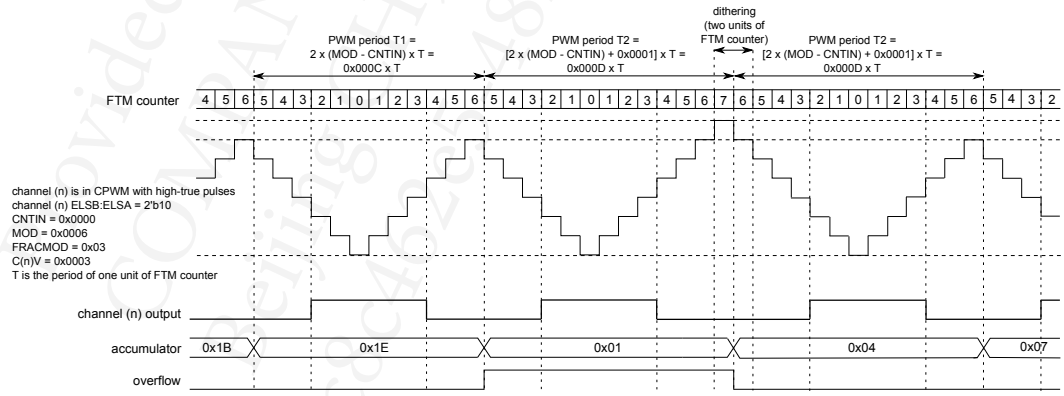

Figure 340. PWM Period Dithering with Up-Down Counting

NOTE

For the generation of 100% PWM signal in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using CPWM mode and PWM Period Dithering, it is recommended to use (C(n)V[15] = 0) and (C(n)V > MOD + 1) and (MOD ≠ 0x0000).

43.5.33.2 PWM Edge Dithering

The channel (n) internal accumulator used in the PWM edge dithering is reset when:

- the field VAL of the register C(n)V_MIRROR is updated with the value of its write buffer,
- the FRACVAL is updated with the value of its write buffer, or
- the FTM counter is stopped.

NOTE

For the PWM edge dithering, the register C(n)V_MIRROR should be used instead of the register C(n)V.

To avoid inconsistencies, the field FRACVAL is cleared when the field VAL of the register C(n)V is updated with the value of its write buffer.

The PWM edge dithering is not available:

- to the channel in input modes, and
- to the channel in output compare mode.

43.5.33.2.1 EPWM Mode

The PWM edge dithering for channel (n) in EPWM mode is enabled when a non-zero value is written to the channel (n) FRACVAL.

If the channel (n) is in EPWM mode and the PWM edge dithering is enabled, at the end of each EPWM period, the channel (n) FRACVAL value is added to the channel (n) internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

In this configuration, the initial edge of EPWM duty cycle happens when (FTM counter = CNTIN), its position is not modified by the PWM edge dithering. If there was not the overflow of the channel (n) accumulator in the current EPWM period, then the final edge of EPWM duty cycle happens on the channel (n) match (FTM counter = C(n)V), that is, its position is not modified by the edge dithering. However, if there was the overflow of the channel (n) accumulator in the current EPWM period, then the final edge of EPWM duty cycle happens when (FTM counter = C(n)V + 0x0001).

The following figures show some examples of PWM edge dithering when the channel (n) is in EPWM mode.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a9-a1d3-390d3a0c24c1

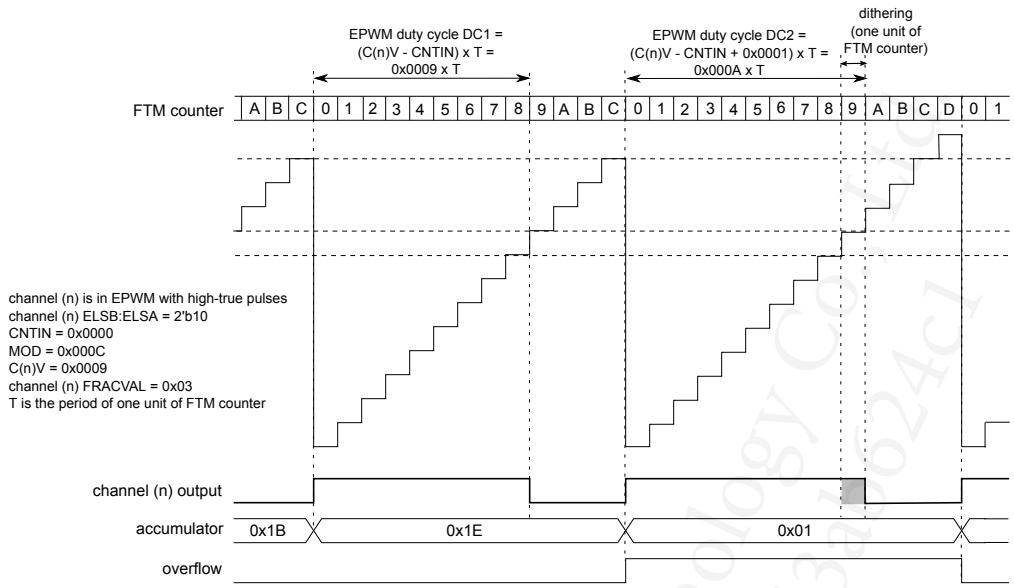

Figure 341. Channel (n) is in EPWM Mode with PWM Edge Dithering

Assuming:

- the channel (n) is in EPWM mode,
- T is one unit of FTM counter,
- the EPWM duty cycle without edge dithering is [(C(n)V - CNTIN) x T],
- the number of PWM periods which duty cycle that has edge dithering is FRACVAL,
- the EWM duty cycle with edge dithering is [(C(n)V - CNTIN + 1) x T],

thus, the average duty cycle (in decimal) is [(C(n)V - CNTIN) + (FRACVAL/32)] x T, where the integer value is (C(n)V - CNTIN) and the fractional value is (FRACVAL/32). See the example below.

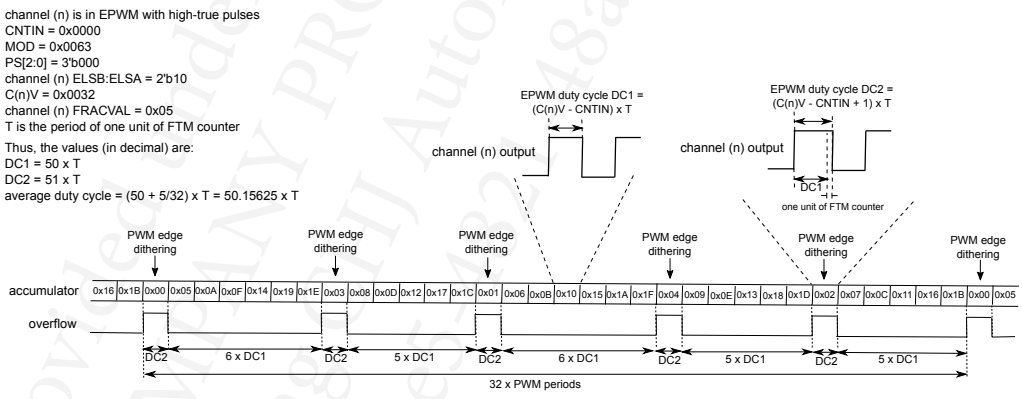

Figure 342. Example of Average Duty Cyle when the Channel (n) is in EPWM Mode with PWM Edge Dithering

43.5.33.2.2 CPWM Mode

The PWM edge dithering for channel (n) in CPWM mode is enabled when a non-zero value is written to the channel (n) FRACVAL.

If the channel (n) is in CPWM mode and the PWM edge dithering is enabled, at the end of each CPWM period, the channel (n) FRACVAL value is added to the channel (n) internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

In this configuration, if there was not the overflow of the channel (n) accumulator in the current CPWM period, then the duty cycle is not modified by the PWM edge dithering, that is, the initial edge of CPWM duty cycle happens on channel (n) match (FTM counter = C(n)V) when the FTM counter is decrementing, and the final edge of CPWM duty cycle on channel (n) match when the FTM counter is incrementing.

However, if there was the overflow of the channel (n) accumulator in the current CPWM period, then the initial edge of CPWM duty cycle happens when (FTM counter = C(n)V + 0x0001) and the FTM counter is decrementing, and the final edge of CPWM duty cycle when (FTM counter = C(n)V + 0x0001) and the FTM counter is incrementing.

The following figure shows an example of PWM edge dithering when the channel (n) is in CPWM mode.

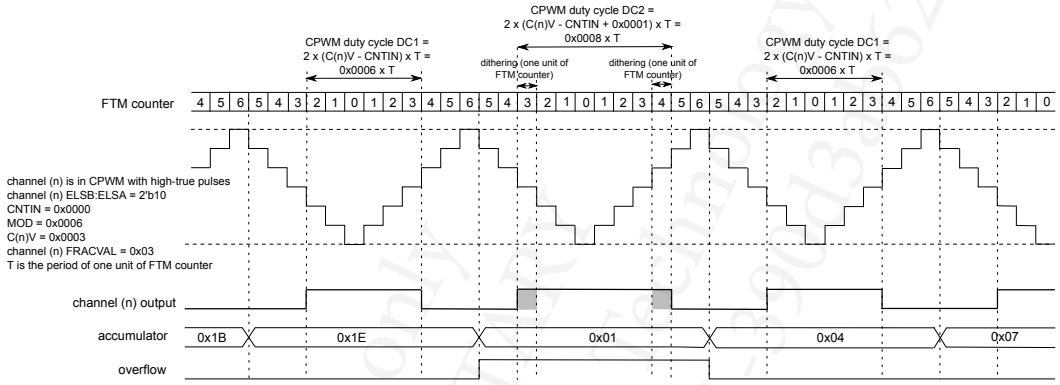

Figure 343. Channel (n) is in CPWM Mode with PWM Edge Dithering

43.5.33.2.3 Combine Mode

In the Combine mode, the PWM edge dithering can be done:

- in the channel (n) match (FTM counter = C(n)V) edge or
- in the channel (n+1) match (FTM counter = C(n+1)V) edge.

The channel (n) match edge dithering is enabled when a non-zero value is written to the channel (n) FRACVAL.

For the channel (n) match edge dithering, the channel (n) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n) FRACVAL value is added to the channel (n) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n) accumulator in the current PWM period, the channel (n) match edge is not modified, that is, it happens on channel (n) match. However, if there was the overflow of the channel (n) accumulator, the channel (n) match edge happens when (FTM counter = C(n)V + 0x0001).

The following figure shows an example of the channel (n) match edge dithering when the channels (n) and (n+1) are in Combine mode.

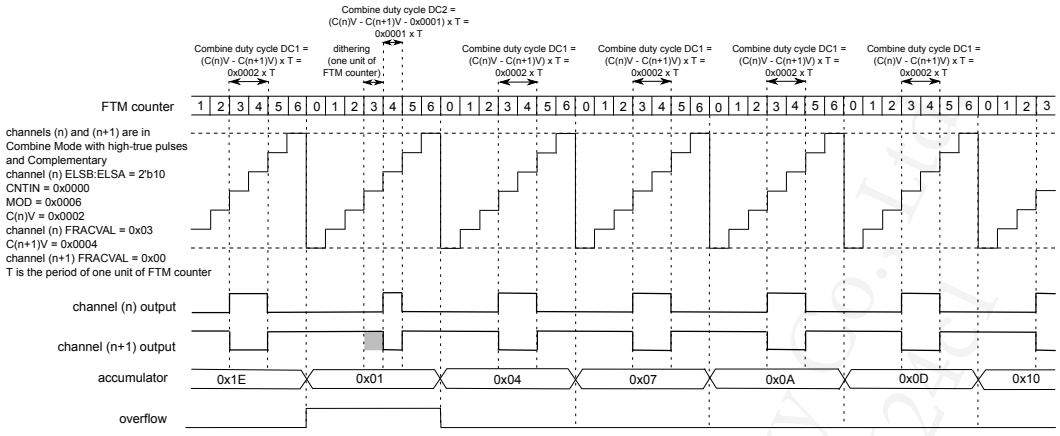

Figure 344. Channel (n) Match Edge Dithering in Combine Mode

The channel (n+1) match edge dithering is enabled when a non-zero value is written to the channel (n+1) FRACVAL.

For the channel (n+1) match edge dithering, the channel (n+1) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n+1) FRACVAL value is added to the channel (n+1) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n+1) accumulator in the current PWM period, the channel (n+1) match edge is not modified, that is, it happens on channel (n+1) match. However, if there was the overflow of the channel (n+1) accumulator, the channel (n+1) match edge happens when (FTM counter = C(n+1)V + 0x0001).

The following figure shows an example of the channel (n+1) match edge dithering when the channels (n) and (n+1) are in Combine mode.

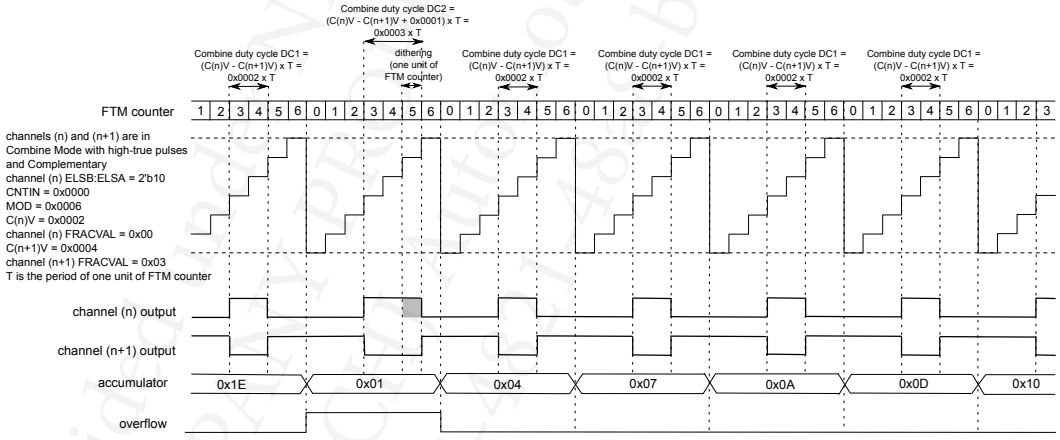

Figure 345. Channel (n+1) Match Edge Dithering in Combine Mode

NOTE

It is recommended to use only one PWM Edge Dithering (channel (n) PWM Edge Dithering or channel (n+1) PWM Edge Dithering) at a time.

For the generation of 0% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Combine mode and PWM Edge Dithering, it is recommended to use:

- (C(n)V < CNTIN or C(n)V > MOD) and (channel (n) FRACVAL is zero) and
- (channel (n+1) FRACVAL is zero).

For the generation of 100% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Combine mode and PWM Edge Dithering, it is recommended to use:

- (C(n)V = CNTIN) and (channel (n) FRACVAL is zero) and
- (C(n+1)V < CNTIN or C(n+1)V > MOD) and (channel (n+1) FRACVAL is zero).

43.5.33.2.4 Modified Combine PWM Mode

In the Modified Combine PWM mode, the PWM edge dithering can be done:

- in the channel (n) match (FTM counter = C(n)V) edge or
- in the channel (n+1) match (FTM counter = C(n+1)V) edge.

The channel (n) match edge dithering is enabled when a non-zero value is written to the channel (n) FRACVAL.

For the channel (n) match edge dithering, the channel (n) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n) FRACVAL value is added to the channel (n) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n) accumulator in the current PWM period, the channel (n) match edge is not modified, that is, it happens on channel (n) match. However, if there was the overflow of the channel (n) accumulator, the channel (n) match edge happens when (FTM counter = C(n)V + 0x0001).

The following figure shows an example of the channel (n) match edge dithering when the channels (n) and (n+1) are in Modified Combine PWM mode.

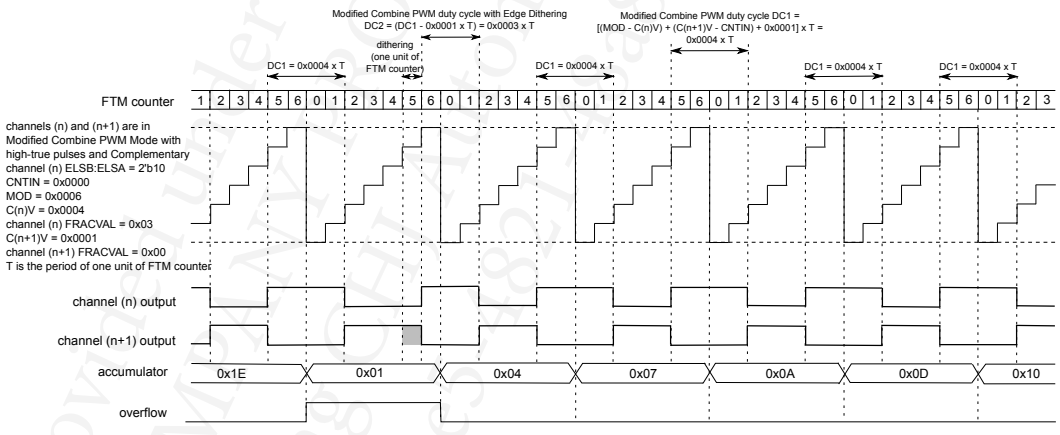

Figure 346. Channel (n) Match Edge Dithering in Modified Combine PWM Mode

The channel (n+1) match edge dithering is enabled when a non-zero value is written to the channel (n+1) FRACVAL.

For the channel (n+1) match edge dithering, the channel (n+1) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n+1) FRACVAL value is added to the channel (n+1) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n+1) accumulator in the current PWM period, the channel (n+1) match edge is not modified, that is, it happens on channel (n+1) match. However, if there was the overflow of the channel (n+1) accumulator, the channel (n+1) match edge happens when (FTM counter = C(n+1)V + 0x0001).

The following figure shows an example of the channel (n+1) match edge dithering when the channels (n) and (n+1) are in Modified Combine PWM mode.

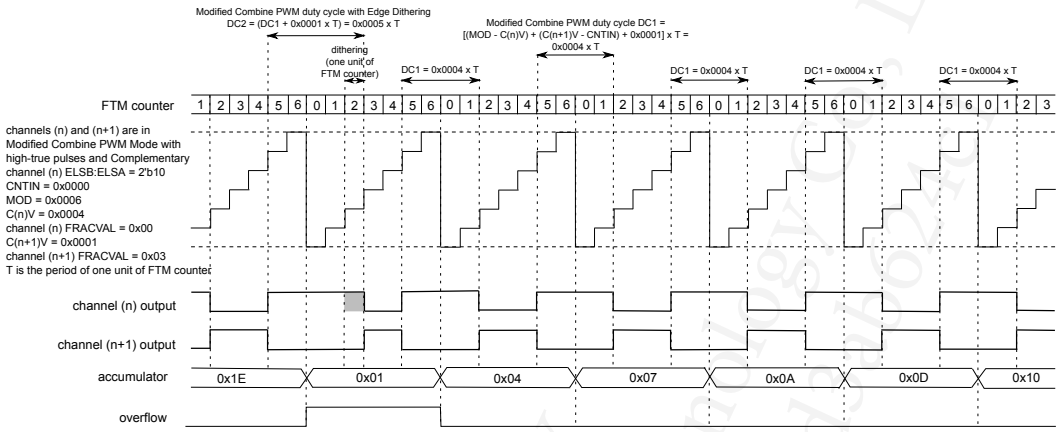

Figure 347. Channel (n+1) Match Edge Dithering in Modified Combine PWM Mode

NOTE

It is recommended to use only one PWM Edge Dithering (channel (n) PWM Edge Dithering or channel (n+1) PWM Edge Dithering) at a time.

For the generation of 0% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Modified Combine PWM mode and PWM Edge Dithering, it is recommended to use:

- (C(n)V < CNTIN or C(n)V > MOD) and (channel (n) FRACVAL is zero) and
- (CNTIN ≤ C(n+1)V ≤ MOD) and (channel (n+1) FRACVAL is zero).

For the generation of 100% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Modified Combine PWM mode and PWM Edge Dithering, it is recommended to use:

- (CNTIN ≤ C(n)V ≤ MOD) and (channel (n) FRACVAL is zero) and
- (C(n+1)V < CNTIN or C(n+1)V > MOD) and (channel (n+1) FRACVAL is zero).

43.6 Reset Overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 2'b00);
- the timer overflow interrupt is zero (Timer Overflow Interrupt);
- the channels interrupts are zero (Channel (n) Interrupt);
- the channels are in input capture mode (Input Capture Mode);
- the channels outputs are zero;
- the channels ELSB:ELSA = 0:0 (Channel Modes) and PWMEN = 0 (External Control of Channels Output).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (CLKS[1:0] = 2'b00), its value is updated to zero and the pins are not controlled by FTM (Channel Modes).

After the reset, the FTM should be configurated (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) (Counter reset).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero.

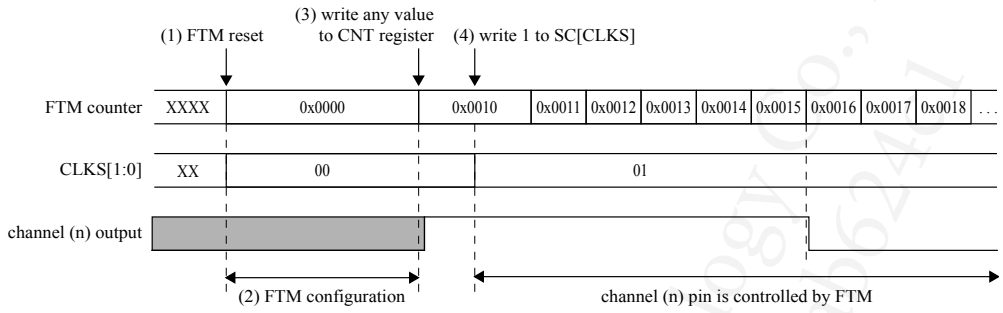

Figure 348. FTM behavior after reset when the channel (n) is in Combine mode

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control (Software Output Control Mode) or the initialization (Initialization) to update the channel output to the selected value (item 4).

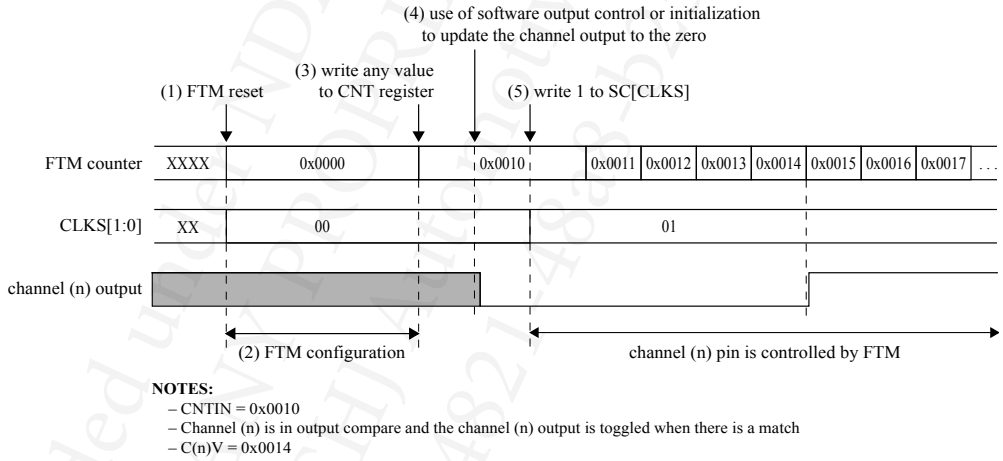

Figure 349. FTM behavior after reset when the channel (n) is in Output Compare mode

43.7 FTM Interrupts

43.7.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

43.7.2 Reload Point Interrupt

The Reload Point interrupt is generated when (RIE = 1) and (RF = 1).

43.7.3 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHIE = 1) and (CHF = 1).

43.8 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer. This procedure can also be used to do a new configuration.

1. Define the POL bits.
2. Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels outputs are in the safe value.
3. (Re)Configuration FTM counter and channels to generation of periodic signals:
    a. Disable the clock. Disable the Quadrature Decoder mode.
    b. Examples of (re)configuration:
    - Write to MOD
    - Write to CNTIN
    - Configure the channels that will be used
    - Write to CnV for the channels in output modes
    - (Re)Configure deadtime
    - Do not use the SWOC without SW synchronization (see item 6)
    - Do not use the Inverting without SW synchronization (see item 6)
    - Do not use the Initialization
    - Do not change the polarity control
    - Do not configure the HW synchronization
4. Write any value to CNT. The FTM Counter is reset and the channels outputs are updated according to new configuration.
5. Enable the clock. Write to CLKS[1:0] bits a value different from zero. Enable the Quadrature Decoder mode (if it is desired).
6. Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
    a. Select synchronization for Output Mask
        - Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
    b. Write to SYNCONF
        - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0)
        - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1]
        - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1]
        - SW Synchronization for SWOM (always): SWOM = 1
        - No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2’b00): SWWRBUF = 0 and CNTINC = 0
        - SW Synchronization for counter reset (always): SWRSTCNT = 1
        - Enhanced synchronization (always): SYNCMODE = 1

c. If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.

d. If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.

e. Write to OUTMASK to enable the masked channels.

7. Generate the Software Trigger

   - Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

8. Configure PWMEN bits (External Control of Channels Output).

Chapter 44
Real Time Clock (RTC)

44.1 Chip-specific RTC information

44.1.1 RTC clocking

SIRC is the only clock available to the RTC module during Standby mode. For SIRC specification, see the SIRC section in the Data Sheet of chip.

44.2 Introduction

The Real-Time Clock (RTC) is a free-running counter used for time keeping applications. The RTC can be configured to generate an interrupt at a pre-defined interval. The RTC also supports an API function used to generate a periodic wakeup request to exit a low-power mode or an interrupt request.

44.2.1 Features

RTC features include:

- 32-bit counter
- Selectable counter clock sources (IRCs and OSCs)
  - Clock source 0
  - Clock source 1
  - Clock source 2
  - Clock source 3
- Optional 512 prescaler and optional 32 prescaler to run the 32 bit counter.
- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC counter is reset when the counter is disabled by software and by reset to RTC block.
- Autonomous periodic interrupt support includes:
  - 32-bit compare value to support range of wakeup intervals/interrupts
  - API logic has a separate enable to support changing compare value while RTC is running
  - API interrupt with interrupt enable
  - Operates in all modes
  - API compare value can be modified while RTC is running
- Optional interrupt for RTC match, API match, and RTC rollover.

44.2.2 Block diagram

The following figure shows Clock gating for RTC clocks.

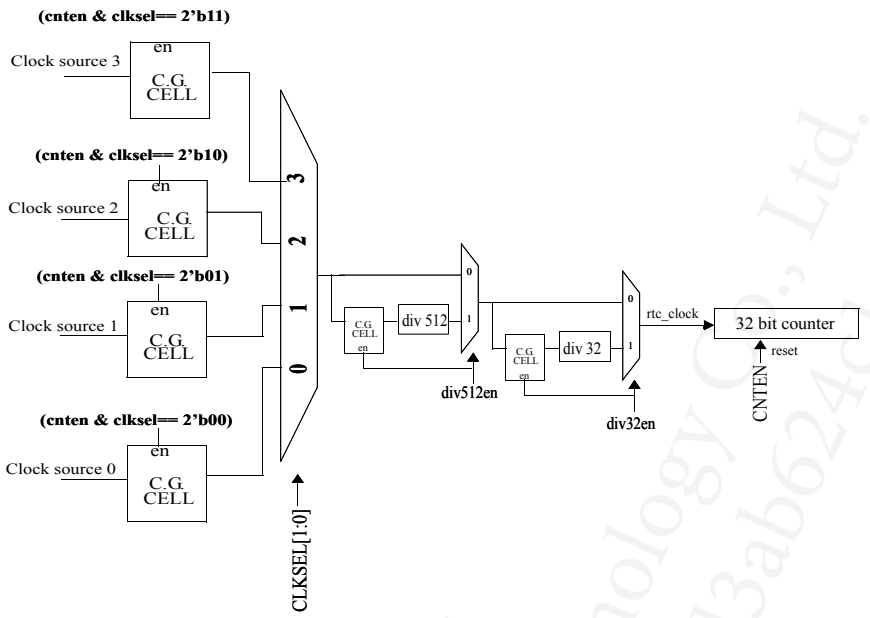

Figure 350. Clock gating for RTC clocks

The following figure shows the block diagram of RTC.

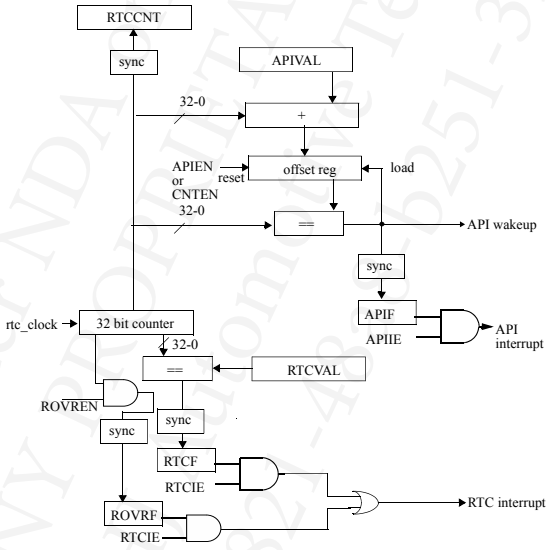

Figure 351. Block diagram

44.2.3 Modes of operation

44.2.3.1 Functional mode

There are two functional modes of operation for RTC: normal operation and low-power mode. In normal operation, all RTC registers can be read or written . The RTC/API and associated interrupts are optionally enabled. In low-power mode, the bus interface is disabled. The RTC/API is enabled (if enabled prior to entry into low-power mode).

44.2.3.2 Debug mode

On entering into the debug mode, the RTC counter freezes on the last valid count if the FRZEN is set. On exit from debug mode, counter continues from the frozen value.

44.3 RTC register descriptions

The RTC registers are listed in this section.

NOTE

Address offset - 0x18h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at this offset.

NOTE

XFR error will be generated when RTCSUPV is accessed in user mode, any other register is accessed in user mode when SUPV bit is set, write attempt is made for RTCCNT register and any register accessed out of address range.

44.3.1 RTC memory map

RTC base address: 4006_0000h

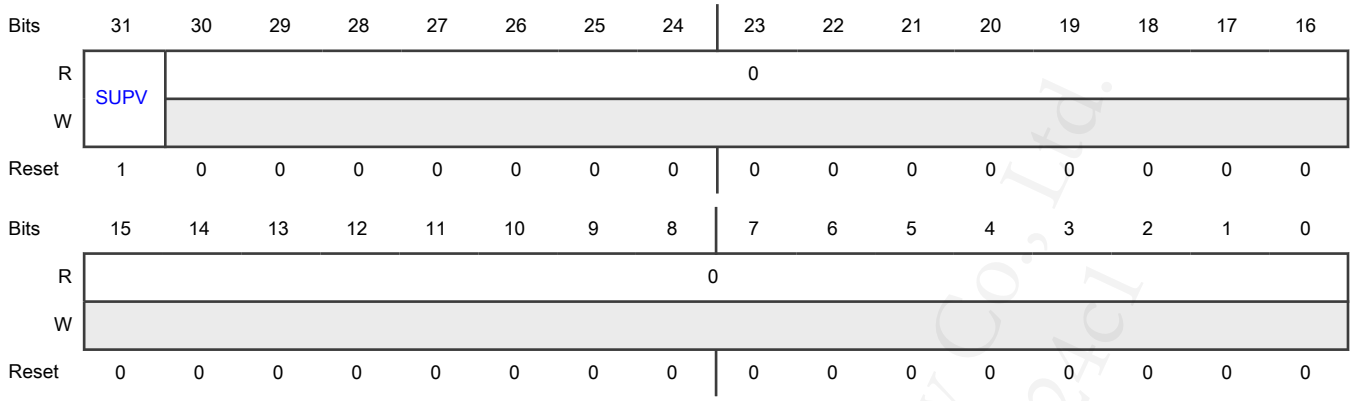
Offset	Register	Width (In bits)	Access	Reset value
0h	RTC Supervisor control register (RTCSUPV)	32	RW	8000_0000h
4h	RTC Control register (RTCC)	32	RW	0000_0000h
8h	RTC Status register (RTCS)	32	W1C	0000_0000h
Ch	RTC Counter register (RTCCNT)	32	RO	0000_0000h
10h	API Compare value register (APIVAL)	32	RW	0000_0000h
14h	RTC Compare value register (RTCVAL)	32	RW	0000_0000h

44.3.2 RTC Supervisor control register (RTCSUPV)

Offset

Register	Offset
RTCSUPV	0h

Function



The RTCSUPV register contains the SUPV bit that determines whether other registers are accessible in supervisor mode or user mode.

NOTE

You can access this register only in Supervisor mode, and you must write a value only to the SUPV field of the register.

Beijing CHJ Automotive Technology Co., Ltd.
c8a2e548-21-48a8-b251-30d3ab624c1

Fields

Field	Function
31 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Setting CNTEN bit to 0b has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic. This allows RTC configuration and clock source selection to be updated without causing synchronization issues. **NOTE** CNTEN should be disabled when INV_RTC, INV_API are cleared. 0b - Counter disabled 1b - Counter enabled
30 RTCIE	RTC Interrupt Enable. The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0b - RTC interrupts disabled. 1b - RTC interrupts enabled.
29 FRZEN	Freeze Enable Bit The counter freezes on entering the debug mode on the last valid count value if the FRZEN bit is set. After passing of the debug mode counter starts from the frozen value. This bit should not be changed when debug mode is enabled. 0b - Counter does not freeze in debug mode. 1b - Counter freezes in debug mode.
28 ROVREN	Counter Roll Over Interrupt Enable. The ROVREN bit enables interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0b - RTC rollover interrupt disabled 1b - RTC rollover interrupt enabled.
27-16 —	Reserved
15 APIEN	Autonomous Periodic Interrupt Enable. The APIEN bit enables the autonomous periodic interrupt function. Setting this bit to 0b, asynchronously disables API wakeup output of RTC as well. 0b - API disabled. 1b - API enabled.
14 APIIE	API Interrupt Enable. The APIIE bit enables interrupts requests to the system if APIF is asserted. 0b - API interrupts disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - API interrupts enabled.
13-12 CLKSEL	Clock select The CLKSEL[1:0] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. **NOTE** Refer the RTC clocking section in the Clocking chapter of this document. 00b - Clock source 0 01b - Clock source 1 10b - Clock source 2 11b - Clock source 3
11 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0b - Divide by 512 is disabled. 1b - Divide by 512 is enabled.
10 DIV32EN	Divide by 32 enable. The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0b - Divide by 32 is disabled 1b - Divide by 32 is enabled
9-1 —	Reserved
0 —	Reserved

44.4 Functional description

44.4.1 RTC

The RTC consists of a 32-bit free running counter enabled with the CNTEN bit (CNTEN, when negated, asynchronously resets the counter and synchronously enables the counter when enabled). After disabling CNTEN, RTCVAL, APIVAL, needs to be written again for desired functionality. The value of the counter may be read via the RTC Counter register (RTCCNT) register. Note that because of clock synchronization, the RTC Counter register (RTCCNT) value may represent a previous counter value. The difference between the counter and the read value depends on the ratio of counter clock and bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the CLKSEL field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be on these:Clock source 0, Clock source 1, Clock source 2, and Clock source 3. The output of the clock mux can be optionally divided by a combination of 512 and 32 to give various count periods for different clock sources. Note that the CNTEN bit should be disabled when the RTC/API clock source is switched.

When the RTC Counter register (RTCCNT) counter value for counter bits 31-0 match the 32-bit value in the RTCVAL field, then the RTCF interrupt flag bit is set (after proper clock synchronization). If the RTCIE interrupt enable bit is set, then the RTC interrupt request is generated. RTC Compare value register (RTCVAL) register can be written only when INV_RTC bit is clear. Initially

INV_RTC=0, and hence RTC Compare value register (RTCVAL) can be written once and hence INV_RTC gets set. This bit can now be cleared only by enabling the RTC counter. After the counter is enabled, RTC Compare value register (RTCVAL) can be written anytime, until RTC is disabled again. RTC Compare value register (RTCVAL) is first synchronized to the RTC clock domain, therefore, if RTC Compare value register (RTCVAL) is updated at the point where a counter match is due to happen in the next 2-3 RTC clocks because of previous RTC Compare value register (RTCVAL), the RTCF flag is set. However, if the RTC Compare value register (RTCVAL) is updated at the point where no counter match is due as per the previous RTC Compare value register (RTCVAL), the RTCF flag is set when the counter matches the new RTC Compare value register (RTCVAL).

If RTC Compare value register (RTCVAL) is updated just after counter match, new RTC Compare value register (RTCVAL) value should not be within next 6 RTC counter values.

A rollover interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the ROVREN bit. If RTCIE is enabled, an interrupt request is generated for an RTC counter rollover.

All the flags and counter values are synchronized with the Bus clock. It is assumed that the Bus clock and RTC clock selected through CLKSEL follows the below relation:

Bus clock >= (1.5 * RTC clock)/(div_factor)

- if both DIV32EN and DIV512EN bits are disabled, div_factor = 1
- if DIV32EN=1 and DIV512EN=0, div_factor = 32
- if DIV32EN=0 and DIV512EN=1, div_factor = 512
- if both DIV32EN and DIV512EN bits are enabled, div_factor = 512*32 = 16384

In case, RTC wakeup's are used as a wakeup source, Bus clock should be disabled after enabling the required wakeup and ensuring sufficient time gap (few Bus clock or RTC clock cycles, whichever is slower) between Bus clock disabling and wakeup event.

44.4.2 API functional description

Setting APIEN bit enables the autonomous interrupt function. The 32-bit APIVAL field selects the time interval for triggering an interrupt and/or wakeup event. Because the RTC is a free-running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, an interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN bits are asserted and APIVAL is non-zero. Also, APIVAL can be updated anytime. After APIVAL is updated, the first API interrupt is generated according to the previous value. From the second interrupt onwards, the API interrupt is generated with the new APIVAL. When a compare is reached, the APIF interrupt flag bit is set (after proper clock synchronization). If the APIIE interrupt enable bit is set, then the API interrupt request is generated. If there is a match while being in the low-power mode, then the API first generates a wakeup request to force a wakeup into normal operation, and then the APIF flag is set.

When the CNTEN is de-asserted, the API function is reset , though wakeup API is not asynchronously de-asserted with CNTEN. If APIEN is disabled when counter matches the offset, APIF can be missed.

44.5 Recommended programming flow

1. Program RTCVAL register with the value greater than 4 if RTCF related functionality is required.
2. Program APIVAL register with the value greater than 4 if API functionality is required.
3. Program all fields (as required) of RTC Control register (RTCC) register with CNTEN=1. After setting CNTEN field, counter starts running and RTC/API functionality will be active as per the configurations.
4. If RTCVAL or APIVAL needs to be updated during run, check corresponding INV_RTC or INV_API bit is cleared before writing and do meet all the restrictions of the corresponding register.
5. If CLKSEL or DIV32EN or DIV512EN needs to be updated, first update RTC Control register (RTCC) register with CNTEN=0 (when all INV_RTC or INV_API are 0) keeping other field values same. Wait for minimum 3 RTC clock cycles so that CNTEN will be synchronized to RTC clock domain. Then write the RTC Control register (RTCC) register with new configuration required with CNTEN=1.

44.6 Glossary

Chapter 45
Inter-Integrated Circuit (I2C)

45.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) module implemented on this chip and presents the following topics:

- Introduction to I2C
- External signal descriptions
- I2C register descriptions
- Functional description
- Initialization/application information

45.2 Introduction to I^2C

This section presents the following topics:

- Definition: I2C module
- Module block diagram
- Features
- Modes of operation
- Definition: I2C conditions

45.2.1 Definition: I^2C module

The I^2C module is a functional unit that provides a two-wire—serial data (SDA) and serial clock (SCL)—bidirectional serial bus. This bus provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

45.2.2 Module block diagram

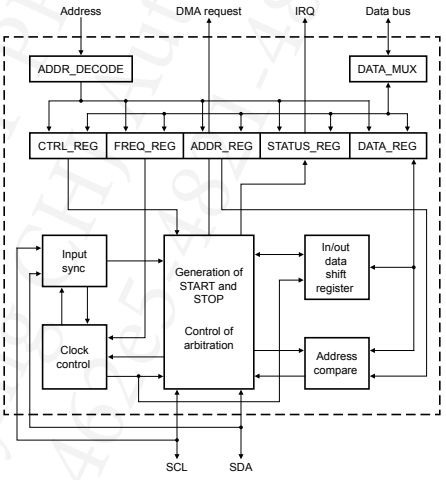

Figure 352. I^2C block diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing Huatom Automotive Technology Co., Ltd.
c8c4b5e4-92f7-4a8a-8951-390d3ab624c1

45.2.3 Features

The I²C module has the following key features:

- Compatible with I²C bus standard[2]
- Operating speeds
  - Up to 100 kbps in the Standard Mode defined by the I²C protocol specification
  - Up to 400 kbps in the Fast Mode defined by the I²C protocol specification
  - Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
  - Actual baud rate dependent on the SCL rise time (which depends on external pullup resistor values and bus loading)
- Multi-master operation
- Software-programmable for one of 256 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- DMA interface

45.2.4 Modes of operation

The I²C module supports the chip modes described in Table 286.

Table 286. Chip modes supported by the I²C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See DEBUG mode.

In addition to chip modes, the I²C module has several module-specific modes. These are described in Table 287.

Table 287. Module-specific modes supported by the I²C module

Module mode	Description	Important notes
Master mode	The I²C module is the driver of the SDA line.	• Do not use the I²C module's slave address as a calling address.

Table continues on the next page...

[2] Compliant with I²C 2.0 standard with the exception that HS (high speed) mode is not supported

Table 287. Module-specific modes supported by the I²C module (continued)

Module mode	Description	Important notes
		• The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I²C module is not the driver of the SDA line.	• Enable the I²C module before a START condition from a non-I²C master is detected. • By default the I²C module performs as a slave receiver.

45.2.5 Definition: I²C conditions

The following table shows the I²C-specific conditions defined for the I²C module.

Table 288. I²C conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in the following figure.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in the following figure.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

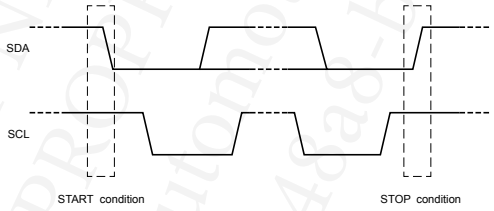

Figure 353. START and STOP conditions

45.3 External signal descriptions

This section presents the following topics:

- Signal overview
- Detailed external signal descriptions

45.3.1 Signal overview

The I²C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The I²C bus connects the SDA lines of all devices together, thus performing a logical AND of the SDA signals. Similarly, the I²C bus connects all the SCL lines together, thus performing a logical AND of the SCL signals. The combined SDA and SCL lines also connect to their respective pullup resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

45.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in the following table.

Table 289. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

45.4 I2C register descriptions

The memory map for the I^2C module is given below. The total address for each register is the sum of the base address for the I^2C module and the address offset for each register.

Address location 0x0007 is a reserved location, but access to this location will not generate any bus error.

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must align to 16-bit boundaries, and 32-bit accesses must align to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and you can access it in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

You cannot access the IBFD register by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

45.4.1 I2C memory map

I2C_0 base address: 401E_4000h

I2C_1 base address: 401E_8000h

I2C_2 base address: 401E_C000h

I2C_3 base address: 402D_8000h

I2C_4 base address: 402D_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	I2C Bus Address Register (IBAD)	8	RW	00h
1h	I2C Bus Frequency Divider Register (IBFD)	8	RW	00h
2h	I2C Bus Control Register (IBCR)	8	RW	80h
3h	I2C Bus Status Register (IBSR)	8	W1C	80h

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-4ca8-b251-390d3ab624d1

Table continued from the previous page...

Field	Function
	This field controls the software reset of the entire I^2C module. **NOTE** If the I^2C module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent START condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated, the current bus cycle may become corrupt. This ultimately results in either the current bus master or the I^2C module losing arbitration, after which bus operation returns to normal. 0b - The module is enabled. You must clear this field before any other IBCR fields have any effect. 1b - The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register fields (IBSR) are not valid when the module is disabled.
6 IBIE	I2C bus interrupt enable 0b - Interrupts from the I2C module are disabled. This does not clear any currently pending interrupt condition. 1b - Interrupts from the I2C module are enabled. An I2C interrupt occurs if IBSR[IBIF]=1.
5 MSSL	Master/slave mode select When you change this field from 0 to 1, the module generates a START signal on the bus and selects the master mode. When you change this field from 1 to 0, the module generates a STOP signal and changes the operation mode from master to slave. You should generate a STOP signal only if IBSR[IBIF]=1. The module clears this field without generating a STOP signal when the master loses arbitration. 0b - Slave mode 1b - Master mode
4 TXRX	Transmit/receive mode select This field selects the direction of master and slave transfers. When the I^2C module is addressed as a slave, your software must program this field based on IBSR[SRW]: • When IBSR[SRW]=0, program TXRX=0. • When IBSR[SRW]=1, program TXRX=1. In master mode, your software must program this field according to the type of transfer required. Therefore, for address cycles, this field will always be 1. 0b - Receive 1b - Transmit
3 NOACK	Data acknowledge disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. When the I²C module is enabled, it always acknowledges address matches, regardless of the value of NOACK. **NOTE** Values written to this field are only used when the I²C module is a receiver, not a transmitter. 0b - The module sends an acknowledge signal to the bus at the 9th clock bit after receiving one byte of data. 1b - The module does not send an acknowledge-signal response (that is, acknowledge bit = 1).
2 RSTA	Repeat START If the I²C module is the current bus master, and you program RSTA=1, the I²C module generates a repeated START condition. This field always reads as a 0. If you attempt a repeated START at the wrong time—if the bus is owned by another master—the result is loss of arbitration. 0b - No effect 1b - Generate repeated START condition
1 DMAEN	DMA enable When this field is 1, and the I²C module requires data to be read or written to I2C Bus Data I/O Register (IBDR), the module asserts the DMA Tx and Rx lines. When DMAEN=1, the I²C module does not generate an interrupt after the transfer of a byte is complete (that is, when the I²C module detects the falling edge of the 9th clock cycle). However, the module generates an interrupt if arbitration is lost or the module is addressed as a slave. The DMA mode is only valid when the I²C module is configured as a master, and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See DMA application information for more details. 0b - Disable the DMA TX/RX request signals 1b - Enable the DMA TX/RX request signals
0 —	Reserved Although this field supports read/write access, writing to this field is not required, and can produce unexpected results.

45.4.5 I2C Bus Status Register (IBSR)

Offset

Register	Offset
IBSR	3h

Function

Access: Supervisor mode only (the module ignores user mode accesses and does not assert an error response if you access this register in user mode)

Diagram

Bits	7	6	5	4	3	2	1	0
R	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
W				W1C			W1C	
Reset	1	0	0	0	0	0	0	0

Fields

Field	Function
7 TCF	Transfer complete The I2C module programs this field to 0 during the time that the module transfers one byte of data. After the I2C module detects the falling edge of the 9th clock of a byte transfer, the module programs this field to 1. **NOTE** This field is relevant to you only during or immediately after a transfer to or from the I2C module. 0b - Transfer in progress 1b - Transfer complete
6 IAAS	Addressed as a slave When its own specific address (I-Bus Address Register) is matched with the calling address, this field is set. The CPU is interrupted if IBCR[IBIE]=1. Then the CPU needs to check SRW and set the TXRX field accordingly. Writing to the I-Bus Control Register clears IAAS. 0b - Not addressed 1b - Addressed as a slave
5 IBB	Bus busy This field indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. **NOTE** Software must ensure that the I2C bus is idle by checking the IBSR[IBB] field (bus busy) before switching to master mode and attempting a START cycle. 0b - Bus is idle 1b - Bus is busy
4 IBAL	Arbitration Lost The I2C module programs IBAL=1 when the arbitration procedure is lost. Arbitration is lost in the following circumstances: • SDA is sampled low when the master drives a high during an address or data transmit cycle. • SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. Your software must clear this field by writing a one to it. A write of zero has no effect.
3 —	Reserved
2 SRW	Slave Read/Write When IAAS=1, SRW indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when all of these are true: • The I-Bus is in slave mode. • A complete address transfer has occurred with an address match. • No other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0b - Slave receive, master writing to slave 1b - Slave transmit, master reading from slave
1 IBIF	I2C bus interrupt flag IBIF=1 when one of the following conditions occurs: • Arbitration lost (IBAL=1) • Byte transfer complete (TCF=1 and DMAEN=0) • Addressed as slave (IAAS=1) • NoAck from Slave (MS and Tx bits set) • I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if IBIE=1. Your software must clear IBIF by writing a one to it. A write of zero has no effect. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
0 RXAK	Received acknowledge This is the value of SDA during the acknowledge bit of a bus cycle. If RXAK=0, it indicates an acknowledge signal has been received after the completion of eight bits of data transmission on the bus. If RXAK=1, it means no acknowledge signal is detected at the ninth clock. RXAK is valid only after transfer is complete. 0b - Acknowledge received 1b - No acknowledge received

Preliminary NDA only

45.4.6 I2C Bus Data I/O Register (IBDR)

Offset

Register	Offset
IBDR	4h

Function

In master transmit mode, when your software writes to IBDR, the I^2C module initiates a data transfer. The module sends the most significant bit first.

In master receive mode, when your software reads IBDR, the I^2C module initiates the reception of the next data byte.

In slave mode, the same functions are available after an address match has occurred.

NOTE

The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

When the the I^2C module is configured for master-receive or slave-receive modes, and your software reads IBDR, the I^2C module returns the most-recent byte received. The IBDR does not reflect every byte transmitted on the I^2C bus. Your software also cannot verify that it wrote a byte to IBDR correctly by reading the byte back.

In master transmit mode, the I^2C module takes the first byte of data written to IBDR after assertion of MSSL and uses this byte for the address transfer. This byte must comprise the calling address (in position DATA[7:1]) concatenated with the required R/W_b bit (in position D0). (In the I^2C bus specification, the R/W_b bit is presented as R/W with an overbar on the W.)

Access: Supervisor mode only (the module ignores user mode accesses and does not assert an error response if you access this register in user mode)

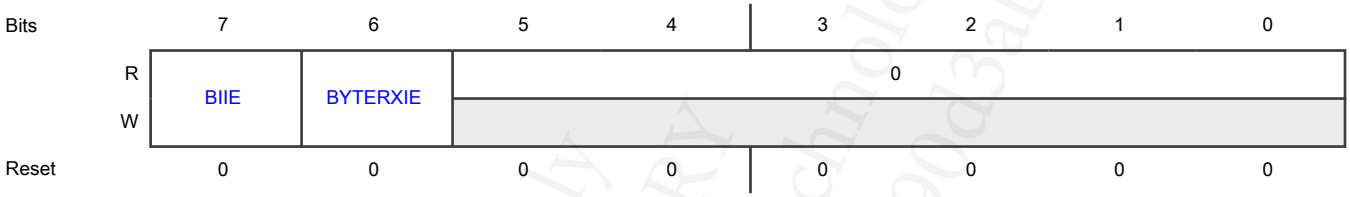
45.4.7 I2C Bus Interrupt Config Register (IBIC)

Offset



Register	Offset
IBIC	5h

Function

To program BIIE = 1, you must ensure that IBCR[MDIS] = 0.

Access: Supervisor mode only (the module ignores user mode accesses and does not assert an error response if you access this register in user mode)

Diagram

Fields

Field	Function
7 BIIE	Bus idle interrupt enable You can use this configuration field to enable the generation of an interrupt after the I^2C bus becomes idle. After BIIE=1, a high-to-low transition of IBSR[IBB] results in IBSR[IBIF]=1. You can use this feature to inform the CPU about the completion of a STOP on the I^2C bus. 0b - Bus idle interrupts disabled 1b - Bus idle interrupts enabled
6 BYTERXIE	Byte receive interrupt enable You can use this field to generate an interrupt every time the I^2C master/slave receives a new byte. This feature can be useful when an I^2C master receives data from a slave that transmits on an irregular basis. The I^2C module updates BYTERXIE only when the module is enabled (IBCR[MDIS]=0).
5-0 —	Reserved

45.4.8 I2C Bus Debug Register (IBDBG)

Offset

Register	Offset
IBDBG	6h

Function

Access: Supervisor mode only (the module ignores user mode accesses and does not assert an error response if you access this register in user mode)

Diagram

Bits	7	6	5	4	3	2	1	0
R	0				GLFLT_EN	BYTE_RX	IPG_DEB...	IPG_DEB...
W						W1C		
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7-4 —	Reserved
3 GLFLT_EN	Glitch filter enable This field allows you to filter out any glitch on the SCL or SDA line that may cause the I^{2}C module to enter an unrecoverable state. **NOTE** When GLFLT_EN = 1, the effect of the SCL and SDA lines is delayed by six IPG clock cycles. So, in cases where a glitch is not expected at the SCL or SDA inputs, you should not program GLFLT_EN = 1. 0b - The I2C module allows all pulses on the SCL or SDA input lines to pass through. 1b - The I2C module filters out any pulse (rising or falling) on the SCL or SDA input line that is shorter than six IPG clock cycles.
2 BYTE_RX	The I2C module programs BYTE_RX=1 when an I2C master/slave receives a new byte. The module generates an interrupt if IBIC[BYTERXIE]=1.
1 IPG_DEBUG_HALTED	Debug halted This is a status field that you can read back after asserting the debug enable signal. The field informs you whether the I^{2}C module entered DEBUG mode or not. 0b - The I2C module is still executing a transaction. 1b - The I2C module entered DEBUG mode.
0 IPG_DEBUG_EN	Debug enable This field allows the I^{2}C module to enter the DEBUG mode when the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If your software programs IPG_DEBUG_EN=1, and the IPG DEBUG signal becomes high in the middle of a transaction, the I^2C module enters DEBUG mode only after successfully completing the current transaction, after which no further transactions can occur until the I^2C module exits DEBUG mode. 0b - Normal operation. The bus idle interrupts are disabled. 1b - The I2C module is in DEBUG mode.

45.5 Functional description

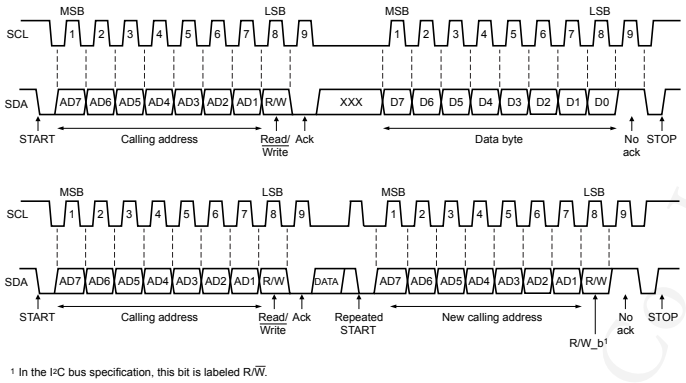
This section presents the following topics:

- Notes about module operation
- Transactions
- Arbitration procedure
- Clock behavior
- Interrupts
- DEBUG mode
- DMA interface

45.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

45.5.2 Transactions



This section presents the following topics:

- Protocol overview
- Transaction protocol definitions
- High-level protocol steps
- START condition
- Slave address transmission
- Data transmission
- STOP condition
- Repeated START condition

45.5.2.1 Protocol overview

The following figure shows the behavior of SCL and SDA during a typical I^2C transaction.

Figure 354. I²C transaction protocol

45.5.2.2 Transaction protocol definitions

This section defines several important terms presented in Figure 354.

Table 290. I²C definitions

Term	Definition
START	A START condition, as defined in Definition: I2C conditions
STOP	A STOP condition, as defined in Definition: I2C conditions
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus (see I2C calling address requirements for the requirements for specifying this address)
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: • 0=The data is being transferred from the master to the slave ("write") • 1=The data is being transferred from the slave to the master ("read")
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low

45.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

45.5.2.4 High-level protocol steps

The I²C protocol conceptually supports two types of transfers, as illustrated in Figure 354. The significant steps in these transfers are presented in the following table. Details of each of these steps are presented in subsequent sections.

Table 291. I²C high-level protocol steps

Standard transfer	Repeated START transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Acknowledgment from slave	3. Acknowledgment from slave
4. Data transfer	4. Data transfer
5. STOP condition	5. Repeated START condition
6. (repeat Steps 1-4)	6. (repeat Steps 2-4 as needed)
	7. STOP condition
	8. (repeat Steps 1-7)

45.5.2.5 START condition

When the bus is free (no master device engages the bus; both SCL and SDA lines are at logical high), a master can initiate communication by sending a START condition (see Definition: I2C conditions). This signal denotes the beginning of a new data transfer (which may contain several bytes of data) and brings all slaves out of their idle states.

See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (IBFD) for the associated timing requirements.

45.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (see START condition). The following table presents the process of slave address transmission.

Table 292. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: • The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. • The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

45.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the slave must leave the SDA line high. The master can then generate a STOP condition (to abort the data transfer) or a repeated START condition.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that as reaching the end of data. The slave then releases the SDA line for the master to generate a STOP or a START condition.

45.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see Definition: I2C conditions). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see Repeated START condition.

See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (IBFD) for the associated timing requirements.

45.5.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of Figure 354.

45.5.3 Arbitration procedure

The I^2C bus is a true multi-master bus that allows more than one master to be connected to the bus. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock. For this clock, the low period is equal to the longest clock low period and the high period is equal to the shortest period among the masters. A data arbitration procedure determines the relative priority of the contending masters. A bus master loses arbitration if it transmits logic "1" while another master transmits logic "0". The losing masters immediately switch over to slave mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, the I^2C module sets IBSR[IBAL] to indicate loss of arbitration.

45.5.4 Clock behavior

This section presents the following topics:

- Clock synchronization
- Clock stretching
- Handshaking
- Clock rate and IBFD settings

45.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached.

However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see the following figure). When all devices concerned have counted off their

low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

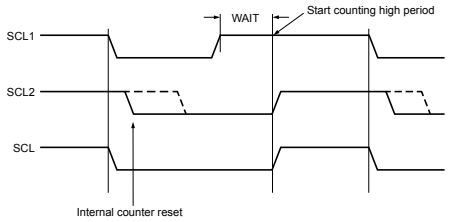

Figure 355. I²C bus clock synchronization

45.5.4.2 Clock stretching

Slaves can use the clock synchronization mechanism to slow down the bit rate of a transfer. After the master drives SCL low, the slave can drive SCL low for the required period and then release it. If the slave's SCL low period is greater than the master's SCL low period, the resulting SCL bus signal low period is stretched.

45.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (nine bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

45.5.4.4 Clock rate and IBFD settings

45.5.4.4.1 Timing definitions

Table 293. Timing definitions relevant to clock rate and IBFD settings

Term	Definition
SCL Divider	The factor used to prescale the CPU clock for bit rate selection. This is relevant to: • Figure 356 • Table 295 • Table 296
SCL period	(CPU clock period)×(SCL Divider)
SCL Hold	The required number of CPU clocks to generate a START or STOP condition. This is relevant to: • Figure 356 • Table 295 • Table 296
SDA Hold	This is relevant to: • Figure 357 • Table 295 • Table 296

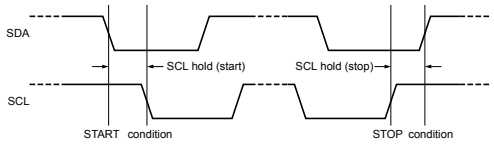

Figure 356. SCL Divider and SDA Hold

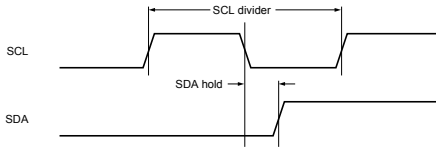

Figure 357. SDA Hold time

45.5.4.4.2 Divider and hold values

Table 295 provides the values for:

- SCL Divider
- SDA Hold
- SCL Hold (start)
- SCL Hold (stop)

when the glitch filter is disabled. (To disable this filter, write IBDBG[GLFLT_EN]=0.)

You have up to three MUL options available for all divider values, as shown in Table 294. Your choice of MUL determines the internal monitor rate of the I^2C bus (SCL and SDA signals):

- A lower MUL value results in a higher sampling rate of the I^2C signals.
- A higher MUL value results in a lower sampling rate of the I^2C signals. This gives the I^2C module greater immunity against glitches in the I^2C signals.

Table 294. MUL values as a function of IBC

When IBC is...	MUL is...
00h–3Fh	1
40h–7Fh	2
80h–BFh	4

NOTE

The frequency divider values listed in Table 295 and Table 296 depend on the board parasitics at the SCL pad. The observed I^2C frequency may differ from the expected frequency by 10–15%.

45.5.5 Interrupts

This section presents the following topics:

- Interrupt vector
- Interrupt description

45.5.5.1 Interrupt vector

The I²C module uses only one interrupt vector.

Provided under NDA only

Table 297. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I2C interrupt	—	—	—	IBAL, TCF, IAAS, IBB fields in IBSR	When any of IBAL, TCF, or IAAS fields are 1, the I2C module may cause an interrupt based on Arbitration lost, Transfer Complete, or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

45.5.5.2 Interrupt description

There are five types of internal interrupts in the I2C. The interrupt service routine can determine the interrupt type by reading the Status register.

I2C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBSR[IBAL]=1)
- Byte Transfer condition (IBSR[TCF]=1 and IBCR[DMAEN]=0)
- Address Detect condition (IBSR[IAAS]=1)
- No Acknowledge from slave received when expected
- Bus idle (IBSR[IBB]=0)

The IBCR[IBIE] field enables the I2C interrupt. To clear this field, program IBSR[IBIF]=1 in the interrupt service routine.

To use the Bus idle interrupt, you must enable it by using the IBIC[BIIE] field.

45.5.6 DEBUG mode

This mode allows the CPU to debug the I2C module by freezing all the counters, registers, and status bits. To enter this mode, the I2C module must receive a DEBUG mode request, defined as this combination of actions:

- Another module on the chip sends an internal debug signal to the I2C module.
- You program IBDBG[IPG_DEBUG_EN]=1.

The I2C module completes all the ongoing transactions and comes to a graceful halt after receiving a DEBUG mode request.

The I2C module programs IBDBG[IPG_DEBUG_HALTED]=1 to indicate that the module has successfully serviced the DEBUG mode request.

The I2C module programs IBDBG[IPG_DEBUG_HALTED]=0 after the module that sent the DEBUG mode request ends that request and you program IBDBG[IPG_DEBUG_EN]=0.

As soon as the I2C module enters DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I2C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of eight bytes and you initiated DEBUG mode at the time of the second byte, the IPG Debug Halted signal will be asserted after the eighth byte is transmitted/received. See the simulation result in Figure 358 for more details.

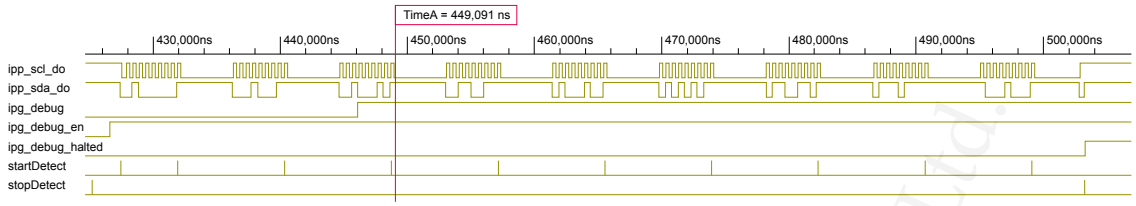

Figure 358. Simulation result of IPG Debug Halted in case of frame transmission

The I^{2}C module enters DEBUG mode after completing the transmission or reception of the current byte when both of these conditions are true:

- Any DMA transaction (transmit or receive) is in progress
- The I^{2}C module receives a DEBUG mode request at the same time that a byte reception or transmission occurs

As soon as the module exits DEBUG mode, transmission or reception of the remaining bytes resumes. See the simulation snapshot shown in Figure 359 for details where the I^{2}C is transmitting eight bytes using DMA and the I^{2}C module receives a DEBUG mode request while the module is transmitting the second byte. The I^{2}C module enters DEBUG mode after the module successfully transmits the second byte (IPG Debug Halted signal asserted). As soon as the module exits DEBUG mode and deasserts the IPG Debug Halted signal, transmission resumes successfully.

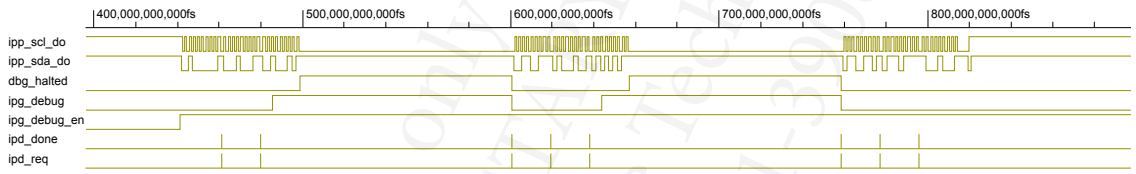

Figure 359. Simulation result of IPG Debug Halted in case of frame transmission using DMA

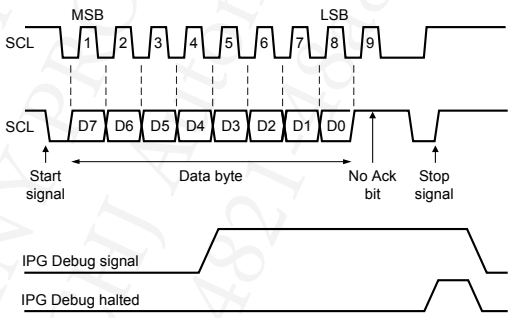
No more transactions can occur until the module that sent the DEBUG mode request ends that request. At that time, the I^{2}C module starts functioning normally. You can examine the IBDBG[IPG_DEBUG_HALTED] field to determine whether the I^{2}C module is in DEBUG mode. See Figure 360 for more details.



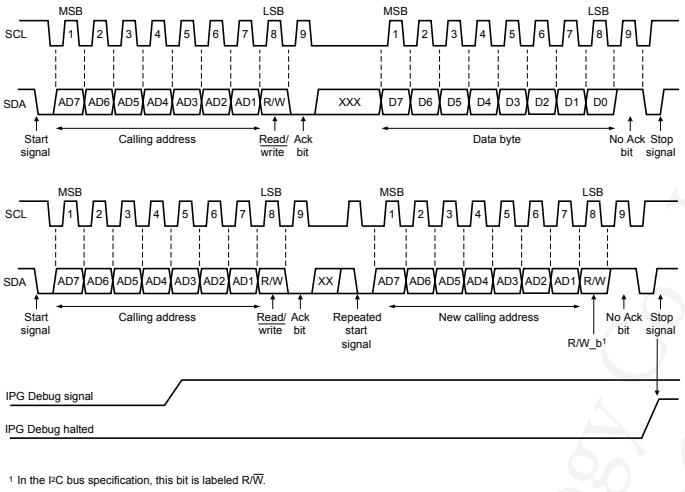


Figure 360. DEBUG mode

Figure 361 shows a case of DEBUG mode with repeated START transaction. In this case, if another module on the chip sends an internal debug signal to the I^{2}C module in the middle of a transaction, the I^{2}C module completes the entire transaction with multiple repeated START before the module enters DEBUG mode.

[1] In the I²C bus specification, this bit is labeled R/$\overline{W}$.

Figure 361. DEBUG mode with repeated START

45.5.7 DMA interface

The I²C module implements a simple DMA interface so that the module can request data transfers with minimal support from the CPU (see DMA application information). You enable DMA mode by programming IBCR[DMAEN].

The DMA interface is operational when the I²C module is configured for Master mode.

You must transfer at least three bytes of data per frame to/from the slave when using DMA mode. However, in practice, DMA mode is only worthwhile when you have a large number of data bytes to transfer per frame.

The I²C module uses two internal signals—TX request and RX request—to signal the DMA controller when the I²C module must write data to IBDR or read data from IBDR.

See Initialization/application information for further details of the DMA interface.

45.6 Initialization/application information

This section presents the following topics:

- Recommended interrupt service flow
- General programming guidelines (for both master and slave mode)
- Programming guidelines specific to Master mode
- Programming guidelines specific to Slave mode
- DMA application information

45.6.1 Recommended interrupt service flow

The following figure shows a flowchart for the recommended I²C interrupt service routine. Deviation from the flowchart may result in unpredictable I²C bus behavior.

Preliminary NDA Only

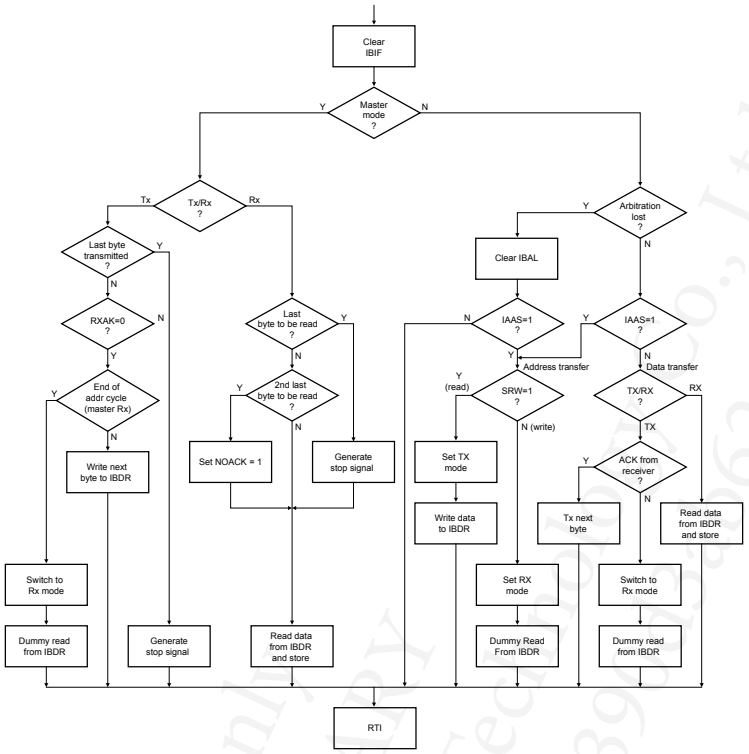

Figure 362. Recommended I²C interrupt service routine flowchart

45.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I²C module in both master and slave mode. It presents the following topics:

- Initializing the I2C module
- Software response after a transfer

45.6.2.1 Initializing the I²C module

The following table describes how to initialize the I²C module.

Table 298. I²C initialization procedure

Step	Action
1	Use I2C Bus Frequency Divider Register (IBFD) to select the required division ratio to obtain SCL frequency from the system clock.
2	Use I2C Bus Address Register (IBAD) to define the slave address.
3	Clear the MDIS field in I2C Bus Control Register (IBCR) to enable the I²C interface system.
4	Use I2C Bus Control Register (IBCR) to select Master/Slave mode, Transmit/Receive mode, and whether interrupts are enabled or disabled.
5	(Optional) Use I2C Bus Interrupt Config Register (IBIC) to further refine the interrupt behavior.

45.6.2.2 Software response after a transfer

Transmission or reception of a byte causes the I^2C module to program IBSR[TCF]=1. This indicates that the I^2C module transmitted one byte. The I^2C module also programs the interrupt flag IBSR[IBIF]=1 and generates an interrupt if your software enabled the interrupt function (by programming IBCR[IBIE]=1) during initialization. Your software can clear IBSR[IBIF] by writing a 1 to that field (in the interrupt service routine, if interrupts are used).

The I^2C module programs IBSR[TCF]=0 to indicate data transfer in progress whenever your software:

- Writes to IBDR in transmit mode
- Reads the IBDR in receive mode

Do not use IBSR[TCF] as a "data transfer complete" flag. This is because the flag timing depends on a number of factors, including the I^2C bus frequency. This field may not conclusively provide an indication of a transfer-complete situation. Your software must detect transfer-complete situations by using IBSR[IBIF].

Your software may service the I^2C I/O in the main program by monitoring IBSR[IBIF] if your software disabled the interrupt function. Your software must poll IBSR[IBIF] instead of IBSR[TCF] because these fields function differently when arbitration is lost.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode—that is, the I^2C module transmits the address. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the master's IBCR[TXRX] field must be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, the I^2C module programs IBSR[IAAS]=1 if the Slave address (I2C Bus Address Register (IBAD)) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), your software reads IBSR[SRW] to determine the direction of the subsequent transfer and programs IBCR[TXRX] accordingly. For slave mode data cycles (IBSR[IAAS]=0), IBSR[SRW] is not valid. Your software must read IBCR[TXRX] to determine the direction of the current transfer.

45.6.3 Programming guidelines specific to Master mode

This section presents the following topics:

- Generating START
- Transmit/receive sequence
- Generating STOP
- Generating repeated START
- Loss of arbitration

45.6.3.1 Generating START

After the I^2C module completes its initialization procedure, the module can transmit serial data when your software selects the master transmitter mode. If the device is connected to a multi-master bus system, your software must test the state of IBSR[IBB] to check whether the serial bus is free.

Your software can configure the I^2C module to send the START condition and the first byte (the slave address) if the bus is free (IBSR[IBB]=0). The data that your software writes to the data register (I2C Bus Data I/O Register (IBDR)) comprises the slave calling address and the LSB. Your software configures the LSB to indicate the direction of transfer required from the slave.

The bus free time (the time between a STOP condition and the following START condition) is built into the I^2C module that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, your software must wait until the I^2C bus is busy after writing the calling address to the IBDR before proceeding with the next instructions. This is illustrated in the following example.

Here is an example of the sequence of events which generates the START signal and transmits the first byte of data (slave address):

```
while (IBSR[IBB]==1)               // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1  // master and transmit mode, that is,
                                   // generate start condition
IBDR = calling_address             // send the calling address to the data register
while (bit 5, IBSR ==0)            // wait in loop for IBB flag to be set
```

45.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 299. Master transmit sequence

Step	Action
a	Use I2C Bus Frequency Divider Register (IBFD) to select the required division ratio to obtain SCL frequency from platform clock/2.
b	Write a 0 to IBCR[MDIS] to enable the I^2C interface system.
c	Use I2C Bus Control Register (IBCR) to select Master mode, Transmit mode, and interrupt enable.
d	Write a 0 to IBSR[IBIF].
e	Write data to I2C Bus Data I/O Register (IBDR).
f	Observe changes in IBSR[TCF]: • When IBSR[TCF] becomes 0, the transfer is in progress. • When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until IBSR[IBIF] becomes 1.
h	Read the fields in I2C Bus Status Register (IBSR) to determine what happened: • If TCF = 1, the transfer completed. • If RXAK = 1, a No Acknowledge condition occurred. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE** You can ignore Address Detect (IAAS = 1) for master mode (it is valid only for slave mode).
i	Examine IBSR[RXAK] for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Provided under NXP Proprietary Binding Agreement c8a3b2e5-2121-4da8-b251-3a0d3ab624c1

Table 300. Master receive sequence

Step	Action
a	Execute steps a through i in Table 299 for address dispatch.
b	Write a 0 to IBSR[IBIF].
c	Write a 0 IBCR[TXRX] to select Receive mode.
d	Perform a dummy read of I2C Bus Data I/O Register (IBDR) to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. This proves that the transfer is complete.
f	Wait until IBSR[IBIF] becomes 1.
g	Read the fields in I2C Bus Status Register (IBSR) to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read I2C Bus Data I/O Register (IBDR) to determine the data received from the slave.
i	Change IBSR[IBIF] and IBSR[TCF] to 0 by writing 1 to those fields.
j	Repeat steps e through i to read subsequent bytes.

Table 301. Slave transmit sequence

Step	Action
a	Use I2C Bus Address Register (IBAD) to define the slave address.
b	Write a 0 to IBCR[MDIS] to enable the I^2C interface system.
c	Examine fields in I2C Bus Status Register (IBSR) as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 1, write a 1 to IBCR[TXRX] to select Transmit mode.
d	Write data to I2C Bus Data I/O Register (IBDR).
e	Wait until IBSR[IBIF] becomes 1.
f	Wait until IBSR[RXAK] becomes 0.
g	Write a 0 to IBSR[IBIF].
h	Repeat steps d through g for the next consecutive data transfers.

Table 302. Slave receive sequence

Step	Action
a	Use I2C Bus Address Register (IBAD) to define the slave address.
b	Write a 0 to IBCR[MDIS] to enable the I^2C interface system.

Table continues on the next page...

Table 302. Slave receive sequence (continued)

Step	Action
c	Examine fields in I2C Bus Status Register (IBSR) as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 0, write a 0 to IBCR[TXRX] to select Receive mode.
d	Write a 0 to IBSR[IBIF].
e	Perform a dummy read of I2C Bus Data I/O Register (IBDR) to initiate the receive operation.
f	Wait until IBSR[TCF] becomes 1. This proves that the transfer is complete.
g	Wait until IBSR[IBIF] becomes 1.
h	Read the fields in I2C Bus Status Register (IBSR) to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
i	Read I2C Bus Data I/O Register (IBDR) to determine the data received from the master.
j	Change IBSR[IBIF] and IBSR[TCF] to 0 by writing 1 to those fields.
k	Repeat steps f through j to read subsequent bytes.

45.6.3.3 Generating STOP

A data transfer ends with a STOP condition generated by the master device. A master transmitter can simply generate a STOP condition after it transmits all the data. Here is an example showing how a master transmitter generates a STOP condition.

```
if (tx_count == 0) or     // check to see if all data bytes have been transmitted
  (bit 0, IBSR == 1) {    // or if no ACK generated
    clear bit 5, IBCR     // generate STOP condition
  }
else {
 IBDR = data_to_transmit  // write byte of data to DATA register
   tx_count --            // decrement counter
 }                        // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data. The master receiver can do this by programming IBCR[NOACK]=1 before reading the second-to-last byte of data. Before reading the last byte of data, the master receiver must first generate a STOP condition. Here is an example showing how a master receiver generates a STOP condition.

```
rx_count --           // decrease the rx counter
if (rx_count ==1)     // 2nd last byte to be read ?
 bit 3, IBCR = 1      // disable ACK
 if (rx_count == 0)   // last byte to be read ?
 bit 5, IBCR = 0      // generate STOP condition
```

```
else
data_received = IBDR   // read RX data and store
```

45.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. Here is a program example.

```
bit 2, IBCR = 1             // generate another start (restart)
IBDR == calling_address     // transmit the calling address
```

45.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave mode by the I^{2}C module. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBSR[IBAL]=1 and IBCR[MSSL]=0. If one master attempts to start transmission while the bus is being engaged by another master, the hardware:

- Inhibits the transmission
- Switches IBCR[MSSL] from 1 to 0 without generating a STOP condition
- Generates an interrupt to the CPU
- Programs IBSR[IBAL]=1 to indicate that the attempt to engage the bus is failed
- Does not program IBSR[TCF]=1 due to the loss of data during arbitration

When considering these cases, your slave service routine should test IBSR[IBAL] first and your software should program IBSR[IBAL]=0 if IBSR[IBAL]=1.

45.6.4 Programming guidelines specific to Slave mode

In the slave interrupt service routine, IBSR[IAAS] should be tested to check if a calling of its own address has just been received. If IBSR[IAAS]=1, software should program IBCR[TXRX]=1 according to IBSR[SRW]. Writing to the IBCR clears IBSR[IAAS] automatically. The only time you will read a value of 1 from IBSR[IAAS] is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared.

A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low between byte transfers. SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, IBSR[RXAK] must be tested before transmitting the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

45.6.5 DMA application information

The DMA interface on the I^{2}C module is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Your software must ensure that the DMAEN field in I2C Bus Control Register (IBCR) is not set when the I^{2}C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because the I^{2}C module does not have a FIFO.

The CPU should also keep the I^{2}C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN field in I2C Bus Control Register (IBCR) can disable the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, depending on the setting of IBCR[DMAEN]. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode because the I^{2}C should never be configured for slave operation.

The following sections provide details on setting up a DMA transfer and what intervention is required from the CPU. The sections assume that the system DMA controller can generate an interrupt after a certain number of DMA transfers have occurred.

The sections present the following topics:

- DMA mode, master transmit
- DMA mode, master reception
- Exiting DMA mode and system requirement considerations

45.6.5.1 DMA mode, master transmit

The following flowchart describes the exact operation for using a DMA controller to transmit *n* data bytes to a slave. The CPU always transmits the first byte (the slave calling address) and last byte. The DMA controller can transfer all other data bytes.

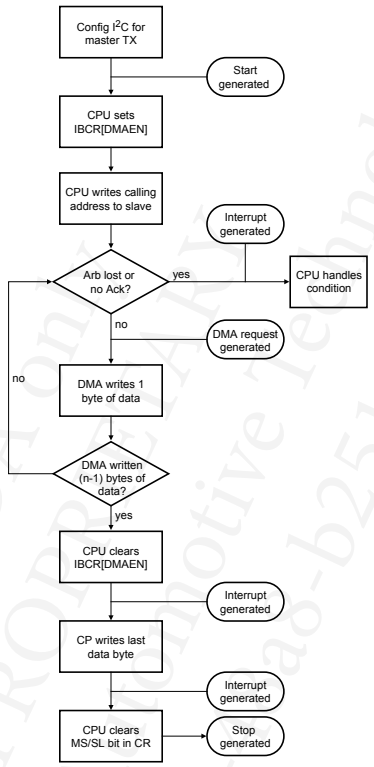

Figure 363. Flowchart of DMA mode master transmit

45.6.5.2 DMA mode, master reception

The following flowchart describes the exact operation for using a DMA controller to receive *n* data bytes from a slave. The CPU always transmits the first byte (the slave calling address) and the last two bytes. The DMA controller can read all other data bytes.

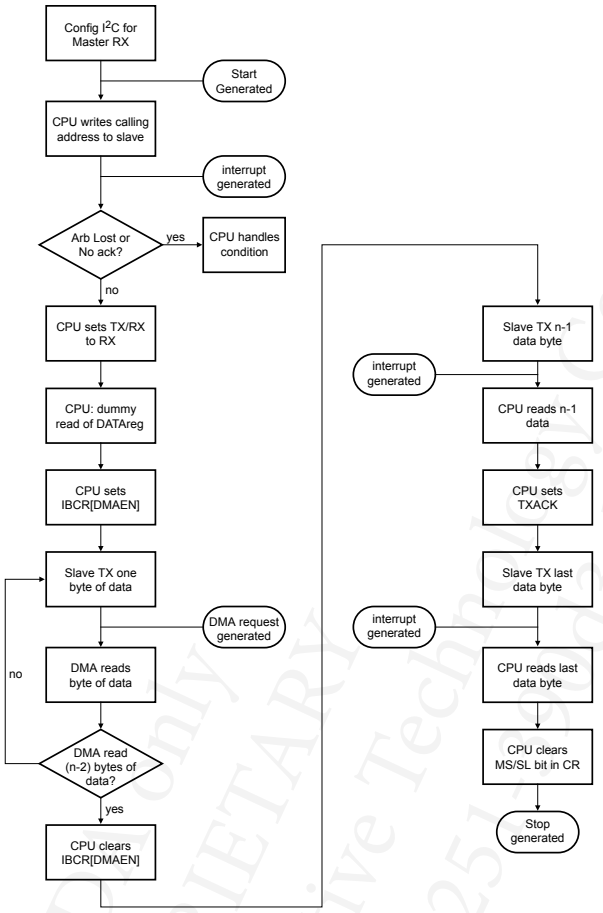

Figure 364. Flowchart of DMA mode master receive

45.6.5.3 Exiting DMA mode and system requirement considerations

As described above, the CPU must request an interrupt to process the last few bytes of a TX or RX transfer. To change from DMA to interrupt-driven transfers in the I^{2}C module, you must disable IBCR[DMAEN]. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^{2}C module.

After the last DMA write (TX mode) to the I^{2}C the module immediately starts the next I^{2}C bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^{2}C bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   IBCR[DMAEN] is cleared before the next I^{2}C bus transfer completes. In this case, the I^{2}C module raises an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   IBCR[DMAEN] is cleared after the next I^{2}C bus transfer has already completed. In this case, the I^{2}C module does not raise an interrupt request to the CPU. Instead, IBSR[TCF] can be read to determine that the transfer completed and the I^{2}C module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable IBCR[DMAEN] after the last DMA controller access to the I^{2}C is the time required for one byte transfer over the I^{2}C. For a fast reaction, the disabling must occur before the 9th (ACK) bit of the data transfer. Therefore, the time available is eight times the SCL period.

$$T_R = 8 \times T_{SCL}$$

In fast mode, with 400 kbit/s, T_{SCL} is 2.5 µs, so T_R is 20 µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of IBCR[DMAEN]. Three options are:

1. CPU intervention via interrupt

   The DMA controller is programmed to signal an interrupt to the CPU. The CPU is then responsible for programming IBCR[DMAEN]=0. This scheme should be supported by most systems but it can result in a slow reaction time if other higher-priority interrupts interfere. Therefore, the interrupt handling routine can become complicated. This is because the routine must check which of the two cases happened (by checking IBSR[TCF]) and act accordingly. In case of a slow reaction, you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

   NOTE

   The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and IBCR[DMAEN] and checks IBSR[TCF].

2. DMA channel linking

   If the TCD in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

   NOTE

   In this case, you must ensure—at the system level—that no higher-priority DMA requests occur between the two linked TCDs. Such requests could again create a scenario of slow reaction.

3. DMA scatter/gather process

   If the TCD in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature initiates a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a "ready-for-I^2C-transfer" state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead, and a little increase in application code complexity.

   NOTE

   Here you must ensure—at the system level—that no higher-priority DMA requests occur during the scatter/gather process. Such requests could again create a scenario of slow reaction.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half-speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/16 MHz = 250 ns

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

  $8 \times T_{AHD}$ = 8/32 MHz = 250 ns

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/150 MHz = 26.6 ns

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

  $4 \times T_{AHD}$ = 4/150 MHz = 26.6 ns

With the DMA scatter/gather process, the required IBCR access can finish in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. You must decide which usage model best suits your overall requirement.

Chapter 46
Gigabit Ethernet Media Access Controller (GMAC)

46.1 Introduction

NOTE

The remaining sections in the chapter are Synopsys Proprietary. Used with permission.

GMAC enables a host application to transmit and receive data over an Ethernet network in compliance with IEEE 802.3-2015. GMAC supports 10/100/1000/2500 Mbit/s [3] applications.

Table 303. Terms and definitions

Term	Definition
APB	Advanced Peripheral Bus—An implementation of the Arm® AMBA® APB interface.
AVB	Audio Video Bridging—Transmission of audio and video signals over an Ethernet network.
AXI	Advanced eXtensible Interface—An implementation of the Arm AMBA AXI interface. GMAC has an AXI master interface that connects to all GMAC DMA channels.
Backpressure	A mechanism for stalling reception of packets transmitted over an Ethernet network.
CRC	Cyclic Redundancy Check—A calculation performed on received data packets used to detect corrupted data.
DMA	Direct Memory Access—Hardware within GMAC that enables movement of data to/from system memory with minimal intervention from the core.
FIFO	First In First Out—A type of data buffer from which data is retrieved in the same order in which it was stored in the buffer.
GMII	Gigabit Media Independent Interface—A data interface and management interface that connects a MAC to a PHY, defining speeds of up to 1000 Mbit/s.
IEEE 802.1AS-Rev	The enhanced IEEE standard for Timing and Synchronization for Time-Sensitive Applications (AVB, for example).
IEEE 802.1Q	The IEEE standard for VLANs on an IEEE 802.3 Ethernet network.
IEEE 802.1Qbu	An amendment to the IEEE 802.1Q standard that supports frame preemption.
IEEE 802.1Qbv	An amendment to the IEEE 802.1Q standard that supports scheduled traffic.
IEEE 802.3-2015	The IEEE standard that specifies Ethernet network operation.
IPv4, IPv6	Internet Protocol version *n*—Refers to versions of the Internet Protocol specification.
Layer 3, Layer 4	Refers to layers defined within the Open System Interconnection (OSI) model of networking. The layers are:

Layer	Name
1	Physical
2	Data Link
3	Network

[3] Supported PHY interface speeds vary per device

Term	Definition
	<table><tr><th>Layer</th><th>Name</th></tr><tr><td>4</td><td>Transport</td></tr><tr><td>5</td><td>Session</td></tr><tr><td>6</td><td>Presentation</td></tr><tr><td>7</td><td>Application</td></tr></table>
MAC	Media Access Controller—Refers to the data-link layer defined by the IEEE 802.3 standard.
MDIO	Management Data Input/Output—A serial interface used for PHY configuration.
MII	Media Independent Interface—A data interface and management interface that connects a MAC to a PHY. The IEEE 802.3 standard defines it..
MTL	MAC Translation Layer—The GMAC component that contains the receive and transmit FIFOs.
Pause packet	Refers to a mechanism defined by the IEEE 802.3x standard, used to request a temporary halt to data transmission on an Ethernet network.
PHY	The physical interface transceiver that implements the OSI physical layer for an Ethernet network. The IEEE 802.3 standard defines it.
RGMII	Reduced Gigabit Media Independent Interface—A GMII specification that has a reduced pin count.
RMII	Reduced Media Independent Interface—An MII specification with a reduced number of signals.
RMON	Remote Network Monitoring—An extension of the Simple Network Management Protocol (SNMP) that enables monitoring of Ethernet network statistics.
Rx	Receive
SFD	Start Frame Delimiter—A field within an Ethernet frame.
SGMII	Serial Gigabit Media Independent Interface—A variant of the GMII that has a reduced pin count and lower power consumption.
TCP	Transmission Control Protocol—A network protocol that provides a mechanism for transmitting and receiving an ordered and error-checked stream of information packets.
Tx	Transmit
UDP	User Datagram Protocol—A network protocol that provides higher speeds than TCP but does not include error checking.
VLAN	Virtual Local Area Network.

46.2 Features

In addition to the default features defined in the IEEE 802.3 specifications, GMAC supports the following:

- MII 10/100 Mbit/s, RMII (10/100 Mbit/s), RGMII (100/1000 Mbit/s)
- GMII to support SGMII (1000/2500 Mbit/s) (supported PHY interface speeds vary per device—check the specifications for each chip)

- Time Aware Shaper (IEEE 802.1Qbv), Time Synchronization (IEEE 802.1AS-Rev), and Frame Preemption (IEEE 802.1Qbu) for time-sensitive networking
- Media clock recovery and generation for AVB
- AXI4 master and APB3 slave
- RMII specification version 1.2 from RMII consortium
- RGMII specification version 2.6 from HP/Marvell
- Separate interfaces for transmit, receive, and control paths
- Full-duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with RMON counters
- Flexibility to control Pulse per Second (PPS) output signals and support for auxiliary snapshot input signals
- Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the transmit or receive status of PTP packet) (both one-step and two-step timestamping are supported in transmit direction)
- MDIO (clause 22 and clause 45) interface for configuration and management of the PHY
- Preamble and start of packet data (SFD) insertion/deletion
- Automatic CRC and pad generation/stripping option, with an option to disable CRC checking
- Programmable interpacket gap
- Source address insertion/replacement, VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control IEEE 802.1Q VLAN tag detection, and option to delete in received packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes:
  - Up to 1 additional 48-bit perfect destination address filters with masks for each byte
  - Up to one 48-bit source address comparison check with masks for each byte
  - Optional 256-bit hash filter for multicast and unicast destination addresses
  - Option to pass all multicast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and optional hash-based filtering (filtering can be based on either outer or inner VLAN tag)
  - Layer 3 and Layer 4-based TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering—32 filter selections
  - Programmable lookup-table-based flexible parser for filtering and steering received packets

46.3 Architecture

46.3.1 Interfaces

GMAC supports the following interfaces:

- AXI
- PHY interfaces.

The AXI interface connects to the chip's AXI master interface. It provides the path for transferring data to and from system memory.

The PHY supports the following interfaces, which you can use alone or in combination:

- Media Independent Interface (MII)
- Reduced GMII (RGMII)
- Serial GMII (SGMII) supported through GMII.

46.3.2 DMA controller

The GMAC DMA controller includes:

- Independent transmit and receive engines:
  - The transmit engine transfers data from system memory to the device port (MTL).
  - The receive engine transfers data from the device port to system memory.
- Control and status registers.

Based on data transfer profiles contained in DMA descriptors, the GMAC DMA controller efficiently moves data from source to destination with minimal intervention from the application core.

46.3.3 MAC Transaction Layer (MTL)

The MAC Transaction Layer (MTL) provides a FIFO memory interface to buffer and regulate packets being transferred between system memory and the MAC. It also enables data to be transferred between the application clock domain and the MAC clock domain. The MTL has two data paths—a transmit path and a receive path. The data path for each can be 64-bit wide.

46.3.4 Media Access Controller (MAC)

The MAC transmits data to the PHY and, when a transmission completes, provides the transmission status to the MTL. When the MAC detects a Start Frame Delimiter (SFD) on the interface, it begins receiving data from the PHY. The MAC also verifies the integrity of the transmitted packet via CRC and drops any packet that fails the CRC check.

46.3.5 Interrupts

Application software can configure GMAC to trigger interrupts based on events captured in status registers. You can independently enable or disable interrupt generation for each interrupt source. GMAC can generate interrupts from events associated with:

- MAC
- MTL
- GMAC DMA.

46.4 Transmit and receive FIFOs

The transmit FIFO buffers data transferred from the application to GMAC. Similarly, the receive FIFO stores packets received from the network interface until they are transferred to the application. Both FIFOs are asynchronous because they also transfer data between the application clock and the MAC line clock domains.

46.5 Flow control

GMAC supports Full-Duplex and Half-Duplex mode packet flow control for transmit operation, and full-duplex packet flow control for receive operation.

Transmit packet flow control involves transmitting *pause packets* in Full-Duplex mode and backpressure in Half-Duplex mode to control the flow of packets from the remote end.

Receive packet flow control is functional only in Full-Duplex mode. GMAC treats any pause packet received as a normal control packet.

46.6 Double VLAN tagging

This feature enables the MAC to process two VLAN tags, and supports:

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path
- Packet filtering and stripping based on either one of the two VLAN tags in the receive path
- Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

46.7 Descriptors

The GMAC DMA controller transfers data based on a ring of descriptors. Application software creates the descriptors in system memory. GMAC supports the following types of descriptors:

- A *normal descriptor* is used for packet data and provides control information for packets to be transmitted.
- A *context descriptor* provides control information for a packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. The buffers enable the adapter port to be compatible with various types of memory management schemes.

46.7.1 Descriptor structure

GMAC supports a ring structure for DMA descriptors as shown in the following figure. The Descriptor Tail Pointer register contains the pointer to the descriptor address (N). The base address of the descriptor ring and the Current Descriptor Pointer determine the address of the current descriptor that the GMAC DMA controller can process. The GMAC DMA controller has ownership of the descriptors up to the location before the one specified by the Descriptor Tail Pointer (N – 1). The GMAC DMA controller continues to process the descriptors until Current Descriptor Pointer == Descriptor Tail Pointer.

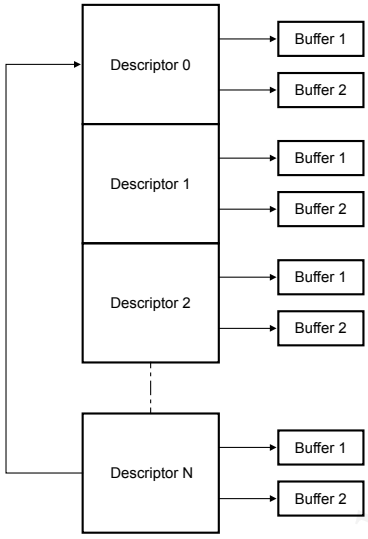

Figure 366. Ring structure

46.7.2 Transmit descriptor

The GMAC DMA controller requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor contains fields that control MAC operation on a per-transmit packet basis.

46.7.3 Receive descriptor

The GMAC DMA controller attempts to read a descriptor only if the Descriptor Tail Pointer is not equal to the descriptor ring base address or the Current Descriptor Pointer. We recommend that you have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the unavailability of the descriptors significantly degrades DMA performance. In this scenario, the receive FIFO in the MTL becomes full and starts dropping packets.

GMAC supports the following types of receive descriptors:

- Normal descriptors
- Context descriptors

Application software creates all receive descriptors. The GMAC DMA controller treats them as Normal descriptors. The GMAC DMA controller:

1. Reads a descriptor.
2. Transfers all or part of a received packet to the buffers pointed to by the descriptor.
3. Closes the descriptor with the appropriate packet status.

The configuration data within a Normal descriptor is insufficient for writing a complete status for some packets. In this case, the GMAC DMA controller writes the extended status to the next descriptor, without processing the buffers or pointers contained in the descriptor. The format and content of the descriptor is that of a Context descriptor.

46.8 Functional description

Prior to using GMAC functions, application software must perform configuration tasks to ensure proper operation:

- Configure the appropriate GMAC control and status registers for the desired behavior.
- Initialize the receive and transmit DMA descriptors. Among other options, software must provide the descriptors with pointers to the buffers where the GMAC DMA controller will transfer the data to/from.

- When application software transfers data via GMAC, it must manage the DMA descriptors:
  - When GMAC receives one or more packets, the GMAC DMA controller transfers the data to buffers. Software must update the descriptors, including a new buffer address.
  - When application software transmits data, it must:
    - Update the transmit DMA descriptor(s) with the desired buffer addresses.
    - Advance the Descriptor Tail Pointer.
    - Set the appropriate ownership field (also called the "OWN bit") to 1.

    The GMAC DMA controller then begins transferring the data until the Current Descriptor Pointer and Descriptor Tail Pointer values are equal or the descriptor is marked as owned by the application.

During chip operation, application software uses GMAC functions to transfer data between the application and network as detailed below:

- Transmitting data:
  1. The GMAC DMA controller transfers data from the application buffer to the MTL transmit FIFO.
  2. The MAC transfers packets to the PHY via the selected interface—RGMII, for example.
- Receiving data:
  1. When the MAC receives a packet from the PHY, it saves it to the MTL receive FIFO.
  2. The GMAC DMA controller transfers the data from the receive FIFO to the application buffer.

Chapter 47
Packet Forwarding Engine (PFE)

47.1 Introduction

PFE offloads the processing of Ethernet packets from the host cores, yielding higher performance and lower power than pure software processing can achieve. PFE is capable of 2 Gbit/s packet forwarding even at small packet sizes, with virtually no host core load.

47.2 Features

- Three Ethernet ports (PFE_MAC0, PFE_MAC1 and PFE_MAC2)
- Performs the IEEE 802.3 protocol for 10/100/1000
  - MII: 10/100 Mbit/s
  - RMII: 10/100 Mbit/s
  - RGMII: 100/1000 Mbit/s
  - SGMII: 100/1000 Mbit/s
- PFE_MAC0 also supports 2.5 Gbit/s SGMII. When this mode is enabled, PFE_MAC1 must be used in RGMII/RMII/MII mode if enabled.
- Supports packet sizes from 64 bytes up to 1522 bytes
- Capable of autonomously handling all packets belonging to a given stream, without host core intervention, following stream creation
- Capable of performing slow-path or fast-path processing of a packet
- Capable of addressing DDR, security co-processor (HSE_H), and internal on-chip memory
- Capable of routing/bridging an aggregate of 2 Gbit/s of traffic with a 64 byte packet size. Higher rates are achievable for larger packet sizes.
- Supports packet parsing based on standard L2/3/4 header fields or using a flexible parser to take forwarding decisions based on proprietary fields up to 208 bytes from start of frame
- Supports 802.1AS-Rev and IEEE 1588 precision clock synchronization protocol
  - Supports one-step and two-step timestamping
- Full-duplex flow control with recognition of incoming pause frames and hardware generation of transmitted pause frames
- VLAN packet identification and tagging
- Quality of Service (QoS)
  - On transmit, implements flexible configuration of shapers and schedulers
    - Support for credit based shaper algorithm
  - On receive, supports ingress QoS
    - Classification of packets to be managed / unmanaged / reserved traffic
    - Weighted Random Early Drop (WRED)
    - Ingress port based rate shaper
- Four channel DMA host interface for slow path traffic
  - Embedded DMA engine

Freescale NXP Confidential Proprietary
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c20e5 482-48 8125139 0d3ab624c1

  - Interrupt per channel
  - Supports interrupt coalescing
- Independent MDIO interface per MAC

47.3 Initialization

PFE is a firmware-based module. Load the firmware before using PFE. The PFE cores boot during initialization by the host core. After initialization completes, PFE moves to Normal mode and is ready for full operation. The NXP-provided host interface driver and the PFE firmware abstract the initialization.

47.4 Functional description

PFE is based on programmable packet processing engines (PE).

PFE implements a fast-path/slow-path architecture. Fast-path packets can be completely offloaded from host core processing. Slow-path packets (such as control packets) can handle packet processing on the host cores.

The classification module classifies and performs header modification tasks, such as network address translation (NAT). The classifier performs traffic management and also maintains packet counters for statistics.

47.5 Packet parsing

The classifier has many different options for parsing of the packets such as:

- VLAN
- Multicast
- Broadcast
- ARP
- IPv4
- IPv6
- UDP
- TCP
- ICMP

The parsing block parses each packet and uses a handshake mechanism to provide inputs to the PFE processing engines. Firmware then processes the packet routing.

47.6 Layer 2 parsing

The first step in the packet classifier module is the Layer 2 classification. The link layer headers (VLAN, and so on) of the packet are parsed and information is saved into the packet buffer's header structure. If the link layer header is unknown, the packet is marked with a special flag and sent to the slow path for proper processing. After parsing, the packet is sent to bridge processing if bridging is enabled. Otherwise, the packet is sent to route processing.

47.7 Bridge classifier

This module performs the following actions:

- Processes the packet after Layer-2 parsing
- Uses bridge groups and port related information
- Uses a bridge MAC address table for MAC destination address lookup to forward the packets onto transmit bridge ports
- Performs lookups of the source MAC address for learning and aging support

- Sends the packet to the slow path for processing if no matched entries are found as part of the lookup.

47.8 Layer 3 parsing

In route mode, the module looks into Layer 3 and Layer 4 protocol headers of the packet and updates the packet buffer header structure with the parsed information. The route classifier module uses the flow information extracted from the packet to decide which action to take. This module also performs:

- IP version check
- IP packet length check
- IP checksum verification
- Fragment packet identification
- Unknown layer 4 protocols
- TCP flags (SYN, FIN, RST)
- Identification of IPSec tunnel and transport headers

47.9 Route classifier

This module performs the following actions on the packet:

- Hash calculation using specific header fields
- Lookup in the route hash table to match with flow entry
- If no entry is matched, then send the packet to host for slow-path processing
- TTL decrement and increment checksum update
- Perform NAT processing if required
- Construct TX port related link layer headers
- Send the packet to the traffic manager unit

47.10 Queuing block

The queuing block:

- Takes packets and schedules them for the processing blocks
- Moves packet headers from internal/external memory to the PE data memory
- Tags the packets with a sequence number that is used to maintain packet ordering within the module

47.11 Traffic manager unit (TMU)

TMU implements the QoS functionality in the egress packet processing chain. The classifier sends the packets to TMU after the packet is classified and modified. The classifier determines the queue mapping for the packet. The module works closely with the peripheral blocks and schedules the packets for transmission. The traffic manager has programmable queuing disciplines (WRR, WFQ or PQ) for implementing QoS.

TMU has weights (and credits) for guaranteed service and for distribution of the available bandwidths with the following features:

- Eight classes queues per port
- Programmable weights, scheduler tick, and max credits per class

In the case of multicast traffic, multiple references to the same buffer are written to TMU, and TMU processes them independently. TMU contains four shaper units that implement a credit-based shaper algorithm. Association of a shaper to a queue/scheduler is not fixed in hardware; this is maintained by software.

47.12 Buffer management

The buffer management module allocates and de-allocates buffers for the packets. Its structure is very generic and amenable to any operating system. The buffer allocation and freeing is managed within the buffer pool without calling time-consuming memory-allocation and memory-freeing functions for every packet.

47.13 Host Interface (HIF)

The chip host cores transmit and receive packets via the PFE HIF. HIF has a built-in DMA controller that transfers the slow-path packets to/from the host cores. HIF supports chained buffer descriptors (BD). The host software prepares the buffer descriptors, allocates associated buffers, and chains the descriptors. Host software ensures that invalid buffer descriptors have their descriptor enable bit set to zero so that they are not processed erroneously. The end of the BD chain always has a BD with a descriptor-enable bit equal to 0. The host interface has four virtual channels to allow distribution of packets across multiple host cores. Each virtual channel has its own RX/TX buffer descriptor rings and also a dedicated interrupt signal to generate events on the host cores. See the chip interrupt mapping for details.

The interrupt line of channel 3 (the last channel) connects directly to LLCE. You can therefore configure that channel to trigger events to the host core(s) and/or LLCE.

HIF implements interrupt coalescing. You can enable coalescing based on frame count and on a timer. If you enable only timer-based coalescing, PFE generates a coalesce interrupt after the timer reaches its value. If you enable only frame-based coalescing, PFE generates a coalesce interrupt after the number of interrupts equals the frame counter. If you enable both types of coalescing, PFE generates an interrupt when either of the previously-mentioned conditions is true.

47.14 PHY interface options

You have various pin-muxing options available to support a wide range of PHY interface modes and port numbers. For details on pin multiplexing options, see the IOMUX spreadsheet attached to this document.

47.15 PFE configuration

The software solutions described in the following sections abstract the PFE programming.

These software solutions allow configuration of the following features:

- IPv4/IPv6 forwarder/router
  - NAPT
  - IPSec offload
  - Configuration API
- L2 bridging
  - VLAN support
  - VLAN table control API
  - MAC table control API
  - Port control API
- QoS control API
- Statistics

47.16 Software components

The PFE driver loads into the OS networking stack and provides access to PFE Ethernet interfaces. The driver supports basic networking functions such as:

- Frame transmission

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-39023ab62

- Frame reception
- Link status monitoring

Offload functions, including forwarding of Ethernet packets without host core intervention and QoS, are also implemented as part of the API.

For further details on the PFE software support (CMM and LibFCI), see the PFE software product brief and Fast Control Interface (FCI) API reference documents.

Chapter 48
LINFlexD

48.1 Chip-specific LINFlexD information

48.1.1 Number of LINFlexD filters and channels

There are three instances of LINFlexD on the chip.

The following table shows the numbers of filters and channels for each instance of LINFlexD.

Description	LINFlexD_0	LINFlexD_1	LINFlexD_2
Number of filters (no_of_filters)	0	0	0
Number of Tx DMA channels ($2^{TX\_CH\_NUM}$)	1	1	1
Number of Rx DMA channels ($2^{RX\_CH\_NUM}$)	1	1	1
Slave mode enabled	1	1	1
UART mode enabled	1	1	1
Auto-synchronization enabled	0	0	0
DMA support	Yes	Yes	Yes

48.1.2 LIN_CLK and bus clock relationship

PBRIDGEx_CLK = LIN_CLK/2

48.2 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages after the software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

LINFlexD:

- Supports LIN protocol version 1.3, 2.0, 2.1
- Provides an 8-byte buffer for transmission/reception data
- Supports some of the basic UART transfers of 8-bit, 9-bit frames
- Supports multi channels and parametric DMA Tx/Rx interface in LIN/UART operating mode

48.2.1 Block diagram

The following figure shows the LINFlexD block diagram.

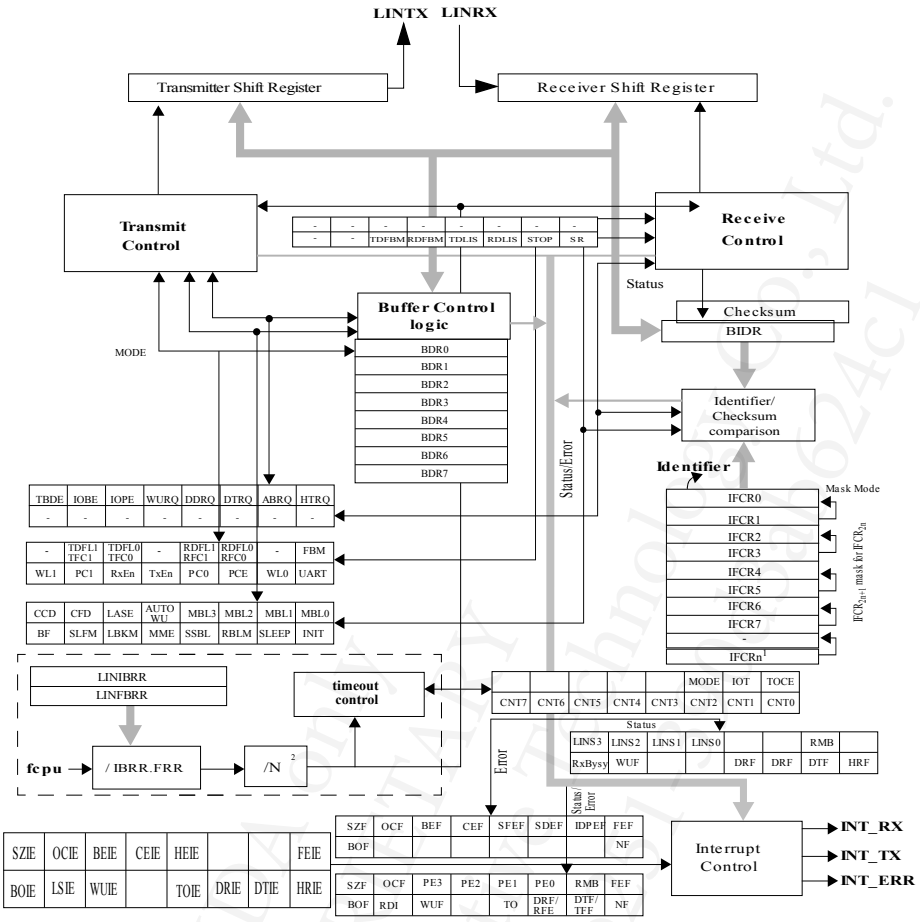

Figure 367. Block diagram

Notes:

1. The value of n depends on the no_of_filters. See the chip configuration details to see the number of filters used in this device.
2. For LIN mode N = 16, N is programmable by user in UART mode.
3. FBRR is not usable when reduced over sampling is enabled in UART mode.

48.3 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features that are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- Three operating modes for power saving and configuration registers lock
  - — Initialization
  - — Normal
  - — Sleep
- Test mode: Loop Back
- Maskable interrupts

48.3.1 LIN mode features

- Supports LIN protocol versions 1.3, 2.0, 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave modes
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for transmission/reception
- Timeout management
- DMA interface
- Master mode with autonomous message handling
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling

48.3.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers. See Baud rate generation for details.
- 7/8 bits data, parity
- 1/2/3 stop bits
- 4-byte buffer for reception; 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is LIN_CLK/4 Mbit/s.
- For bit rate ≤ LIN_CLK/16 Mbit/s
  - 16 times oversampling
  - 3:1 majority voting
- For LIN_CLK/16 Mbit/s < bit rate ≤ LIN_CLK/8 Mbit/s
  - User-programmable reduced oversampling
  - 3:1 majority voting for reduced over sampling of 8 samples per bit
- For LIN_CLK/8 Mbit/s < bit rate ≤ LIN_CLK/4 Mbit/s
  - User-programmable reduced oversampling
  - 1:1 voting for all reduced over sampling of 4, 5, and 6 samples per bit

48.4 Functional description

48.4.1 LIN protocol

LIN is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task. All other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

48.4.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Transmittion or reception of LIN frames occurs as shown in Figure 368 and Figure 369.

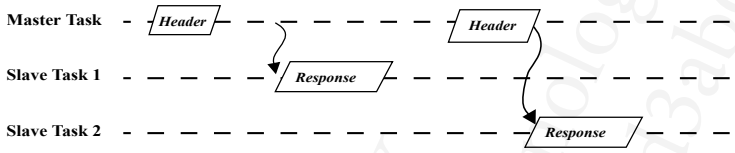

Figure 368. Frames

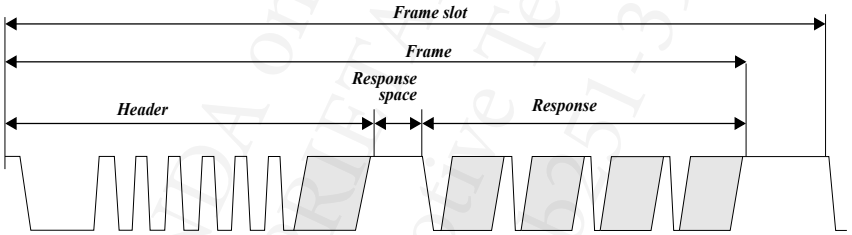

Figure 369. Structure of LIN frame

48.4.1.2 Data field

Nodes and tasks transmit each byte as shown in Figure 370. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and the stop bit is encoded as bit value one (recessive).

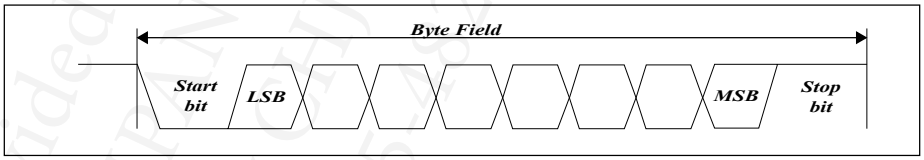

Figure 370. Structure of byte field

48.4.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. Only the master generates the break. The break must be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in Figure 371. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

Figure 371. Break field

48.4.1.4 Sync byte

Sync is a byte field with the data value of 55h.

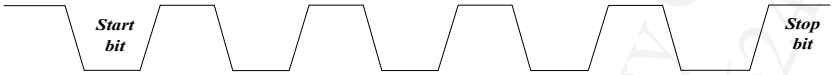

Figure 372. Sync byte field

48.4.1.5 Identifier

The identifier field consists of two sub fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 373. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

48.4.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes and the identifier. The following table shows the types of checksums.

Table 305. Checksum types

Type	Bytes used	Use
Classic	Only the data bytes	Communication with LIN 1.3 slaves
Enhanced	Data bytes and protected identifier byte	Communication with LIN 2.0 slaves

48.4.2 LINFlexD features

48.4.2.1 Operating modes

The LINFlexD includes three operating modes: Initialization, Normal, and Sleep. After hardware reset, LINFlexD enters the Sleep mode to reduce power consumption. Figure 374 shows the state diagram of operating modes.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
ca462e2-4821-48a8-b251-3904d3ab624d1

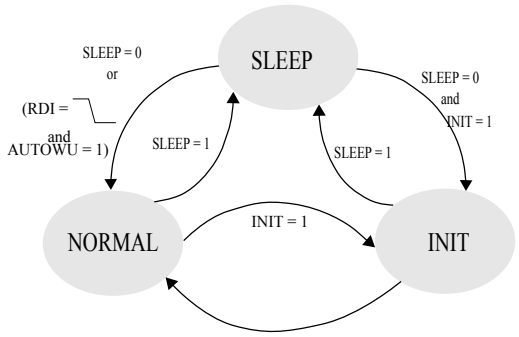

Figure 374. Operating modes

Initialization mode (INITM)

To enter this mode, software writes a 1 to LINCR1[INIT]. To exit INIT, the software must write a 0 to LINCR1[INIT].

When in INIT, LINFlexD stops all message transfers to and from the LIN bus and the status of LIN bus output LINTX is recessive (high). Use this mode only to configure the IP. Your software must not initiate a data transmission in INITM.

If software invokes the INITM when a bus transfer is in progress, the LINFlexD aborts the transfer. Therefore, your software must check the LIN state before writing a 1 to LINCR1[INIT].

To initialize the LINFlexD controller, your software must:

1. Set up the baud rate registers
2. Write a 0 to UARTCR[UART].
3. Select the mode (Master or Slave)
4. Configure checksum control bits

Normal mode (NM)

After the software initializes LINFlexD, the software can enter NM by writing a 0 to LINCR1[INIT].

Sleep mode (SM)

This mode reduces power consumption. To enter this mode, write a 1 to LINCR1[SLEEP]. In this mode, the LINFlexD clock stops. You can awaken LINFlexD from SM by writing a 0 to LINCR1[SLEEP].

If software detects a wakeup pulse of 150 µs on the LIN bus, it can request LINFlexD to wake up from SM. See Wakeup management.

48.4.2.2 Test mode

Loop Back mode

You can use this mode for self-test functions.

Enter this mode by writing a 1 to LINCR[LBKM].

In this mode, LINFlexD:

- Receives the identifier and data that LINFlexD itself transmits
- Writes the identifier and data to the BIDR and data buffers, respectively
- Checks bit errors

- Ignores the LINRX signal
- Feeds back its TX output to its RX input

You can disconnect the TX pin from the LINTX pin using a setting in SIUL2.

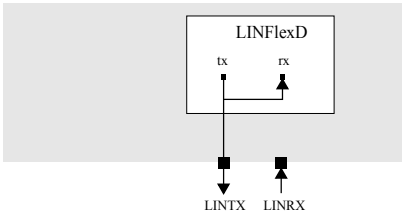

Figure 375. LINFlexD in Loop Back mode

48.4.2.3 Master mode

Enter Master mode by writing a 1 to LINCR1[MME].

48.4.2.3.1 Header transmission

According to the LIN protocol, the master triggers any communication on the LIN bus by sending a header. The master task of a node transmits the header. The slave task of a node transmits the response.

To transmit the header:

1. Use BIDR to program:
   - The identifier
   - Data field length
   - Message direction
   - Checksum enable
2. Write a 1 to LINCR2[HTRQ]

After header transmission starts, do not modify BIDR fields until the current frame completes.

The master node receives the transmitted ID and copies it to BIDR.

48.4.2.3.2 Data transmission

Consider the scenario in which the master sends an identifier and the master node publishes the data corresponding to that identifier. In this scenario, the node's slave task must send the data in the response part of the frame. Therefore, your software must provide the data to LINFlexD before LINFlexD requests the header transmission.

LINFlexD stores the to-be-transmitted data in the BDRL and BDRM message buffers. The number of to-be-transmitted bytes depends on BIDR[DFL]. Your software must use BIDR[CCS] to configure the checksum type (classic or enhanced) for each message.

If LINFlexD successfully sends the response, LINFlexD writes a 1 to LINSR[DTF]. If an error occurs, LINFlexD:

- Does not write a 1 to LINSR[DTF]
- Writes a 1 to the corresponding error flag in LINESR (see Errors for details)

BIDR[DIR] determines the direction of the message buffer. The same node also receives the transmitted data and copies the data to the buffer.

Preliminary Information under NDA only
COMPANY PROPRIETARY
Beijing CUI Automotive Technology Co., Ltd.
ce46e8e7-214a8-b251-390d3ab624c1

48.4.2.3.3 Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. LINFlexD then:

- Receives data from the slave
- Stores the data in the message buffer
- Stores the status of the message in LINESR

If LINFlexD successfully receives the response, LINFlexD writes a 1 to LINSR[DRF]. If an error occurs, LINFlexD:

- Does not write a 1 to LINSR[DRF]
- Writes a 1 to the corresponding error flag in LINESR (see Errors for details)

48.4.2.3.4 Data discard

If you want to discard the data after header transmission, write a 1 to LINCR2[DDRQ].

48.4.2.4 Slave mode

LINFlexD enters this mode when you write a 0 to LINCR1[MME].

48.4.2.4.1 Data transmission

After receiving a header, LINFlexD:

- Writes a 1 to LINSR[HRF]
- Generates an RX interrupt

The software must then:

1. Read the received ID in BIDR.
2. Fill the BIDR.
3. Program the CCS and DIR fields in BIDR.
4. Write the data field length to BIDR[DFL].
5. Write a 1 to LINCR2[DTRQ] to trigger data transmission.

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits after RXBUSY is asserted in LINSR.

The same node also receives the transmitted data and copies it to the buffer.

48.4.2.4.2 Data reception

When LINFlexD is the subscriber of the data of the received identifier, and LINFlexD receives a header, LINFlexD:

- Writes a 1 to LINSR[HRF]
- Generates an RX interrupt

The software must read the received ID from BIDR and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BIDR and the RMB bit is set. Software must then release the data buffer by writing a 1 to LINSR[RMB].

If your software filters the identifier, you can discard the data by writing a 1 to LINCR2[DDRQ] while the value of LINSR[HRF] =1.

For software filtering, software must choose the checksum type (BIDR[CCS]) before receiving data. Otherwise, the checksum calculation uses the previous value of BIDR[CCS].

48.4.2.5 Errors

48.4.2.5.1 Header error

A header error is an error during the header reception. The error types are:

- Sync delimiter error (SDEF)
- Sync field error (SFEF)
- Identifier parity error (IDPEF)

48.4.2.5.2 SDEF

The delimiter must be 1 for at least one bit time; otherwise it is considered short and consequently the receiver discards synchronization on the current header. Therefore LINFlexD discards the frame. LINFlexD also generates an interrupt if LINEIER[HEIE]=1.

48.4.2.5.3 IDPEF

The identifier field has two parity bits. LINFlexD checks these bits against the hardware-calculated parity over the other six identifier bits according to these equations:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

LINFlexD checks this parity after transferring the ID to BIDR. If LINCR2[IOPE]=1, and parity mismatch occurs, the receiver state machine exits the identifier state immediately.

48.4.2.6 Bit error

LinFlexD flags this error in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if the transceiver delay is less than one bit time minus 6 LIN_CPU cycles. LINFlexD does not check for bit errors.

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) - (6 LIN_CLK cycles) = 49.925 µs

If LINCR2[IOBE]=1, LINFlexD stops transmitting the frame after the corrupted bit. If LINCR2[IOBE]=0, LINFlexD continues to transmit despite the bit error. LINFlexD generates an interrupt if LINIER[BEIER]=1.

If the master does not detect the break delimiter within one bit time after delimiter transmission (for example, because of transceiver delay or bus error), LINFlexD generates a train of bit-error interrupts. In this case, LINFlexD may not replace the identifier in BIDR. Similarly, if the transmitter node does not detect the start of a falling edge of data within one bit time after transmission of the start bit, LINFlexD generates a train of bit-error interrupts. In this case:

- Data replacements in the BIDR are not guaranteed.
- Checksum replacements in the LINCFR are not guaranteed.

48.4.2.7 Framing error

LINFlexD flags this error when it samples a dominant state on the stop bit of the current received character (Sync field, identifier field, data field, or checksum field). LINFlexD discards the current frame and returns to the Idle state. LINFlexD generates an interrupt if LINEIER[FEIE]=1.

LINFlexD also takes the byte that caused the framing error and shifts it to the buffer, but does not write a 1 to LINSR[DRF].

48.4.2.8 Checksum error

LINFlexD flags this error when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to the Idle state. LINFlexD generates an interrupt if LINEIER[CEIE]=1.

48.4.2.9 Overrun error

After the message buffer is full (LINSR[RMB]=1), the next valid message reception leads to an overrun and the message is lost. LINFlexD signals the overrun condition by writing a 1 to LINESR[BOF]. The buffer lock function control (LINCR1[RBLM]) determines which message is lost.

If RBLM=0, the old message in the buffer is overwritten by the most recent message. If RBLM=1, the most recent message is discarded and the oldest message is available to the software. In the case of master, during overrun condition, internal state machine moves to idle state and any transition from 1 to 0 is considered as a wakeup state till the end of current transfer. Under this scenario, the software must entertain only one WUF interrupt and ignore the rest. In the case of slave, if buffer is not released (RMB is not reset) before reception of next Identifier and if RBLM=1, then the ID along with the data is discarded.

48.4.2.10 Timeout error

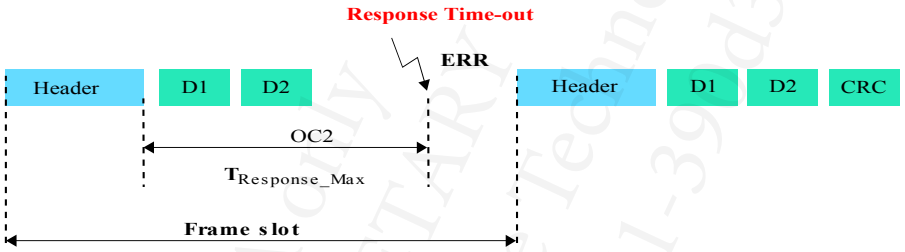

Figure 376. Incomplete response (for example, missing checksum)

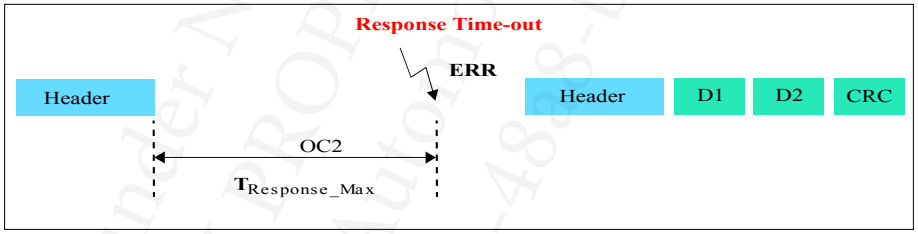

Figure 377. No response

48.4.2.10.1 Response timeout mechanism

Master mode

OC2 is loaded with 1.4 x ((DFL+2)x(10 bit times)) + LINTCSR[CNT] at the end of the stop bit of the Identifier field. This equation is defined according to the reset values of LINTOCR[RTO] and LINCR1[CFD], and it changes with any change in the values of these fields. Here, 1.4 corresponds to (LINTOCR[RTO])/10 and 2 corresponds to (2- LINCR1[CFD]).

This loading takes place at the end of the Identifier field (and not at the beginning of Data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.

In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change is compared to earlier implementation).

In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).

Slave mode

- As the DFL value needs to be updated by software after the identifier field has been received, the implementation is the following:
  - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT].
  - At the end of the first_data_byte it is reloaded again according to DFL
  - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

48.4.2.10.2 Header timeout mechanism

Master mode

Because LINFlexD generates the header, there are only two cases:

- No error on the bus and timing is correct (nominal header length).
- An error (typically a bit error) occurs on the bus and LINFlexD flags it in LINESR.

Therefore there is no meaning of header timeout in master mode, so it is disabled.

Slave mode

- header_nominal = 13 + 2 + 10 + 10 = 35 Tbit.
- header_max = 1.4 × Header_nominal = 49 Tbit.
- Taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit..
- If the counter starts after 11 Tbit (break duration), the HTO value is 56 –11 = 45 Tbit.

The reset value of HTO is 45, and this register can only be programmed in Slave mode. Counter restarts after break duration and OC1 gets loaded with the value of HTO.

As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be reset and the output compare value can be updated in the LINTOCR Register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, LINFlexD writes a 1 to LINESR[SZF]. If the same dominant pulse prolongs, the subsequent SZF setting is 87 (instead of 100) bit times apart.

48.4.2.11 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8^{th}, 9^{th} and 10^{th} samples. If any one of these three samples has a value different from the other two, this error is flagged.

When UARTCR[OSR] = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise.

When UARTCR[OSR] < 8, noise checking is disabled.

This error is flagged when there is noise detected in the start bit (see LIN Error Status Register (LINESR)).

48.4.2.12 Start detection and break delimiter detection in receiver

There is a 10-bit-shift register sample register in the receiver that shifts signal data to the next least significant bit on each incoming sample.

Therefore, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two of the three verification samples are one. The Noise flag is set if the start is verified with only two valid samples.

0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

48.4.2.12.1 Start detection mechanism

Here are the steps for detecting a start bit:

1. See Table 306 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (that is, 2) out of these 3 samples are equal to 0, then start bit is said to be detected.

   These three samples, RT3, RT5, and RT7 are called the “verification samples” that are checked at count = 6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” that are checked at count = 6.
5. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to 0 then Noise flag is set.

48.4.2.12.2 Break delimiter detection mechanism

Here are the steps for detecting a delimiter bit:

1. See Table 306 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (that is, 2) out of these 3 samples are equal to 1, then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” that are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” that are checked at count = 6.

Therefore, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise flag is set if the start is verified with only two valid samples.

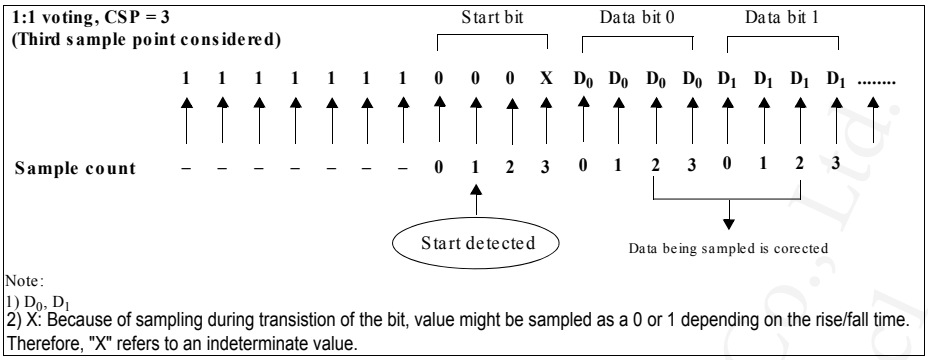

Figure 378. Start detection and sampling for oversampling rate = 4 (Case 1)

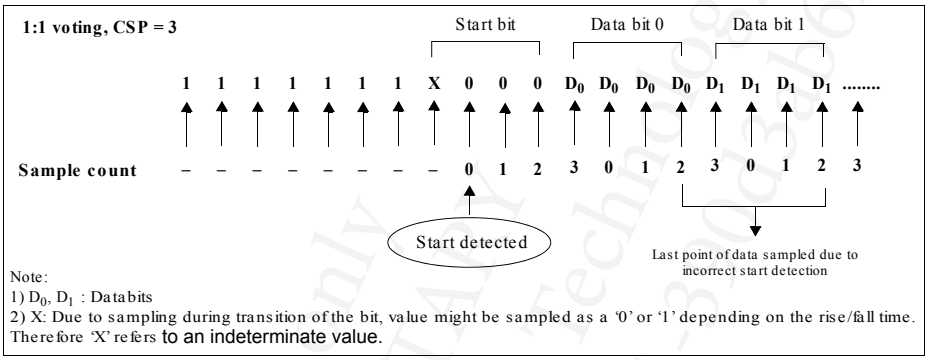

Figure 379. Start detection and sampling for oversampling rate = 4 (Case 2a)

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

Therefore, to sample at the correct point, you must write a 2 to CSP, resulting in the following situation:

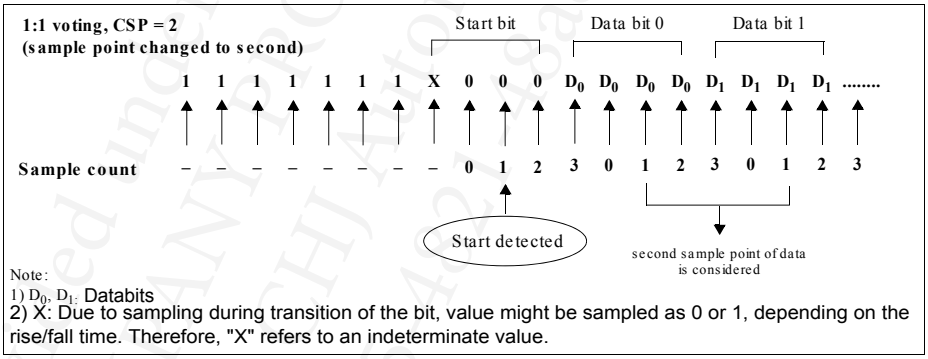

Figure 380. Start detection and sampling for oversampling rate = 4 (Case 2b)

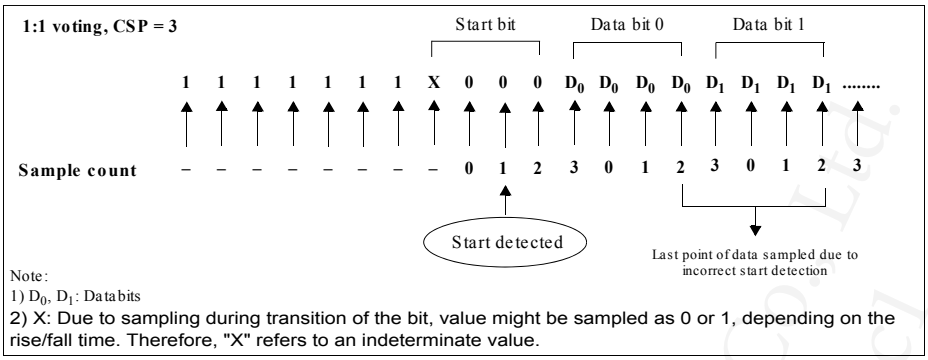

Figure 381. Start detection and sampling for oversampling rate = 4 (Case 3)

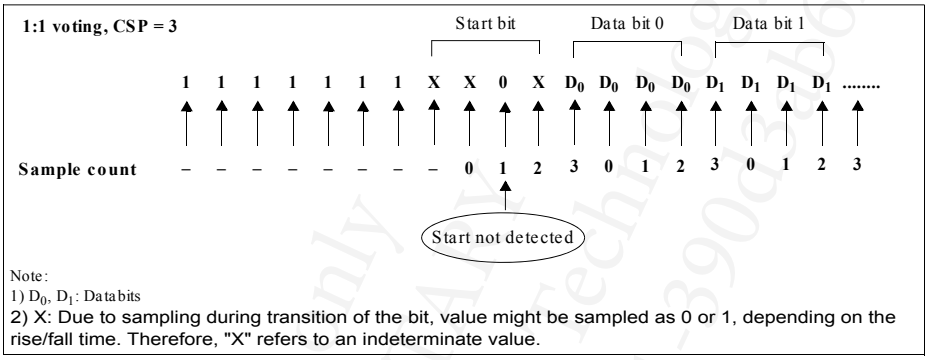

Figure 382. Start detection and sampling for oversampling rate = 4 (Case 4)

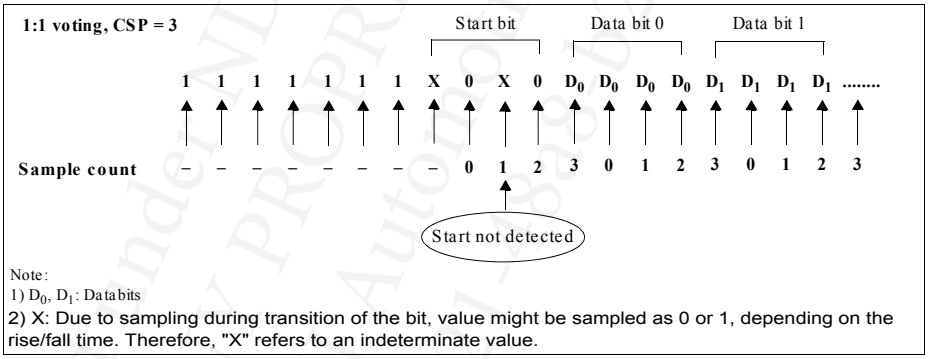

Figure 383. Start detection and sampling for oversampling rate = 4 (Case 5)

48.4.2.13 Baud rate generation

LINIBRR and LINFBRR control the LIN baud rate. You can program these registers only during INITM.

Baud rate is calculated with the following formula for both receiver and transmitter.

When UARTCR[ROSE] = 1, Tx = Rx = LIN_CLK / (OSR × LDIV). When UARTCR[ROSE = 0, Tx = Rx = LIN_CLK / (16 × LDIV), where LIN_CLK is the frequency of the baud clock.

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR[IBR] and the fraction is coded on 4 bits of LINFBRR[FBR].

When reduced oversampling is enabled, LINFBRR must not be used and programmed to zero, and LDIV contains only the integer part of LINIBRR.

Table 307. Examples of baud rate calculations

UARTCR1[ROSE]	Mode(s)	LDIV	LIN_CLK	LINIBRR[IBR]	LINFBRR[FBR]	Baud rate
ROSE = 0	LIN and UART	468.75 d	36 MHz	468 d	12	36 MHz/ (16 × 468.75) = 4.8 Kbit/s
ROSE = 1	UART	5 d	80 MHz	5 d	4	LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 5) = 4 Mbit/s

48.4.2.14 Wakeup management

Any node in a sleeping LIN cluster can request a wakeup. The node issues the wakeup request by forcing the bus to the dominant state for 250 µs to 5 ms. Every slave node must detect the wakeup request (a dominant pulse longer than 150 µs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes after detecting a wakeup request, and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the requesting node can try issuing a new wakeup request.

In LINFlexD, you can generate a wakeup request by:

- Writing the wakeup character (F0h for LIN 2.0) to BDR0
- Writing a 1 to LINCR2[WURQ]

After you write a 1 to LINCR2[WURQ], LINFlexD transmits the character in BDR0.

In LINFlexD, wakeup can be detected in two ways.

Table 308. Wakeup direction

LINCR1[AUTOWU]	Details
0	After detecting a falling edge, LINFlexD: • Writes a 1 to LINSR[WUF] • Generates an interrupt if LINIER[WUIE]=1 Your software must then write a 0 to LINCR1[SLEEP].
1	After detecting a falling edge in Sleep mode, LINFlexD: • Writes a 0 to LINCR1[SLEEP] • Writes a 1 to LINSR[WUF] • Generates an interrupt if LINIER[WUIE]=1 LINFlexD is now in Normal mode and ready to receive frames.

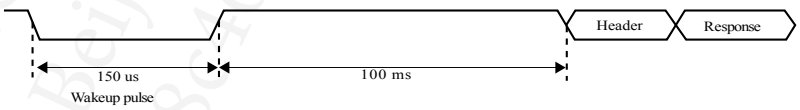

Figure 384. Wakeup sequence

48.4.3 Timer

LinflexD has an 8-bit counter which has different behavior in different modes as described below:

Table 309. Timer behavior

Mode	Details
Output Compare (LINTCSR[MODE]=1)	• Runs even in Sleep and Initialization modes • The counter value, which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generates output compare interrupt (LINESR[OCF]) if LINTCSR[TOCE]=1. • After an interrupt occurs, LINFlexD generates subsequent interrupts only when the application has reset the stuck FSM state.
LIN	• The software has no control over LINTCSR[TOCE] and LINFlexD uses output-compare registers to generate LIN timeout interrupts (header, frame, and response time out). • If LIN moves to SM or INIT state, then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter remains in Reset state.

48.4.4 UART mode

Main features in UART mode are:

- Full-duplex communication
- 8-bit, 9-bit, and
- Even/Odd/0/1 parity
- User-programmable oversampling rate to obtain a baud rate of up to LIN_CLK/4 Mbit/s

48.4.4.1 8-bit data frames

The eighth bit can be a data or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity is set if the modulo-2 sum of the seven data bits is 1. An odd parity is cleared in this case.

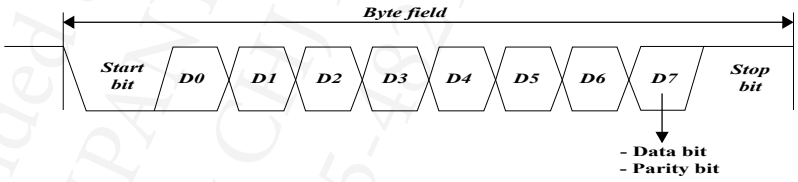

Figure 385. UART mode 8-bit data frame

48.4.4.2 9-bit frames

The ninth bit must be a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] field in the same register. An even parity is set if the modulo-2 sum of the seven data bits is 1. An odd parity is cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

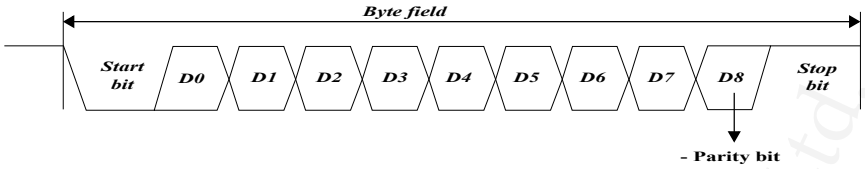

Figure 386. UART mode 9-bit data frame

48.4.4.3 Buffer in UART mode

The 8-byte buffer includes two parts—receiver and transmitter—as shown in the following figure:

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

Figure 387. Structure of 8-byte buffer

48.4.4.4 UART transmitter

To start transmission in UART mode, UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the UARTCR[TDFL].

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1). Therefore, the transmission that you trigger can have a maximum of four bytes (two halfwords). After the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If UARTCR[TxEn] is reset in the middle of a transmission, then the current transmission completes and no further transmissions can start.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by writing a 1 to UARTCR[TFBM].

NOTE

If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Table 310. BDRL access in UART mode

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Byte0	BDRL	FIFO	Byte	OK
Write Byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write Half-word0-1	BDRL	FIFO	Byte	IPS transfer error
Write Word	BDRL	FIFO	Byte	IPS transfer error
Write Byte0-1-2-3	BDRL	FIFO	Half-word	IPS transfer error
Write Half-word0	BDRL	FIFO	Half-word	OK

Table continues on the next page...

Table 310. BDRL access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Half-word1	BDRL	FIFO	Half-word	IPS transfer error
Write Word	BDRL	FIFO	Half-word	IPS transfer error
Read Byte0-1-2-3	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Half-word0-1	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Word	BDRL	FIFO	Byte/Half-word	IPS transfer error
Write Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Write Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Write Word	BDRL	BUFFER	Byte/Half-word	OK
Read Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Read Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Read Word	BDRL	BUFFER	Byte/Half-word	OK

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

48.4.4.5 UART receiver

The reception of a data byte starts as soon as you:

- Exit INIT mode
- Write a 1 to UARTCR[RXEN]
- Detect the start bit

LINFlexD has a dedicated data buffer for received data. This buffer comprises 4 bytes if UARTCR[WL1]=0 or two half-words if UARTCR[WL1]=1. After the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception finishes. You must write a 1 to UARTCR[RxEn] only to start the reception. The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by writing a 1 to UARTCR[RFBM].

Table 311. BDRM access in UART mode

IPS operation	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Byte4	FIFO	Byte	OK
Read Byte5-6-7	FIFO	Byte	IPS transfer error
Read Half-word2-3	FIFO	Byte	IPS transfer error

Table continues on the next page...

Table 311. BDRM access in UART mode (continued)

IPS operation	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Word	FIFO	Byte	IPS transfer error
Read Byte4-5-6-7	FIFO	Half-word	IPS transfer error
Read Half-word2	FIFO	Half-word	OK
Read Half-word3	FIFO	Half-word	IPS transfer error
Read Word	FIFO	Half-word	IPS transfer error
Write Byte4-5-6-7	FIFO	Byte/Half-word	IPS transfer error
Write Half-word2-3	FIFO	Byte/Half-word	IPS transfer error
Write Word	FIFO	Byte/Half-word	IPS transfer error
Read Byte4-5-6-7	BUFFER	Byte/Half-word	OK
Read Half-word2-3	BUFFER	Byte/Half-word	OK
Read Word	BUFFER	Byte/Half-word	OK
Write Byte4-5-6-7	BUFFER	Byte/Half-word	IPS transfer error
Write Half-word2-3	BUFFER	Byte/Half-word	IPS transfer error
Write Word	BUFFER	Byte/Half-word	IPS transfer error

NOTE

See the layout of the BDRL and BDRM registers to identify the mapping between byte x and data bits of these registers.

Consider the following for UART receiver:

- If you do not know in advance how many bytes are to be received, RDFL must not be programmed in advance. The reset value of RDFL is 0. This ensures that the reception happens byte by byte. The state machine moves to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number of bytes are not received, then reception hangs. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to Idle state.
- If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout. When the state machine moves to Idle state, then only a stop request is served.
- If during the reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. LINFlexD does not generate an interrupt in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if FEIE bit in LINIER is set. As there is only one register bit for framing error, this interrupt is helpful in identifying which byte has framing error.
- If the last received frame has not been read from the buffer (in other words, you did not write a 1 to LINSR[RMB]), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR is set) and one message is depending on RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.

48.4.5 DMA interface

48.4.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

Table 312. LINFlexD DMA features

Node	Mode	Details
LIN Master	TX	Single DMA channel
LIN Master	RX	Single DMA channel
LIN Slave	TX	1 to DMA_TX_CH_NUM DMA channel See the chip-specific LINFlexD information for the value of DMA_TX_CH_NUM used in this chip.
LIN Slave	RX	1 to DMA_RX_CH_NUM DMA channel See the chip-specific LINFlexD information for the value of DMA_RX_CH_NUM used in this chip.
UART	TX	Single DMA channel
UART	RX	Single DMA channel plus timeout

48.4.5.2 Definitions

The LINFlexD control register and their fields are described in Table 313.

Table 313. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0]	High	Logical AND between the 2 DMA enable bits (LINFlexD and eDMA).
DMA_REN	LIN master Rx or UART Rx	DMARXE[0]	High	Logical AND between the 2 DMA enable bits (LINFlexD and eDMA).

Control/status fields of the transfer control descriptors referred to in this document are described in Table 314.

Table 314. TCD control fields description

TCD Field	Level	Description
CITER[14:0]	—	Current "major" iteration count

Table continues on the next page...

Table 314. TCD control fields description (continued)

TCD Field	Level	Description
BITER[14:0]	—	Beginning "major" iteration count
NBYTES[31:0]	—	Inner "minor" byte transfer count. Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request.
DONE	High	Channel done (the DMA has completed the outer major loop).
D_REQ	High	Disable request. If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

48.4.5.3 Master node – TX mode

On a master node in TX mode, the DMA interface requires a single TX channel. Each TCD controls a single frame. The following figure shows the memory map associated with the TCD chain (RAM area and LINFlexD registers).

Provided under NDA
COMPANY CONFIDENTIAL
Freescale Semiconductor, Inc.
c4625a21-8a8-b25-390d3ab6241

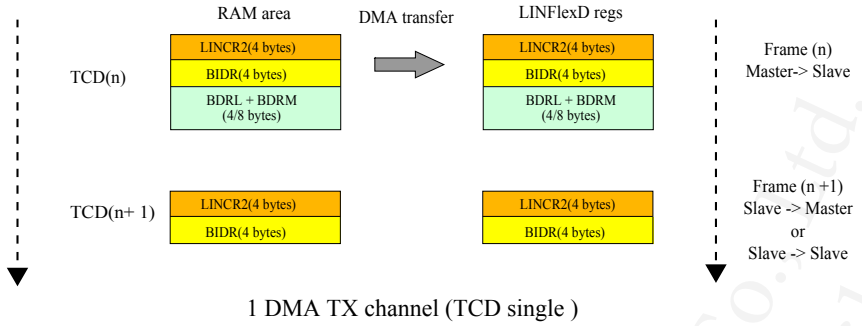

Figure 388. Master node – TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the Rx channel on the master node controls the data reception
- Slave to Slave: transmission of the header

The following table provides the settings for LINCR2 and BIDR for each class of LIN frame.

Table 315. Master node – Tx mode – Register setting

LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The DMA Tx interface is shown in Figure 389. DMA TX moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in Table 316. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 316. TCD setting – Master node – Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop

Table continues on the next page...

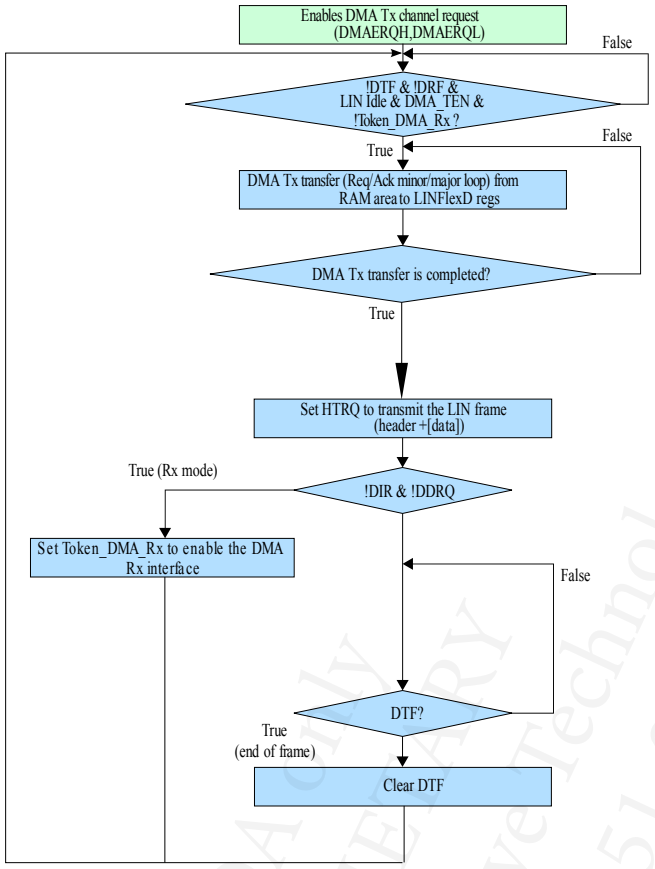

Figure 389. Master node – DMA Tx (concept scheme)

48.4.5.4 Master node - RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame. The following figure shows the memory map associated with the TCD chain (RAM area and LINFlexD registers).

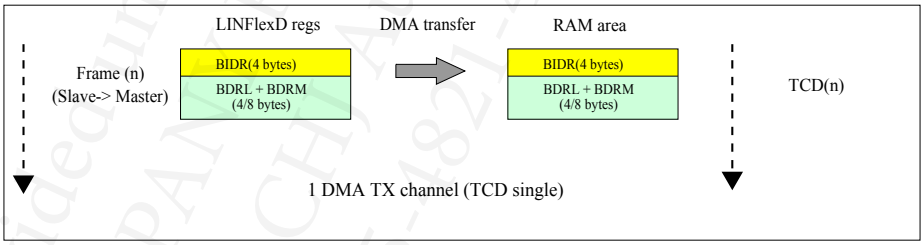

Figure 390. Master node – RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR is optionally copied into the RAM area, and this register (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The DMA Rx interface is shown in Figure 391. DMA RX moves to Idle state immediately at the next clock edge if DMARXE[0] are 0. The TCD setting (word transfer) is given in the next table. All other TCD fields are 0. TCD settings based on halfword or byte transfer are allowed.

Table 317. TCD setting – Master node – Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop

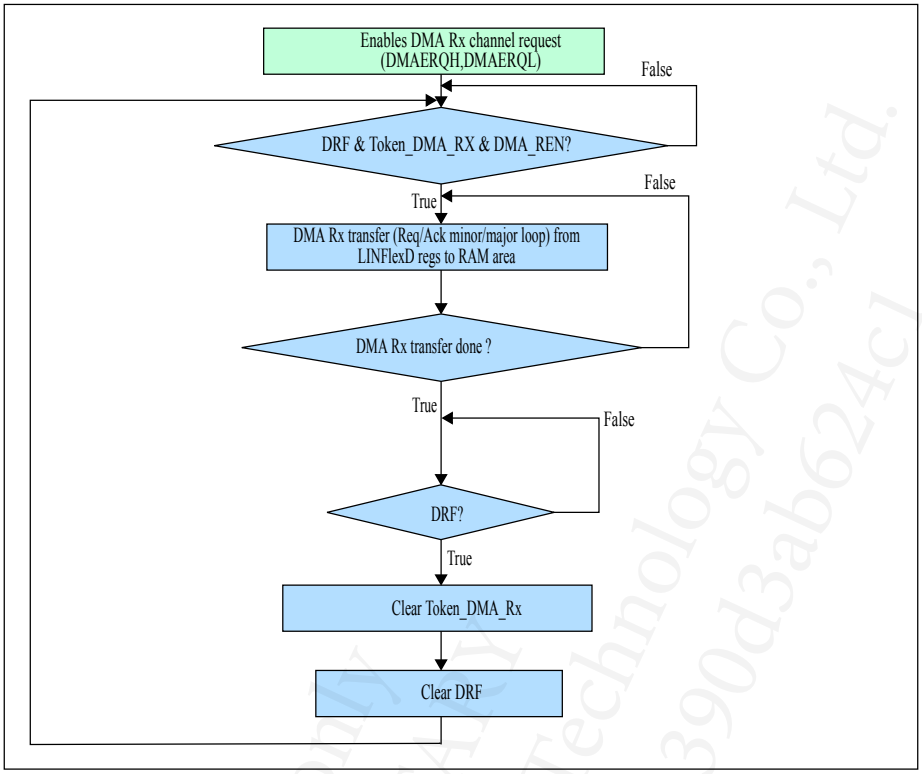

Figure 391. Master node – DMA Rx (concept scheme)

48.4.5.5 UART – TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The following figure shows the memory map associated with the TCD chain (RAM area and LINFlexD registers).

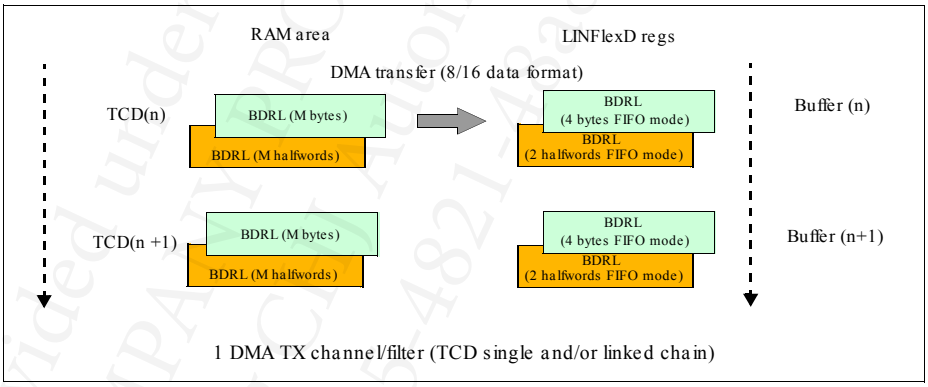

Figure 392. UART – TX memory map

The UART TX buffer must be configured in FIFO mode to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (because of the DMA arbitration), to move data from the RAM to the FIFO
- Use low-priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format

FIFO-not-full (TX) status signals trigger a DMA request.

The concept FSM to control the DMA Tx interface is given in Figure 393. DMA Tx FSM will move to Idle state if DMATXE[0] = 0.The TCD setting (typical case) is given in Table 318. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 318. TCD setting – UART – Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		RAM address
SOFF[15:0]	1	2	Byte/Half-word increment

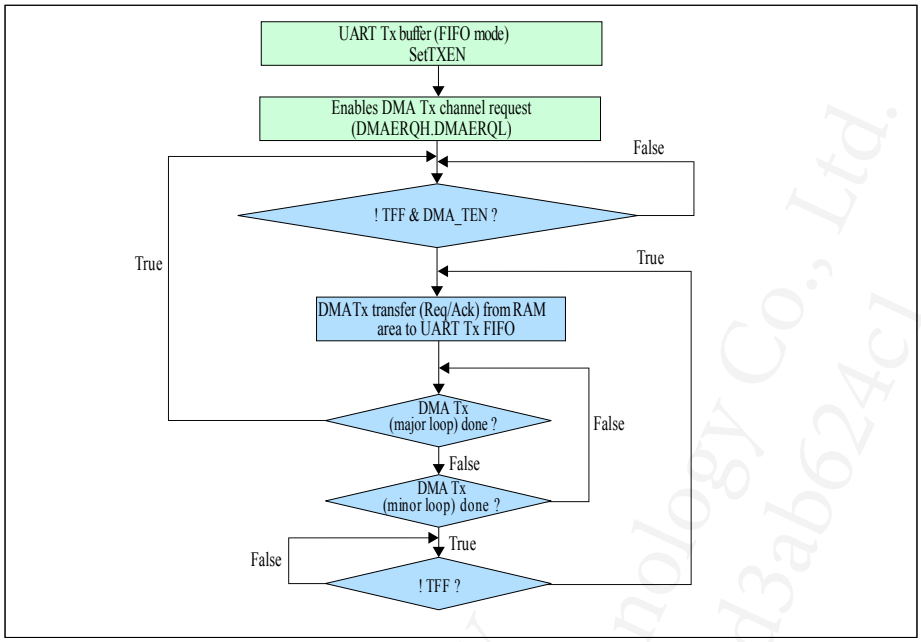

Figure 393. UART – DMA Tx FSM (concept scheme)

48.4.5.6 UART – RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The following figure shows the memory map associated with the TCD chain (RAM area and LINFlexD registers).

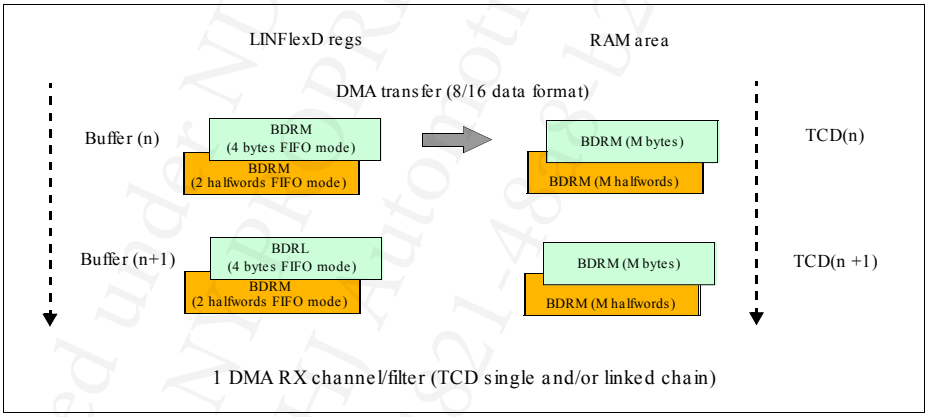

Figure 394. UART – RX memory map

The UART RX buffer must be configured in FIFO mode to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO comprises 4 bytes in an 8-bit data format.

This is sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. FIFO triggers a DMA request. Empty (Rx) status signals do not trigger a DMA request.

The DMA Rx interface is shown in Figure 395. DMA Rx moves to Idle state if DMARXE[0] = 0.The TCD setting (typical case) is shown in the next table. All other TCD fields equal 0. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. You can rewrite the timeout counter at any time to extend the timeout period.

Table 319. TCD setting – UART – Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		BDRM address
SOFF[15:0]	0		No increment (FIFO)

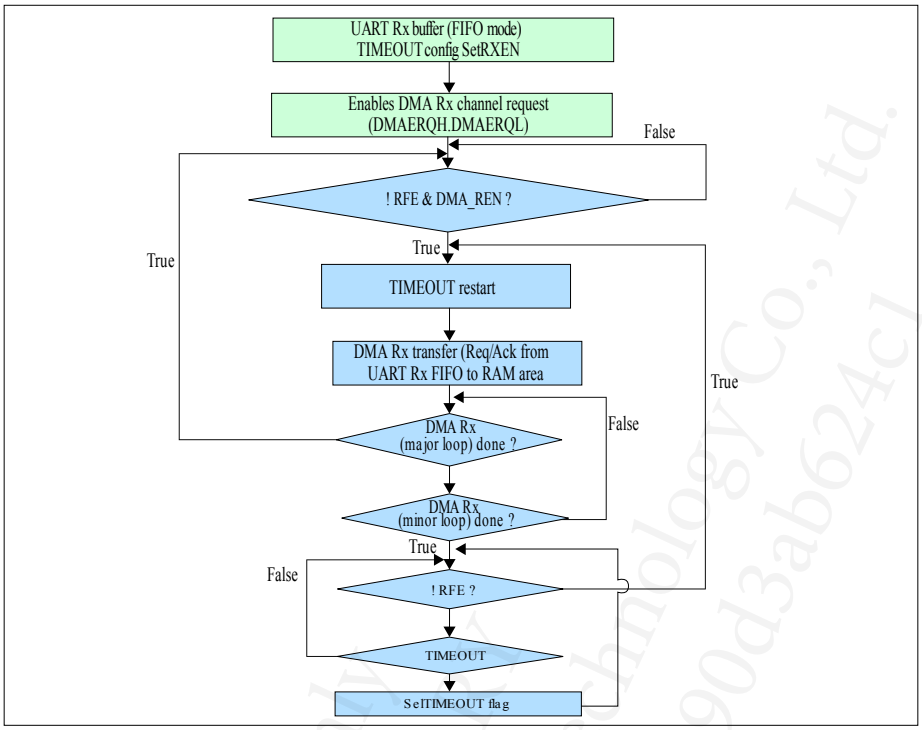

Figure 395. UART – DMA Rx (concept scheme)

48.4.5.7 Use cases and limitations

In LIN master mode, both the DMA channels (TX and RX) must be enabled in case DMA is required.

In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.

DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. After a DMA transfer finishes, the CPU can manage subsequent accesses.

Error management must always be executed via the CPU enabling the related error interrupt sources. DMA does not support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.

The DMA programming model must be coherent with the TCD setting defined in this document.

48.5 LINFlexD register descriptions

The following points should be considered for LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of (generic) slave = 0 and (generic) slave = 1.

Table 320. Register offsets based on master slave configuration and number of filters available

Register	Master only mode	Master Slave mode

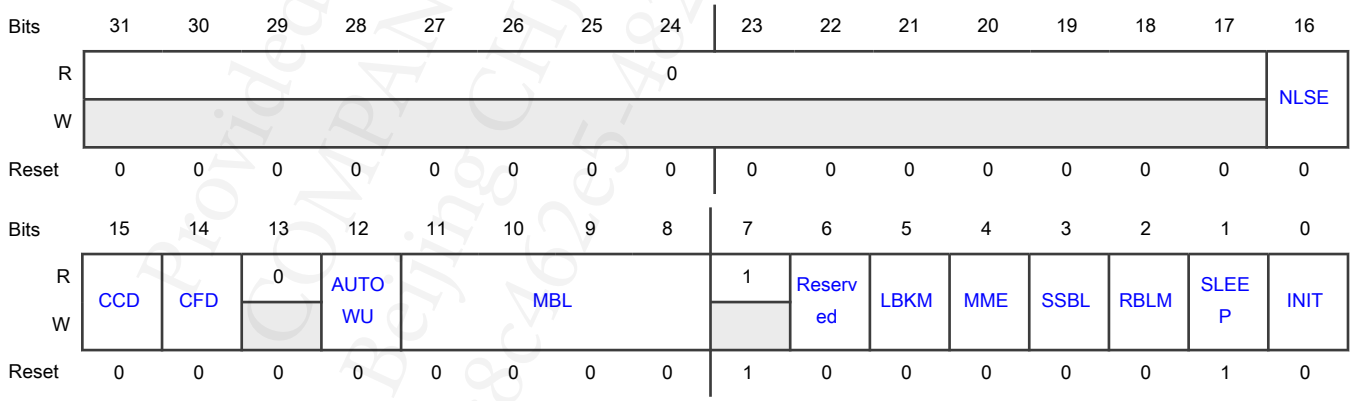
48.5.2 LIN Control Register 1 (LINCR1)

Offset



Register	Offset
LINCR1	0h

Function

Provides control bits used to configure features of the LINFlexD.

When accessing the LINCR1 register, each reserved bit must be written to its original reset value.

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
ca4626e5-4821-48a8-b251-39d6ab6a1a1a

Fields

Field	Function
31-17 —	Reserved
16 NLSE	LIN State Capture Enable on Bit Error Enables capture of LIN state, LINSR[LINS] whenever bit error flag occur, that is, LINESR[BEF] set to 1. If this bit is set to 1, internal LIN state is not captured when LINCR2[IOBE]=1 and the state transition to IDLE occurs; and LINSR[LINS] shows error state only. 0b - LIN state, LINSR[LINS] shows the current LIN state and does not capture the LIN state if a bit error occurs. 1b - LIN state, LINSR[LINS] is captured whenever LINESR[BEF] occurs.
15 CCD	Checksum Calculation Disable You can read this field at any time and write to it only in Initialization mode. 0b - Hardware performs the checksum calculation. When this bit is reset, the LINCFR becomes read only. 1b - Checksum calculation disabled. When this field is set, the LINCFR is read/write. You can program this register to send a software calculated checksum/CRC (provided CFD is reset).
14 CFD	Checksum Field Disable You can read this field at any time and write to it only in Initialization mode. 0b - Checksum field is sent after the required number of data bytes are sent 1b - No checksum field is sent in the frame
13 —	Reserved
12 AUTOWU	Auto Wakeup You can read this field at any time and write to it only in Initialization mode. This bit is utilized in UART mode also. 0b - Sleep bit is cleared by software only 1b - Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set
11-8 MBL	Master Break Length Chooses the length of the Sync break that the master generates. You can read this field at any time and write to it only in Initialization mode. 0000b - 10-bit break length 0001b - 11-bit break length 0010b - 12-bit break length 0011b - 13-bit break length

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0100b - 14-bit break length 0101b - 15-bit break length 0110b - 16-bit break length 0111b - 17-bit break length 1000b - 18-bit break length 1001b - 19-bit break length 1010b - 20-bit break length 1011b - 21-bit break length 1100b - 22-bit break length 1101b - 23-bit break length 1110b - 36-bit break length 1111b - 50-bit break length
7 —	Reserved
6 —	Reserved
5 LBKM	Loop Back mode See "Loop back mode" in Test mode. You can read this field at any time and write to it only in Initialization mode. This bit is utilized in UART mode also. 0b - Loop Back mode disabled 1b - Loop Back mode enabled
4 MME	Master Mode Enable You can read this field at any time and write to it only in Initialization mode. 0b - Slave mode 1b - Master mode
3 SSBL	Slave Mode Sync Break Length You can read this field at any time and write to it only in Initialization mode. 0b - 11-bit break length 1b - 10-bit break length
2 RBLM	Receiver Buffer Locked mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You can read this field at any time and write to it only in Initialization mode. This bit is utilized in UART mode also. 0b - Receiver buffer not locked. Next incoming message overwrites the old one. 1b - Receiver buffer locked against overrun. After the buffer is full, the next incoming message will be discarded if buffer is not released (UARTSR[RMB]).
1 SLEEP	Sleep Mode Request Write a 1 to this field to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
0 INIT	Initialization Mode Request Write a 1 to this field to request LINFlexD to enter Initialization mode. On clearing this bit (and if LINCR1[SLEEP]=0), LINFlexD enters Normal mode. This bit is utilized in UART mode also.

48.5.3 LIN Interrupt Enable Register (LINIER)

Offset

Fields

Field	Function
31-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 SZIE	Stuck at Zero Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set. 0b - No interrupt 1b - Interrupt enabled
14 OCIE	Output Compare Interrupt Enable 0b - No interrupt 1b - Interrupt generated when OCF bit in LINESR or UARTSR is set
13 BEIE	Bit Error Interrupt Enable 0b - No interrupt 1b - Interrupt generated when BEF bit in LINESR is set
12 CEIE	Checksum Error Interrupt Enable An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR. 0b - No interrupt 1b - Interrupt enabled
11 HEIE	Header Error Interrupt Enable An interrupt is generated when this bit is set and either of the following flags are set: SFEF, SDEF, or IDPEF. **NOTE** If generic slave = 0, then this bit will always read a 0 and cannot be programmed. 0b - No interrupt 1b - Interrupt enabled
10-9 —	Reserved
8 FEIE	Frame Error Interrupt Enable 0b - No interrupt 1b - Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
7 BOIE	Buffer Overrun Error Interrupt Enable An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR. 0b - No interrupt 1b - Interrupt enabled
6 LSIE	LIN State Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Interrupt is generated only when entering the above fields. You can use this interrupt for debugging purposes. The interrupt has no status flag. 0b - No interrupt 1b - Interrupt generated when entering the following states: Sync Del, Sync Field, Identifier field, Checksum
5 WUIE	Wakeup Interrupt Enable If WUIE=1 and the WUF in LINSR or UARTSR is set then an interrupt is generated. 0b - No interrupt 1b - Interrupt enabled
4 —	Reserved
3 TOIE	Timeout Interrupt Enable An interrupt is generated if this bit is set and UARTSR[TO]=1 (in UART mode). 0b - No interrupt 1b - Interrupt enabled
2 DRIE	Data Reception Complete Interrupt Enable An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set. 0b - No interrupt 1b - Interrupt enabled
1 DTIE	Data Transmitted Interrupt enable An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set. 0b - No interrupt 1b - Interrupt enabled
0 HRIE	Header Received Interrupt An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **NOTE** If generic slave = 0, then this bit will always read a 0, and cannot be programmed. 0b - No interrupt 1b - Interrupt enabled

Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19 —	Reserved
18-16 RDC	Receive Data Byte Count Contains the number of entries (bytes) in the Receive data buffer in LIN mode. You can use this field for debug purposes. 000b - 1 byte 001b - 2 bytes 010b - 3 bytes 011b - 4 bytes 100b - 5 bytes 101b - 6 bytes

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - 7 bytes 111b - 8 bytes
15-12 LINS	LIN State In UART mode, Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits. **NOTE** The value of this field does not change by any write operation to it. Writing Fh to this field clears the Rx interrupt, only when set because of the LIN state event. 0000b - Sleep mode: LINFlexD is in Sleep mode, to save power consumption. 0001b - Init mode: LINFlexD is in Initialization mode. 0010b - Idle mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/ reception has been completed/aborted 0011b - Sync break: In Slave mode, if a falling edge is detected followed by a dominant state, it indicates that the sync break reception is ongoing. In Master mode, this indicates that the sync break transmission is ongoing. In slave mode, upon any error LIN state could be either Idle or Rec_Break, depending on last bit detected on LIN_RX. If the last bit detected is dominant then Rec_Break, otherwise Idle. 0100b - Sync Del: In Slave mode, valid sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0101b - Sync Field: In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0110b - Identifier Field: In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0111b - Header Reception/Transmission: In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 1000b - Data Reception/Data Transmission: In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 1001b - Checksum: Data transmission/reception completed, checksum transmission/reception ongoing.
11-10 —	Reserved
9 RMB	Release Message Buffer 0b - Buffer data is free and is reset by hardware when it in Initialization mode. 1b - Buffer data ready to be read by software. This bit must be cleared by software after reading the data received in the buffer.
8	Data Reception Buffer Not Empty

Table continues on the next page...

Table continued from the previous page...

Field	Function
DRBNE	LINFlexD writes a 1 to this field as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software must clear it after reading all the buffers. LINFlexD writes a 0 to this field in Initialization mode. This flag could be checked by software in case of a response timeout event.
7 RXBUSY	Receiver Busy In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case, you cannot write a 1 to LINCR2[DTRQ]. 0b - Receiver idle 1b - Reception ongoing
6 RDI	Receiver Data Input Reflects the current status of the Rx pin **NOTE** After reset is released, RDI reflects the actual value of Rx pin.
5 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin. • When slave is in Sleep mode • When master is in Sleep mode or Idle mode LINFlexD writes a 0 to this field in Initialization mode.
4-3 —	Reserved
2 DRF	Data Reception Completed Flag This bit is set by hardware and indicates that data reception completed. This flag must be cleared by software. LINFlexD writes a 0 to this field in Initialization mode. **NOTE** In case framing error or checksum error occurs then this flag is not set.
1 DTF	Data Transmission Completed Flag This bit is set by hardware and indicates that data transmission completed. This flag must be cleared by software. LINFlexD writes a 0 to this field in Initialization mode. **NOTE** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
0 HRF	Header Received flag This bit is set when the header reception is completed. It must be cleared by software.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit is set only when: • All filters are inactive and Bypass filter (BF) bit is set • No match in any filter and Bypass filter (BF) bit is set • TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **NOTE** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

48.5.5 LIN Error Status Register (LINESR)

Offset

Register	Offset
LINESR	Ch

Function

See Errors for a detailed description of all errors.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 SZF	Stuck At Zero Flag This bit is set when there is a stuck-at-zero timeout error. It must be reset by software.
14 OCF	Output Compare Flag This bit must be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If LINTCSR[MODE]=0, then LINflexD writes a 0 to OCF in Initialization mode. If LINTCSR[MODE]=1, then OCF maintains its value regardless of the LIN state. 0b - No output compare event occurred 1b - In master mode, LINESR[OCF] flag is set when counter LINTCSR[CNT] has matched the content of LINOCR[OC2]. In slave mode, LINESR[OCF] is set when the content of the counter LINTCSR[CNT] has matched the content of LINOCR[OC1] or LINOCR[OC2].
13 BEF	Bit Error Flag LINFlexD writes a 1 to this field when a bit error occurs. It should be cleared by software. LINFlexD writes a 0 to this field in Initialization mode.
12 CEF	Checksum Error Flag LINFlexD writes a 1 to this field if the received checksum does not match the hardware-calculated checksum. It must be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. LINFlexD writes a 0 to this field in Initialization mode.
11 SFEF	Sync Field Error Flag LINFlexD writes a 1 to this field when the received Sync Field is inconsistent. It must be cleared by software. LINFlexD writes a 0 to this field in Initialization mode. If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
10 SDEF	Sync Delimiter Error Flag TLINFlexD writes a 1 to this field when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. LINFlexD writes a 0 to this field in Initialization mode. **NOTE** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
9 IDPEF	ID Parity Error Flag TLINFlexD writes a 1 to this field when an error in the ID parity occurs. It should be cleared by software. **NOTE** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
8 FEF	Framing Error Flag LINFlexD writes a 1 to this field when a framing error (invalid stop bit) occurs. It should be cleared by software. LINFlexD writes a 0 to this field in Initialization mode.
7 BOF	Buffer Overrun Flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. LINFlexD writes a 0 to this field in Initialization mode.
6-1 —	Reserved
0 NF	Noise Flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. LINFlexD writes a 0 to this field in Initialization mode.

48.5.6 UART Mode Control Register (UARTCR)

Offset

Register	Offset
UARTCR	10h

Function

NOTE

When accessing the UARTCR register, reserved bits must always be written to zero.

Provided under NDA only
COMPANY PROPRIETARY

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 MIS	Monitor Idle State Controls what UARTCTO monitors. Register bit can be read in any mode, written only in initialization mode when UART bit is set. 0b - UARTCTO monitors the number of bits to be received. 1b - UARTCTO monitors the idle state of the reception line.
30-28 CSP	Configurable Sample Point Decides the sample point during reduced oversampling. CSP can take the following range of values for a given oversampling rate: OSR / CSP: 4 — 2,3 5 — 2, 3, 4 6 — 3, 4, 5 8 — NA Register bit can be read in any mode, written only in initialization mode when UART bit is set.
27-24 OSR	Over Sampling Rate Configures the number of samples taken for a bit when reduced oversampling is enabled. In most cases, OSR can be 4, 5, 6 or 8. When idle state monitoring is enabled (MIS=1), OSR can be only 4 or 8. 4 or 8. Register bit can be read in any mode, written only in initialization mode when UART bit is set.
23	Reduced Over Sampling Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ROSE	Register bit can be read in any mode, written only in initialization mode when UART bit is set. 0b - Each bit is over sampled sixteen times. 1b - OSR determines the oversampling rate.
22-20 NEF	Number of expected frames Configures the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received. Register bit can be read in any mode, written only when UART bit is set. Register bit is a read/write field.
19 DTU_PCETX	Disable Timeout in UART mode This bit can be programmed in Initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received. **In Buffer mode:** This timer gets reset whenever the number of bytes received (rec_byte_cnt) is equal to RDFL. At this point, the DRF bit is set. Also, the num_of_frames (number of frames received) and rec_byte_cnt are reset. When num_of_frames equals NEF, Disable Timeout is generated. But this clears num_of_frames also. Thus the timer restarts. The value of counter is 0 when it restarts. **In FIFO mode:** When num_of_frames equals NEF, Disable Timeout is generated which clears num_of_frames and causes the timer to restart. The value of counter is 0 when it restarts. Notes: • Disable Timeout causes only the Timer to restart which enables Timeout again. • Timer reset means it resets and starts counting again and the Timeout is enabled. 0b - Timeout has to be handled by software 1b - Timeout in UART mode is disabled after the configured number of data frames are received
18-17 SBUR	Stop Bits In UART Reception Mode When the UART is used for transmission and reception, you need to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. Register bit can be read in any mode, written only in Initialization mode when UART bit is set. 00b - 1 stop bit 01b - 2 stop bits 10b - 3 stop bits 11b - reserved
16 —	Reserved This reserved field is writable but do not write any value to it other than its reset value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). Bit 15 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes Register bit is a read/write field. TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is available for debug purposes. 000 : empty 001 : 1 byte 010 : 2 bytes 011 : 3 bytes 100 : 4 bytes Others : reserved TDFL_TFC can be programmed and is significant only when the UART bit is set. When you have connected a debugger, TDFL_TFC decrements if you read TxFIFO through the debugger. If the data path functions normally, LINFlexD clears the RFC/TFC counters internally.
12-10 RDFL_RFC	Reception Data Field Length/RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). Bit 19 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is available for debug purposes. 000 : Empty 001 : 1 byte 010 : 2 bytes 011 : 3 bytes 100 : 4 bytes

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Others - Reserved RDFL_RFC can be programmed and is significant only when the UART bit is set. **NOTE** In buffer mode, RDFL_RFC must be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint. When you have connected a debugger, RDFL_RFC decrements if you read RxFIFO through the debugger. If the data path functions normally, LINFlexD clears the RFC/TFC counters internally.
9 RFBM	Rx FIFO/Buffer Mode Register bit can be read in any mode, written only in initialization mode when UART bit is set. 0b - Rx Buffer mode enabled 1b - Rx FIFO mode enabled (mandatory in DMA Rx mode)
8 TFBM	Tx FIFO/Buffer Mode Register bit can be read in any mode, written only in initialization mode when UART bit is set. 0b - Tx Buffer mode enabled 1b - Tx FIFO mode enabled (mandatory in DMA Tx mode)
7 WL1	Word Length In UART Mode Works with WL0 to configure word length as shown in the following table. Register bit can be read in any mode, written only in initialization mode when UART bit is set.

WL1	WL0	Description
0	0	7 bits data + parity
0	1	8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1
1	0	15 bits data + parity
1	1	16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1

6 PC1	Parity Control Works with PC0 to configure parity as shown in the following table. Register bit can be read in any mode, written only in initialization mode when UART bit is set.

PC1	PC0	Description
0	0	Parity sent is Even
0	1	Parity sent is Odd

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15 SZF	Stuck At Zero Flag LINFlexD writes a 1 to this field when LINFlexD detects 100 dominant bits. It must be cleared by software. An interrupt is generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when not in Initialization mode and the UART bit is set.
14 OCF	Output Compare Flag An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when not in Initialization mode and the UART bit is set. **NOTE** For Baud rate above 1 Mbit/s, this flag is not usable. 0b - No output compare event occurred 1b - The content of the counter has matched the content of LINOCR
13-10 PE	Parity Error Flag Indicates whether a parity error occurred in the corresponding byte. No interrupt is generated if this error occurs.

Table continues on the next page...

Table continued from the previous page...

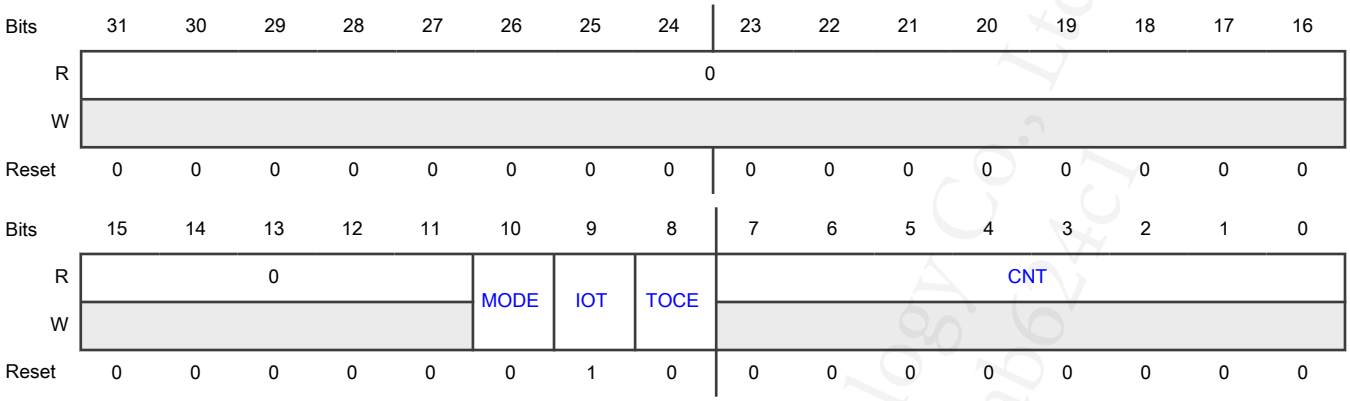
Field	Function
	This bit will reflect the same value as in LINESR, when not in initialization mode and UART bit set. Parity is checked only after complete frame is received. Following are the conditions when WL bits = 01 or 11 (either PE0 or PE2 is only set). • When PE0 is set, it indicates Parity error in either the first or second received byte. • When PE2 is set, it indicates Parity error in either the third or fourth received byte. 0000b - No parity error 0001b - Parity error in the corresponding received byte
9 RMB	Release Message Buffer This bit must be cleared by software. This bit reflects the same value as in LINSR, when not in Initialization mode and the UART bit is set. 0b - Buffer data is free 1b - Buffer data ready for software to read
8 FEF	Framing Error Flag LINFlexD writes a 1 to this field when a framing error (invalid stop bit) occurs. It must be cleared by software. It generates an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when not in Initialization mode and the UART bit is set. 0b - No framing error 1b - Framing error occurs
7 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the new value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when not in Initialization mode and the UART bit is set.
6 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin when UART bit is set.
5 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINSR when not in Initialization mode and the UART bit is set.
4 RFNE	Receive FIFO Not Empty

Table continues on the next page...

Table continued from the previous page...

Field	Function
	RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
3 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.TOIE bit is set on the Error interrupt line in UART mode.
2 DRFRFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set when the configured number of valid stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error in case framing error is in the last STOP bit configured, parity error or overrun error. This bit will reflect the same value as in LINSR when not in Initialization mode and the UART bit is set. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
1 DTFTFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINSR when not in Initialization mode and the UART bit is set. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
0 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when not in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

48.5.8 LIN Time-Out Control Status Register (LINTCSR)



Offset

Register	Offset
LINTCSR	18h

Function

This register contains control and status bits for timeout feature.

Diagram

Fields

Field	Function
31-11 —	Reserved
10 MODE	Time-out counter mode This bit can be configured only during initialization. Register bit can be read in any mode, written only in initialization mode. 0b - LIN mode 1b - Output compare mode
9 IOT	Idle on timeout Register bit can be read in any mode, written only in initialization mode. This feature is applicable only when MODE bit in LINTCSR is cleared. 0b - LIN state machine does not reset to Idle on timeout 1b - LIN state machine resets to Idle on timeout event
8 TOCE	Time-out counter enable TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE. 0b - Time-out counter disable. OCF flag is not set on an output compare event. 1b - Time-out counter enable. OCF flag is set if an output compare event occurs.
7-0 CNT	Counter Value These bits reflect the value of a counter used for timeout. **NOTE** For proper functionality of this counter, LINIBRR should be >= 5.

48.5.13 LIN Checksum Field Register (LINCFR)

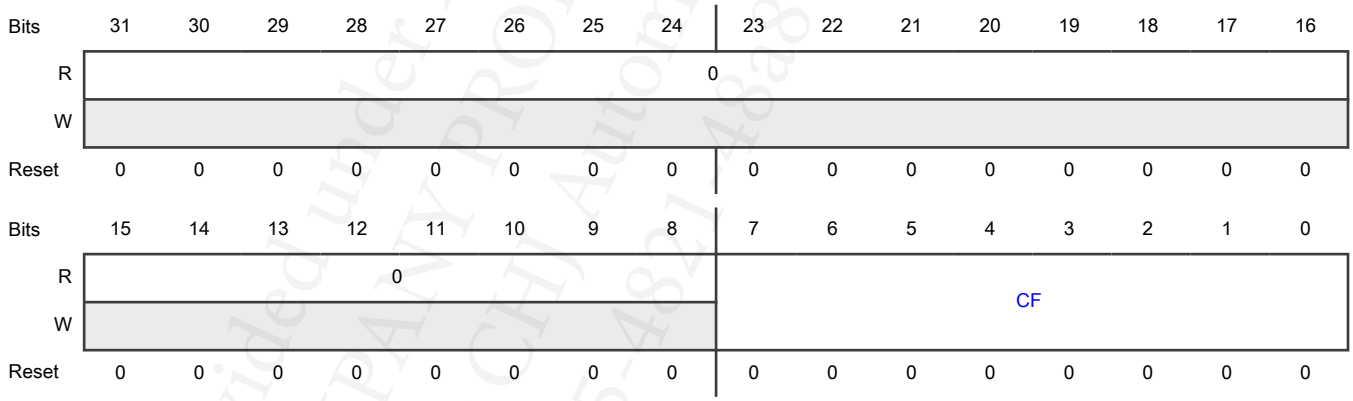
Offset

Register	Offset
LINCFR	2Ch

Function

NOTE

There is a delay between 4 to 6 clock cycles of LIN_XBAR_CLK for the internal checksum's value (which is clocked with LIN_CLK/16 * LDIV) to reflect on LINCFR.



This register consists of checksum bits.

NOTE

Due to synchronization structures between the two input clocks to LINFlexD, the write to this register is delayed between 2 to 3 clock cycles and read is delayed between 4 to 6 clock cycles of LIN_XBAR_CLK .

CFD	CCD	LINCHKSUM read/write	Checksum sent
1	1	read/write	None
1	0	read-only	None
0	1	read/write	Programmed checksum
0	0	read-only	Calculated checksum

Diagram

Fields

Field	Function

Table continues on the next page...

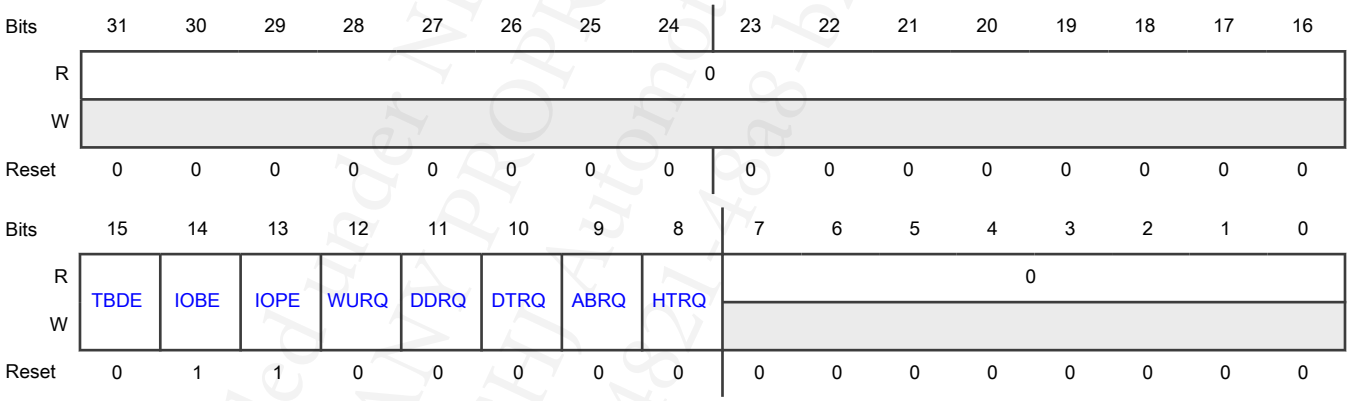
Table continued from the previous page...

Field	Function
7-0 CF	Checksum bits When the CCD bit is reset these bits are read-only and are calculated by hardware. When the CCD bit is set, these bits can be written by software.

48.5.14 LIN Control Register 2 (LINCR2)

Offset

Register	Offset
LINCR2	30h



Function

This register includes control status bits related to buffer operations.

NOTE

- When accessing the LINCR2 register, each reserved bit should be written to its original reset value.
- In Normal mode, write 1 to only those fields that you must configure and write 0 to all the other non-reserved fields. Because only the module clears these fields, writing 0 does not change their current values.

Diagram

Fields

Field	Function
31-16 —	Reserved When accessing the LINCR2 register, each reserved bit should be written to its original reset value.
15 TBDE	Two Bit delimiter bit This bit can be set in Initialization mode only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Register bit can be read in any mode, written only in initialization mode. 0b - Delimiter length in break field is 1 bit 1b - Delimiter length in break field is 2 bits
14 IOBE	Idle on Bit Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0b - Bit Error does not reset LIN state machine 1b - Bit Error resets LIN state machine
13 IOPE	Idle on Identifier Parity Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. **NOTE** If generic slave = 0, then this bit will always read a '0', and cannot be programmed. 0b - Parity Error does not reset LIN state machine 1b - Parity Error resets LIN state machine
12 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request. Register bit can be read/set by software
11 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered. Register bit can be read/set by software
10 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete. Register bit can be read/set by software

Table continues on the next page...

Table continued from the previous page...

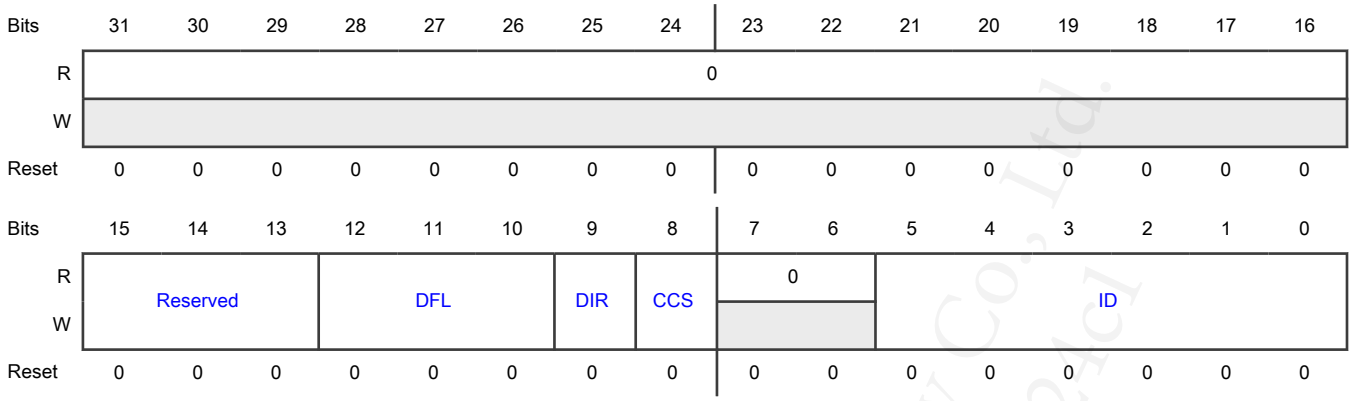
Field	Function
9 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also. Register bit can be read/set by software
8 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **NOTE** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.
7-0 —	Reserved When accessing the LINCR2 register, each reserved bit should be written to its original reset value.

48.5.15 Buffer Identifier Register (BIDR)

Offset

Register	Offset
BIDR	34h

Function



This register contains the bits which provide information about the identifier of the transaction and other related information.

NOTE

All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Provided under NDA only

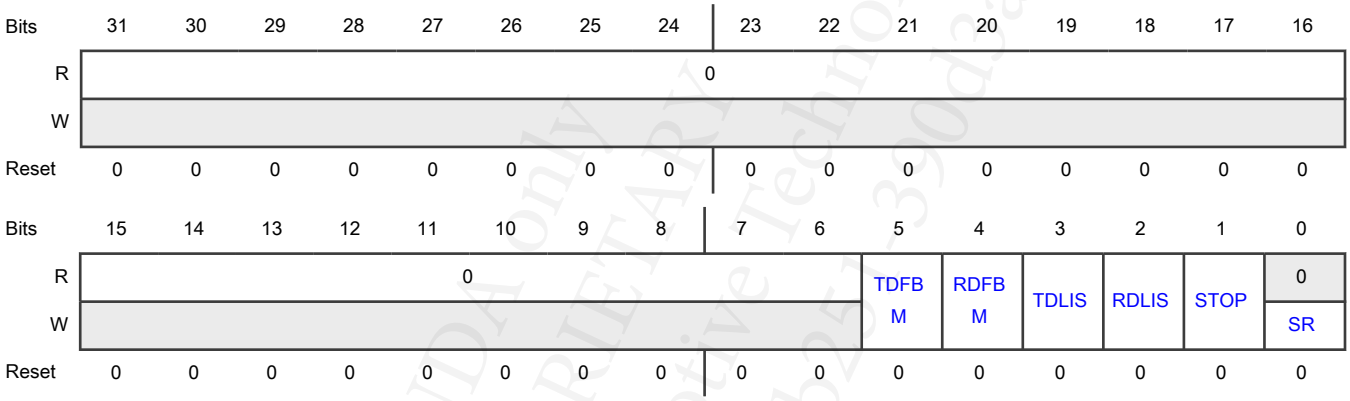
48.5.18 Global Control Register (GCR)

Offset

Register	Offset
GCR	4Ch

Function

This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.



The address offset depends on the no_of_filters. See chip configuration details for the number of filters used in this device.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8162e5-4821-48a8-b251-390d3ab624c1

Table 321. Register fields reset by SR

Register	Comment
LINSR	All fields except RXBUSY and AUTOSYNC_COMP are reset
LINESR	All fields are reset
LINTCSR	Only CNT[0:7] is reset
UARTSR	All fields except RFE & TFF are reset
UARTCR	Only TFC & RFC are reset
UARTCTO	All fields are reset

Diagram

Fields

Field	Function
31-6 —	Reserved
5 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0b - The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1b - The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
4 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes.

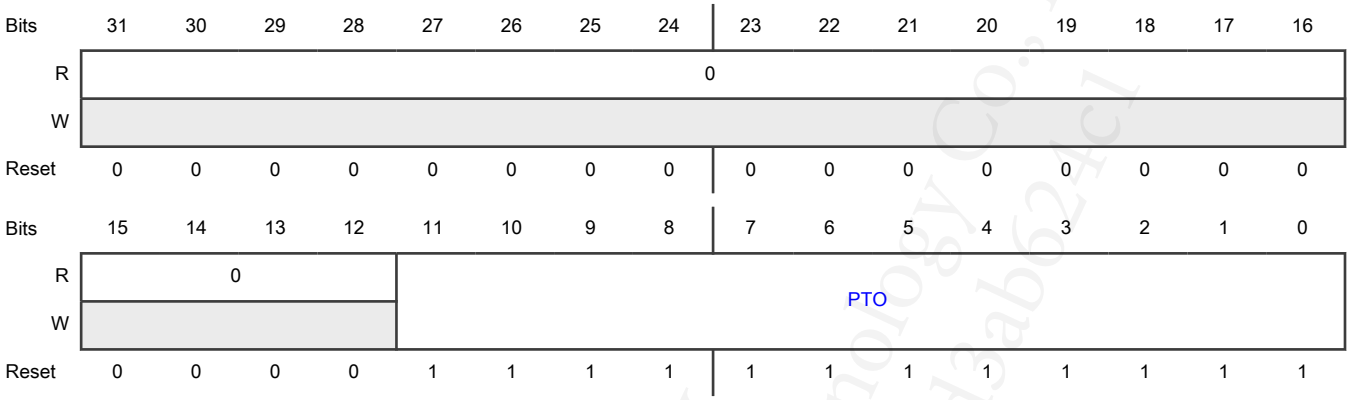
Table continues on the next page...

Table continued from the previous page...

Field	Function
	Register bit can be read in any mode, written only in initialization mode. 0b - The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1b - The first bit of received data is MSB — in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
3 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0b - Transmitted data is not inverted 1b - Transmitted data is inverted
2 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0b - Received data is not inverted 1b - Received data is inverted
1 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). Register bit can be read in any mode, written only in initialization mode. 0b - 1 stop bit 1b - 2 stop bits
0 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). Register bit can be written only be software in initialization mode. Table 321 describes the register fields reset by SR.

48.5.19 UART Preset Timeout Register (UARTPTO)

Offset



Register	Offset
UARTPTO	50h

Function

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

The address offset depends on no_of_filters. See chip configuration details for the number of filters used in the device.

Diagram

Fields

Field	Function
31-12 —	Reserved
11-0 PTO	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Also see register UARTCTO.

48.5.20 UART Current Timeout Register (UARTCTO)

Offset

Register	Offset
UARTCTO	54h

Function

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see UART Preset Timeout Register (UARTPTO)) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

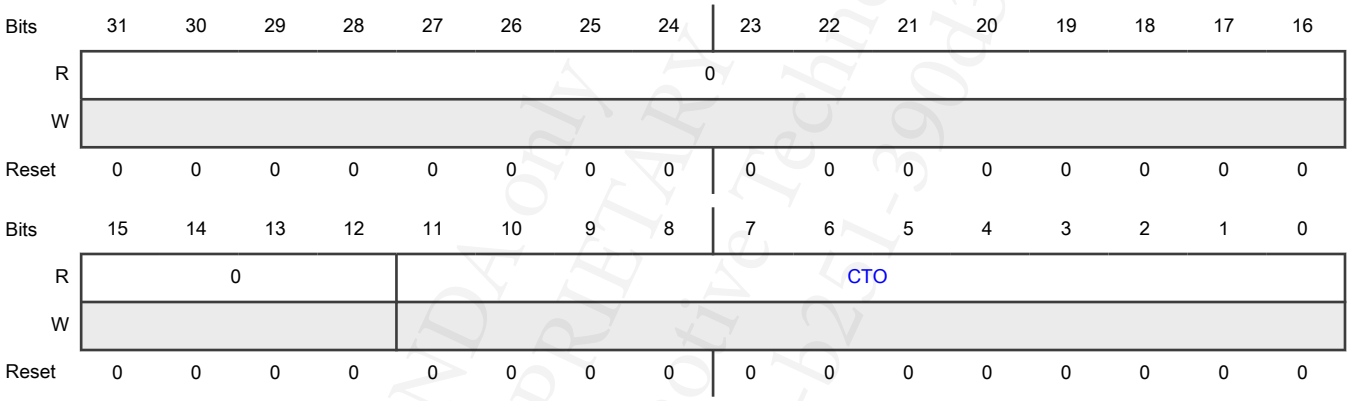
The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to LIN_XBAR_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to LIN_XBAR_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

NOTE

Due to this synchronization there is a delay between 4 to 6 clock cycles of LIN_XBAR_CLK for the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) to reflect on UARTCTO.

It is reset when:



- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

The address offset depends on no_of_filters. See chip configuration details for the number of filters used in the device.

NOTE

Write access to this RO register generates transfer error.

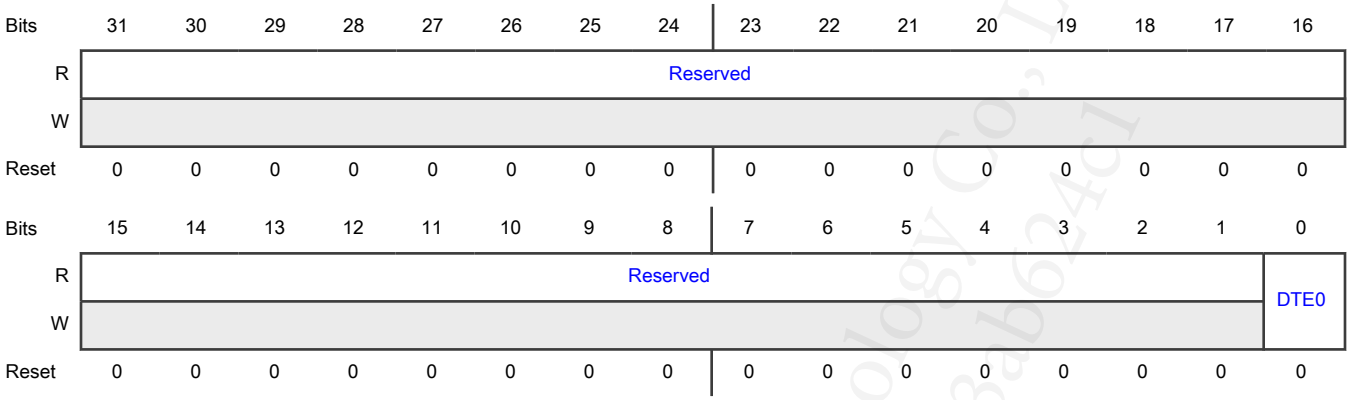
Diagram

Fields

Field	Function
31-12 —	Reserved
11-0 CTO	Current Timeout CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

48.5.21 DMA Tx Enable Register (DMATXE)

Offset



Register	Offset
DMATXE	58h

Function

This register enables the DMA TX interface. This register can be written and read by software anytime.

The address offset depends on no_of_filters. See chip configuration details for the number of filters used in the device.

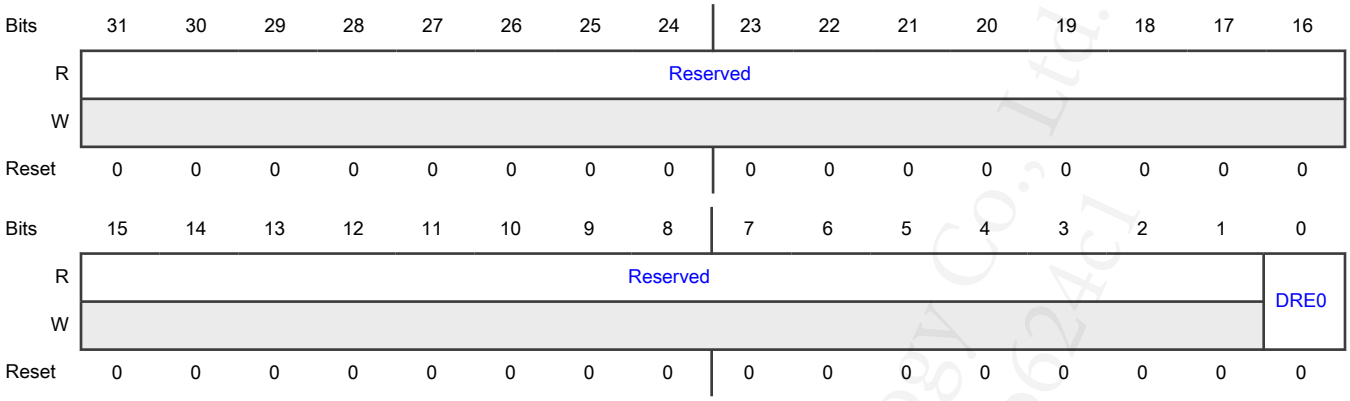
Diagram

Fields

Field	Function
31-1 —	Reserved
0-0 DTEn	DMA Tx channel enable The number of DTE bits varies, and is equal to DMA_TX_CH_NUM. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state. **NOTE** See chip configuration details for the value of DMA_TX_CH_NUM used in this device. **NOTE** The value of n is 0. 0b - nth DMA Tx channel disabled 1b - nth DMA Tx channel enabled

48.5.22 DMA Rx Enable Register (DMARXE)

Offset



Register	Offset
DMARXE	5Ch

Function

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no_of_filters. See device configuration chapter for the number of filters used in the device.

Diagram

Fields

Field	Function
31-1 —	Reserved
0-0 DREn	DMA Rx channel enable The number of DRE bits varies, and is equal to DMA_RX_CH_NUM. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state. **NOTE** See chip configuration details for the value of DMA_RX_CH_NUM used in this device. **NOTE** The value of n is 0. 0b - nth DMA Rx channel disabled 1b - nth DMA Rx channel enabled

48.6 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

LINFlexD writes a 1 to multiple fields (such as status fields). It also writes a 0 to multiple other fields (such as LINCR2[HTRQ] and LINCR2[ABRQ]). Software must check the status of the bits before initiating the next sequence to ensure that LINFlexD completed its work. This ensures that LINFlexD and software are working in sync.

48.6.1 Master node

LINFlexD acts as master when LINCR1[MME]=1.

48.6.4 UART mode

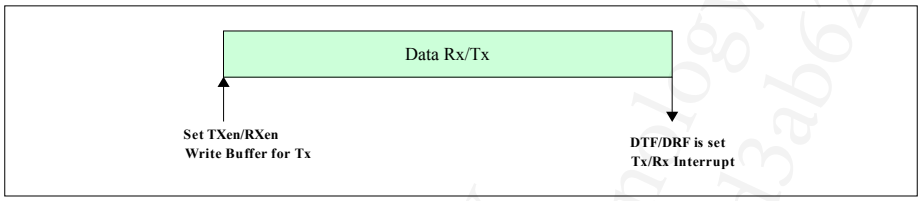

Figure 409. UART mode configuration

48.6.5 Interrupts

This section describes interrupt handling and interrupt concentration. Interrupt listed in Table 322 are corresponding to status registers LINSR, LINESR, and UARTSR. Corresponding interrupt enables bit are present in LINIER register. Instead of having multiple interrupt output lines, these interrupts are concentrated into three output signals as shown in Figure 410.

Table 322. Interrupts

Interrupt event	Event flag	Enable control bit	Interrupt vector
Stuck at zero	SZF	SZIE	Error
Output compare	OCF	OCIE	Error
Bit error	BEF	BEIE	Error
Checksum error	CEF	CEIE	Error
Header error	SFEF orSDEF orIDPEF	HEIE	Error
Frame error	FEF	FEIE	Error
Buffer overrun error	BOF	BOIE	Error
UART timeout error	TO	TOIE	Error
LIN state	Sync Del, Sync Field,Identifier field or Checksum Field	LSIE	Rx
Wakeup	WUF	WUIE	Rx

Table continues on the next page...

Table 322. Interrupts (continued)

Interrupt event	Event flag	Enable control bit	Interrupt vector
Data reception complete	DRF	DRIE	Rx
Data transmitted	DTF	DTIE	Tx
Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

The following figure shows an interrupt flow diagram.

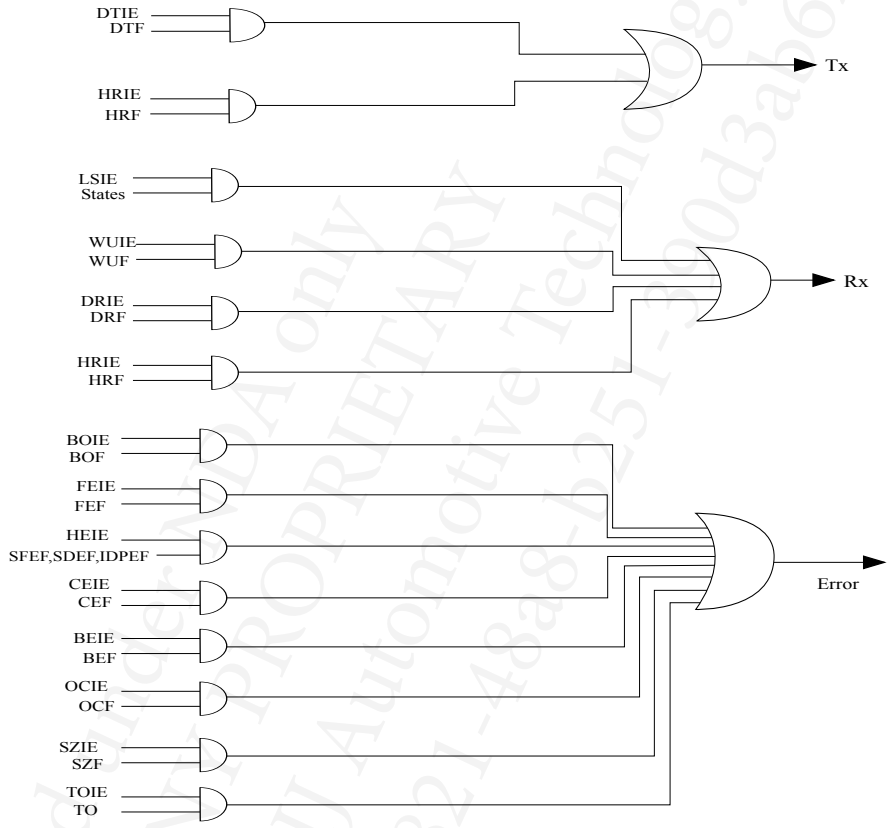

Figure 410. Interrupt diagram

Rx interrupt due to LIN state event is cleared by writing LINSR[LINS] field with 0xF when LSIE is enabled. In loopback mode, Rx interrupt is set earlier than Tx interrupt.

48.6.6 LINFlexD clock tolerance

48.6.6.1 Faster receiver tolerance

In this case, the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct noise and framing error free reception bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

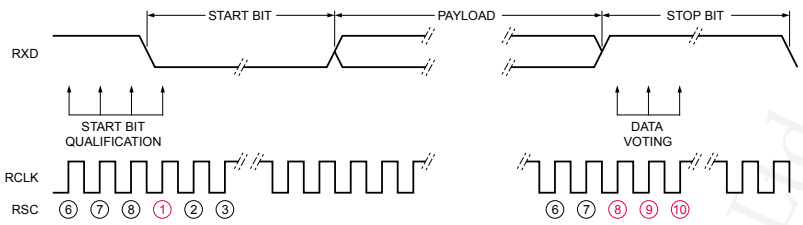

Figure 411. Faster receiver

48.6.6.2 Slower receiver tolerance

In this case, the receiver has a slower baud rate than the transmitter. Therefore, the stop bit sampling is still running while transmission of the next start bit is already occurring. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

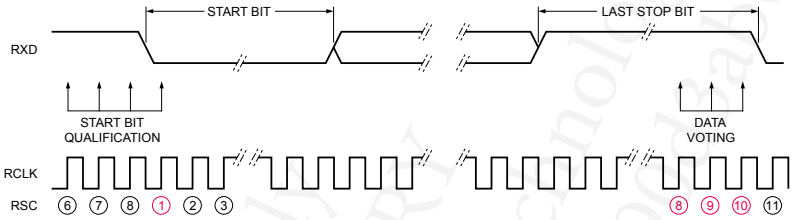

Figure 412. Slower receiver

Chapter 49
Serial Peripheral Interface (SPI)

49.1 Chip-specific SPI information

49.1.1 Module instance information

This chip contains six instances of SPI. The following table shows the configuration of each instance.

Description	SPI_0	SPI_1	SPI_2	SPI_3	SPI_4	SPI_5
Extended (32-bit) SPI mode support	1	1	1	1	1	1
CSI and DSI mode support	0	0	0	0	0	0
TX FIFO	5	5	5	5	5	5
RX FIFO	5	5	5	5	5	5
CMD FIFO	5	5	5	5	5	5
CTAR registers (transfer attribute configuration)	6	6	6	6	6	6
PCS signals	8	5	5	5	5	5
Mode	Master/Slave	Master/Slave	Master/Slave	Master/Slave	Master/Slave	Master/Slave

49.2 Introduction

The SPI module provides a synchronous serial bus for communication between a chip and an external peripheral device.

49.2.1 Block diagram

The following figure represents the module's block diagram.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-9251-3900d3ab624f:1

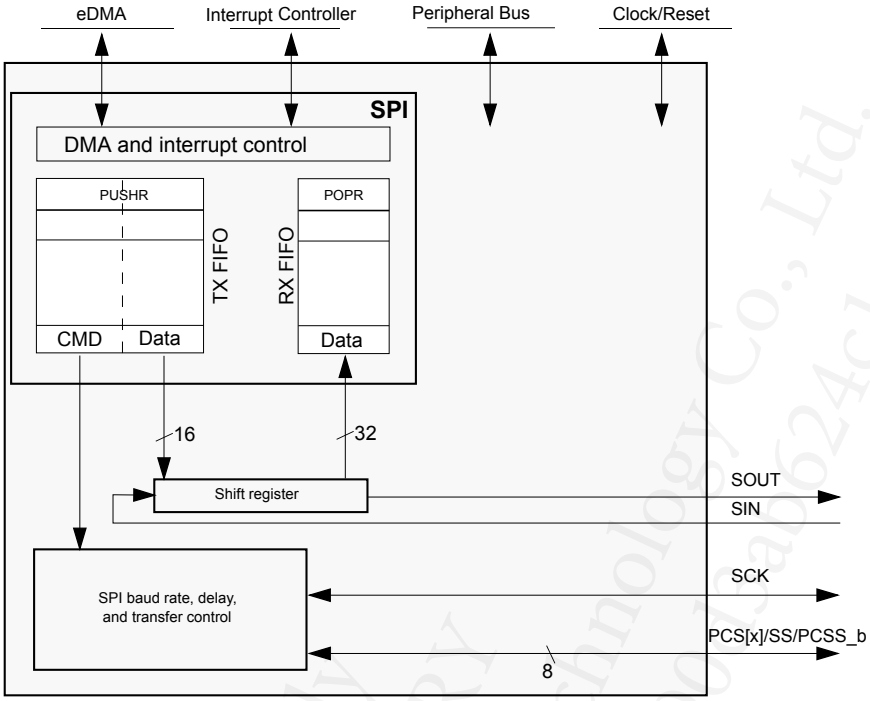

Figure 413. SPI block diagram

49.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in the Slave mode with continuous slave selection
- Buffered transmit operation using transmit first in first out (TX FIFO) with a depth of 5 entries
- Support for 8- or 16-bit accesses to PUSHR_SLAVE[TXDATA]
- Buffered receive operation using the Receive FIFO (RX FIFO) with a depth of 5 entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - 6 transfer attribute registers
  - 6 extended transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 32
    - The continuous selection format can support SPI frames longer than 32 bits.
  - Continuously held chip-select capability
  - Parity control

- 8 peripheral chip selects (PCSes), expandable to 2 ^ (8 – 1) with an external demultiplexer
- Deglitching support for up to 8 peripheral chip selects (PCSes) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO when:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - Command (CMD) FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End of queue reached (EOQF)
  - TFFF
  - CMDFFF
  - Transfer of current frame complete (TCF)
  - Transfers due from current command frame complete (CMDTCF)
  - Attempt to transmit with an empty transmit FIFO (TFUF)
  - RFDF
  - Frame received while RX FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
  - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line
- Modified SPI transfer formats for communication with slower peripheral devices

49.2.3 Interface configurations

49.2.3.1 SPI configuration

The SPI configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting the external queue operation. Transmitted data and received data are included in separate FIFOs. The host CPU or a DMA controller reads the received data from the RX FIFO and writes transmit data to the transmit FIFO.

For queued operations, the SPI queues can be included in system RAM, external to the module. A DMA controller or host CPU accomplishes data transfers between the queues and the module FIFOs. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

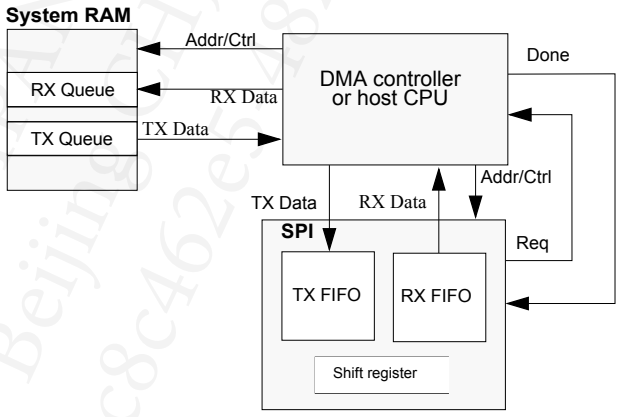

Figure 414. SPI with queues and DMA

49.2.4 Modes of operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- Chip-specific modes:
  - Debug mode

The module enters module-specific modes when the host writes to a module register. The signals external to the module control the chip-specific modes. The chip may enter these modes in parallel to the module-specific modes.

49.2.4.1 Master mode

The Master mode allows the module to initiate and control serial communication. In this mode, the module controls the following signals, which the module configures as outputs:

- SCK
- SOUT
- PCS[*x*]

49.2.4.2 Slave mode

The Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The module configures the SCK signal and the PCS[0]/SS_b signals as inputs, which are driven by the SPI bus master.

49.2.4.3 Module Disable mode

The Module Disable mode can be used for chip-power management. In this mode, you can stop the clock to the non-memory mapped logic in the module.

49.2.4.4 Debug mode

The Debug mode is used for system development and debugging. MCR[FRZ] controls module behavior when the chip is in this mode.

- If you write a 1 to this field, the module stops all serial transfers .
- If you write a 0 to the field, this mode has no effect on the module.

49.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

Table 323. Module signal descriptions

Signal	Master mode	Slave mode	I/O
PCS0/SS_b	Peripheral Chip Select 0 (O)	Slave Select (I)	I/O
PCS1	Peripheral Chip Select 1	Unused	O

Table continues on the next page...

Table 323. Module signal descriptions (continued)

Signal	Master mode	Slave mode	I/O
PCS2	Peripheral Chip Select 2	Unused	O
PCS3	Peripheral Chip Select 3	Unused	O
PCS4	Peripheral Chip Select 4	Unused	O
PCS5/PCSS_b	Peripheral Chip Select 5/Peripheral Chip Select Strobe	Unused	O
PCS[6:7]	Peripheral Chip Selects 6–7	Unused	O
SCK	Serial Clock (O)	Serial Clock (I)	I/O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O

49.3.1 PCS0/SS_b

Master mode: Peripheral Chip Select 0 (O)—Selects SPI slave to receive data transmitted from the module

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from the SPI master

NOTE

Do not tie the SPI slave select pin to ground. Otherwise, SPI cannot function properly.

49.3.2 PCS1

Master mode: Peripheral Chip Select 1 (O)—Selects SPI slave to receive data that the module transmits

Slave mode: Unused

49.3.3 PCS2

Master mode: Peripheral Chip Select 2 (O)—Selects SPI slave to receive data that the module transmits

Slave mode: Unused

49.3.4 PCS3

Master mode: Peripheral Chip Select 3 (O)—Selects SPI slave to receive data that the module transmits

Slave mode: Unused

49.3.5 PCS4

Master mode: Peripheral Chip Select 4 (O)—Selects SPI slave to receive data that the module transmits

Slave mode: Unused

49.3.6 PCS5/PCSS_b

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strobes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

49.3.7 PCS6–PCS7

Master mode: Peripheral Chip Selects 6–7 (O)—Selects an SPI slave to receive data transmitted by the module

Slave mode: Unused

49.3.8 SCK

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from the SPI master

49.3.9 SIN

Master mode: Serial Input (I)—Receives serial data

Slave mode: Serial Input (I)—Receives serial data

49.3.10 SOUT

Master mode: Serial Output (O)—Transmits serial data

Slave mode: Serial Output (O)—Transmits serial data

49.4 SPI register descriptions

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any write access to the POPR and RXFR*n* also results in a transfer error.

NOTE

While the module is in the running state, do not write to:

- CTAREn

</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This field can only be written when the value of the MDIS field is 0. 0b - RX FIFO is enabled. 1b - RX FIFO is disabled.
11 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO counter. The value of this field is always read as 0. 0b - Do not clear the TX FIFO counter. 1b - Clear the TX FIFO counter.
10 CLR_RXF	Clear RX FIFO Flushes the RX FIFO. Writing a 1 to this field clears the RX counter. The value of this field is always read as 0. **NOTE** After every RX FIFO clear operation (MCR[CLR_RXF] = 0b1), followed by an RX FIFO overflow (SR[RFOF] = 0b1) scenario, you must immediately perform a single POP from the RX FIFO and discard the read data. The POP and discard operations must be completed before receiving a new incoming frame. 0b - Do not clear the RX FIFO counter. 1b - Clear the RX FIFO counter.
9-8 SMPL_PT	Sample Point Controls when the module master samples SIN in the modified transfer format. This field is valid only when the value of CTAR*n*[CPHA] is 0. 00b - Zero protocol clock cycles between SCK edge and SIN sample 01b - One protocol clock cycle between SCK edge and SIN sample 10b - Two protocol clock cycles between SCK edge and SIN sample 11b - Reserved
7-4 —	Reserved
3 XSPI	Extended SPI Mode Enables the usage of Command and Transfer Attribute Register Extended (CTARE) registers. These registers allow you to send up to 32-bit SPI frames. Command cycling is also enabled, which allows you to

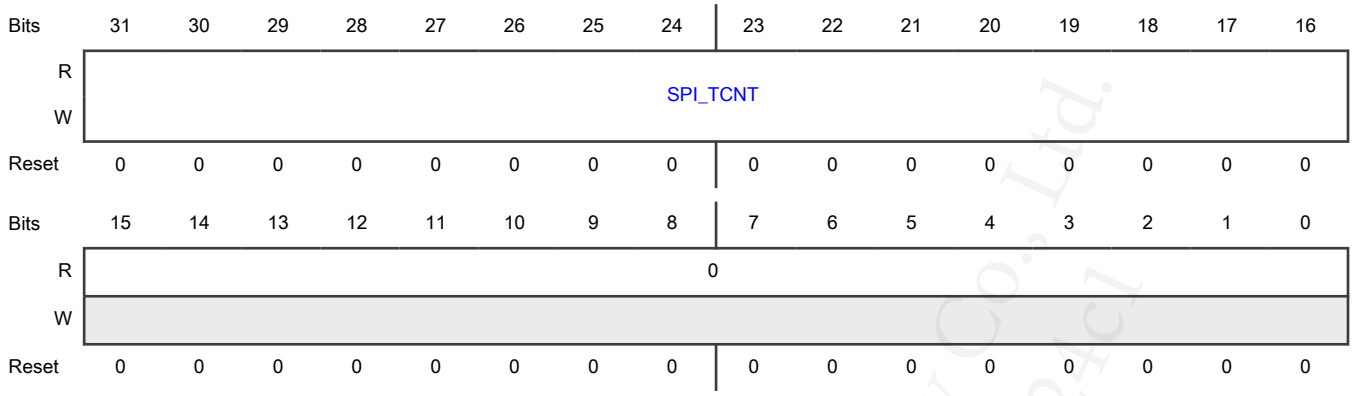
Table continues on the next page...

Table continued from the previous page...

Field	Function
	send multiple data frames using a single command frame. When MCR[DIS_TXF] is asserted, the Extended SPI mode cannot be used to transmit SPI frames that are more than 16 bits in size. 0b - Normal SPI mode. Frame size can be up to 16 bits. Command cycling is not available in this mode. 1b - Extended SPI mode. Up to 32-bit SPI frames, along with command cycling, are enabled.
2 FCPCS	Fast Continuous PCS Mode Enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in the Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via PUSHR[MASC] and PUSHR[MCSC]. The firmware should select appropriate masks when providing continuous frames via the PUSHR. 0b - Normal or slow continuous PCS mode. Masking of delays is disabled. 1b - Fast continuous PCS mode. Delays are masked via control fields in the PUSHR.
1 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame 0b - SPI frame transmission continues. 1b - SPI frame transmission stops.
0 HALT	Halt Starts and stops frame transfers. See Start and Stop of Module transfers for details. 0b - Starts transfers 1b - Stops transfers

49.4.3 Transfer Count Register (TCR)

Offset



Register	Offset
TCR	8h

Function

This register contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. You must not write to the TCR when the module is in the running state.

Preliminary Information NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462f5-4821-48a8-b251-390d8bb24c

Diagram

Fields

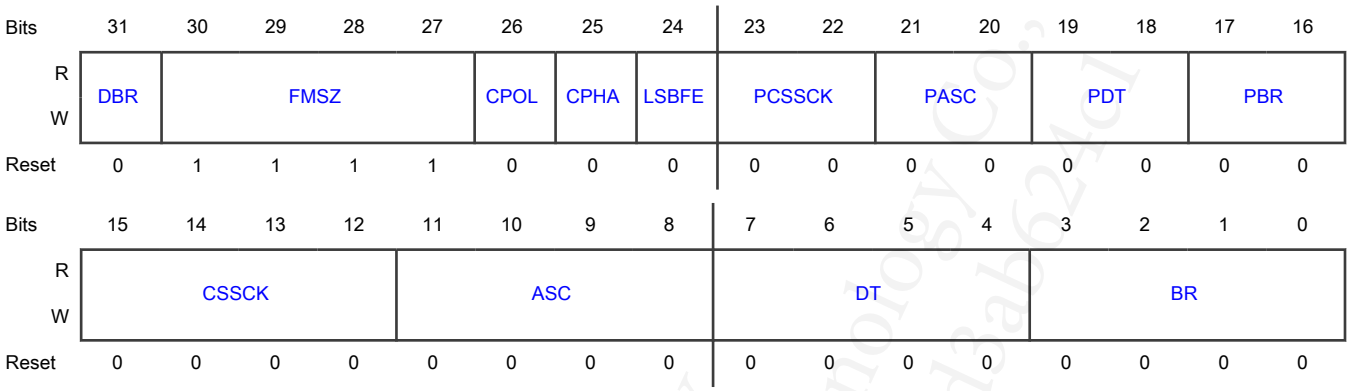
Field	Function
31-16 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers that the module performs This field increments every time the last bit of an SPI frame is transmitted, and a value written to this field presets the counter to that value. The field is reset to 0 at the beginning of a frame if the value of PUSHR[CTCNT] is 1. If the counter is not overwritten or cleared, it eventually overflows at value 65535 to 0.
15-0 —	Reserved

49.4.4 Clock and Transfer Attributes Register (in Master mode) (CTAR0 - CTAR5)

Offset

Register	Offset
CTAR0	Ch
CTAR1	10h
CTAR2	14h
CTAR3	18h
CTAR4	1Ch
CTAR5	20h

Function



This set of registers is used to define different transfer attributes. You must not write to the CTARs when the module is in the running state.

Provided under NDA ONLY
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
c8462e5-4821-48a2-b251-390d3ab624c1

In Master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In Slave mode, a subset of the fields in CTAR0 is used to configure the slave transfer attributes.

When the module is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTARs is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

Diagram

Fields

Field	Function
31 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in Master mode. It effectively halves the baud rate division ratio, supporting faster frequencies, and odd division ratios for SCK. If the value of this field is 1, the duty cycle of the SCK depends on the value in the baud rate prescaler and the CPHA field, as listed in the following table. See the description of the VR field in this register for details on how to compute the baud rate.

Table 324. SPI SCK duty cycle

DBR	CPHA	PBR	SCK duty cycle
0	Any	Any	50/50
1	0	00	50/50
1	0	01	33/66
1	0	10	40/60
1	0	11	43/57
1	1	00	50/50
1	1	01	66/33
1	1	10	60/40
1	1	11	57/43

0b - The baud rate is computed normally with a 50/50 duty cycle.

1b - The baud rate is doubled with the duty cycle depending on the baud rate prescaler.

Table continued from the previous page...

Field	Function
30-27 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4.
26 CPOL	Clock Polarity Selects the inactive state of the SCK. This field is used in both Master and Slave modes. For successful communication between serial devices, the devices must have identical clock polarities. When the continuous selection format is selected, switching between clock polarities without stopping the module can cause errors in the transfer because of the peripheral device interpreting the switch of clock polarity as a valid clock edge. **NOTE** In case of Continuous SCK mode, when the module goes in low-power mode (disabled), the inactive state of SCK is not guaranteed. 0b - The inactive state value of SCK is low. 1b - The inactive state value of SCK is high.
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This field is used in both Master and Slave modes. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the field value is ignored and the transfers are done considering 1 as the value of this field. 0b - Data is captured on the leading edge of SCK and changed on the following edge. 1b - Data is changed on the leading edge of SCK and captured on the following edge.
24 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. 0b - Data is transferred to MSB first. 1b - Data is transferred to LSB first.
23-22 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK delay. See PCS to SCK Delay (t_{CSC}) for details. 00b - PCS to SCK prescaler value is 1. 01b - PCS to SCK prescaler value is 3. 10b - PCS to SCK prescaler value is 5. 11b - PCS to SCK prescaler value is 7.
21-20 PASC	After SCK Delay Prescaler

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the "After SCK Delay". See After SCK Delay (t_{ASC}) for details. 00b - Delay after Transfer Prescaler value is 1. 01b - Delay after Transfer Prescaler value is 3. 10b - Delay after Transfer Prescaler value is 5. 11b - Delay after Transfer Prescaler value is 7.
19-18 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. This field is only used in Master mode. See the DT field description for details on how to compute the "Delay after Transfer". See Delay after Transfer (t_{DT}) for details. 00b - Delay after Transfer Prescaler value is 1. 01b - Delay after Transfer Prescaler value is 3. 10b - Delay after Transfer Prescaler value is 5. 11b - Delay after Transfer Prescaler value is 7.
17-16 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in Master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00b - Baud Rate Prescaler value is 2. 01b - Baud Rate Prescaler value is 3. 10b - Baud Rate Prescaler value is 5. 11b - Baud Rate Prescaler value is 7.
15-12 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$. The following table lists the delay scaler values.

Table 325. Delay scaler encoding

Field value	Delay scaler value
0000	2
0001	4
0010	8

Table continues on the next page...

Table continued from the previous page...

1100	8192
1101	16384
1110	32768
1111	65536

	See PCS to SCK Delay (t_{CSC}) for details.
11-8 ASC	After SCK Delay Scaler Selects the scaler value for the "After SCK Delay". This field is used only in master mode. The "After SCK Delay" is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. See After SCK Delay (t_{ASC}) for details.
7-4 DT	Delay After Transfer Scaler Selects the "Delay after Transfer" scaler. This field is used only in Master mode. The "Delay after Transfer" is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the continuous serial communications clock operation, the DT value is fixed to one SCK clock period. The "Delay after Transfer" is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in the CTAR*n*[CSSCK] field description for scaler values.
3-0	Baud Rate Scaler

Table continues on the next page...

Table continued from the previous page...

Field	Function
BR	Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the baud rate scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: SCK baud rate = (f_P/PBR) x [(1+DBR)/BR] The following table lists the baud rate scaler values.

Table 326. Baud rate scaler

CTARn[BR]	Baud rate scaler value
0000	2

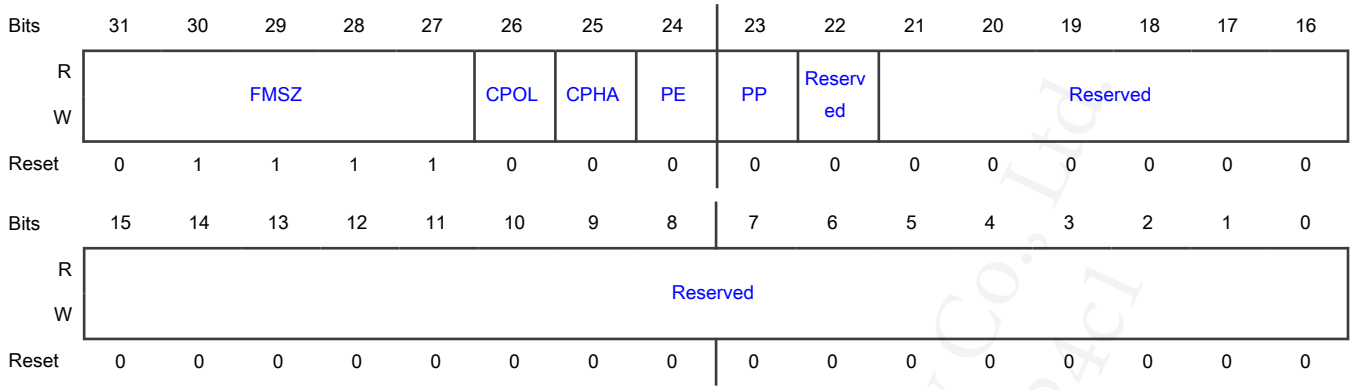
49.4.5 Clock and Transfer Attributes Register (in Slave mode) (CTAR0_SLAVE)

Offset



Register	Offset
CTAR0_SLAVE	Ch

Function

When the module is configured as an SPI bus slave, the CTAR0 register is used.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4625-4821-48a8-b251-390d3ab624c1

Diagram

Fields

Field	Function
31-27 FMSZ	Frame Size The number of bits transferred per frame is equal to the value of this field plus 1. Note that the minimum valid value of frame size is 4.
26 CPOL	Clock Polarity Selects the inactive state of the SCK. **NOTE** In case of Continuous SCK mode, when the module goes in low-power mode (disabled), the inactive state of SCK is not guaranteed. 0b - The inactive state value of SCK is low. 1b - The inactive state value of SCK is high.
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This field is used in both Master and Slave modes. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the field value is ignored and the transfers are done considering 1 as the value for this field. 0b - Data is captured on the leading edge of SCK and changed on the following edge. 1b - Data is changed on the leading edge of SCK and captured on the following edge.
24 PE	Parity Enable Enables parity bit transmission and reception for the frame 0b - No parity bit included/checked 1b - Parity bit is transmitted instead of last data bit in frame; and parity is checked for the received frame
23 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Even parity: the number of 1 bits in the transmitted frame is even. SR[SPEF] is set if the number of 1 bits is odd in the received frame. 1b - Odd parity: the number of 1 bits in the transmitted frame is odd. SR[SPEF] is set if the number of 1 bits is even in the received frame.
22 —	Reserved
21-0 —	Reserved

49.4.6 Status Register (SR)

Offset

Register	Offset
SR	2Ch

Function

This register includes status and flag fields, which reflect the status of the module and indicate the occurrence of events that can generate interrupts or DMA requests. The software can clear the fields of this register by writing a 1, and writing a 0 does not effect the fields. The register may not be writeable in the Module Disable mode because of the use of power-saving mechanisms.

Diagram

Fields

Field	Function
31	Transfer Complete Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCF	Indicates that all bits in a frame are shifted out. This field remains set until it is cleared by writing a 1 to it. 0b - Transfer is incomplete. 1b - Transfer is complete.
30 TXRXS	TX and RX Status Reflects the run status of the module 0b - Transmit and receive operations are disabled when the module is in the Stopped state. 1b - Transmit and receive operations are enabled when the module is in the Running state.
29 —	Reserved
28 EOQF	End of Queue Flag Indicates that the last entry in a queue had been transmitted when the module was in Master mode. This field is set when the TX FIFO entry has the EOQ field set in the command halfword and the end of the transfer is reached. The field remains set until cleared by writing a 1 to it. When this field is set, the TXRXS field is automatically cleared. 0b - EOQ is not set in the executing command. 1b - EOQ is set in the executing SPI command.
27 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for SPI blocks operating in Slave mode and SPI configuration. This field is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The field remains set until cleared by writing a 1 to it. 0b - No TX FIFO underflow occurred. 1b - TX FIFO underflow had occurred.
26 —	Reserved
25 TFFF	Transmit FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either DMA or an interrupt can be used to add another entry to the FIFO. Note that this field is set if at least one location is free in the FIFO. The field can be cleared by writing a 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request, when the TX FIFO is full. If FIFO is filled manually, and not by DMA, see Transmit FIFO fill interrupt or DMA request **NOTE** The reset value of this field is 0 when the module is disabled(MCR[MDIS]=1). 0b - TX FIFO is full.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - TX FIFO is not full.
24 BSYF	Busy Flag Indicates that the current command frame is being used for transmitting multiple data frames. This field is valid only when the value of MCR[XSPI] is 1, and is not set for the last data frame of a cyclic command transfer or when the value of CTARE[DTCP] is 1. See CMD FIFO buffering mechanism for details. 0b - No cyclic command transfer is in progress. 1b - Cyclic command transfer is in progress. Current data frame is not the last data frame for on-going cyclic command transfer.
23 CMDTCF	Command Transfer Complete Flag Indicates that the last data frame for the current cyclic command has been transmitted. Therefore, this field is set only for the last data frame of a cyclic command transfer or when the value of CTARE[DTCP] is 1. The field remains set until it is cleared by writing a 1 to it. 0b - Data transfer by current command is incomplete. 1b - Data transfer by current command is complete.
22 —	Reserved
21 SPEF	SPI Parity Error Flag Indicates that SPI frame with parity error had been received. The field remains set until it is cleared by writing a 1 to it. 0b - No parity error occurred. 1b - Parity error had occurred.
20 —	Reserved
19 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and Shift register are full and a transfer is initiated. The field remains set until it is cleared by writing a 1 to it. 0b - No RX FIFO overflow occurred. 1b - RX FIFO overflow has occurred.
18 TFIWF	Transmit FIFO Invalid Write Flag Indicates data write on TX FIFO when CMD FIFO is empty. Without a command, the data entries present in TX FIFO are invalid. This field remains set until it is cleared by writing a 1 to it. 0b - No invalid data is present in TX FIFO. 1b - Invalid data is present in TX FIFO because CMD FIFO is empty.

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 RFDF	Receive FIFO Drain Flag Indicates whether there is an available location to be drained from the FIFO. Either DMA or an interrupt can be used to read from the FIFO. Note that this field is set if at least one location can be read from the FIFO. The field can be cleared by writing a 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0b - RX FIFO is empty. 1b - RX FIFO is not empty.
16 CMDFFF	Command FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this field is set if at least one location is free in the FIFO. The CMDFFF is cleared by writing a 1 to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0b - CMD FIFO is full. 1b - CMD FIFO is not full.
15-12 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. This field increments every time the PUSHR is written and decrements every time SPI command is executed and the SPI data is transferred to the Shift register.
11-8 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. This field updates every time SPI data is transferred from the TX FIFO to the Shift register. **NOTE** If TX FIFO is cleared by writing 1 to MCR[CLR_TXF], the value of the TXNXTPTR field does not change immediately to 0. Only when the next transfer starts, the field reflects the latest value, TXNXTPTR = 1.
7-4 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. This field decrements every time the POPR is read and increments every time data is transferred from the Shift register to the RX FIFO.
3-0 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. This field is updated when the POPR is read.

49.4.7 DMA/Interrupt Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	30h

Function

This register controls DMA and interrupt requests. You must not write to the register when the module is in the Running state.

Field	Function
31 TCF_RE	Transmission Complete Request Enable Enables SR[TCF] to generate an interrupt request. 0b - TCF interrupt requests are disabled. 1b - TCF interrupt requests are enabled.
30 CMDFFF_RE	Command FIFO Fill Flag Request Enable Enables SR[CMDFFF] to generate a request. The CMDFFF_DIRS field of this register selects between generating an interrupt request or a DMA request. 0b - CMDFFF interrupts or DMA requests are disabled. 1b - CMDFFF interrupts or DMA requests are enabled.
29 —	Always write the reset value to this field.
28 EOQF_RE	Finished Request Enable Enables SR[EOQF] to generate an interrupt request 0b - EOQF interrupt requests are disabled. 1b - EOQF interrupt requests are enabled.
27 TFUF_RE	Transmit FIFO Underflow Request Enable Enables SR[TFUF] to generate an interrupt request. 0b - TFUF interrupt requests are disabled. 1b - TFUF interrupt requests are enabled.
26	Always write the reset value to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25 TFFF_RE	Transmit FIFO Fill Request Enable Enables SR[TFFF] to generate a request. The TFFF_DIRS field of this register selects between generating an interrupt request or a DMA request. 0b - TFFF interrupts or DMA requests are disabled. 1b - TFFF interrupts or DMA requests are enabled.
24 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request. 0b - TFFF flag generates interrupt requests. 1b - TFFF flag generates DMA requests.
23 CMDTCF_RE	Command Transmission Complete Request Enable Enables SR[CMDTCF] to generate an interrupt request 0b - CMDTCF interrupt requests are disabled. 1b - CMDTCF interrupt requests are enabled.
22 —	Always write the reset value to this field.
21 SPEF_RE	SPI Parity Error Request Enable Enables SR[SPEF] to generate an interrupt request 0b - SPEF interrupt requests are disabled. 1b - SPEF interrupt requests are enabled.
20 —	Always write the reset value to this field.
19 RFOF_RE	Receive FIFO Overflow Request Enable Enables SR[RFOF] to generate an interrupt request 0b - RFOF interrupt requests are disabled. 1b - RFOF interrupt requests are enabled.
18 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables SR[TFIWF] to generate an interrupt request 0b - TFIWF interrupt requests are disabled. 1b - TFIWF interrupt requests are enabled.

Table continues on the next page...

Table continued from the previous page...

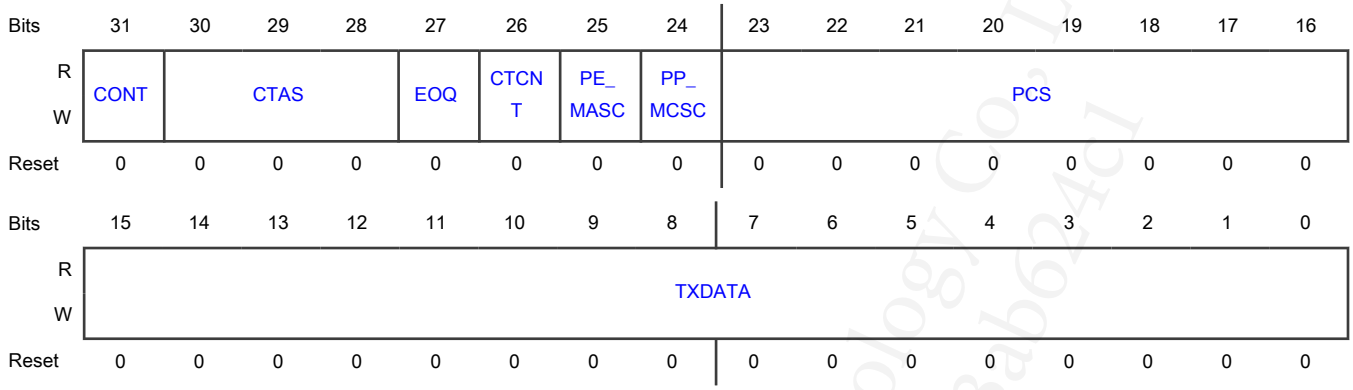
Field	Function
17 RFDF_RE	Receive FIFO Drain Request Enable Enables SR[RFDF] to generate a request. The RFDF_DIRS field of this register selects between generating an interrupt request or a DMA request. 0b - RFDF interrupt or DMA requests are disabled. 1b - RFDF interrupt or DMA requests are enabled.
16 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. If SR[RFDF] is set, and the value of the RFDF_RE field in this register is 1, the RFDF_DIRS field selects between generating an interrupt request or a DMA request. 0b - Interrupt request 1b - DMA request
15 CMDFFF_DIRS	Command FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. If SR[CMDFFF] is set, and the value of the CMDFFF_RE field in this register is 1, the CMDFFF_DIRS field selects between generating an interrupt request or a DMA request. 0b - CMDFFF flag generates interrupt requests. 1b - CMDFFF flag generates DMA requests.
14 —	Always write the reset value to this field.
13-0 —	Reserved

49.4.8 PUSH TX FIFO Register In Master Mode (PUSHR)

Offset

Register	Offset
PUSHR	34h

Function



Specifies data to be transferred to the TX FIFO and CMD FIFO. You must write 16 bits of data into the TXDATA field. An 8- or 16-bit write access to the TXDATA field transfers 16 bits of data bus to the TX FIFO. A write access to the command fields transfers the 16 bits of command information to the CMD FIFO. In Master mode, the register transfers 16 bits of data to the TX FIFO and 16 bits of command information to the CMD FIFO.

If Extended SPI Mode is disabled (MCR[XSPI]), the TX FIFO and CMD FIFO must be filled simultaneously. In other words, you must perform write accesses to both the data and command fields for every PUSHR operation. With Extended SPI Mode disabled and both the TX FIFO and CMD FIFO written to and read from simultaneously, they behave as a single 32-bit FIFO. When Extended SPI mode is enabled (MCR[XSPI]), the TX FIFO and CMD FIFO can be written to independently.

A read access of PUSHR returns the top-most TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Diagram

Fields

Field	Function
31 CONT	Continuous Peripheral Chip Select Enable Selects a continuous selection format. This field is used in SPI Master mode. The field enables the selected PCS signals to remain asserted between transfers. 0b - Return PCSn signals to their inactive state between transfers. 1b - Keep PCSn signals asserted between transfers.
30-28 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in Master mode to specify the transfer attributes for the associated SPI frame. In SPI Slave mode, CTAR0 is used. See the chip-specific section for details to determine how many CTARs this chip has. You should not program a value in this field for a register that is not present. 000b - CTAR0 001b - CTAR1 010b - CTAR2 011b - CTAR3 100b - CTAR4 101b - CTAR5 110b - Reserved 111b - Reserved
27 EOQ	End of Queue The host software uses this field to signal to the module that the current SPI transfer is the last in a queue. At the end of the transfer, SR[EOQF] is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - SPI data is not the last data to transfer. 1b - SPI data is the last data to transfer.
26 CTCNT	Clear Transfer Counter Writes a 0 to TCR[TCNT], and the TCNT field is cleared before the module starts transmitting the current SPI frame. 0b - Do not clear TCR[TCNT] 1b - Clear TCR[TCNT]
25 PE_MASC	Parity Enable or Mask TASC Delay in Current Frame PE – This bit enables parity bit transmission and parity reception check for the SPI frame. MASC - The current frame has the “after SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE** This field is used as Mask T_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0b - PE - No parity bit is included/checked. MASC - T_{ASC} delay is not masked and the current frame has the "After SCK delay". 1b - PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - T_{ASC} delay is masked in the current frame.
24 PP_MCSC	Parity Polarity or Mask TCSC Delay in Next Frame PP: It controls the polarity of the parity bit transmitted and checked. MCSC: The next frame has the “PCS to SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for details. **NOTE** This field is used as Mask T_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0b - PP - Even Parity: the number of 1 bits in the transmitted frame is even. SR[SPEF] is set if the number of 1 bits is odd in the received frame. MCSC - T_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1b - PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. SR[SPEF] is set if the number of 1 bits is even in the received frame. MCSC - T_{ASC} delay is masked in the next frame.
23-16 PCS	PCS Selects which PCS signals are to be asserted for the transfer. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

</table>

49.4.9 PUSH TX FIFO Register In Slave Mode (PUSHR_SLAVE)

Offset

Register	Offset
PUSHR_SLAVE	34h

Function

Specifies the data to be transferred to the TX FIFO in Slave mode. An 8- or 16-bit write access to PUSHR transfers the 16-bit TXDATA field to the TX FIFO.

If the value of MCR[XSPI] is 1, up to 32-bit DSPI frames may be queued for transmission or reception.

Fields

Field	Function
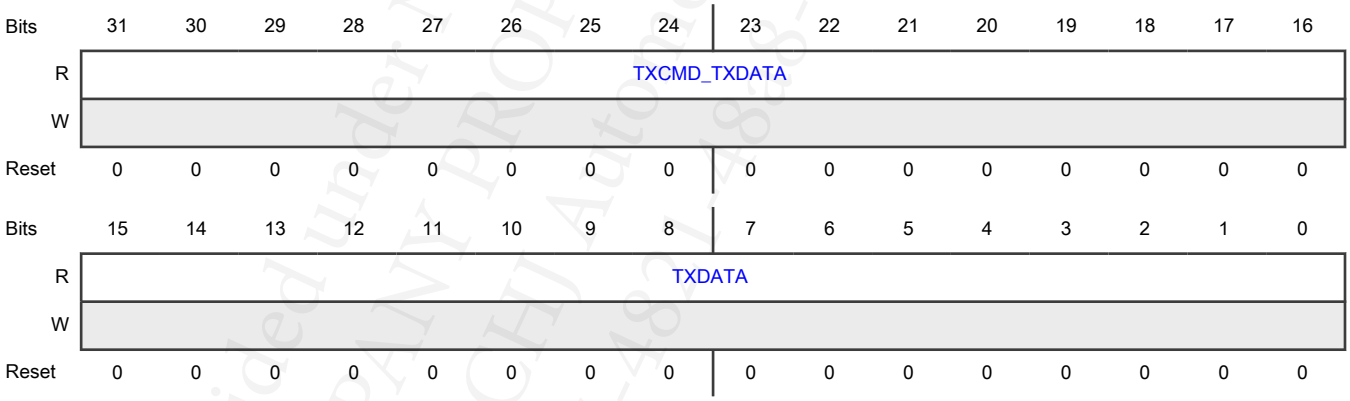
31-0 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the pop next data pointer points

49.4.11 Transmit FIFO Registers (TXFR0 - TXFR4)



Offset

Register	Offset
TXFR0	3Ch
TXFR1	40h
TXFR2	44h
TXFR3	48h
TXFR4	4Ch

Function

These registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers can only be read and not modified. Reading the TXFR*x* registers does not alter the state of the TX FIFO. Also, reading these registers is invalid if the module is operating in the Extended SPI mode.

Diagram

Fields

Field	Function
31-16 TXCMD_TXDATA	Transmit Command or Transmit Data In Master mode, the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, this field is reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 TXDATA	Transmit Data Contains the SPI data to be shifted out.

49.4.12 Receive FIFO Registers (RXFR0 - RXFR4)

Offset

Register	Offset
RXFR0	7Ch
RXFR1	80h
RXFR2	84h
RXFR3	88h
RXFR4	8Ch

Function

These read-only registers provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. Reading the RXFR*x* registers does not alter the state of the RX FIFO. However, the value of MCR[MDIS] must be 0 when RXFR is read.

NOTE

Accessing a RXFR*n* register causes all subsequent SPI register accesses to be incorrect. Therefore, you must only read received data through SPI_POPR.

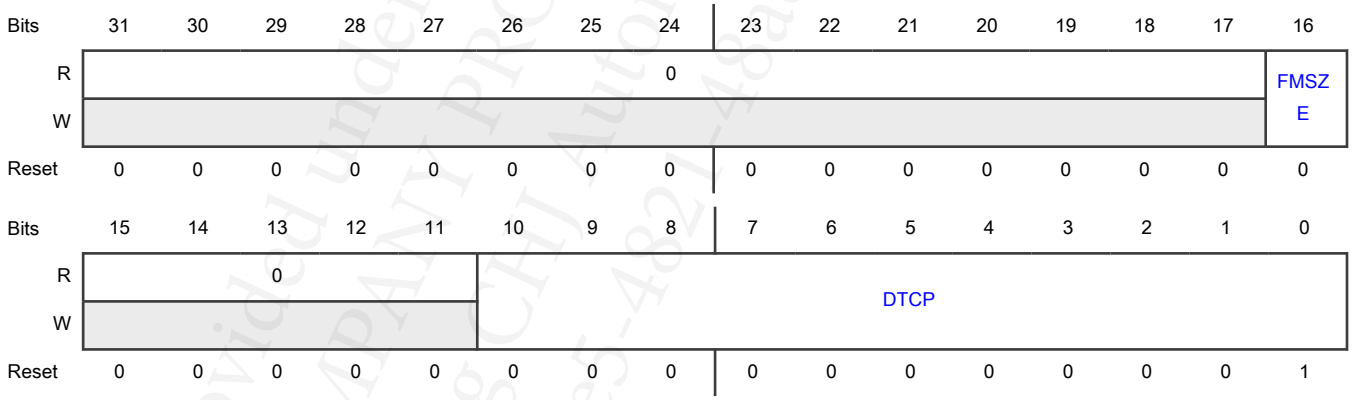
49.4.13 Clock and Transfer Attributes Register Extended (CTARE0 - CTARE5)

Offset



Register	Offset
CTARE0	11Ch
CTARE1	120h
CTARE2	124h
CTARE3	128h
CTARE4	12Ch
CTARE5	130h

Function

CTARE registers are used to define the extended transfer attributes for an SPI frame. These registers are valid only when Extended SPI mode is enabled (MCR[XSPI]).

When the module is configured as a SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.

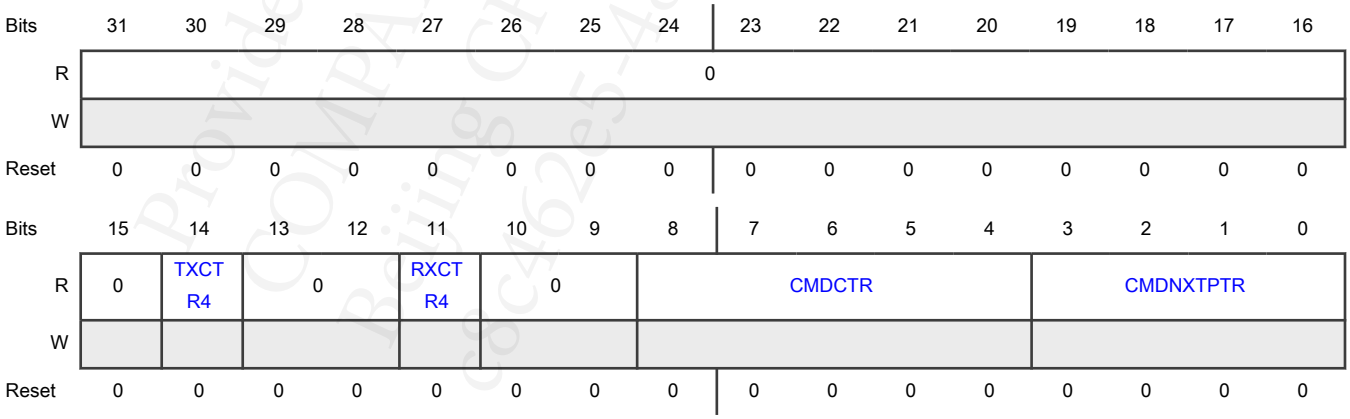
Table continued from the previous page...

Field	Function
—	
16 FMSZE	Frame Size Extended This field is valid only when MCR[XSPI] is set. This field concatenated with CTAR[FMSZ] defines the Frame size of the SPI frames to be transmitted. Effective frame size would be the concatenation of {CTARE[FMSZE], CTAR[FMSZ]} plus 1. 0b - Default Mode. Up to 16 bit SPI frames can be transfered. 1b - Up to 32 bit SPI frames can be transferred. Each Frame transfer will be a result of 2 simultaneous TX FIFO Pop Operation.
15-11 —	Reserved
10-0 DTCP	Data Transfer Count Preload This field is valid only when SPIx_MCR[XSPI] is set. This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame which selected this SPIx_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

49.4.14 Status Register Extended (SREX)



Offset

Register	Offset
SREX	13Ch

Function

The register contains status fields. The fields reflect the status of the module and indicate the occurrence of events. This register is not writeable.

Diagram

Fields

Field	Function
31-15 —	Reserved
14 TXCTR4	TX FIFO Counter[4] This bit is an extension of SR[TXCTR]. The concatenated field {TXCTR4, TXCTR} indicates the number of valid entries in the TX FIFO. This field is incremented every time the PUSHR is written. And this field is decremented every time an SPI command is executed and the SPI data is transferred to the Shift register.
13-12 —	Reserved
11 RXCTR4	RX FIFO Counter[4] This bit is an extension of SR[RXCTR]. The concatenated field {RXCTR4, RXCTR} indicates the number of entries in the RX FIFO. This field is decremented every time the POPR is read. And this field is incremented every time data is transferred from the Shift register to the RX FIFO.
10-9 —	Reserved
8-4 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
3-0 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

49.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module includes the following configuration:

- SPI configuration in which the module operates as a basic SPI or a queued SPI

MCR[DCONF] determines the module configuration. SPI configuration is selected when the value of MCR[DCONF] is 0.

The CTAR*n* registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use, on a frame-by-frame basis, by setting a field in the SPI command. MCR[XSPI] further allows the usage of CTARE*n* registers. This allows you to send multiple data frames using a single command frame.

Typical master-to-slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted to a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was included in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, if the value of SR[TCF] is 1, it indicates a completed frame transfer.

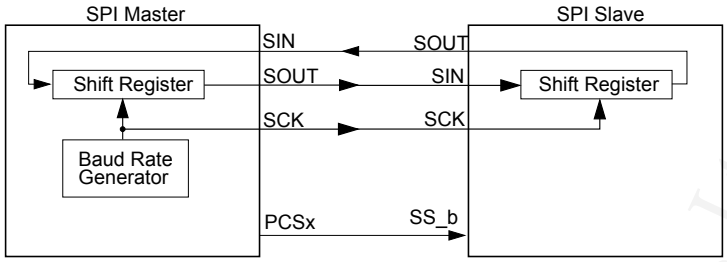


Figure 415. Serial protocol overview

Generally, more than one slave device can be connected to the module master, and 8 PCS signals of the module masters can be used to select which of the slaves to communicate with.

The SPI configuration shares transfer protocol and timing properties that are described independently of the configuration in Transfer formats. The transfer rate and delay settings are described in Module baud rate and clock delay generation.

49.5.1 Starting and stopping module transfers

The module has two operating states: Stopped and Running. Both the states are independent of their configuration. The default state of the module is Stopped. In this state, the module initiates no serial transfers in the Master mode and responds to no transfers in the Slave mode. The Stopped state is also a safe state for writing to the various configuration registers of the module, without causing undetermined results. In the Running state, serial transfers take place.

SR[TXRXS] indicates the state of the module. The value of this field is 1 if the module is in the Running state.

The module starts or transitions to the Running state when all of the following conditions are true:

- The value of SR[EOQF] = 0.
- The chip is not in the Debug mode or the value of MCR[FRZ] = 0.
- The value of MCR[HALT] = 0.

The module stops or transitions from the Running state to the Stopped state after the current frame, when any one of the following conditions exist:

- The value of SR[EOQF] = 1.
- The chip is in Debug mode and the value of MCR[FRZ] = 1.
- The value of MCR[HALT] = 1.

State transitions from running to stopped occur on the next frame boundary if a transfer is in progress, and occur immediately if no transfers are in progress.

49.5.2 SPI configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the value of MCR[DCONF] is 0. The SPI frames can be 32-bit long. The host CPU or a DMA controller transfers the external SPI data to the module RAM queues and to a TX FIFO buffer. The received data is stored in the entries of the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to a memory external to the module. The operation of FIFO buffers is described in the following sections:

- TX FIFO buffering mechanism
- CMD FIFO buffering mechanism
- RX FIFO buffering mechanism

The interrupt and DMA request conditions are described in Interrupts/DMA requests.

The SPI configuration supports two module-specific modes—Master mode and Slave mode. In the Master mode, the module initiates and controls the transfer according to the fields of the executing SPI command. In the Slave mode, the module responds only to transfers initiated by a bus master external to it, and the SPI command field is reserved.

49.5.2.1 Master mode

In the SPI Master mode, the module initiates serial transfers by controlling the SCK and the PCS signals. The executing SPI command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See PUSH TX FIFO Register In Master Mode (PUSHR) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the SOUT pin. In the SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis. In the Extended SPI Master mode, multiple SPI frames can have a single command associated with them allowing efficient SPI frame transfers requiring common transfer attributes. In addition, the Extended SPI mode allows larger frame sizes of up to 32 bits.

49.5.2.2 Slave mode

In the SPI Slave mode, the module responds to transfers that an SPI bus master initiates. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be configured for successful communication with SPI master. The SPI Slave mode transfer attributes are configured in the CTAR0 and CTARE0 registers. The data shifts out with MSB first, and the module does not support shifting out of LSB.

49.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO, or RX FIFO. The module operates as a double-buffered, simplified SPI when the FIFOs are disabled. The transmit and receive sides of the FIFOs are disabled separately. Writing a 1 to MCR[DIS_TXF] disables the TX FIFO and CMD FIFO, and writing a 1 to MCR[DIS_RXF] disables the RX FIFO.

The FIFO disable mechanisms are transparent to you and to the host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO and CMD FIFO are disabled:

- SR[TFFF], SR[TFUF], SR[CMDFFF], SREX[CMDCTR], and SR[TXCTR] behave as if there is a one-entry FIFO.
- The contents of TXFRs, SR[TXNXTPTR], and SREX[CMDNXTPTR] are undefined.

Similarly, when the RX FIFO is disabled, SR[RFDF], SR[RFOF], and SR[RXCTR] behave as if there is a one-entry FIFO, but the contents of the RXFR registers and SR[POPNXTPTR] are undefined.

49.5.2.4 TX FIFO buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. It holds 5 words, each consisting of SPI data. The number of entries in the TX FIFO is chip-specific. SPI data is added to the TX FIFO by writing to the data field of PUSHR. TX FIFO entries can only be removed from the TX FIFO if they are shifted out or by flushing the TX FIFO.

SR[TXCTR] indicates the number of valid entries in the TX FIFO. The field updates every time an 8- or 16-bit write takes place on PUSHR[TXDATA] or SPI data is transferred into the Shift register from the TX FIFO.

SR[TXNXTPTR] indicates the TX FIFO entry that will be transmitted during the next transfer. The TXFR*n* registers are invalid in the Extended SPI mode because the TX FIFO and CMD FIFO can be used independently. The TXNXTPTR field increments every time SPI data is transferred from the TX FIFO to the Shift register. The maximum value of this field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

49.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the value of DR[TFFF] is set to 1, and the value is set to 0 when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. You can also write a 1 to clear the field, which can generate a DMA request or an interrupt request. See Transmit FIFO fill interrupt or DMA request for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition occurs.

49.5.2.4.2 Draining the TX FIFO

The module removes (drains) the TX FIFO entries by shifting SPI data out through the Shift register. It transfers entries from the TX FIFO to the Shift register, and the entries are shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the Shift register, the TX FIFO counter decrements by 1. When the value of MCR[XSPI] is 1, and if the frame size of SPI data to be transmitted is more than 16 bits, then it causes two data entries to be popped from TX FIFO simultaneously. These entries are transferred to the Shift register. The first of the two popped entries forms the 16 least significant bits of the SPI frame to be transmitted. Such an operation also causes the TX FIFO counter to decrement by 2. At the end of a transfer, the value of SR[TCF] is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a 1 to MCR[CLR_TXF].

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the value of SR[TFUF] is configured as 1. See Transmit FIFO underflow interrupt request for details.

49.5.2.5 CMD FIFO buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. When Extended SPI Mode (MCR[XSPI]) is disabled, the TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHR operation.When Extended SPI Mode (MCR[XSPI]) is enabled, the TX FIFO and CMD FIFO can be filled independently.

The CMD FIFO holds 5 words, each representing SPI command fields. The number of entries in the CMD FIFO is chip-specific. SPI command is added to the CMD FIFO by writing to the command field of PUSHR. CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (MCR[XSPI]) is disabled, every CMD FIFO entry has a corresponding single TX FIFO entry attached to it because both these FIFO's are filled simultaneously.

When Extended SPI Mode (MCR[XSPI]) is enabled, every CMD FIFO entry can have multiple TX FIFO entries attached to it. Thus a single CMD FIFO entry can be used to transmit multiple TX FIFO entries. The CTARE[DTCP] field decides the number of SPI Data Frames having frame size as {FMSZE, FMSZ} to be transmitted using the current Command Entry. The CTAR/CTARE registers pointed by the CTAS field in the Command frame gives the FMSZ and FMSZE fields respectively. The time for which a command entry is in use is known as a Command Cycle. The Busy Flag SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the SPI Status Register extended(SREX) indicates the number of valid entries in the CMD FIFO. The CMDCTR field is updated every time a 8- or 16-bit write takes place on the lower half of SPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO can be used independently. The CMDNXTPTR field indicates which CMD FIFO Entry will be used during the next command cycle. The CMDNXTPTR field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register and it rolls over after reaching the maximum.

49.5.2.6 RX FIFO buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The FIFO holds 5 received SPI data frames. The number of entries in the RX FIFO is chip-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the Shift register is transferred into the RX FIFO. SPI data is removed (popped) from the RX FIFO by reading the POPR. RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

SR[RXCTR] indicates the number of valid entries in the RX FIFO. The field is updated every time the POPR is read or SPI data is copied from the Shift register to the RX FIFO.

SR[POPNXTPTR] points to the RX FIFO entry that is returned when the POPR is read. The field contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR = 2 means that the RXFR2 contains the received SPI data that

is returned after the POPR is read. The POPNXTPTR field increments every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

49.5.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the Shift register. While the RX FIFO is not full, SPI frames from the Shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO, the RX FIFO counter is incremented by 1.

If the RX FIFO and Shift register are full and a transfer is initiated, the value of SR[RFOF] equals 1, indicating an overflow condition. Depending on the state of MCR[ROOE], the data from the transfer that generated the overflow is either ignored or shifted to the Shift register. If the value of the ROOE field is 1, the incoming data is shifted in to the Shift register. If the value of ROOE is 0, the incoming data is ignored.

49.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the POPR. A read of the POPR decrements the RX FIFO counter by 1. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the value of SR[RFDF] is 1. The value of the RFDF field turns 0 when the RX FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

49.5.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

Figure 416. Communications clock prescalers and scalers

49.5.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 327. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are provided as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

49.5.3.2 PCS to SCK delay (t_{CSC})

The "PCS to SCK delay" is the duration from assertion of the PCS signal to the first SCK edge. See Figure 418 for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*x* registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 328. PCS to SCK delay computation example

f_{SYS}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

NOTE

The clock frequency mentioned in the preceding table is given as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

49.5.3.3 After SCK delay (t_{ASC})

The "After SCK Delay" is the duration between the last edge of SCK and the negation of PCS. See Figure 418 and Figure 419 for illustrations of this type of delay. The PASC and ASC fields in the CTAR*x* registers select the "After SCK Delay" by the formula in the ASC field description. The following table shows an example of how to compute the "After SCK Delay".

Table 329. After SCK Delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

NOTE

The clock frequency mentioned in the preceding table is given as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

49.5.3.4 Delay after transfer (t_{DT})

The "Delay after Transfer" is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See Figure 418 for an illustration of this type of delay. The PDT and DT fields in the CTAR*x* registers select the "Delay after Transfer" by the formula in the DT field description. The following table shows an example of how to compute the "Delay after Transfer".

Table 330. "Delay after Transfer" computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

When in Non-Continuous Clock mode, the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

49.5.3.5 PCSS enable (PCSS_b)

The PCSS_b signal provides a delay to allow the PCS signals to settle after a transition occurs, thereby avoiding glitches. When the module is in the Master mode and the value of MCR[PCSSE] is 1, PCSS_b provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the PCSS_b signal relative to PCS signals.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CUA Automotive Technology Co., Ltd.
c8622e4a91484a8a9351-90a3ab04c1

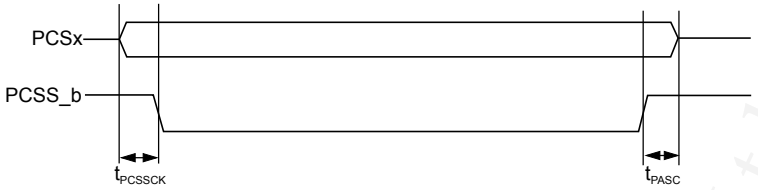

Figure 417. PCSS timing

CTAR[PCSSCK] selects the delay between the assertion of the PCS signals and the assertion of PCSS_b based on the following formula:

$$t_{\mathrm{PCSSCK}} = \frac{1}{f_{\mathrm{P}}} \times \mathrm{PCSSCK}$$

At the end of the transfer, CTAR[PASC] selects the delay between PCSS_b negation and PCS negation based on the following formula:

$$t_{\mathrm{PASC}} = \frac{1}{f_{\mathrm{P}}} \times \mathrm{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 331. PCSS assert computation example

f_P	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 332. PCSS negate computation example

f_P	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The PCSS_b signal is not supported when the Continuous SCK mode is enabled.

NOTE

The clock frequency mentioned in the tables above is an example. See the Clocking chapter for details on the frequency used to drive this module in the chip.

49.5.4 Transfer formats

The SPI serial communication is controlled by the SCK signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, CTAR*n*[CPOL] and CTAR*n*[CPHA] select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even if the bus slave does not control the SCK signal, in Slave mode, the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA = 0
- Classic SPI with CPHA = 1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MCR[MTFE] selects between the classic SPI format and modified transfer format.

In the interface configurations, the module provides the option of having the PCS signals asserted between frames. See Continuous selection format for details.

49.5.4.1 Classic SPI transfer format (CPHA = 0)

The transfer format shown in the following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

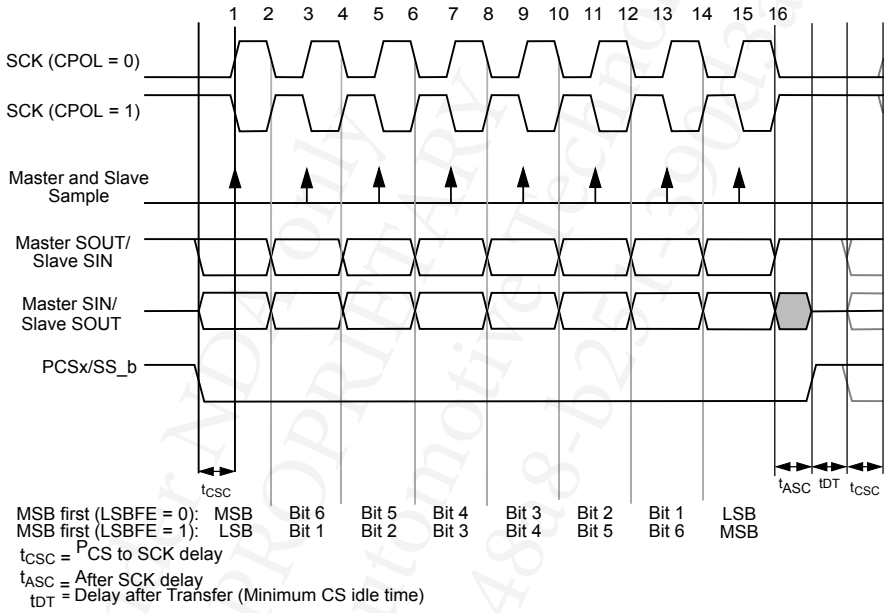

Figure 418. Module transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate PCS signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame, the master and the slave sample their SIN pins on the odd-numbered clock edges and change the data on their SOUT pins for the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

49.5.4.2 Classic SPI transfer format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins for the even-numbered SCK edges.

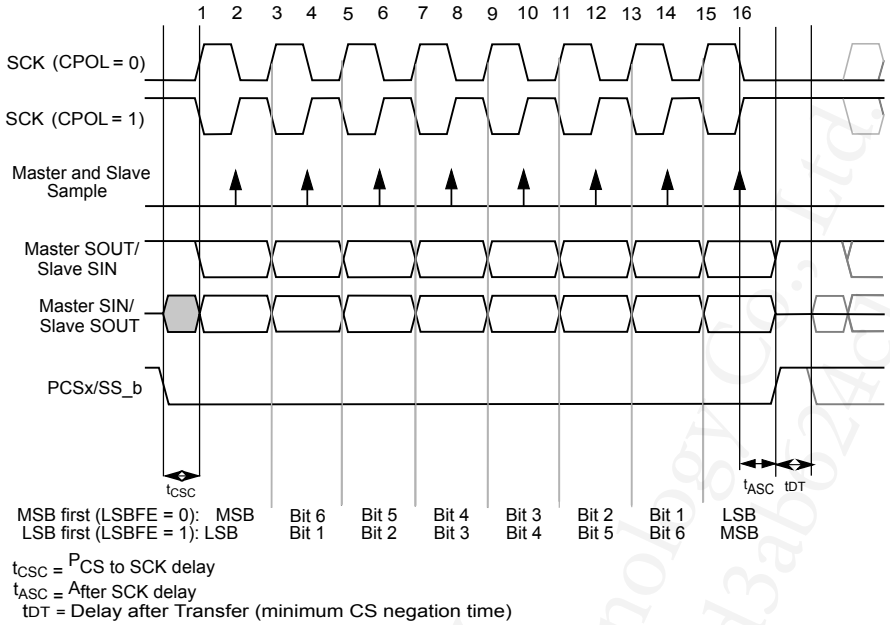

Figure 419. Module transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay elapses, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK, the master and slave sample their SIN pins. For the rest of the frame, the master and the slave change the data for their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before the master can initiate a new frame transfer.

49.5.4.3 Modified SPI transfer format (MTFE = 1, CPHA = 0)

In the modified transfer format, both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay elapses, the first SCK edge is generated. The slave samples the master SOUT signal on every odd-numbered SCK edge. The SPI in the Slave mode, when the value of MTFE is 1, also places new data on the slave SOUT on every odd-numbered clock edge. Regular external slave, configured with CPHA=0 format, drives its SOUT output at every even-numbered SCK clock edge.

The SPI master places its second data bit on the SOUT line, one protocol clock after the odd-numbered SCK edge, if the protocol clock frequency to SCK frequency ratio is higher than 3. If this ratio is below 4, the master changes SOUT at the even-numbered SCK edge. MCR[SMPL_PT] selects the point where the master samples the SIN. The master sample point can be delayed by one or two protocol clock cycles. The value of SMPL_PT must be 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The timing delays are as follows:

- T_{csc} - PCS to SCK assertion delay
- T_{acs} - After SCK PCS negation delay
- T_{su_ms} - master SIN setup time
- T_{hd_ms} - master SIN hold time
- T_{vd_sl} - slave data output valid time, time between slave data output SCK driving edge and when data becomes valid

- T_{su_sl} - data setup time on slave data input
- T_{hd_sl} - data hold time on slave data input
- T_{sys} - protocol clock period

The following timing diagrams illustrate the SPI operation with MCR[MTFE] = 1 and show the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges, and here are the two possible slave behaviors:

- Signal, marked "SOUT of Ext Slave" presents regular SPI slave serial output.
- Signal, marked "SOUT of SPI Slave" presents SPI in the slave mode with MTFE = 1.

Other MTFE = 1, diagrams show SPI SIN input as being driven by a regular external SPI slave, configured according to SPI master CPHA programming.

NOTE

In the following diagrams, f_{sys} represents the protocol clock frequency from which the baud frequency f_{sck} is derived.

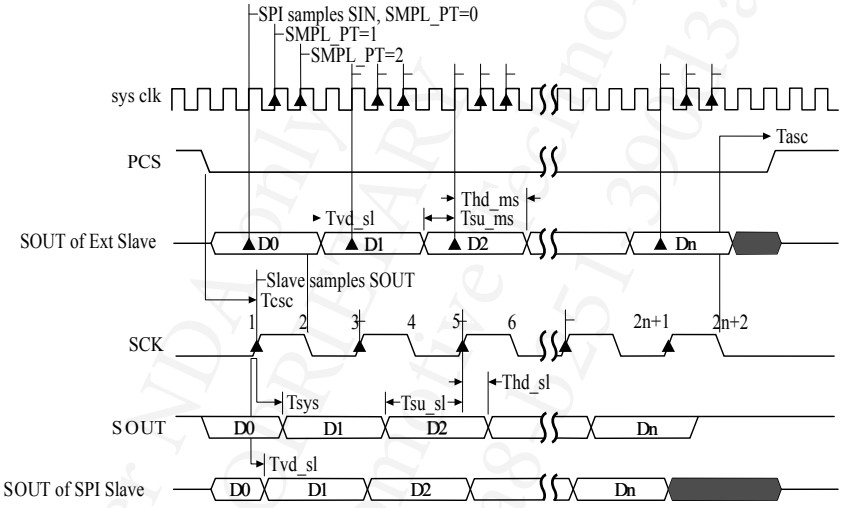

Figure 420. SPI modified transfer format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/4$)

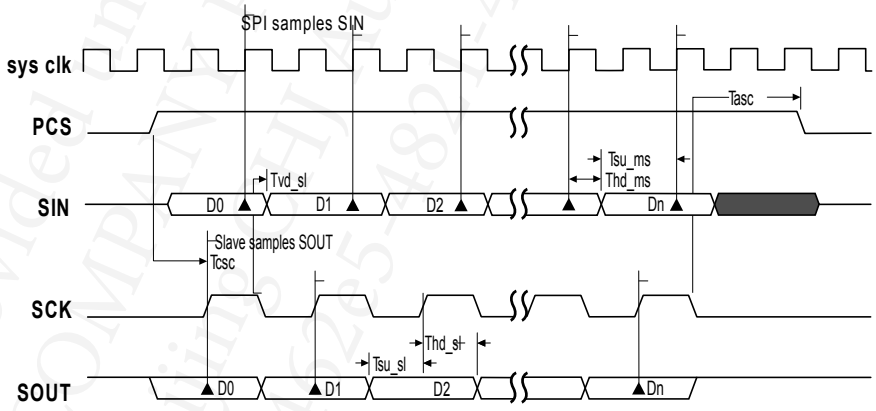

Figure 421. SPI modified transfer format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/2$)

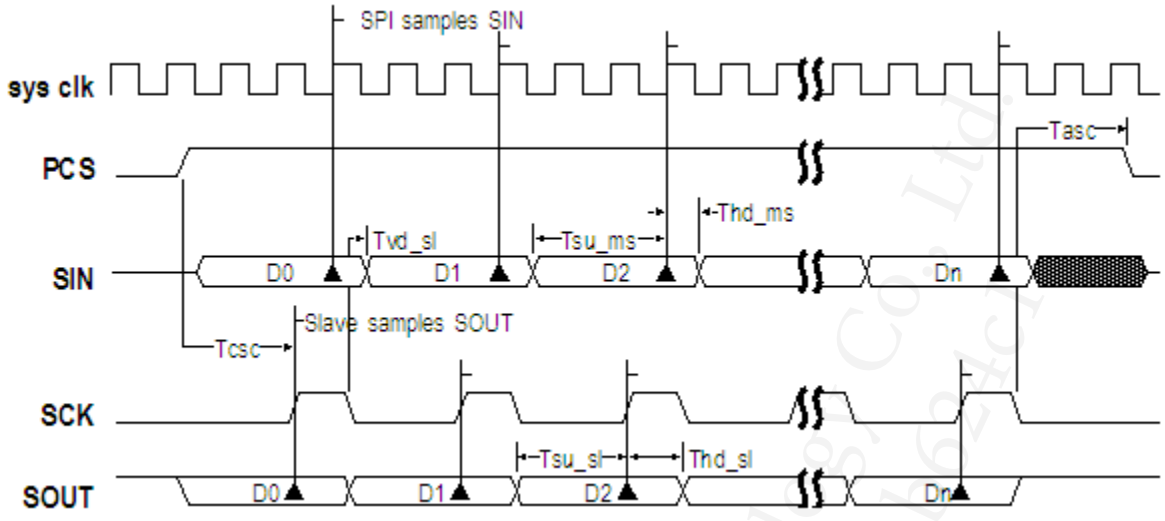

Figure 422. SPI modified transfer format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/3$)

49.5.4.4 Modified SPI transfer format (MTFE = 1, CPHA = 1)

The following figures show the modified transfer ormat for CPHA = 1. Only the condition where CPOL = 0 is shown. At the start of a transfer, the SPI asserts the PCS signal to the slave device. After the PCS to SCK delay elapses, the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even-numbered edges of SCK. The master samples the slave SOUT signal on the odd-numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit on half SCK cycle after the last edge of SCK. No clock edge is visible on the master SCK pin during the sampling of the last bit. The SCK to PCS delay and the after SCK delay must be greater or equal to half of the SCK period.

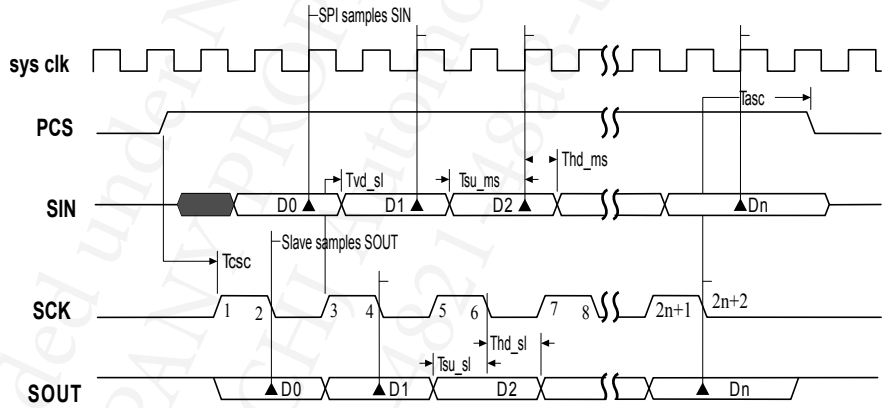

Figure 423. SPI modified transfer format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/2$)

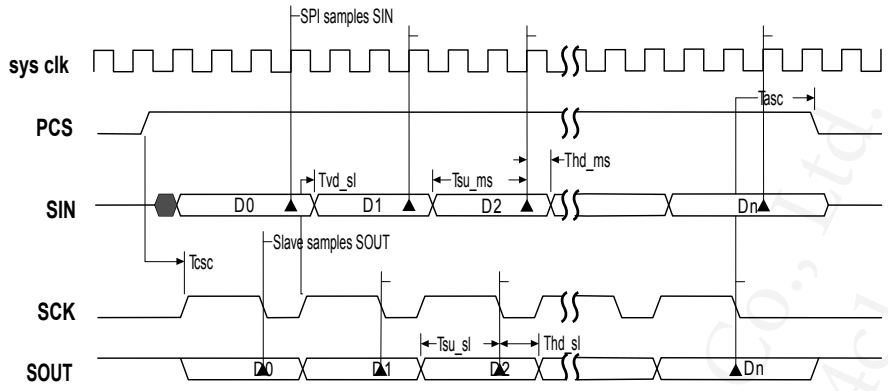

Figure 424. SPI modified transfer format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/3$)

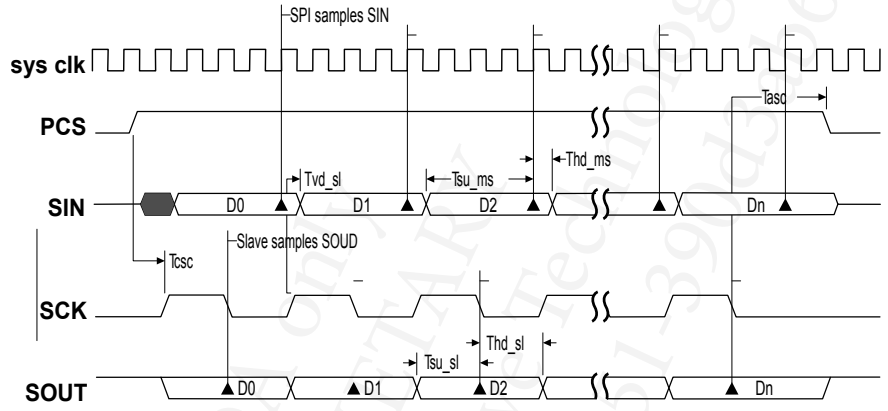

Figure 425. SPI modified transfer format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/4$)

49.5.4.5 Continuous selection format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The continuous selection format provides the flexibility to handle the following case. The format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

When the value of CONT is 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of these signals are selected by the PCSIS*n* fields in the MCR. The following figure shows the timing diagram for two 4-bit transfers with CPHA = 1 and CONT = 1.

Beijing CHJ Information Technology Co., Ltd.
c8c462e5-4821-4c8-b251-39015b6241

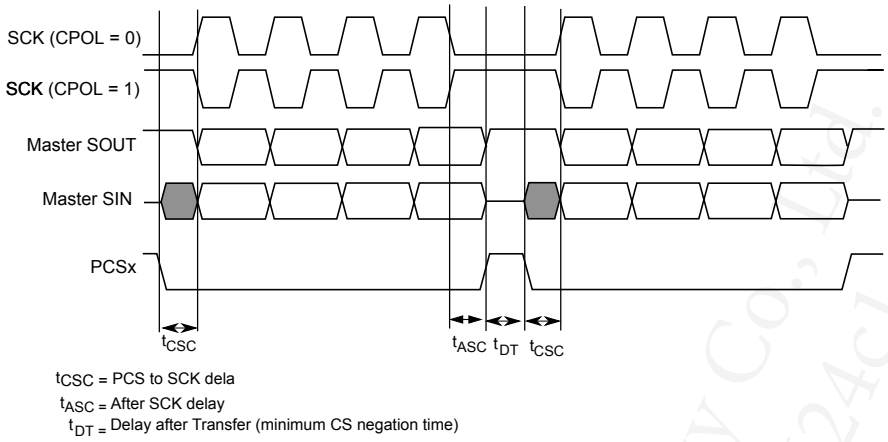

Figure 426. Example of non-continuous format (CPHA=1, CONT=0)

When CONT = 1, the PCS signal remains asserted for the duration of the two transfers. The "Delay between Transfers" (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two 4-bit transfers with CPHA = 1 and CONT = 1.

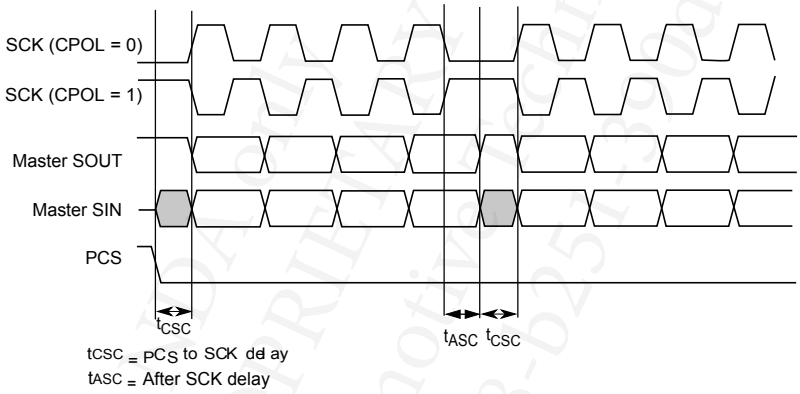

Figure 427. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection, follow these rules:

- All transmit commands must have the same PCS*n* field programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only the FMSZ field can be programmed differently in these CTARs.
- When transmitting multiple frames in this mode, the software must ensure that the last frame has USHR[CONT] deasserted in Master mode and the software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This ensures that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer causes the PCSn signals to remain asserted and hence the slave device cannot transition from Running to Stopped state.

NOTE

You must fill the TX FIFO with the number of entries that are concatenated together under one PCS assertion for both master and slave before the TX FIFO is empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

49.5.4.6 Fast continuous selection format

The fast continuous selection format has a functioning similar to the continuous selection format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

NOTE

The fast continuous selection format is available in the SPI configuration only when the Continuous SCK mode is disabled. Masking of delays is not allowed if the transfer is non-continuous.

The fast continuous selection format is enabled by writing a 1 to MCR[FCPCS]. When this field is asserted, the MASC and MCSC fields of the PUSHR perform the function of mask bits for the transmit frame. These fields individually mask the t_{ASC} and t_{CSC} delays as programmed by the software. A normal continuous selection format includes these two delays for each frame, which is transmitted with the CONT field asserted. To avoid these delays and to speed up the transfer process, the software can mask these delays while programming the command in the PUSHR.

While masking the delays, the software must follow these masking rules, otherwise, correct operation is not guaranteed.

- The MASC field masks the “After SCK” delay for the current frame.
- The MCSC field masks the “PCS to SCK” delay for the next frame.
- The t_{ASC} delay must not be masked when the current frame is the last frame in the continuous selection format.
- The "PCS to SCK" delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If it is masked, then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate (baud rate is 1 SCK cycle duration) configured by the software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the software must ensure that the t_{ASC} time is greater than the baud rate.
- The software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the continuous selection format are applicable here too.

The following figure shows the timing for a fast continuous selection format transfer. Here, seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

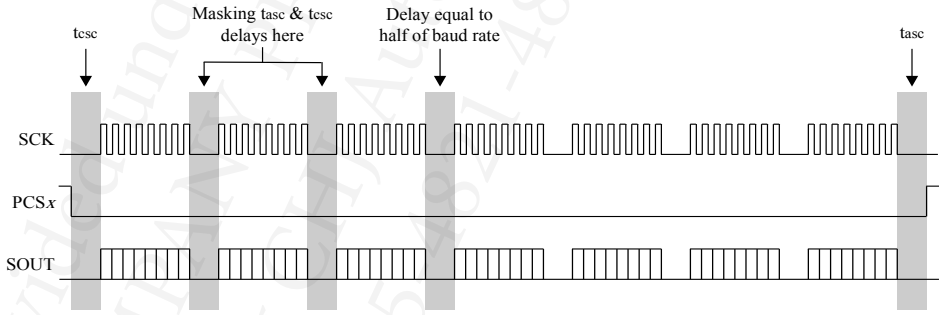

Figure 428. Example of fast continuous selection format

In case any chip select is to be changed, first the fast continuous selection format should be terminated and appropriate delays must be introduced.

49.5.5 Continuous SCK

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by writing a 1 to MCR[CONT_SCKE]. Enabling this field generates the Continuous SCK only if MCR[HALT] is low. Continuous SCK is valid for all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the value of the CONT_SCKE field is 1. Continuous SCK is supported for Modified Transfer Format

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using continuous SCK. Switching clock polarity between frames while using continuous SCK can cause errors in the transfer. The Continuous SCK operation is not guaranteed if the module is put into the Module Disable mode.

Enabling continuous SCK disables the PCS to SCK delay, and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. The following figure is the timing diagram for the Continuous SCK format with continuous selection disabled.

NOTE

In the Continuous SCK mode, for the SPI transfer, CTAR0 should always be used and the TX FIFO must be cleared through MCR[CLR_TXF] before initiating a transfer.

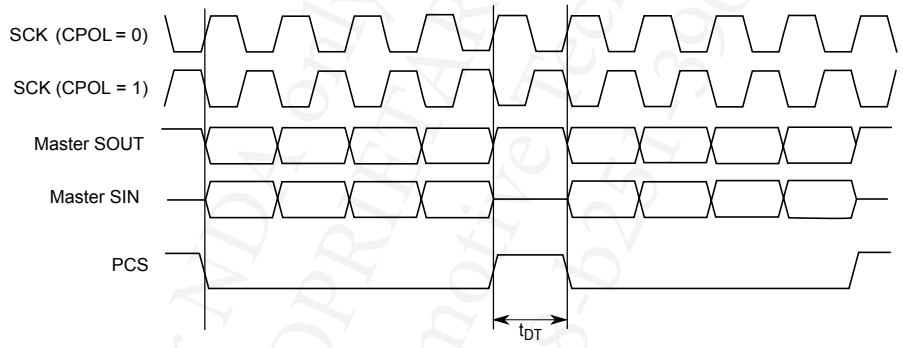

Figure 429. Continuous SCK timing diagram (CONT = 0)

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, which means when SOUT is pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO
- Continuous SCK with CONT bit set and entering the Stopped state (see Starting and stopping module transfers)
- Continuous SCK with CONT bit set and entering the Module Disable mode

The following figure shows the timing diagram for the Continuous SCK format with continuous selection enabled.

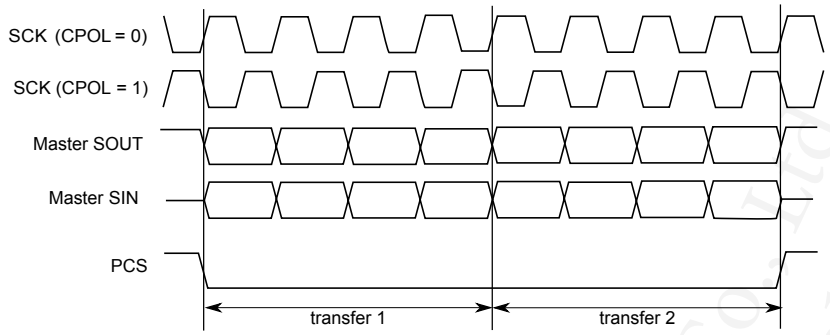

Figure 430. Continuous SCK timing diagram (CONT = 1)

49.5.6 Slave mode operation constraints

The slave mode logic shift register is buffered. This allows the data streaming operation when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at the second SCK clock edge of each frame to the Shift register if the SS_b signal is asserted, and at and any time when transmit data is ready and the SS_b signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR.

If the SS_b signal negates before that last SCK edge, the data from the Shift register is lost.

49.5.7 Parity generation and check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation and control are done on a frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit or receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity errors in the received frame set parity error flags in the Status register. The parity error interrupt requests are generated, if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

49.5.7.1 Parity for SPI frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. The PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate or check parity for the whole frame
- Generate or check parity for each sub-frame separately

To generate or check parity for the whole frame, set PE bit only in the last command or TX FIFO entry, forming this frame with the PUSHR.

To generate or check parity for each sub-frame, set PE bit in each command or TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, SR[SPEF] is set. If the value of MCR[PES] is 1, the module stops SPI frames transmission. To resume SPI operation, clear SR[SPEF] or MCR[PES].

In Slave mode, the parity is controlled by CTAR0[PE] and CTAR0[PP], as in the case of master mode parity generation without continuous PCS selection.

49.5.8 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 333. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	-
Transfer Complete	TCF	Yes	-
CMD Transfer Complete	CMDTCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-

Each condition has a corresponding field in the SR and a Request Enable field in the RSER. Certain fields, as shown in the above table, generate interrupt requests or DMA requests depending on the configuration of this register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

49.5.8.1 EOQ interrupt request

The EOQ interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when the value of RSER[EOQF_RE] is 1 and the value of the EOQ field in the executing SPI command is 1.

If the value of MCR[XSPI] is 1 and the value of the EOQ field in the executing SPI command is 1, the module generates the EOQ interrupt request after the last bit of the last data frame in the command cycle is transmitted.

When the value of MCR[XSPI] is 0, the module generates the interrupt request after the last bit of the SPI frame, with the value of EOQ as 1, is transmitted.

49.5.8.2 Transmit FIFO fill interrupt or DMA request

The transmit FIFO fill request indicates that the TX FIFO is not full. This request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the value of RSER[TFFF_RE] is 1.

RSER[TFFF_DIRS] selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF clears automatically when DMA is used to fill TX FIFO. You must configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until the value of TFFF is 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, the flag does not clear.

49.5.8.3 CMD FIFO fill interrupt or DMA request

The CMD FIFO fill request indicates that the CMD FIFO is not full. This request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the value of RSER[CMDFFF_RE] is 1. RSER[CMDFFF_DIRS] selects whether a DMA request or an interrupt request is generated.

The request is useful when the value of MCR[XSPI] is 1 because TX FIFO and CMD FIFO can be filled independently. If the value of MCR[XSPI] is 0, the TX FIFO fill interrupt or DMA request suffices to fill both the FIFOs, which must be filled simultaneously.

NOTE

The CMDFFF flag clears automatically when DMA is used to fill CMD FIFO.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

1. Wait until the value of CMDFFF is 1.
2. Write data to PUSHR using CPU.
3. Clear CMDFFF by writing a 1 to its location. If CMD FIFO is not full, this flag does not clear.

49.5.8.4 Transmit FIFO invalid write interrupt request

The transmit FIFO invalid write request is valid only when the value of MCR[XSPI] is 1. This request indicates that data exists in the TX FIFO while the CMD FIFO is empty. Because no command fields are associated with the data present in TX FIFO, this data is considered invalid until a command entry is available. The transmit FIFO invalid write request is generated for this condition when the value of RSER[TFIWF_RE] is 1.

49.5.8.5 Transfer complete interrupt request

The transfer complete request indicates the end of the transfer of a serial frame. This request is generated at the end of each frame transfer when the value of RSER[TCF_RE] is 1.

49.5.8.6 Command transfer complete interrupt request

The command transfer complete request indicates the end of transfer of the last SPI frame in a command cycle. This request is generated when the value of RSER[CMDTCF_RE] is 1.

49.5.8.7 Transmit FIFO underflow interrupt request

The transmit FIFO underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in the Slave mode and according to the SPI configuration. The value of SR[TFUF] is 1 when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the value of SR[TFUF] is 1 while the value of RSER[TFUF_RE] is 1, an interrupt request is generated.

49.5.8.8 Receive FIFO drain interrupt or DMA request

The receive FIFO drain request indicates that the RX FIFO is not empty. This request is generated when the number of entries in the RX FIFO is not 0, and the value of RSER[RFDF_RE] is 1.

RSER[RFDF_DIRS] selects whether a DMA request or an interrupt request is generated. You must configure the DMA to drain only one FIFO location per transfer.

49.5.8.9 Receive FIFO overflow interrupt request

The receive FIFO overflow request indicates that an overflow condition in the RX FIFO has occurred. This request is generated when RX FIFO and the Shift register are full, and a transfer is initiated. The value of RSER[RFOF_RE] must be equal to 1 for the interrupt request to be generated.

Depending on the state of MCR[ROOE], the data from the transfer that generated the overflow is either ignored or shifted to the Shift register. If the value of the ROOE field is 1, the incoming data is shifted in to the Shift register. If the value of the ROOE field is 0, the incoming data is ignored.

49.5.8.10 SPI frame parity error interrupt request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

49.5.9 Power saving features

This module supports the following power-saving strategies:

- Module Disable mode: clock gating of non-memory mapped logic

All power-saving features require a logic external to SPI.

49.5.9.1 Module Disable mode

This is a block-specific mode that the module can enter to save power. The host CPU can initiate the Module Disable mode by writing a 1 to MCR[MDIS]. The hardware can also initiate this mode.

When the value of the MDIS field is 1, the module negates the Clock Enable signal at the next frame boundary. After the Clock Enable signal is negated, it is said to have entered the Module Disable Mode. This also puts the module in the Stopped state. The value of SR[TXRXS] must be 0 to indicate the Stopped state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the POPR does not change the state of the RX FIFO. Similarly, writing to the PUSHR does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Also, changes to MCR[DIS_TXF] and MCR[DIS_RXF] have no effect in the Module Disable mode. In this mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Also, writing to the TCR during the Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared in the Module Disable mode.

49.6 Initialization/application information

This section describes how to initialize the module.

49.6.1 How to manage queues

Queues are not a part of this module, but the module includes features to support queue management.

Queues are primarily supported in SPI configuration, and here are the steps to manage them.

1. When the module executes the last command word from a queue, the EOQ bit in the command word indicates that it is the last entry in the queue.
2. At the end of the transfer, the value of SR[EOQF] is configured as 1.
3. If the value of SR[EOQF] is 1, the field disables serial transmission and reception of data, putting the module in the Stopped state. The value 0 is written to SR[TXRXS] indicating the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.

5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO, CMD FIFO, and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA controller.
6. Ensure that all the received data in RX FIFO has been transferred to the memory receive queue by reading SR[RXCNT] or by checking SR[RFDF] after each read operation of the POPR.
7. Modify the DMA descriptor of TX and RX channels for new queues.
8. Flush TX FIFO and CMD FIFO by writing a 1 to MCR[CLR_TXF] and flushing RX FIFO by writing a 1 to MCR[CLR_RXF].
9. Clear the transfer count either by setting the CTCNT bit in the command word of the first entry in the new queue or via the CPU writing directly to TCR[SPI_TCNT].
10. Enable the DMA channel through the DMA enable request. DMA channels are assigned to modules TX FIFO, CMD FIFO, and RX FIFO. For each module, a separate DMA enable request bit is available.
11. Enable serial transmission and serial reception of data by clearing the EOQF field.

49.6.2 Switching Master and Slave modes

When changing modes in the module, follow these steps to guarantee a proper operation.

1. Halt it by writing a 1 to MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to MCR[CLR_TXF] and MCR[CLR_RXF].
3. Set the appropriate mode in MCR[MSTR] and enable it by writing a 0 to MCR[HALT].

49.6.3 Initializing module in Master/Slave modes

After the appropriate mode in MCR[MSTR] is configured, the module is enabled by writing a 0 to MCR[HALT]. The module's slave must be enabled before you enable its master. This ensures that the slave is ready to be communicated with, before the master initializes communication.

49.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler, PBR, and the baud rate scaler, BR, in the CTARs. The values calculated assume a 100 MHz protocol frequency, and the value of the DBR field is 0..

NOTE

The clock frequency provided in this chapter is an example. See the Clocking chapter for details on the frequency used to drive this module in the chip.

Table 334. Baud rate values (bit/s)

		Baud rate divider prescaler values			
		2	3	5	7
Baud rate scaler values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k

Table continues on the next page...

Table 334. Baud rate values (bit/s) (continued)

		Baud rate divider prescaler values			
		2	3	5	7
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k

	32768	1.53k	1.02k	610	436

49.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned in this section is only an example. See the clocking chapter for the frequency used to drive this module in the chip.

Table 335. Delay values

		Delay scaler values (CTAR[PDT])			
		1	3	5	7
Delay scaler values (CTAR[DT])	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns

49.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO, the first-in pointer is Transmit Next Pointer (TXNXTPTR), and for the CMD FIFO, the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO, the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO counter. The TX FIFO is chosen for illustration, but the concepts carry over. See TX FIFO buffering mechanism, CMD FIFO buffering mechanism, and RX FIFO buffering mechanism for details on the FIFO operation.

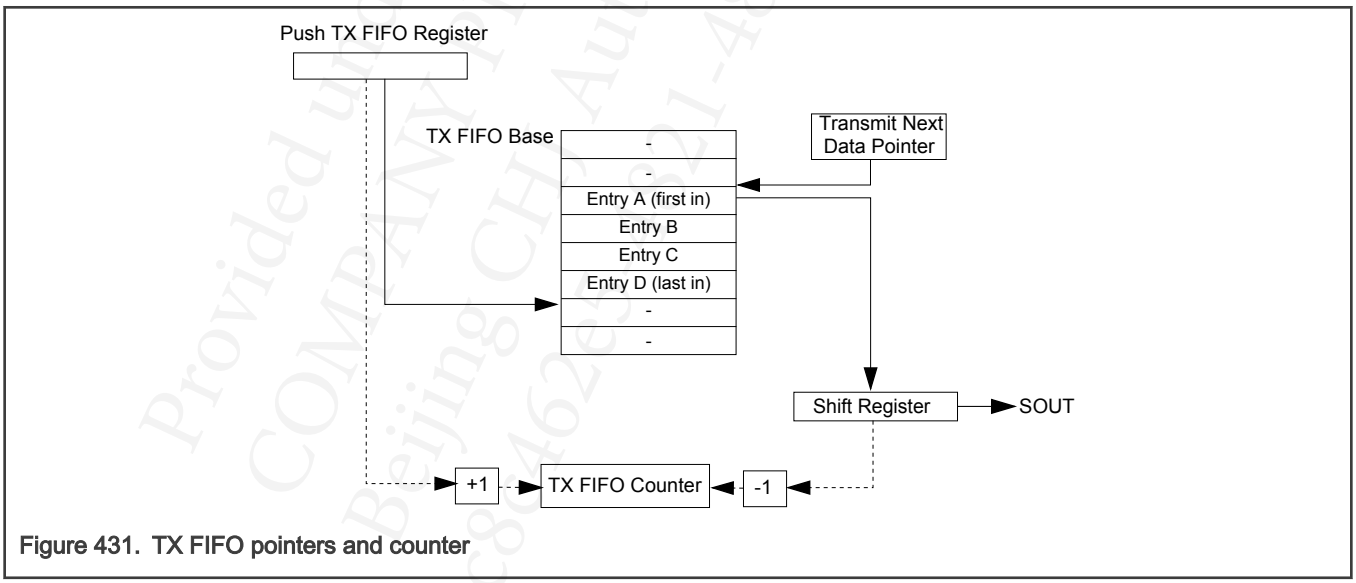

Figure 431. TX FIFO pointers and counter

49.6.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

Use the following equation to compute the memory address of the first-in entry in the TX FIFO:

- First-in EntryAddress = TXFIFOBase+[4xTXNXTPTR]

Use the following equation to compute the memory address of the last-in entry in the TX FIFO:

- Last-in EntryAddress = TXFIFOBase+4x[TXCTR+TXNXTPTR - 1]mod[TXFIFOdepth]

Here is an explanation of the different components of these equations:

- TX FIFO base: Base address of TX FIFO
- TXCTR: TX FIFO Counter
- TXNXTPTR: Transmit Next Pointer
- TX FIFO Depth: Transmit FIFO depth, implementation specific

49.6.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

Use the following equation to compute the memory address of the first-in entry in the CMD FIFO:

- First-in EntryAddress = CMDFIFOBase+[4xCMDNXTPTR]

Use the following equation to compute the memory address of the last-in entry in the CMD FIFO:

- Last-in EntryAddress = CMDFIFOBase+4x[CMDCTR+CMDNXTPTR - 1]mod[CMDFIFOdepth]

Here is an explanation of the different components of these equations:

- CMD FIFO Base: Base address of CMD FIFO
- CMDCTR: CMD FIFO Counter
- CMDNXTPTR: Command Next Pointer
- CMD FIFO Depth: Command FIFO depth, implementation specific

49.6.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

Use the following equation to compute the memory address of the first-in entry in the RX FIFO:

- First-in EntryAddress = RXFIFOBase+[4xPOPNXTPTR]

Use the following equation to compute the memory address of the last-in entry in the RX FIFO:

- Last-in EntryAddress = RXFIFOBase+4x[RXCTR+POPNXTPTR - 1]mod[RXFIFOdepth]

Here is an explanation of the different components of these equations:

- RX FIFO Base: Base address of RX FIFO
- RXCTR: TX FIFO Counter
- POPNXTPTR: Pop Next Pointer
- RX FIFO Depth: Receive FIFO depth, implementation specific

Chapter 50
CAN (FlexCAN)

50.1 Chip-specific FlexCAN information

50.1.1 Overview

This device contains four FlexCAN modules (FlexCAN_0 to FlexCAN_3) that implement the CAN 2.0B and the Flexible Data Rate (FD) CAN protocol specification.

- MCR[MDIS] field is set to 1 by default, each FlexCAN module must be enabled through the software after start-up.
- Doze mode is not supported.

50.1.2 Message buffers and data rate

Each FlexCAN instance support 128 message buffers and upto 8 Mbps programmable bit rate, subject to presence of Flexible Data Rate (FD) feature. All FlexCAN modules support individual receive buffer masks and ECC on the SRAM arrays.

The expanded message buffer memory feature allows the use of 28 additional message buffers of 64-byte payload in CAN FD mode.

50.1.3 Rx FIFO

The enhanced Rx FIFO feature extends the RxFIFO depth and support CAN FD messages.

The module interrupt requests for the Enhanced Rx FIFO feature, enabled with the Enhanced Rx FIFO Interrupt Enable Register (ERFIER), are not mapped to system-level interrupts. If an application enables these module interrupts, software can poll the fields of the Enhanced Rx FIFO Status Register (ERFSR) to determine when the module interrupt requests occur.

50.1.4 Mode configuration

FlexCAN registers always operate in supervisor mode regardless of whether REG_PROT or the system is in user mode.

50.1.5 Booting with FlexCAN

FlexCAN_0 interfaces support booting from boot ROM.

50.1.6 High-resolution timestamp

The FlexCAN instances on this chip use the Timestamp module as the timebase source for the high-resolution timestamp.

You can enable use of the high-resolution timestamp on a per-module basis via the following fields in each FlexCAN instance:

- CTRL2[MBTSBASE] (set to 01b or 10b)
- CTRL2[TSTAMPCAP] (set to 01b, 10b, or 11b)

Using the high-resolution timestamp timebase requires the Timestamp module to be properly configured and running.

NOTE

Changing the timebase source in the Timestamp module requires disabling all module instances using the Timestamp module timebase. To disable a FlexCAN instance, put the instance in Freeze mode.

50.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in Figure 432, which describes the main subblocks implemented in the FlexCAN module, including:

- One associated memory for storing message buffers
- Receive Global Mask registers
- Receive Individual Mask registers
- Receive FIFO filters
- Receive FIFO ID filters

The functions of the submodules are described in subsequent sections.

NOTE

Legacy Rx FIFO cannot be used in FD mode.

NOTE

In CAN FD mode, the Enhanced Rx FIFO feature should be used instead of Legacy Rx FIFO.

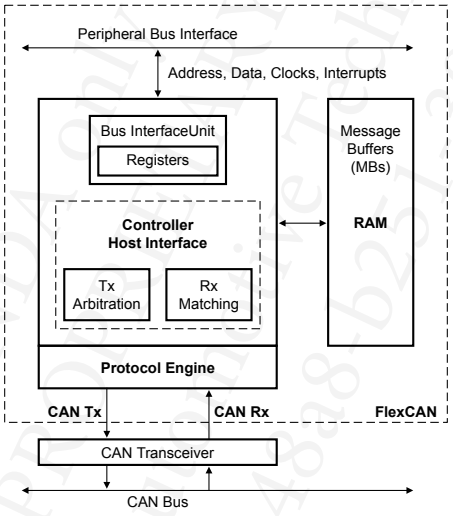

Figure 432. FlexCAN block diagram

50.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol, and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads up to 64 bytes, transferred at faster rates (up to 8 Mb/s—Note that this baud rate can be reached only in the Rx and Tx digital pins, and also depends on the physical layer of the application). The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) submodule manages message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

50.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32, or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured legacy Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Full-featured enhanced Rx FIFO with storage capacity for up to 32 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 128 message buffers of 8 bytes data length each, configurable as Rx or Tx
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 32-bit free running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power mode
- Transceiver delay compensation feature when transmitting CAN FD messages at faster data rates

- Remote request frames may be managed automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to indicate that the module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful legacy Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- Powerful Enhanced Rx FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask + filter, range, and two filters without mask.
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses

  Each byte of FlexCAN memory is associated to 5 parity bits, and the error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors).

50.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode:

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are managed normally, and all CAN Protocol functions are enabled.

- Freeze mode:

  Freeze mode is enabled when MCR[FRZ] is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when CTRL1[LPB] is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

  The module enters this mode when CTRL1[LOM] is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Protocol and CAN 2.0 Protocol 2.0 in an interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

Table 336. Differences between CAN classical and CAN FD

Feature	CAN classical	CAN FD
Legacy Rx FIFO DMA	Yes	No
Legacy Rx FIFO	Yes	No
Enhanced Rx FIFO DMA	Yes	Yes
Enhanced Rx FIFO	Yes	Yes

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when MCR[MDIS] is asserted by the CPU and MCR[LPM_ACK] is asserted by FlexCAN. When disabled, the module issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating MCR[MDIS]. See Module Disable mode for more information.

50.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 337. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN receive pin	Input
CAN Tx	CAN transmit pin	Output

50.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

50.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

50.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

50.4.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and the corresponding mnemonic .

NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

Table 338. Register reset information

Register	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	Yes	Yes
Control 1 register (CTRL1)	Yes	No
Free Running Timer register (TIMER)	Yes	Yes
Rx Mailboxes Global Mask register (RXMGMASK)	No	No
Rx Buffer 14 Mask register (RX14MASK)	No	No
Rx Buffer 15 Mask register (RX15MASK)	No	No
Error Counter Register (ECR)	Yes	Yes
Error and Status 1 Register (ESR1)	Yes	Yes
Interrupt Masks 2 register (IMASK2)	Yes	Yes
Interrupt Masks 1 register (IMASK1)	Yes	Yes
Interrupt Flags 2 register (IFLAG2)	Yes	Yes
Interrupt Flags 1 register (IFLAG1)	Yes	Yes
Control 2 Register (CTRL2)	Yes	No
Error and Status 2 Register (ESR2)	Yes	Yes
CRC Register (CRCR)	Yes	Yes
Rx FIFO Global Mask register (RXFGMASK)	No	No
Rx FIFO Information Register (RXFIR)	No	No
CAN Bit Timing Register (CBT)	Yes	No
Interrupt Masks 4 register (IMASK4)	Yes	Yes
Interrupt Masks 3 register (IMASK3)	Yes	Yes
Interrupt Flags 4 register (IFLAG4)	Yes	Yes
Interrupt Flags 3 register (IFLAG3)	Yes	Yes
Message buffers	No	No
Rx Individual Mask Registers	No	No
Memory Error Control register (MECR)	Yes	Yes

Table continues on the next page...

Table 338. Register reset information (continued)

Register	Affected by hard reset	Affected by soft reset
Error Injection Address register (ERRIAR)	Yes	Yes
Error Injection Data Pattern register (ERRIDPR)	Yes	Yes
Error Injection Parity Pattern register (ERRIPPR)	Yes	Yes
Error Report Address register (RERRAR)	Yes	Yes
Error Report Data register (RERRDR)	Yes	Yes
Error Report Syndrome register (RERRSYNR)	Yes	Yes
Error Status register (ERRSR)	Yes	Yes
Enhanced CAN Bit Timing Prescalers (EPRS)	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	Yes	No
CAN FD Control register (FDCTRL)	Yes	No
CAN FD Bit Timing register (FDCBT)	Yes	No
CAN FD CRC register (FDCRC)	Yes	Yes
Enhanced Rx FIFO Control Register (ERFCR)	Yes	Yes
Enhanced Rx FIFO Interrupt Enable Register (ERFIER)	Yes	Yes
Enhanced Rx FIFO Status Register (ERFSR)	Yes	Yes
High Resolution Time Stamp (HR_TIME_STAMP)	No	No
Extra CAN FD Message Buffers	No	No
Enhanced Rx FIFO	No	No
Enhanced Rx FIFO Filter Element (ERFFEL)	No	No

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

50.4.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–87Fh allocates the one-hundred-twenty-eight 128-bit message buffers (MBs).

The address range from offset 1000h–17FFh allocates an extra message buffer space which can be used for CAN FD operation mode.

The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced Rx FIFO output, and the address range from offset 2050h–29FCh allocates the rest of Enhanced RX FIFO 31 elements.

The memory map for the Enhanced Rx FIFO is in Enhanced Rx FIFO structure.

50.4.2.1 CAN memory map

CAN_0 base address: 401B_4000h

CAN_1 base address: 401B_E000h

CAN_2 base address: 402A_8000h

CAN_3 base address: 402B_2000h

Offset	Register	Width (In bits)	Access	Reset value

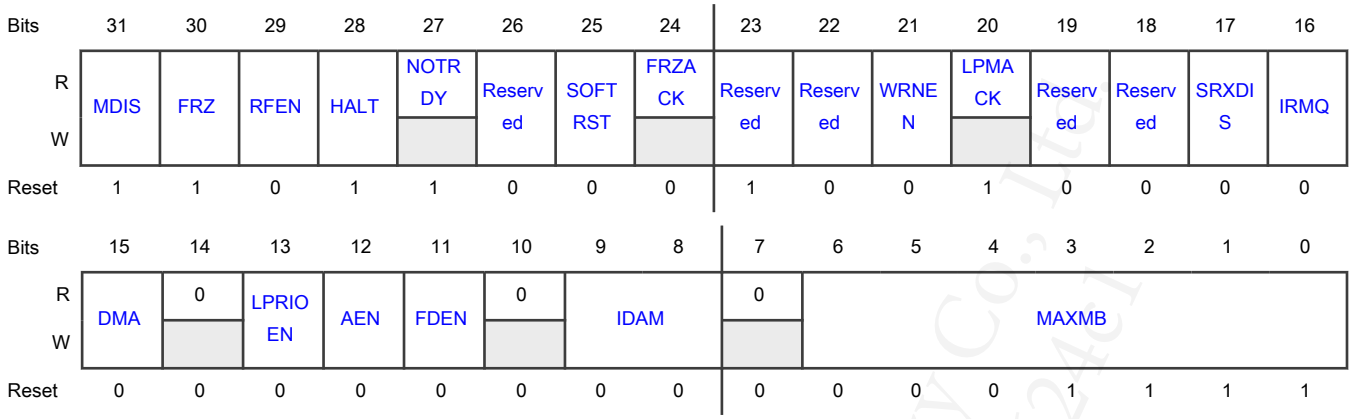
50.4.2.2 Module Configuration register (MCR)



Offset

Register	Offset
MCR	0h

Function

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Diagram

Fields

Field	Function
31 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset. 0b - Enable the FlexCAN module. 1b - Disable the FlexCAN module.
30 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. This bit is set by hardware when a non-correctable error is detected (MECR[NCEFAFRZ] is asserted). 0b - Not enabled to enter Freeze mode. 1b - Enabled to enter Freeze mode.
29 RFEN	Legacy Rx FIFO Enable This bit controls whether the Legacy Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (80h–DCh) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Legacy Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 380. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE** This bit cannot be set when CAN FD operation is enabled (see FDEN bit). **NOTE** RFEN bit must not be set if ERFCR[ERFEN] is set. 0b - Legacy Rx FIFO not enabled. 1b - Legacy Rx FIFO enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 HALT	Halt FlexCAN Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the message buffers and the Control registers CTRL1 and CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered when FlexCAN is in a low power mode. The HALT bit is set by hardware when a non-correctable error is detected and MECR[NCEFAFRZ] is asserted. 0b - No Freeze mode request. 1b - Enters Freeze mode if the FRZ bit is asserted.
27 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode or Freeze mode. It is negated when FlexCAN has exited these modes. This bit is not affected by soft reset. 0b - FlexCAN module is either in Normal mode, Listen-Only mode, or Loop-Back mode. 1b - FlexCAN module is either in Disable mode or Freeze mode.
26 —	Reserved When writing to this field, always write the reset value.
25 SOFTRST	Soft Reset When SOFTRST is asserted, FlexCAN resets its internal state machines and some of the memory-mapped registers. SOFTRST can be asserted directly by the CPU when it writes to the MCR register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted when reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0b - No reset request. 1b - Resets the registers affected by soft reset.
24 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Freeze mode. This bit is not affected by soft reset. **NOTE** FRZACK will be asserted within 178 CAN bits from the Freeze mode request by the CPU, and negated within 2 CAN bits after the Freeze mode request removal (see Protocol timing).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FlexCAN not in Freeze mode, prescaler running. 1b - FlexCAN in Freeze mode, prescaler stopped.
23 —	Reserved
22 —	Reserved When writing to this field, always write the reset value.
21 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0b - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1b - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
20 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset. **NOTE** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0b - FlexCAN is not in a low-power mode. 1b - FlexCAN is in a low-power mode.
19 —	Reserved When writing to this field, always write the reset value.
18 —	Reserved When writing to this field, always write the reset value.
17 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due

Table continues on the next page...

Table continued from the previous page...

Field	Function
	to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Self-reception enabled. 1b - Self-reception disabled.
16 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1b - Individual Rx masking and queue feature are enabled.
15 DMA	DMA Enable DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Legacy Rx FIFO or Enhanced Rx FIFO, so consequently MCR[RFEN] or ERFCR[ERFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes. 0b - DMA feature for Legacy RX FIFO or Enhanced Rx FIFO disabled. 1b - DMA feature for Legacy RX FIFO or Enhanced Rx FIFO enabled.
14 —	Reserved
13 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Local Priority disabled. 1b - Local Priority enabled.
12 AEN	Abort Enable When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating mailboxes configured for transmission. **CAUTION** Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted. 0b - Abort disabled. 1b - Abort enabled.
11 FDEN	CAN FD operation enable This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only. **NOTE** FlexCAN is able to transmit FD frame format according to ISO 11898-1. **NOTE** The Legacy Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted. 0b - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format. 1b - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats.
10 —	Reserved
9-8 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Legacy Rx FIFO ID filter table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Legacy Rx FIFO structure. This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number Of The Last Message Buffer

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE** MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in FlexCAN memory partition for CAN FD. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Legacy Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 380.

50.4.2.3 Control 1 register (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

If CTRL2[BTE] is set, then the PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields in the CTRL1 register are not used by the hardware, are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1).
23-22 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
18-16 PSEG2	Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
15 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off interrupt ESR1[BOFFINT].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Bus Off interrupt disabled. 1b - Bus Off interrupt enabled.
14 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Error interrupt disabled. 1b - Error interrupt enabled.
13 —	Reserved **NOTE** This field is writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot be asserted because this will impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and ETDC[ETDCEN] must be disabled when LPB is asserted. 0b - Loop Back disabled. 1b - Loop Back enabled.
11 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted. 0b - Tx Warning interrupt disabled. 1b - Tx Warning interrupt enabled.
10 RWRNMSK	Rx Warning Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit provides a mask for the Rx Warning interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0b - Rx Warning interrupt disabled. 1b - Rx Warning interrupt enabled.
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE** For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1). 0b - Just one sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used.
6 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. **NOTE** See Bus off in the CAN Protocol standard (ISO 11898-1) for details. 0b - Automatic recovering from Bus Off state enabled. 1b - Automatic recovering from Bus Off state disabled.
5 TSYN	Timer Sync

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If MCR[RFEN] is set (Legacy Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Timer sync feature disabled 1b - Timer sync feature enabled
4 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for message buffer transmission. When asserted, MCR[LPRIOEN] does not affect the priority arbitration. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in the ECR register are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of ESR1[FLTCONF] indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment This 3-bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation segment time = (PROPSEG + 1) × time-quanta. Time-quantum = one Sclock period.

50.4.2.4 Free Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0h after Reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see Mailbox lock mechanism).

50.4.2.5 Rx Mailboxes Global Mask register (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	MG															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 MG	Rx Mailboxes Global Mask Bits These bits mask the mailbox filter bits. Note that the alignment with the ID word of the mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the mailbox. The following table shows in detail which MG bits mask each mailbox filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	—	0	note [2]	note [3]	MG[28:0]	MG[31:29]
0	—	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	—	—	—	—	MG[31:0]
1	1	0	—	—	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called Rx serial message buffer (Rx SMB).
2. If CTRL2[EACEN] is negated, the RTR bit of mailbox is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is negated, the IDE bit of mailbox is always compared with the IDE bit of the incoming frame.

50.4.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e5-4c2-48a8-b251-290d3ab621c1

Function

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
- Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for fast bits Receive error counter for errors detected in the data phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for fast bits Transmit error counter for errors detected in the data phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Receive error counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
7-0 TXERRCNT	Transmit Error Counter Transmit error counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

50.4.2.9 Error and Status 1 register (ESR1)

Offset

Register	Offset
ESR1	20h

Function

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

- Errors detected in CAN frames of any format:
  - BIT1ERR

  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt bits:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- TWRNINT
- RWRNINT

It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames have accumulated.

SYNCH	IDLE	TX	RX	FlexCAN state

Table continues on the next page...

Table continued from the previous page...

0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

Fields

Field	Function
31 BIT1ERR_FAST	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
30 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
29	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
28 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set This bit indicates that a CRC error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a form error has been detected by the receiver node in the data phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a stuffing error has been detected in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-22 —	Reserved
21 ERROVR	Error Overrun This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0b - Overrun has not occurred. 1b - Overrun has occurred.
20 ERRINT_FAST	Error interrupt for errors detected in Data Phase of CAN FD frames with BRS bit set This bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If the corresponding mask bit CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates setting of any error bit detected in the data phase of CAN FD frames with the BRS bit set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
19 BOFFDONEINT	Bus Off Done Interrupt This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall ESR1 register description. 0b - FlexCAN is not synchronized to the CAN bus. 1b - FlexCAN is synchronized to the CAN bus.
17 TWRNINT	Tx Warning Interrupt Flag If MCR[WRNEN] is asserted, TWRNINT is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[WRNEN] is negated, this flag is masked. CPU must clear this flag before disabling MCR[WRNEN]. Otherwise it will be set when MCR[WRNEN] is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0b - No such occurrence. 1b - The Tx error counter transitioned from less than 96 to greater than or equal to 96.
16 RWRNINT	Rx Warning Interrupt Flag If MCR[WRNEN] is asserted, RWRNINT is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0b - No such occurrence. 1b - The Rx error counter transitioned from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - An ACK error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error This bit indicates that a Cyclic Redundancy Check (CRC) error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
11 FRMERR	Form Error This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A Form Error occurred since last read of this register.
10 STFERR	Stuffing Error This bit indicates that a stuffing error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is greater than or equal to 96.
8 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	IDLE This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description. 0b - No such occurrence. 1b - CAN bus is now IDLE.
6 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description. 0b - FlexCAN is not transmitting a message. 1b - FlexCAN is transmitting a message.
5-4 FLTCONF	Fault Confinement State This 2-bit field indicates the confinement state of the FlexCAN module. If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off
3 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall ESR1 register description.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FlexCAN is not receiving a message. 1b - FlexCAN is receiving a message.
2 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters Bus Off state. If the corresponding mask bit in the Control Register 1 (CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt This bit indicates that at least one of the error bits (BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, or STFERR) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates setting of any error bit in the Error and Status register.
0 —	Reserved

50.4.2.10 Interrupt Masks 2 register (IMASK2)

Offset

Register	Offset
IMASK2	24h

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

Field	Function
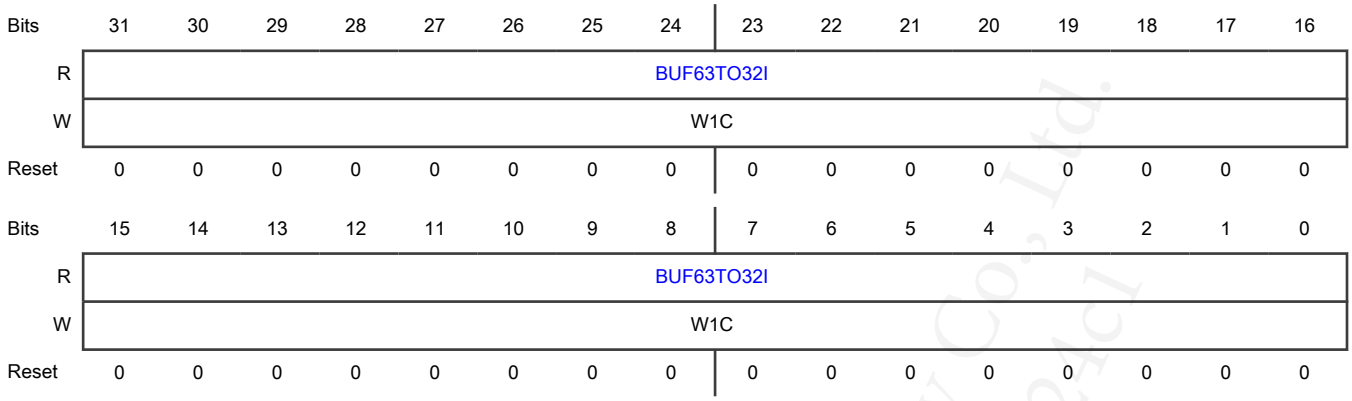
31-0 BUF31TO0M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB31 to MB0. **NOTE** Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

50.4.2.12 Interrupt Flags 2 register (IFLAG2)

Offset

Register	Offset
IFLAG2	2Ch



Function

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Preliminary Information
COMPANY CONFIDENTIAL
Beijing eSOL Automotive Technology Co., Ltd.

Diagram

Fields

Field	Function
31-0 BUF63TO32I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB63 to MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

50.4.2.13 Interrupt Flags 1 register (IFLAG1)

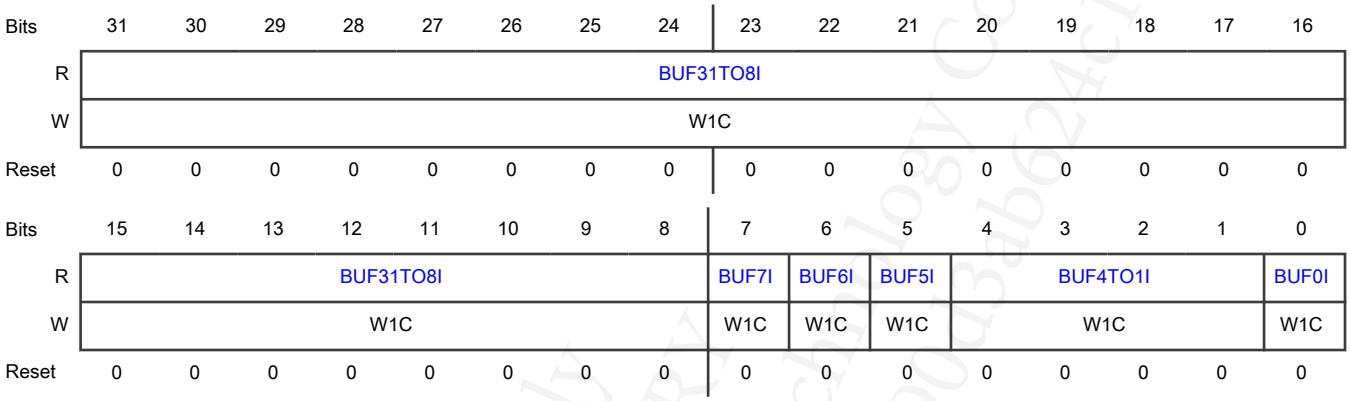
Offset

Register	Offset
IFLAG1	30h

Function

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Legacy Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent Legacy FIFO interrupts when the Legacy Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO , BUF0I is used to empty Legacy FIFO, and BUF4I to BUF1I bits are reserved.



Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Legacy Rx FIFO region; see Legacy Rx FIFO. Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is negated, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy Rx FIFO filters beyond MB7. For example, when RFFN is 8h, the MB0–23 range is occupied by Legacy Rx FIFO filters and related IFLAG bits must be cleared.

When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Legacy Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not

used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of Legacy FIFO, and BUF0I is used to empty Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Legacy Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. When MCR[DMA] is negated, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] is enabled.

Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Diagram

Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB31 to MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt Or Legacy Rx FIFO Overflow When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF7I flag represents Legacy Rx FIFO overflow when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a mailbox. 0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Legacy Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Legacy Rx FIFO overflow when MCR[RFEN]=1
6 BUF6I	Buffer MB6 Interrupt Or Legacy Rx FIFO Warning

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF6I flag represents Legacy Rx FIFO warning when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Legacy Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Legacy Rx FIFO is almost full. Note that if the flag is cleared when the number of unread messages is greater than four, it does not assert again until the number of unread messages within the Legacy Rx FIFO is decreased to be equal to or less than four. 0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Legacy Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Legacy Rx FIFO almost full when MCR[RFEN]=1
5 BUF5I	Buffer MB5 Interrupt Or Frames available in Legacy Rx FIFO When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this field flags the interrupt for MB5. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. When MCR[RFEN] is set (Legacy Rx FIFO enabled), the BUF5I flag represents "Frames available in Legacy Rx FIFO" and indicates that at least one frame is available to be read from the Legacy Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I. 0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the Legacy FIFO, when MCR[RFEN]=1 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Legacy Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.
4-1 BUF4TO1I	Buffer MBi Interrupt Or Reserved When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE** These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when MCR[RFEN] is set. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
0 BUF0I	Buffer MB0 Interrupt Or Clear Legacy FIFO bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this field flags the interrupt for MB0. If the Legacy Rx FIFO is enabled, this bit is used to trigger the clear Legacy FIFO operation. This operation empties Legacy FIFO contents. Before performing this operation the CPU must service all Legacy FIFO related IFLAGs. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

50.4.2.14 Control 2 register (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

This register complements Control1 register, providing control bits for memory write access in Freeze mode, for extending Legacy FIFO filter quantity, and to adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

This table shows how the Legacy Rx FIFO filter structure is determined by the value of CTRL2[RFFN]. See the CTRL2[RFFN] field description for more information.

Table 339. Legacy Rx FIFO filter: possible structures

RFFN[3:0]	Number of Legacy Rx FIFO filter elements	Message buffers occupied by Legacy Rx FIFO and ID filter table	Remaining available mailboxes	Legacy Rx FIFO ID filter table elements affected by Rx individual masks	Legacy Rx FIFO ID filter table elements affected by Legacy Rx FIFO global mask

Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for errors detected in the data phase of fast CAN FD frames This bit provides a mask for the ERRINT_FAST interrupt in ESR1 register. 0b - ERRINT_FAST error interrupt disabled. 1b - ERRINT_FAST error interrupt enabled.
30 BOFFDONEMSK	Bus Off Done Interrupt Mask This bit provides a mask for the bus off done interrupt in ESR1 register. 0b - Bus off done interrupt disabled. 1b - Bus off done interrupt enabled.
29	Error-correction Configuration Register Write Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ECRWRE	This bit enables the MECR register to be updated. This bit is automatically set to 0 if the protocol described in Detection and correction of memory errors is not followed. 0b - Disable update. 1b - Enable update.
28 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. MCR[RFEN] must not be set during FlexCAN memory initialization. 0b - Maintain the write access restrictions. 1b - Enable unrestricted write access to FlexCAN memory.
27-24 RFFN	Number Of Legacy Rx FIFO Filters This 4-bit field defines the number of Rx Legacy FIFO filters, as shown in Table 339. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that cause the number of message buffers occupied by Legacy Rx FIFO and Legacy Rx FIFO ID Filter to exceed the number of mailboxes present, as defined by MCR[MAXMB]. **NOTE** Each group of eight filters occupies a memory space equivalent to two message buffers, which means that the more filters are implemented the fewer mailboxes will be available. Considering that the Legacy Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words, which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy Rx FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), then the exceeding ones will not be functional. **NOTE** • The number of the last remaining available mailboxes is defined by the smaller of NUMBER_OF_MB minus 1 and MCR[MAXMB]. • If Rx Individual Mask registers are not enabled then all Legacy Rx FIFO filters are affected by the Legacy Rx FIFO Global Mask.
23-19 TASD	Tx Arbitration Start Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See Tx arbitration start delay for more details. This field can be written only in Freeze mode because it is blocked by hardware in other modes.
18 MRP	Mailboxes Reception Priority If this bit is set the matching process starts from the mailboxes and if no match occurs the matching continues on the Legacy Rx FIFO or Enhanced RX FIFO . This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Matching starts from Legacy Rx FIFO or Enhanced Rx FIFO and continues on mailboxes. 1b - Matching starts from mailboxes and continues on Legacy Rx FIFO or Enhanced Rx FIFO.
17 RRS	Remote Request Storing If this bit is asserted a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame will be generated. If this bit is negated the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Remote response frame is generated. 1b - Remote request frame is stored.
16 EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes This bit controls the comparison of IDE and RTR bits within Rx mailbox filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Legacy Rx FIFO or Enhanced Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Rx mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1b - Enables the comparison of both Rx mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free running timer counter. This bit can be written in Freeze mode only. 0b - The free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. 1b - The free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device-specific section for details about the external time tick.
14 PREXCEN	Protocol Exception Enable This bit enables the protocol exception feature.

Table continues on the next page...

Table continued from the previous page...

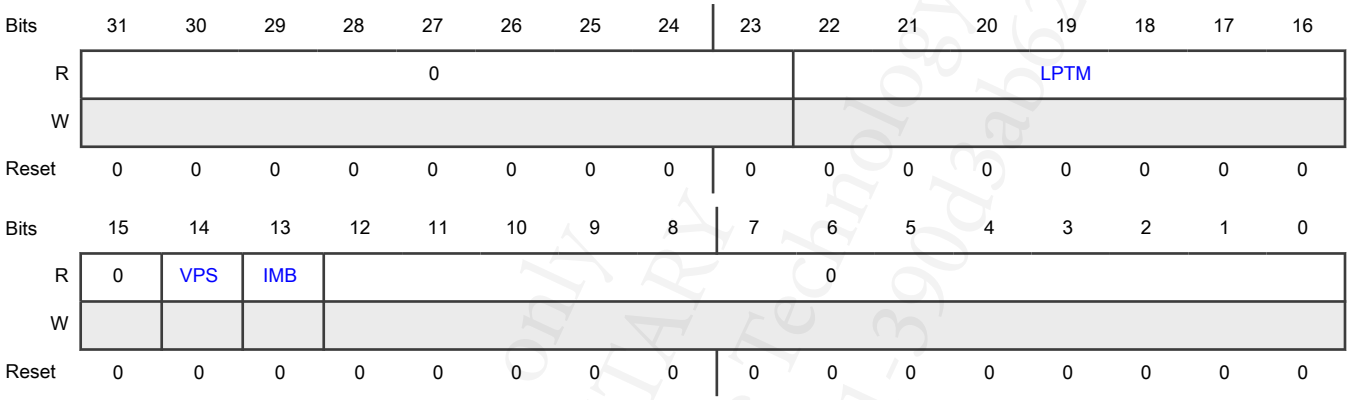
Field	Function
	This field is writable only in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard (ISO 11898-1) for details. 0b - Protocol exception is disabled. 1b - Protocol exception is enabled.
13 BTE	Bit Timing Expansion enable This field enables the use of the EPRS, EDCBT and ENCBT registers to configure the CAN bit timing segments, instead of using the bit timing fields of CBT, FDCBT, and CTRL1 registers. If CTRL2[BTE] is set: • PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields in CTRL1 register are read as zero, and a write operation in them has no effect. • EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 fields in the CBT register, and the FDCBT register, are read as zero and a write operation to them has no effect. • The ETDCOFF, ETDCEN, ETDCFAIL, and ETDCVAL fields of the ETDC register are used by FlexCAN instead of TDCOFF, TDCEN, TDCFAIL, and TDCVAL fields in FDCTRL register, which are read as zero, and a write operation in them has no effect. • ETDC[TDMDIS] can be used for disabling transceiver delay measurement. 0b - CAN Bit timing expansion is disabled. 1b - CAN bit timing expansion is enabled.
12 ISOCANFDEN	ISO CAN FD Enable This field enables the CAN FD protocol according to ISO specification (ISO 11898-1) (see CAN FD ISO compliance). This field is writable only in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1). 0b - FlexCAN operates using the non-ISO CAN FD protocol. 1b - FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1).
11 EDFLTDIS	Edge Filter Disable This bit disables the edge filter used during the bus integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is writable only in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1) for details. 0b - Edge filter is enabled 1b - Edge filter is disabled
10 —	Reserved
9-8 MBTSBASE	Message Buffer Time Stamp Base This field selects which time base is used for capturing the 16-bit TIME_STAMP field of the message buffer register. There are three time base options: 1. TIMER 2. Lower 16 bits of high resolution time base 3. Upper 16 bits of high resolution time base This field can be written in Freeze Mode only. 00b - Message buffer time stamp base is TIMER 01b - Message buffer time stamp base is lower 16 bits of high resolution timer 10b - Message buffer time stamp base is upper 16 bits of high resolution timer 11b - Reserved
7-6 TSTAMPCAP	Time Stamp Capture Point This field configures the point in time when a 32-bit time base is captured during a CAN frame and stored in the high resolution time stamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the 7th bit of end of frame for transmission and the 6th bit of the end of frame for reception. For CAN FD frames, the high resolution time stamp can be captured at the start of frame, the point in time a CAN FD frame is considered valid, or the res bit. This field can be written in Freeze mode only. 00b - The high resolution time stamp capture is disabled 01b - The high resolution time stamp is captured in the end of the CAN frame 10b - The high resolution time stamp is captured in the start of the CAN frame 11b - The high resolution time stamp is captured in the start of frame for classical CAN frames and in res bit for CAN FD frames
5-0 —	Reserved

50.4.2.15 Error and Status 2 register (ESR2)



Offset

Register	Offset
ESR2	38h

Function

This register reports some general status information.

Diagram

Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive mailbox (see the ESR2[IMB] bit description). If there is no inactive mailbox then the mailbox indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] is negated, then the mailbox indicated is the one that has the greatest arbitration value (see Highest-priority mailbox first). If CTRL1[LBUF] is asserted then the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its mailbox number.
15 —	Reserved
14 VPS	Valid Priority Status This bit indicates whether ESR2[IMB] and ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process.

Table continues on the next page...

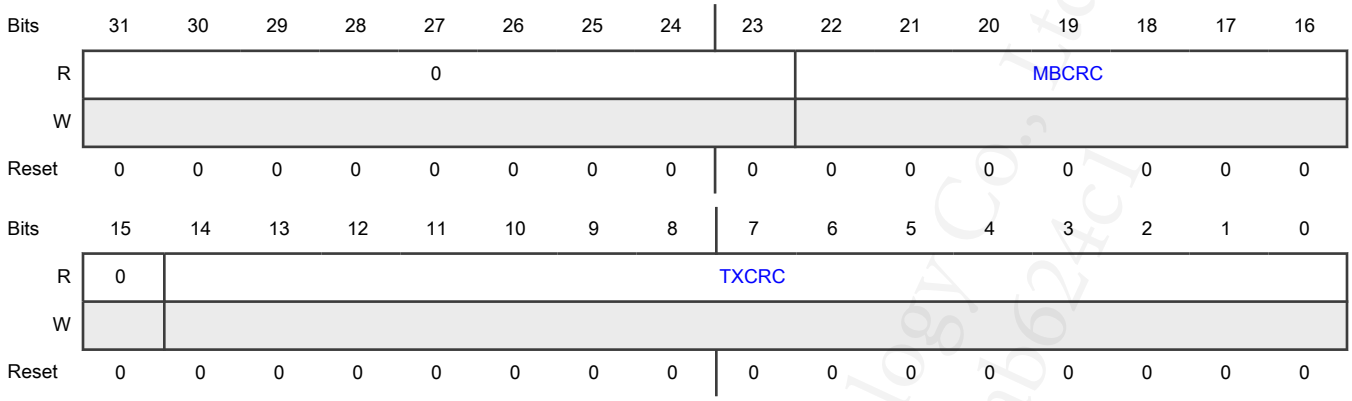
Table continued from the previous page...

Field	Function
	If there is no inactive mailbox and only one Tx mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any mailbox. **NOTE** ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of an MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0b - Contents of IMB and LPTM are invalid. 1b - Contents of IMB and LPTM are valid.
13 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive mailbox (CODE field is either 1000b or 0b). This bit is asserted in the following cases: • During arbitration, if an ESR2[LPTM] is found and it is inactive. • If ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is always cleared in start of arbitration (see Arbitration process). **NOTE** ESR2[LPTM] mechanism has the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0b - If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive mailbox. 1b - If ESR2[VPS] is asserted, there is at least one inactive mailbox. LPTM content is the number of the first one.
12-0 —	Reserved

50.4.2.16 CRC register (CRCR)

Offset

Register	Offset
CRCR	44h



Function

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

Diagram

Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Mailbox This field indicates the number of the mailbox corresponding to the value in CRCR[TXCRC] field.
15 —	Reserved
14-0 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in FDCRC register.

50.4.2.17 Legacy Rx FIFO Global Mask register (RXFGMASK)

Offset

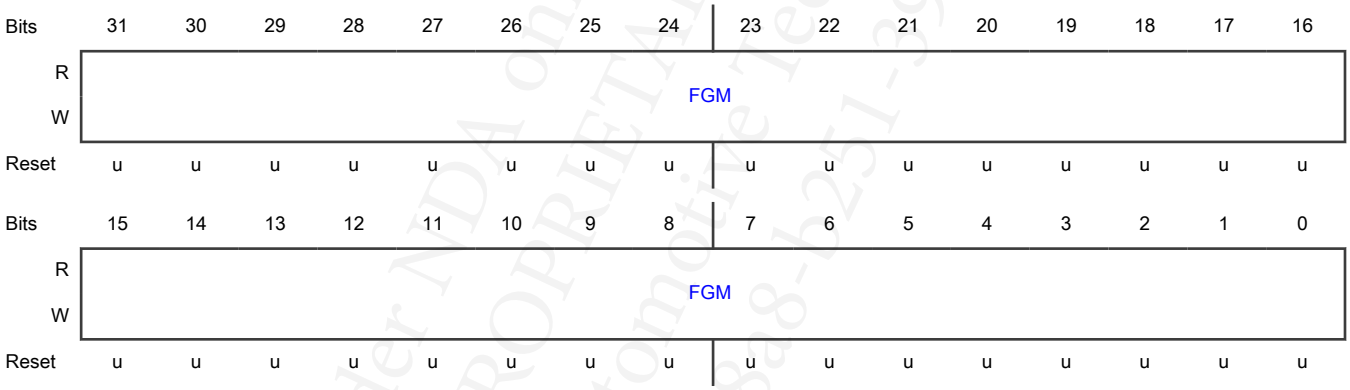
Register	Offset
RXFGMASK	48h

Function

This register is located in RAM.

If Legacy Rx FIFO is enabled, RXFGMASK is used to mask the Legacy Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.



The following table shows how the FGM bits correspond to each IDAF field.

Table 340. Correspondence of Legacy Rx FIFO global mask bits to IDF fields

Legacy Rx FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Legacy Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy Rx FIFO filter.

Diagram

Fields

Field	Function
31-0 FGM	Legacy Rx FIFO Global Mask Bits These bits mask the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

50.4.2.18 Legacy Rx FIFO Information register (RXFIR)

Offset

Register	Offset
RXFIR	4Ch

Function

RXFIR provides information on Legacy Rx FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. The Legacy RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Legacy Rx FIFO. Also, its output is updated whenever the output of the Legacy Rx FIFO is updated with the next message. See Legacy Rx FIFO for instructions on reading this register.

NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case the register is read-only.

50.4.2.19 CAN Bit Timing register (CBT)

Offset

Register	Offset
CBT	50h

Function

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

NOTE

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

NOTE

If CTRL2[BTE] is set, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 fields are read as zero, and a write operation into them has no effect.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BTF	EPRESDIV										ERJW				
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

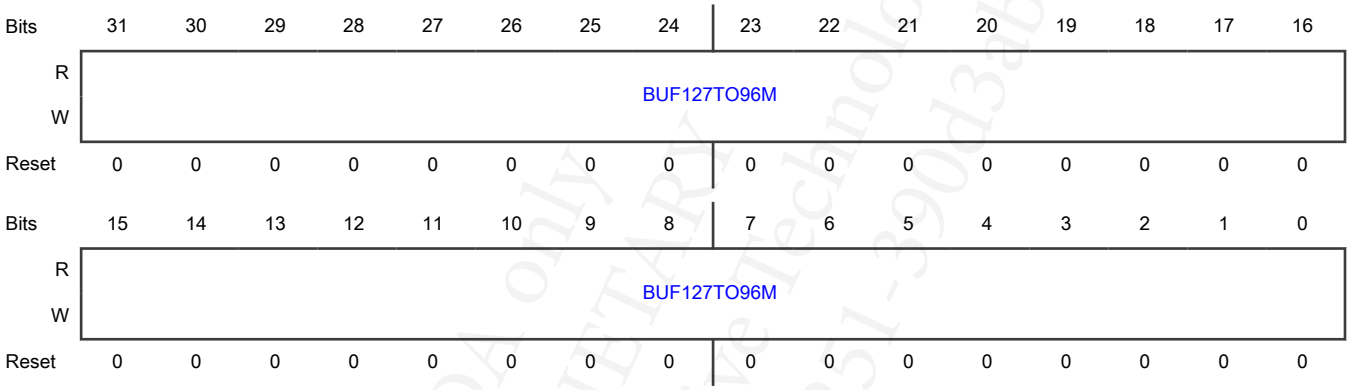
Field	Function
31 BTF	Bit Timing Format Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2. and ERJW replacing the CAN bit timing variables defined in CTRL1 register. This field can be written in Freeze mode only. 0b - Extended bit time definitions disabled. 1b - Extended bit time definitions enabled.
30-21 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] is asserted, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[RJW] value range. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = ERJW + 1.
15-10 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the propagation segment in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 This 5-bit field defines the length of phase segment 1 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of phase segment 2 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

50.4.2.20 Interrupt Masks 4 register (IMASK4)



Offset

Register	Offset
IMASK4	68h

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB127 to MB96. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG4 bit is set.

Diagram

Fields

Field	Function
31-0 BUF127TO96M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB127 to MB96. When CAN FD is enabled, the MB range is defined in accordance with the MBDSRs bit fields of FDCTRL register. **NOTE** Setting or clearing a bit in the IMASK4 Register can assert or negate an interrupt request, if the corresponding IFLAG4 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

50.4.2.21 Interrupt Masks 3 register (IMASK3)

Offset

Register	Offset
IMASK3	6Ch

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB95 to MB64. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG3 bit is set.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BUF95TO64M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF95TO64M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB95 to MB64. When CAN FD is enabled, the MB range is defined in accordance with the MBDSRs bit fields of FDCTRL register. **NOTE** Setting or clearing a bit in the IMASK3 Register can assert or negate an interrupt request, if the corresponding IFLAG3 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

50.4.2.22 Interrupt Flags 4 register (IFLAG4)

Offset

Register	Offset
IFLAG4	70h

Function

This register defines the flags for the 32 message buffer interrupts for MB127 to MB96. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG4 bit. If the corresponding IMASK4 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG4 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

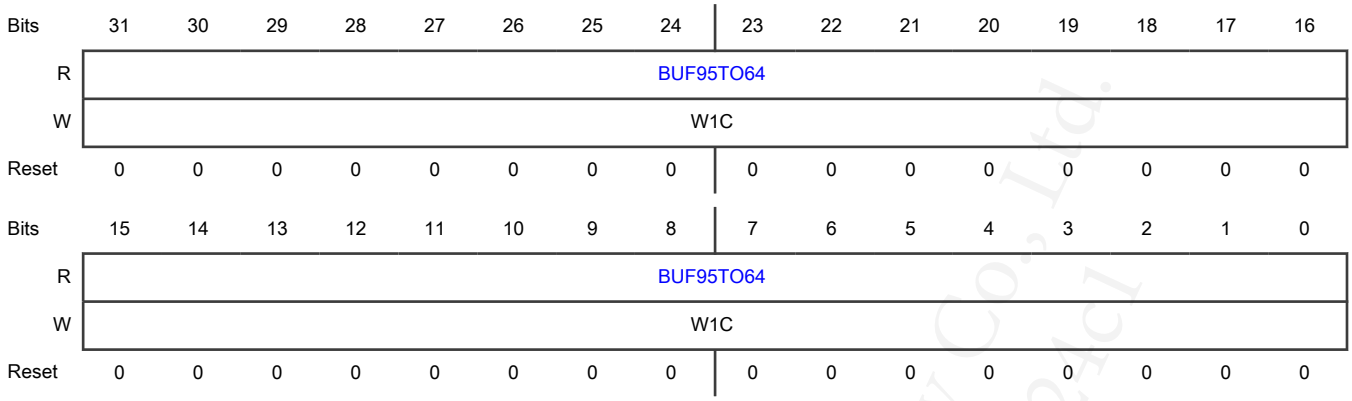
Fields

Field	Function
31-0 BUF127TO96	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB127 to MB96.When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of FDCTRL register. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

50.4.2.23 Interrupt Flags 3 register (IFLAG3)

Offset

Register	Offset
IFLAG3	74h



Function

This register defines the flags for the 32 message buffer interrupts for MB95 to MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 bit. If the corresponding IMASK3 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG3 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

50.4.2.24 Rx Individual Mask registers (RXIMR0 - RXIMR127)

Offset

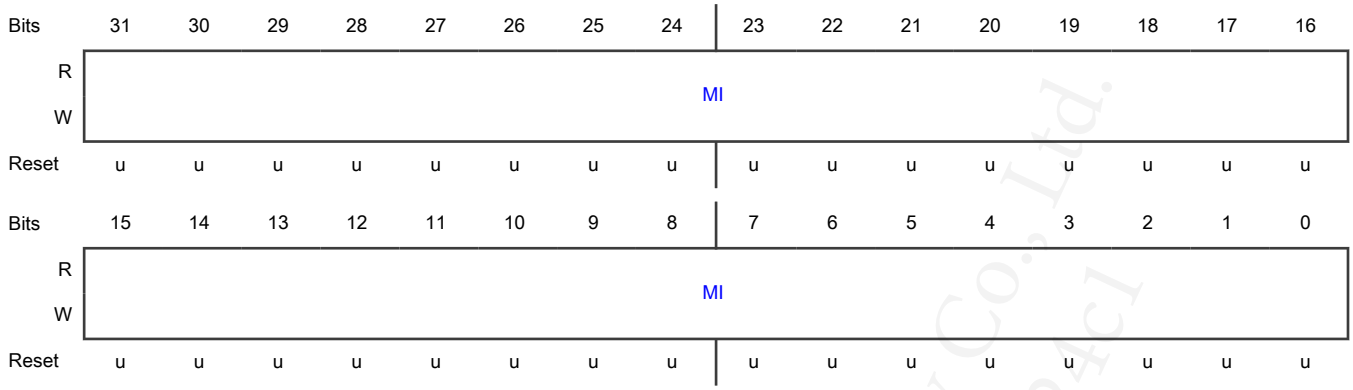
For n = 0 to 127:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Legacy Rx FIFO.

When the Legacy Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Legacy Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Legacy Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see Legacy Rx FIFO).



RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

Diagram

Fields

Field	Function
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This bit is automatically set to 1 (disabled) when CTRL2[ECRWRE] is enabled. The protocol described in section Detection and correction of memory errors must be followed. 0b - Write is enabled. 1b - Write is disabled.
30-20 —	Reserved
19 —	Reserved When writing to this field, always write the reset value.
18 —	Reserved When writing to this field, always write the reset value.
17 —	Reserved
16 —	Reserved When writing to this field, always write the reset value.
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0b - Injection is disabled. 1b - Injection is enabled.
14	FlexCAN Access Error Injection Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
FAERRIE	Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0b - Injection is disabled. 1b - Injection is enabled.
13 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern register (ERRIDPR) and Error Injection Parity Pattern register (ERRIPPR). 0b - Error injection is applied only to the 32-bit word. 1b - Error injection is applied to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE** When reading the report registers, this bit must be set to assure coherence on the consecutive register reads. 0b - Enable updates of the error report registers. 1b - Disable updates of the error report registers.
8 ECCDIS	Error Correction Disable Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0b - Enable memory error correction. 1b - Disable memory error correction.
7 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0b - Keep normal operation. 1b - Put FlexCAN in Freeze mode (see section "Freeze mode").
6-0 —	Reserved

50.4.2.26 Error Injection Address register (ERRIAR)

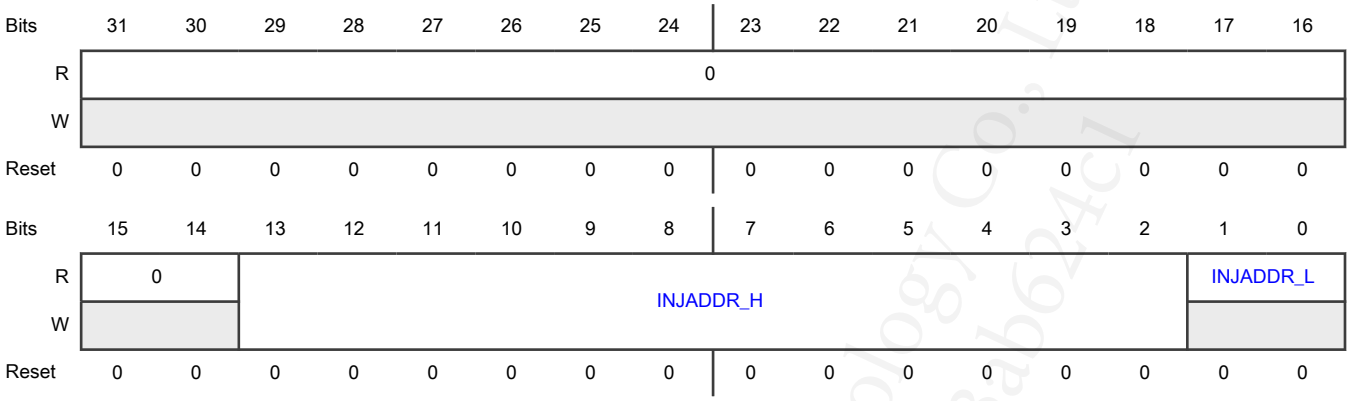
Offset

Register	Offset
ERRIAR	AE4h

Function

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM (where pairs of values are provided, the first is the address for MCR[FDEN] negated, the second is for MCR[FDEN] asserted):



RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	—
MBs	0000h	0080h
RXIMRs	1000h	0880h
RXFIR_0	1200h	0A80h
RXFIR_1	1204h	0A84h

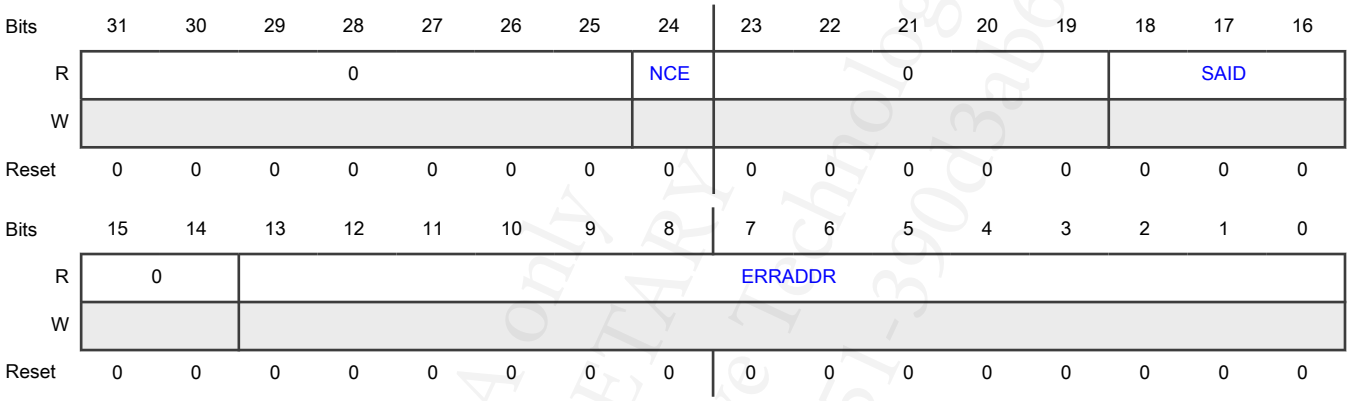
50.4.2.29 Error Report Address register (RERRAR)

Offset

Register	Offset
RERRAR	AF0h

Function

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.



This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Fields

Field	Function
31-0 RDATA	Raw data word read from memory with error

50.4.2.31 Error Report Syndrome register (RERRSYNR)

Offset

Register	Offset
RERRSYNR	AF8h

Function

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 342. Syndrome definition

SYNDn (hex)	Type	Bit affected
00	—	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7

16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeros non-correctable error
1F	—	All-ones non-correctable error
All others	—	Non-correctable error

Provided under NDA on behalf of COMPANY PROPRIETARY Beijing CHJ Automotive Technology Co., Ltd. c8c462e5-4821-48a8-b253-39c03ab624c1

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

50.4.2.33 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

This register defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] is set.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

The contents of this register are not affected by soft reset.

Diagram

Table continued from the previous page...

Field	Function
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor This field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data phase of a CAN FD message when CTRL2[BTE] is set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency / (EDPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for ENPRESDIV and EDPRESDIV. For more details see the first NOTE in section CAN FD frames.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor This field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CTRL2[BTE] is set; otherwise it reads as zero and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency / (ENPRESDIV + 1)

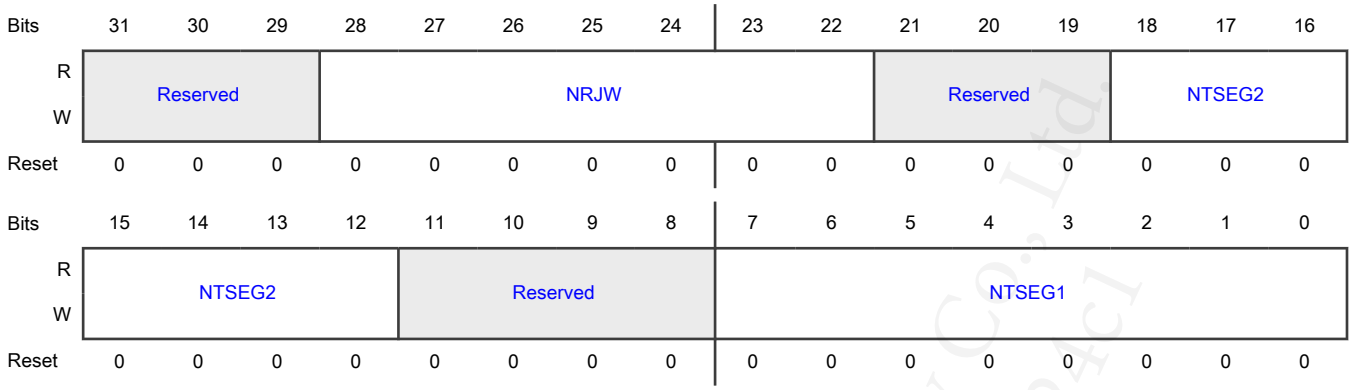
50.4.2.34 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

This register provides an alternative way to store the CAN bit timing variables described in the CTRL1 and CBT registers, to get higher CAN bit timing resolution.



This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

The contents of this register are not affected by soft reset.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

50.4.2.35 Enhanced Data Phase CAN bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

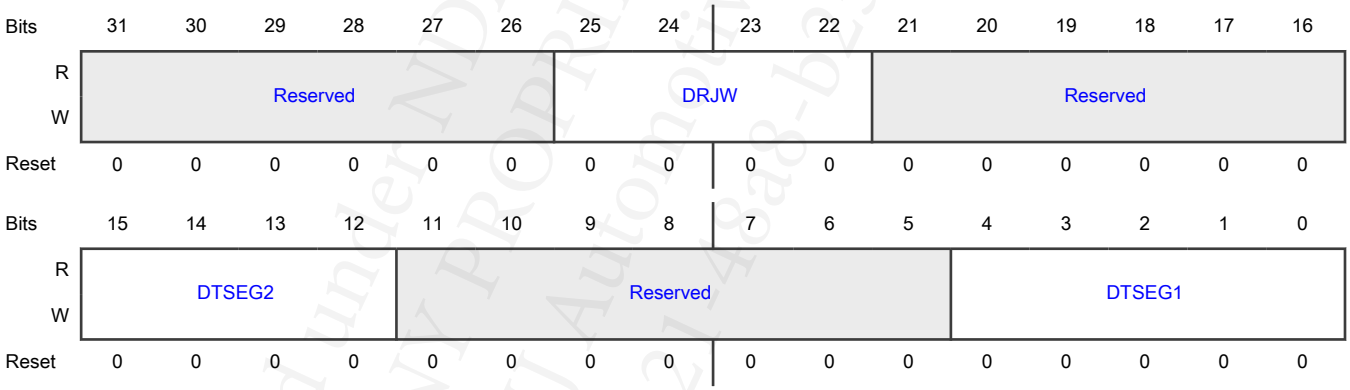
Function

This register provides an alternative way to store the data phase CAN bit timing variables described in the FDCBT register to achieve higher CAN bit timing resolution.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

The contents of this register are not affected by soft reset.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.



NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

NOTE

DTSEG1 must be at least two time quanta.

Diagram

Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width This field defines the maximum number of time quanta that a data phase bit time can be changed by one resynchronization when CTRL2[BTE] is set; otherwise it has no effect.

Table continues on the next page...

Table continued from the previous page...

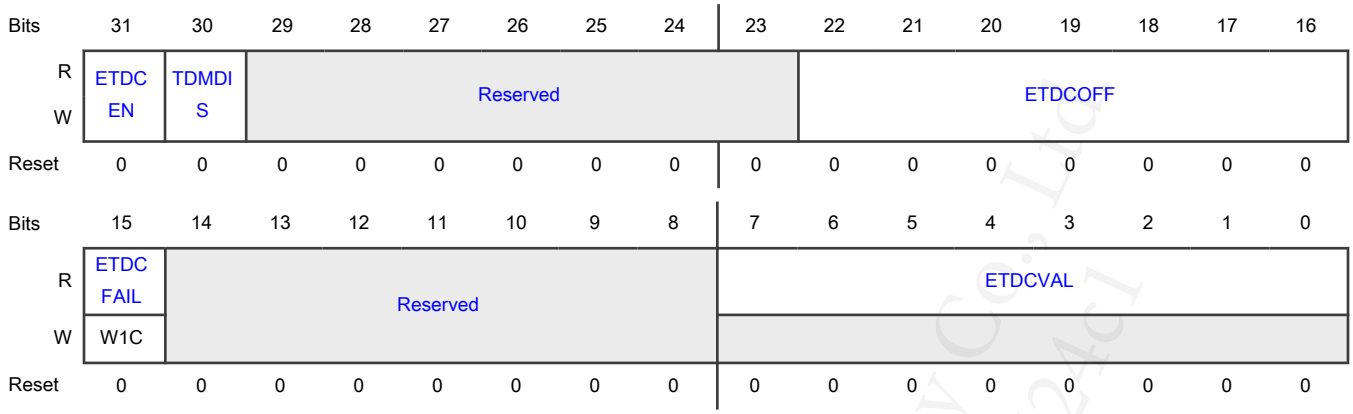
Field	Function
	Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 This field defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] is set; otherwise it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) x Time-Quanta. Time-Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 This field defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] is set; otherwise it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) x Time-Quanta. Time-Quantum = one Sclock period.

50.4.2.36 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

Function



This register contains extended versions of the fields FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the hardware only if CTRL2[BTE] is set; otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.
c8c462e5-4e01-48a8-b251-390d3ab624f1

Diagram

Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable This bit can be used for enabling and disabling the TDC feature. It can be written in Freeze mode only. **NOTE** Refer to Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled (see CTRL1[LPB] register). 0b - TDC is disabled 1b - TDC is enabled
30 TDMDIS	Transceiver Delay Measurement Disable This bit can be used for disabling the transceiver delay measurement. When the TDC measurement is disabled, the secondary sample point position is determined only by the enhanced TDC offset (ETDCOFF) field. Otherwise, if the TCD measurement is enabled, then the secondary sample point position is determined by the sum of the transceiver delay measurement plus the enhanced TDC offset. This field is not affected by soft reset. **NOTE** This bit can be enabled only if CTRL2[BTE] is set. 0b - TDC measurement is enabled 1b - TDC measurement is disabled
29-23 —	Reserved
22-16 ETDCOFF	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. ETDCOFF can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** ETDCOFF must not be configured as zero. **NOTE** If CTRL2[BTE] is set after a chip level hard reset, ETCDOFF is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). ETDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write 1 to clear it. 0b - Measured loop delay is in range. 1b - Measured loop delay is out of range.
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value This register contains the ETDCOFF field added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS equal to recessive. This field is only updated by the hardware if ETDC[ETDCEN] is set. This field is affected by soft reset. **NOTE** If TDMDIS is set, ETDCVAL stores ETDCOFF only.

50.4.2.37 CAN FD Control register (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.
- Block R2 allocates MB64 to MB95.
- Block R3 allocates MB96 to MB127.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

Table 343. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

NOTE

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages. The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle, or Bus Off state, or when the current frame under reception or transmission reaches the interframe space.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	By negating FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, no matter what the value is in the BRS bit of the Tx MBs. 0b - Transmit a frame in nominal rate. The BRS bit in the Tx MB has no effect. 1b - Transmit a frame with bit rate switching if the BRS bit in the Tx MB is recessive.
30-27 —	Reserved
26-25 MBDSR3	Message Buffer Data Size for Region 3 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R3 of message buffers allocated in RAM. It can be written in Freeze mode only. 00b - Selects 8 bytes per message buffer. 01b - Selects 16 bytes per message buffer. 10b - Selects 32 bytes per message buffer. 11b - Selects 64 bytes per message buffer.
24 —	Reserved
23-22 MBDSR2	Message Buffer Data Size for Region 2 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R2 of message buffers allocated in RAM. It can be written in Freeze mode only. 00b - Selects 8 bytes per message buffer. 01b - Selects 16 bytes per message buffer. 10b - Selects 32 bytes per message buffer. 11b - Selects 64 bytes per message buffer.
21 —	Reserved
20-19 MBDSR1	Message Buffer Data Size for Region 1 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R1 of message buffers allocated in RAM. It can be written in Freeze mode only. 00b - Selects 8 bytes per message buffer. 01b - Selects 16 bytes per message buffer.

Table continues on the next page...

	10b - Selects 32 bytes per message buffer. 11b - Selects 64 bytes per message buffer.
18 —	Reserved
17-16 MBDSR0	Message Buffer Data Size for Region 0 This two-bit field selects the data size (8, 16, 32, or 64 bytes) for region R0 of message buffers allocated in RAM. It can be written in Freeze mode only. 00b - Selects 8 bytes per message buffer. 01b - Selects 16 bytes per message buffer. 10b - Selects 32 bytes per message buffer. 11b - Selects 64 bytes per message buffer.
15 TDCEN	Transceiver Delay Compensation Enable This bit can be used to enable and disable the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details. **NOTE** TDC must be disabled when Loop Back mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] is set, TDCEN is read as zero and a write operation has no effect. 0b - TDC is disabled 1b - TDC is enabled
14 TDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write one to clear it. **NOTE** If CTRL2[BTE] is set, TDCFAIL is read as zero and a write operation has no effect. 0b - Measured loop delay is in range. 1b - Measured loop delay is out of range.
13	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
12-8 TDCOFF	Transceiver Delay Compensation Offset This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] is set, TDCOFF is read as zero and a write operation has no effect. **NOTE** It is not recommended to have TDCOFF equal to zero.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK). **NOTE** If CTRL2[BTE] is set, TDCVAL is read as zero. See Protocol timing for more details on how the loop delay measurement is performed.

50.4.2.38 CAN FD Bit Timing register (FDCBT)

Offset

Register	Offset
FDCBT	C04h

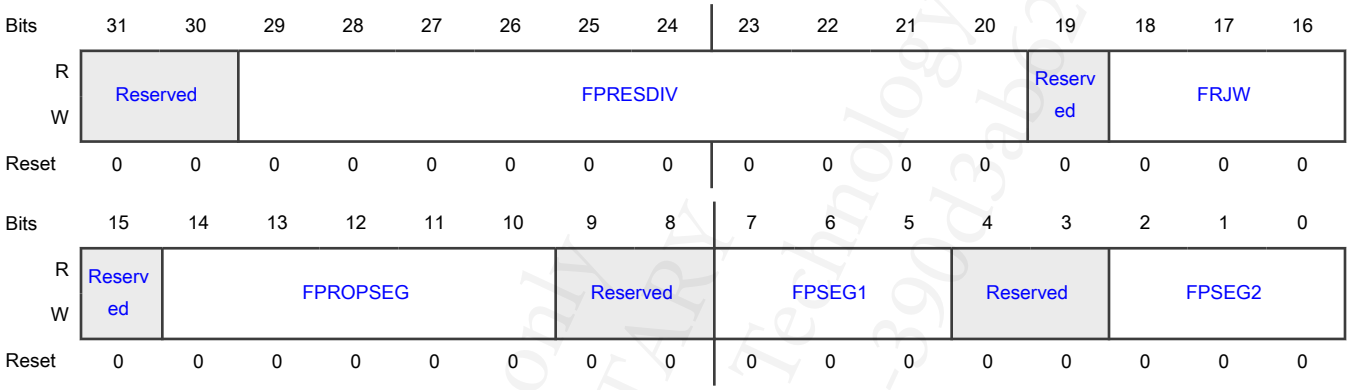
Function

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.



NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

NOTE

If CTRL2[BTE] is set, the FDCBT register is read as zero and a write operation has no effect.

Diagram

Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for FPRESDIV and PRESDIV (in CBT or CTRL1). For more details see the first NOTE in section CAN FD frames.
19 —	Reserved
18-16	Fast Resync Jump Width

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRJW	This 3-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization in the data bit rate portion of a CAN FD message with the BRS bit set. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = FSJW + 1.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment This 5-bit field defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = FPROPSEG × Time-Quanta. Time-Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

50.4.2.39 CAN FD CRC register (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time the Tx Interrupt flag is asserted.

CRC_15 = C599h: $(x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$

CRC_17 = 3685Bh: $(x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$

CRC_21 = 302899h: $(x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

Table continued from the previous page...

Field	Function
FD_TXCRC	This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC register.

50.4.2.40 Enhanced Rx FIFO Control register (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

Function

This register defines the Enhanced Rx FIFO configuration.

This register can be written only in Freeze mode.

All the contents of this register are affected by soft reset.

50.4.2.43 High Resolution Time Stamp (HR_TIME_STAMP0 - HR_TIME_STAMP127)

Offset

For n = 0 to 127:

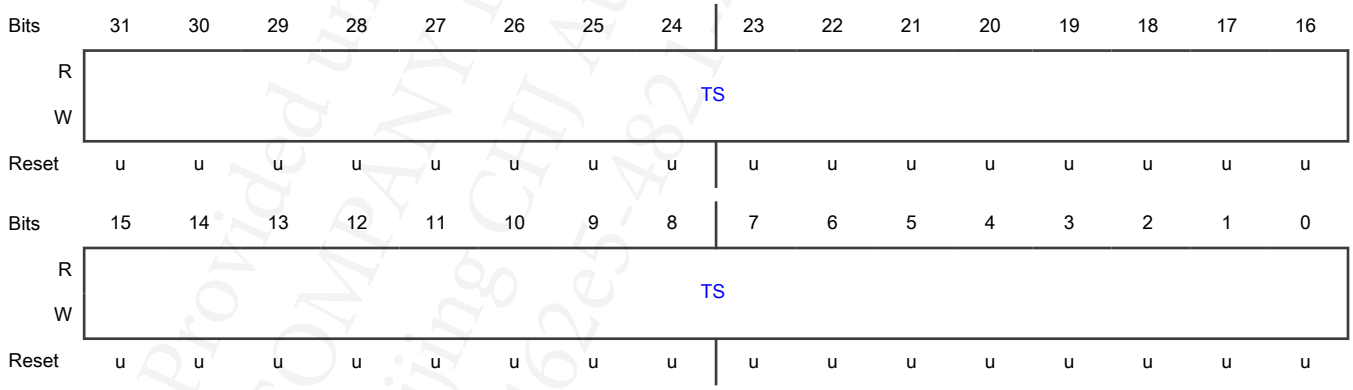
Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Function

The High Resolution Time Stamp registers are used for storing a copy of a 32-bit timer at the start or end of a CAN frame.

HRST0 stores the 32-bit time stamp associated with MB0, HRSTS1 stores the the 32-bit time stamp associated with MB1, and so on.

These registers are not affected by reset.



NOTE

These registers must not be written out of Freeze mode.

Table 347. High Resolution Time Stamp register operation

TSTAMPCAP	Captured time base	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame.
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format.

Fields

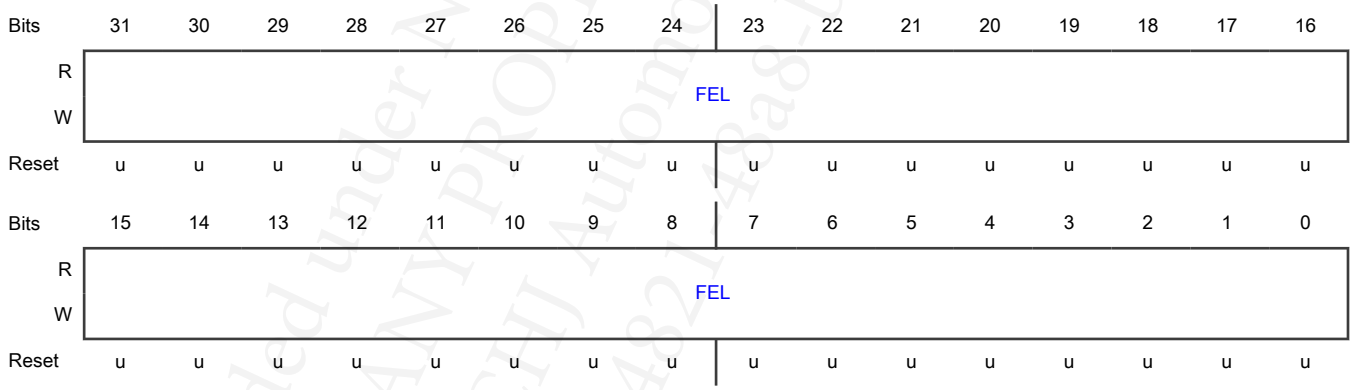
Field	Function
31-0 TS	High Resolution Time Stamp HR_TIME_STAMP register which captures the copy of timestamp of corresponding MB always captures 32-bit timer value.

50.4.2.44 Enhanced Rx FIFO Filter Element (ERFFEL0 - ERFFEL127)

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)



Function

These registers are used for storing the filter elements of the Enhanced Rx FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

Diagram

Fields

50.4.3 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–87Fh is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN memory partition for CAN FD for more detailed information.

When CAN FD is enabled, the memory area 1000h–17FFh can be used for implementing up to 28 64-byte additional MBs. This additional MB region (enhanced MB memory) can be used partially or completely only if the total number of MBs configured by MCR[MAXMB] is less than 128. This means that the maximum number of MBs in the area 80h–87FH and area 1000h–17FFH is 128. See FlexCAN memory partition for CAN FD for more detailed information.

Table 348. Message buffer structure — example with 64-byte payload

EDL — Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 1010b (see table below).

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 349 and Table 350. See Functional description for additional information.

Table 349. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0100b: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the Move-in process), the CODE field is automatically updated to FULL.
0010b: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the MB is FULL and a new frame

Table continues on the next page...

Table 349. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
					for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[6]	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 register (CTRL2)" for details.
4. Code 1010b is not considered Tx and an MB with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 350. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1000b: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.
1001b: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
1100b: DATA — MB is a Tx data frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission,

Table continues on the next page...

Table 350. Message buffer code for Tx buffers (continued)

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
				the MB automatically returns to the INACTIVE state.
1100b: REMOTE — MB is a Tx Remote Request frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
1110b: TANSWER — MB is a Tx Response frame from an incoming Remote Request frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010b). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

cac4520c-4821-48a8-8251-390d3a8624c1

RTR — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 349, Table 350, and the description of the RRS field in Control 2 register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

NOTE

When configuring CAN FD frames, the RTR bit must be negated.

DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 8h–Fh of the MB space (see Table 348). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 352).

TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

Table 351. Time stamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured time base	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception

Table continues on the next page...

Table 351. Time stamp operation (continued)

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured time base	Capture point
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

PRIO — Local priority

This 3-bit field is used only when MCR[LPRIO_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 352. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15

Table continues on the next page...

Table 352. DATA BYTEs validity (continued)

DLC	Valid DATA BYTEs
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

50.4.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL[MBDSRn] bit fields as shown in table below.

Table 353. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload
2	64 to 95	MBDSR2	MBDSR2=00, 32 MBs with 8 bytes payload MBDSR2=01, 21 MBs with 16 bytes payload MBDSR2=10, 12 MBs with 32 bytes payload MBDSR2=11, 7 MBs with 64 bytes payload
3	96 to 127	MBDSR3	MBDSR3=00, 32 MBs with 8 bytes payload

Table continues on the next page...

Table 353. RAM partition (continued)

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
			MBDSR3=01, 21 MBs with 16 bytes payload MBDSR3=10, 12 MBs with 32 bytes payload MBDSR3=11, 7 MBs with 64 bytes payload
4	—	—	7 MBs with 64 bytes (total number of MBs in blocks 0, 1, 2, 3 ≤ 121)
5	—	—	7 MBs with 64 bytes (total number of MBs in blocks 0, 1, 2, 3 ≤ 114)
6	—	—	7 MBs with 64 bytes (total number of MBs in blocks 0, 1, 2, 3 ≤ 107)
7	—	—	7 MBs with 64 bytes (total number of MBs in blocks 0, 1, 2, 3 ≤ 100)

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks 0, 1, 2, and 3, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Block2 to 32 bytes and Block3 to 64 bytes, suppose also MCR[MAXMB] is configured to 95. Then the following table indicates how the message buffers will be arranged in RAM.

Table 354. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31
1	FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52
2	FDCTRL[MBDSR2]=10, 32 bytes payload	12	53 to 64
3	FDCTRL[MBDSR3]=11, 64 bytes payload	7	65 to 71
4	64 bytes payload	7	72 to 78
5	64 bytes payload	7	79 to 85
6	64 bytes payload	7	85 to 92
7	64 bytes payload	3	93 to 95

50.4.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

50.4.6 Legacy Rx FIFO structure

When MCR[RFEN] is set, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy Rx FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy Rx FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy Rx FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy Rx FIFO data structure.

Table 360. Legacy Rx FIFO structure

	31 28	24 23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT		SRR	IDE	RTR	DLC	TIME STAMP	
84h		ID standard				ID extended		
88h	Data byte 0		Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved							
E0h	ID filter table element 0							
E4h	ID filter table element 1							
E8h–2D4h	ID filter table elements 2 to 125							
2D8h	ID filter table element 126							
2DCh	ID filter table element 127							
		= Unimplemented or reserved						

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Legacy Rx FIFO for more information.

Table 361. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std/ext = 31–24)		RXIDC_1 (std/ext = 23–16)		RXIDC_2 (std/ext = 15–8)		RXIDC_3 (std/ext = 7–0)		
	= Unimplemented or Reserved								

RTR — Remote frame

This bit specifies if remote frames are accepted into the Legacy FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

IDE — Extended frame

Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx frame identifier (Format C)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

IDHIT — Identifier acceptance filter hit indicator

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Legacy Rx FIFO. See Legacy Rx FIFO for more information.

50.4.7 Enhanced Rx FIFO structure

When ERFCR[ERFEN] is set, the Enhanced Rx FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced Rx FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The following table shows the Enhanced Rx FIFO data structure.

Table 362. Enhanced RX FIFO Structure

	31	30	29	28 ... 24	23	22	21	20	19	18	17	16	15 ... 8	7	6 ... 0
2000h	EDL	BRS	ESI	RESERVED		SRR	IDE	RTR	DLC				TIME STAMP LEGACY		
2004h	RESERVED			ID (STANDARD/EXTENDED)									ID (EXTENDED)		
2008h	Data byte 0					Data byte 1							Data byte 2		Data byte 3
200Ch	Data byte 4					Data byte 5							Data byte 6		Data byte 7

15	2048h	204Ch

EDL — Extended Data Length

This bit distinguishes between classical CAN format and CAN FD format frames.

0 – Classical CAN frame format

1 – CAN FD frame format

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

0 – Bit rate is not switched in a CAN FD frame

1 – Bit rate is switched in a CAN FD frame

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive. This bit is meaningful only if EDL = 1.

0 – Transmitting node is error active

1 – Transmitting node is error passive

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

0 – Frame format is standard

1 – Frame format is extended

RTR — Remote Frame

0 = Indicates the current frame is a data frame

1 = Indicates the current frame is remote request

DLC — Data Length Code

This 4-bit field defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. Refer to Table 352 for more details.

LEGACY TIME STAMP — 16-bit Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured during the CAN frame. See Table 351 to find more details about legacy time stamp operation.

ID — Frame Identifier

In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be stored in the data field.

IDHIT — Identifier Acceptance Filter Hit Indicator

This field indicates which Enhanced Rx FIFO Filter Element (ERFFELn) was hit by the received message that is in the output of the Enhanced Rx FIFO. For each filter region, standard-ID filter space and extended-ID filter space, there is an independent index starting from zero. Table 364 shows how IDHIT is written by FlexCAN according to each filter element.

Table 364. IDHIT for Enhanced Rx FIFO

Enhanced Rx FIFO filter element — ERFFEL	ID HIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m–1)	m–1	Extended-ID
ERFFEL(m)	0	Standard-ID

Table continues on the next page...

Table 364. IDHIT for Enhanced Rx FIFO (continued)

Enhanced Rx FIFO filter element — ERFFEL	ID HIT value	Filter element type
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n–m+1)	2x(n–m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist, and if NEXIF > NFE, then only extended-ID filter elements exist.

HR TIME STAMP — High-resolution Time Stamp

32-bit time base captured during the CAN frame. When CTRL2[TSTAMPCAP] is different from zero, a 32-bit time base is captured from a dedicated on-chip timer which operates in free running mode. See TSTAMPCAP field description in Control 2 register (CTRL2) to find more details about capture point configuration of the high-resolution time stamp.

50.5 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed of a set of message buffers (MB) that store configuration and control data, time stamp, message ID, and data (see Message buffer structure).

For Classical CAN frames, simultaneous reception through Legacy FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes and Enhanced Rx FIFO. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A message buffer is said to be active at a given time if it can participate in both the matching and arbitration processes. An Rx MB with a 0b code is inactive (see Table 349). Similarly, a Tx MB with a 1000b or 1001b code is also inactive (see Table 350).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The message buffers are sized to adequately store the quantity of data bytes selected by the FDCTRL[MBDSRn] fields. The quantity of FD MBs available for a given quantity of data bytes is described in the FDCTRL register. See also FlexCAN memory partition for CAN FD.

50.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001b) to the CODE field of the Control and Status word to request an abort of the transmission.
3. Wait for the corresponding IFLAG bit to be asserted by polling the IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.
4. Read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO_EN]).

7. Write payload data bytes.
8. Configure the Control and Status word with the desired configuration.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] is enabled, also configure the MB_CS[EDL] and MB_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB_CS[ESI] field, see Table 374.[4]
    d. Set Data Length Code in bytes via MB_CS[DLC]. See Table 352 for detailed information.
    e. Activate the message buffer to transmit the CAN frame by setting MB_CS[CODE] to Ch.

NOTE

It is strongly recommended that all the fields in MB_CS word be configured in only one 32-bit write operation to maximize software performance. If the fields are configured in separate writes, the MB_CS[CODE] must be the last write in the C/S word.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant CCh pattern to complete the expected DLC.

At the end of the successful transmission:

- The value of the free running timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CRC and FDCRC registers are updated.
- A status flag is set in the Interrupt Flag register.
- An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The new CODE field after transmission depends on the code that was used to activate the MB (see Table 349 and Table 350 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

NOTE

If backwards compatibility is desired (MCR[AEN] is negated), write the INACTIVE code (1000b) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see Mailbox inactivation).

50.5.2 Arbitration process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the value of CTRL2[TASD].
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.

[4] The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB_CS[ESI] bit according to the error status of the node which sent the message.

- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is a CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the Intermission field, the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the settings of both CTRL1[LBUF] and MCR[LPRIOEN].

50.5.2.1 Lowest-number mailbox first

If CTRL1[LBUF] is asserted, the first (lowest number) active Tx mailbox found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is asserted.

50.5.2.2 Highest-priority mailbox first

If CTRL1[LBUF] is negated, then the arbitration process searches the active Tx mailbox with the highest priority, which means that this mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the MCR[LPRIOEN] setting.

50.5.2.2.1 Local priority disabled

If MCR[LPRIOEN] is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the local priority is disabled.

Table 365. Composition of the arbitration value when local priority is disabled

Format	Mailbox arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

50.5.2.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be asserted. In this case the mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 366. Composition of the arbitration value when local priority is enabled

Format	Mailbox arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)

Table continues on the next page...

Table 366. Composition of the arbitration value when local priority is enabled (continued)

Format	Mailbox arbitration value (35 bits)					
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values regardless of the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

50.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if MCR[AEN] is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU.
- FlexCAN enters Freeze mode or Bus Off.
- FlexCAN loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process, and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case the first and second C/S write in Bus Idle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in Wait For Bus Idle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during Bus Idle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If there is a re-synchronization during Wait For Bus Idle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found if lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or overload flag in the bus.
- Low Power or Freeze mode request in Idle state.

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated a Rx code to Tx code.
- Entering Bus Off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

50.5.3 Receive process

To be able to receive CAN frames into a mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx) inactivate the mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word into the mailbox.
3. Write the EMPTY code (0100b) to the CODE field of the Control and Status word to activate the mailbox. No setup is required for EDL, BRS, and ESI bits—they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (see Move-in) as follows:

1. The received data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 349 and Table 350 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU to service (read) the frame received in a mailbox is by the following procedure:

1. Read the Control and Status word of that mailbox.
2. Check if the BUSY bit is deasserted, indicating that the mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the mailbox. After the mailbox is locked, its contents won't be modified by FlexCAN move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the free running timer to unlock the mailbox.

The CPU should poll for frame reception by the status flag bit for the specific mailbox in one of the IFLAG registers and not by the CODE field of that mailbox. Polling the CODE field does not work because after a frame is received and the CPU services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 349. If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

CAUTION

In summary: never do polling by reading directly the C/S word of the mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching mailbox, thus the contents of the ID field in a mailbox may change if the match was due to masking. When MCR[SRXDIS] is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when MCR[SRXDIS] is deasserted, FlexCAN can receive frames transmitted by itself if a matching Rx mailbox exists.

When MCR[DMA] is asserted, upon receiving a frame in Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy Rx FIFO under DMA operation). The IMASK1 bits in Legacy Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

50.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. . The matching starts from the lowest number message buffer toward the higher ones.

For enhanced Rx FIFO see Enhanced Rx FIFO.

For legacy Rx FIFO see Legacy Rx FIFO.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in one of the mailboxes, the contents of the Rx SMB are transferred to to the matched mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the matched mailbox at the end of reception.

The matching process scans all matching elements of the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 367. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	—	cmp	no_cmp	cmp	RANSWER

Table continues on the next page...

Table 367. Matching architecture (continued)

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN

1. For mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For Legacy Rx FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.

NOTE

For Enhanced Rx FIFO, see Enhanced Rx FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed.

The scan order for mailboxes is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by MCR[IRMQ]. If it is negated, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched mailbox;
2. the last non free-to-receive matched mailbox.

If a non-safe mailbox inactivation (see Mailbox inactivation) occurs during matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted—it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that IRMQ is enabled, there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per MB (see the description of Rx Individual Mask registers (RXIMR0 - RXIMR127)). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXMGMASK, RX14MASK, and RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR register is negated.

50.5.5 Move process

There are two types of move process: move-in and move-out.

50.5.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox that has matched it. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has either reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB.
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB.
- There is no ongoing matching process.
- The destination mailbox is not locked by the CPU.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in process is to be started at the same time, both are performed and the newest substitutes for the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and self-reception is disabled (MCR[SRXDIS] is asserted).
- Any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It stays on hold, only waiting for Freeze and Low-Power mode to be exited and the module to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Read all data words from the Rx SMB in accordance with the selected payload size for the Rx storage element.
2. Write all data words to the Rx mailbox in accordance with the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
3. Read the Control/Status and ID words from the Rx SMB.
4. Write Control/Status and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination mailbox (see Mailbox inactivation). In this case the mailbox may remain partially updated, thus incoherent.

The BUSY Bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the CPU that the message buffer content is temporarily incoherent.

50.5.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

50.5.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

50.5.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abort of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be asserted.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

- The MB is transmitted correctly.
- The interrupt flag is set in the IFLAG register.
- An interrupt to the CPU is generated (if enabled).

The abort request is automatically cleared when the interrupt flag is set. On the other hand, if only one of the above conditions is reached, the frame is not transmitted; therefore:

- The abort code is written into the CODE field.
- The interrupt flag is set in the IFLAG.
- An interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU only needs to read the abort code to make sure the active MB was safely inactivated. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

50.5.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission mailboxes must be performed just when MCR[AEN] is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a mailbox.

To inactivate a mailbox, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you will not be able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

In order to perform a safe inactivation and avoid the above consequences for Tx mailboxes, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the mailbox (see Mailbox lock mechanism).

50.5.6.3 Mailbox lock mechanism

Other than mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the free running timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that have a code different than INACTIVE (0b) or EMPTY[1] (0100b). Also, Tx MBs cannot be locked.

Suppose, for example, that the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no free-to-receive MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

NOTE

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB.

[1] In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

An MB is unlocked when the CPU reads the Free Running Timer Register (see Free Running Timer (TIMER)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module returns to Normal or Freeze modes.

50.5.7 Enhanced Rx FIFO

FlexCAN supports an enhanced Rx FIFO engine which can store up to 32 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO which should be read by the CPU. The enhanced Rx FIFO is enabled by setting EFRCR[ERFEN]. Although FlexCAN has two FIFO options, Legacy Rx FIFO and Enhanced Rx FIFO, they cannot be enabled at the same time. Refer to Legacy Rx FIFO to find detailed information about Legacy Rx FIFO.

The enhanced Rx FIFO has a watermark which is configured by setting EFRCR[ERFWM]. If EFRCR[ERFWM] is set, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in EFRCR[ERFWM], ERFSR[ERFWMI] is set by the hardware. Optionally, an interrupt or a DMA transfer can be triggered if MCR[DMA] or ERFIER[ERFWMIIE] are set, respectively.

For the Enhanced Rx FIFO to receive, the CPU must execute the configuration procedure below. The same procedure must be done if the CPU needs to change any of the configuration of the Enhanced RX FIFO.

1. Enter Freeze mode.
2. Enable Enhanced Rx FIFO by setting ERFCR[ERFEN], if it is not already enabled.[5]
3. Write one to ERFSR[ERFCLR] to reset Enhanced Rx FIFO engine.
4. Clear EFRSR[ERFUFW], EFRSR[ERFOVF], EFRSR[ERFWMI], and EFRSR[ERFDA], if they are set.
5. Write EFRCR[NFE] to configure the total number of enhanced Rx FIFO filter elements to be used in Enhanced Rx FIFO reception.
6. Write ERFCR[NEXIF] to configure the number of extended ID and standard ID filter elements to be used in Enhanced Rx FIFO reception.[6]
7. Configure the Enhanced Rx FIFO watermark by writing ERFCR[ERFWM].
8. If interrupts will be used, set the interrupt enables in the ERIER register.
9. If DMA will be used, set MCR[DMA] to enable DMA operation and write ERFCR[DMALW] to configure the number of words to transfer for each Enhanced Rx FIFO data element.
10. Configure the filter elements by writing in the ERFFEL*n* registers.[7]
11. Leave Freeze mode.

There are two types of Enhanced Rx FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter element and standard-ID filter element. Each extended-ID filter element is stored in two ERFFEL*n* registers while each standard-ID filter element is stored in one ERFFEL*n* register. The total number of Enhanced RX FIFO filter elements is defined by ERFCR[NFE].

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. The figure below shows how the Enhanced Rx filter elements are defined. Detailed information about the Enhanced Rx FIFO matching process and filter element formats can be found in Enhanced Rx FIFO matching process.

[5] MCR[RFEN] must be cleared so that Enhanced Rx FIFO is enabled.
[6] NEXIF ≤ NFE + 1.
[7] ERFFEL*n* registers are implemented in RAM; thus they must be explicitly initialized prior to any reception.

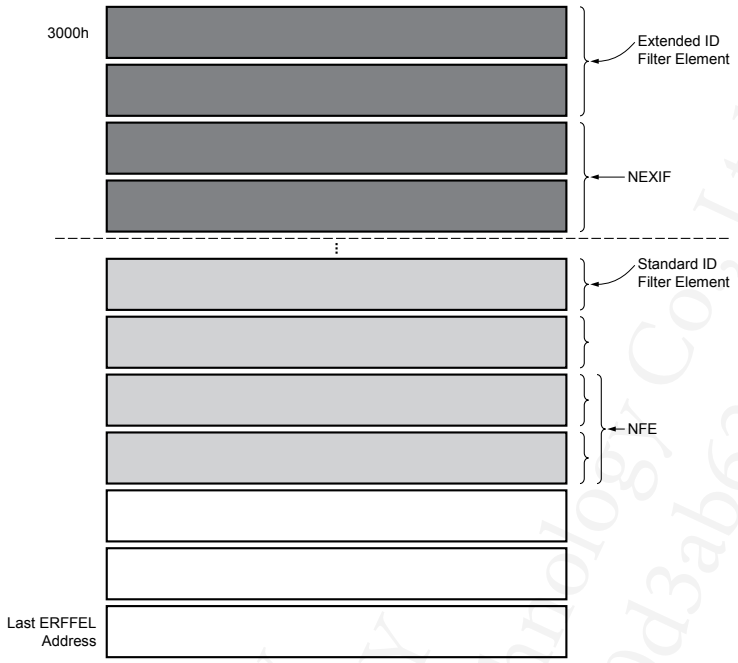

Figure 433. Number of enhanced Rx FIFO filter elemets

50.5.7.1 Enhanced Rx FIFO matching process

When ERFCR[ERFEN] is enabled, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, then the CAN message content is transfered to the enhanced RX FIFO memory.

NOTE

If multiple filters match the incoming message ID, then the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. The matching criteria are defined by ERFFEL*n*[FSCH] in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] =0) for each bit *n* from 0 to 10
  3. (RTR = RTR Filter) or (RTR MASK = 0)

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in this table.

Table 368. Standard ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	27	26										16	15			12	11	10										0
FSCH=b00		Reserved		RTR filter	STD ID filter											Reserved				RTR mask	STD ID mask										

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)

2. ID ≥ STD ID Filter1
3. ID ≤ STD ID Filter2
4. (RTR = RTR filter) or (RTR MASK = 0)

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in this table.

Table 369. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b01		Reserved		RTRfilter	STD ID Filter2		Reserved		RTR mask	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2)

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in this table.

Table 370. Standard ID filter element with 2-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. The matching criteria are defined by ERFFEL*n*[FSCH] in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] =0) for each bit *n* from 0 to 28
  3. (RTR = RTR Filter) or (RTR MASK = 0)

If FSCH = b00, the filters and masks are defined as shown in this table.

Table 371. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR filter	EXT ID filter	
Reserved		RTR mask	EXT ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. ID ≥ EXT ID Filter1

3. ID ≤ EXT ID Filter2
4. (RTR = RTR Filter) or (RTR MASK = 0)

If FSCH = b01, the filters and masks are defined as shown in this table.

Table 372. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR filter	EXT ID Filter2	
Reserved		RTR mask	EXT ID filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2)

If FSCH = b10, the filters and masks are defined as shown in this table.

Table 373. Extended ID filter element with 2-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID filter 1	

50.5.7.2 Enhanced Rx FIFO under DMA operation

The DMA feature is enabled by asserting both ERF[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the Enhanced FIFO output port at the address range defined in Enhanced Rx FIFO structure.

The CPU should not access the Enhanced FIFO output port address range during DMA operation, so that the FIFO engine operates properly. Before enabling MCR[DMA], the CPU must service Enhanced Rx FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must first clear the ERFUFW, ERFOVF, ERMWMI, and ERFDA fields in the ERFSR register, and then clear the Enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

ERFSR[ERFDA] is set by the hardware when there is at least one frame available to be read from the Enhanced Rx FIFO, and ERFSR[ERFWMI] is set by the hardware when the number of frames stored in the FIFO is greater than the watermark defined by ERFCR[ERFWM]. A DMA request is generated when ERFSR[ERFWMI] is set. Upon receiving the request, the DMA controller can read the message in the Enhanced Rx FIFO output. The DMA controller must perform the number of read loops in the FIFO output defined by ERFCR[ERFWM]. Also, each message reading process must end by the address defined in ERFCR[DMALW].

The following rules must be obeyed for Enhanced Rx FIFO DMA operation:

- Because a DMA transfer cannot be dynamically changed, ERFCR[DMALW] should be programmed so that the Enhanced Rx FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 352.

Each time one message is read from FIFO by the DMA controller, ERFSR[ERFDA] is cleared by FlexCAN and set again if there is at least one message stored in the FIFO. Moreover, ERFSR[ERFWMI] is cleared by the hardware when the messages are read in the FIFO output, and set again if the number of messages in the FIFO is greater than the value defined by ERFCR[ERFWM].

For example, suppose that the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution time stamp is enabled. In that case the last Enhanced RX FIFO address offset can be found in Table 362 and Table 363. Using this address offset, ERFCR[DMALW] can be determined like this:

- Maximum number of data bytes = 8
- HR TIME STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

50.5.7.3 Enhanced Rx FIFO clear operation

When ERFCR[ERFEN] is set, the CPU can clear the Enhanced Rx FIFO by writing one into ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers although the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the ERFUFW, ERFOVF, ERFDA, and ERFWMI fields in EFRSR. Consequently the CPU must service all these fields before executing the clear FIFO task.

50.5.8 Legacy Rx FIFO

The Legacy Rx FIFO is receive-only and is enabled by asserting MCR[RFEN]. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the Legacy FIFO feature.

CAUTION

Legacy Rx FIFO must not be enabled when CAN FD feature is enabled.

The Legacy FIFO is 6-message deep. The memory region occupied by the Legacy FIFO structure (both message buffers and Legacy FIFO engine) is described in Legacy Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the Legacy FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and the RXFIR register, and then clear the interrupt. If there are more messages in the Legacy FIFO the act of clearing the interrupt updates the output of the Legacy FIFO with the next message and updates RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the Legacy FIFO is valid only while IFLAG1[BUF5I] is asserted.

IFLAG1[BUF6I] (Legacy Rx FIFO Warning) is asserted when the number of unread messages within the Legacy Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Legacy Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

IFLAG1[BUF7I] (Legacy Rx FIFO Overflow) is asserted when an incoming message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Legacy Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy Rx FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read in the IDHIT field from C/S word, as shown in the Legacy Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the RXFIR register. RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO and is valid while the IFLAG1[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the Legacy FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If MCR[IRMQ] is negated, then the Legacy Rx FIFO filter table is affected by RXFGMASK.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 336.

50.5.8.1 Legacy Rx FIFO under DMA operation

The receive-only Legacy FIFO can support DMA. This feature is enabled by asserting both MCR[RFEN] and MCR[DMA]. The reset value of MCR[DMA] is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port at the 80h–8Ch address range.

When MCR[DMA] is asserted the CPU must not access the Legacy FIFO output port address range. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. Consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch, which clears IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 336.

50.5.8.2 Clear Legacy FIFO operation

When MCR[RFEN] is asserted, the clear Legacy FIFO operation is a feature used to empty Legacy FIFO contents. With MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes one in IFLAG1[BUF0I]. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently the CPU must service all FIFO IFLAGs before executing the clear FIFO task.

When Legacy Rx FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION

Clear Legacy FIFO operation does not clear IFLAGs, except when MCR[DMA] is asserted; in this case only IFLAG1[BUF5I] is cleared.

50.5.9 CAN protocol related features

This section describes the CAN protocol related features.

50.5.9.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CTRL2 register.

50.5.9.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When an FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

Provided under NXP SLA License
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b7...

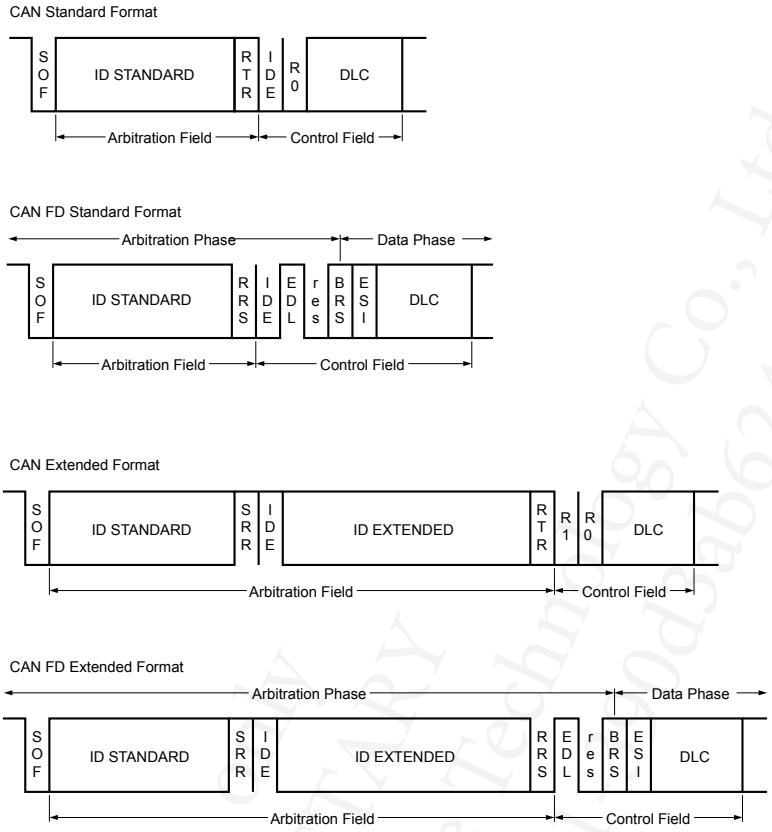

Figure 434. CAN message formats

The ability to receive and transmit CAN FD messages is enabled by MCR[FDEN]. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, and a Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance with the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission returns to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CBT register (also by CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the FDCBT register.

NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

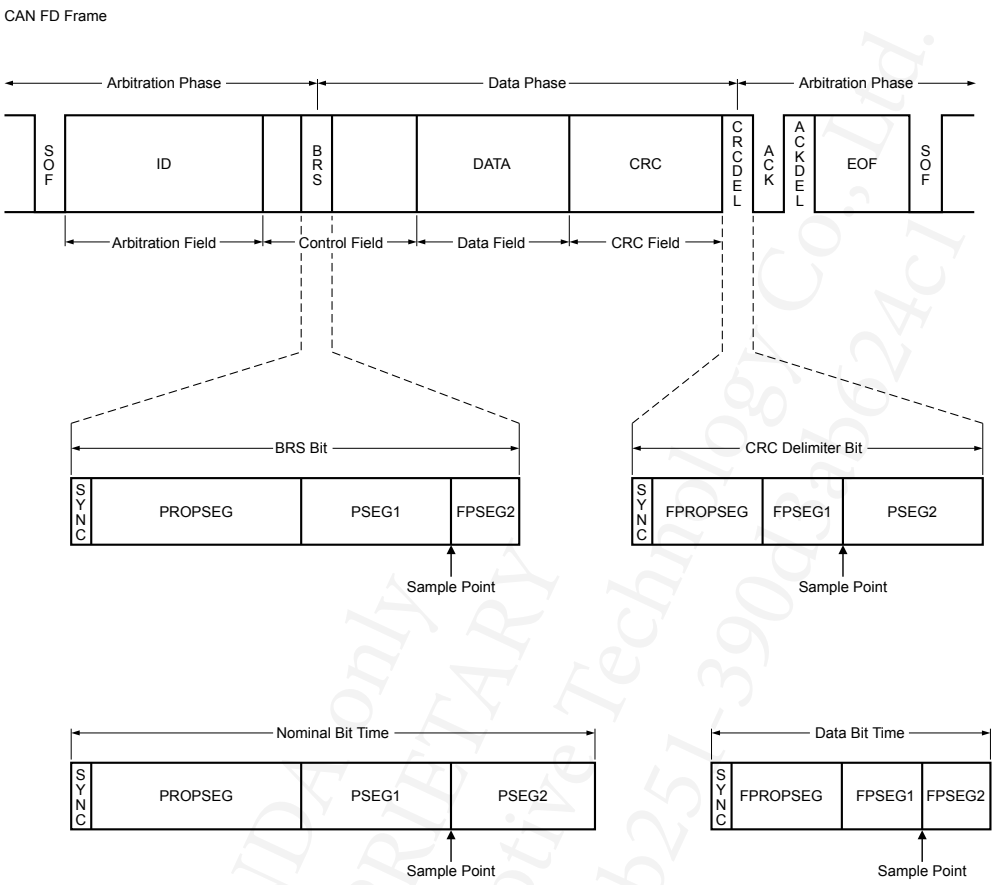

Figure 435. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE subblock. For example, with a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.[8]

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

[8] The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.

Table 374. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit Of Tx MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indiscriminately. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR, and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CTRL1[ERRMSK] is asserted. The ESR1 register has additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST, and STFERR_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag.

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a hard synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

50.5.9.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase

can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by FDCTRL[TDCEN] or ETDC[ETDCEN] and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the transceiver delay compensation mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF]. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

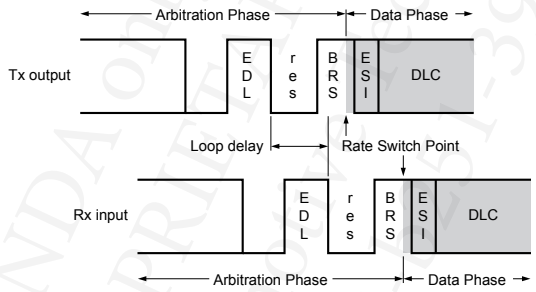

Figure 436. Transceiver loop delay measurement

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF or ETDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF or ETDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

$$\text{Offset} = (\text{FPSEG1} + \text{FPROPSEG} + 2) \times (\text{FPRESDIV} + 1)$$
or
$$\text{Offset} = (\text{DTSEG1} + 2) \times (\text{EDPRESDIV} + 1), \text{ if ETDCEN}$$

The following figure shows the SSP position when these settings are used.

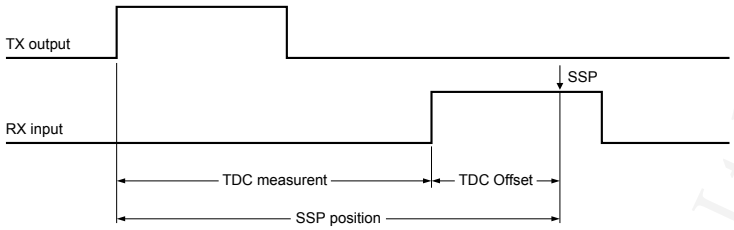

Figure 437. SSP position with optimal values

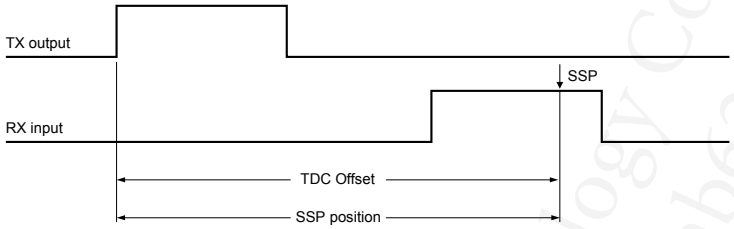

Figure 438. SSP position—TDC measurement disabled by ETDCEN and TDMDIS

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are set, the TDMDIS bit can be set to disable the transceiver delay measurement. In this case, the SSP position is defined only by the ETDCOFF field. Figure 438 shows the secondary sample point position when the transceiver delay measurement is disabled.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times – 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set to indicate when the transceiver delay compensation mechanism is out of range, unable to compensate the transceiver loop delay.

50.5.9.4 Remote frames

A remote frame is a special kind of frame. You can program a mailbox to be a remote request frame by configuring the mailbox as Transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in four ways, depending on remote request storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]):

- If RRS is negated the frame's ID is compared to the IDs of the transmit message buffers with the CODE field 1010b. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0100b, 0010b, or 0110b. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the Legacy FIFO and presented to the

CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered as normal frames, and generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.

- If ERFEN is set, FlexCAN will not generate an automatic response for remote request frames that match the Enhanced Rx FIFO filtering criteria. Remote Request Frames are considered normal frames, and generate an Enhanced Rx FIFO overflow when a sucessful reception occurs and Enhanced Rx FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

50.5.9.5 Overload frames

FlexCAN does transmit overload frames when the following conditions are detected on the CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

50.5.9.6 Message buffer time stamp

The value of the free running timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of move-in in the TIME STAMP field of message buffer, providing network behavior with respect to time.

When CTRL2[TIMER_SRC] is asserted, the free running timer is continuously clocked by an external time tick.

When CTRL2[TIMER_SRC] is negated, the free running timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free running timer is not incremented during Disable and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 register (CTRL1).

Alternatively, by configuring the MTSBASE field of the Control 2 register (CTRL2), the time stamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter.

50.5.9.7 High resolution time stamp

The high-resolution time stamp, HR_TIME_STAMP, uses a dedicated timer with a 32-bit counter operating in free running mode. The high-resolution time stamp is enabled by the TSTAMPCAP field of the Control 2 register (CTRL2). When this field is not zero , the dedicated 32-bit counter value is captured during a valid CAN frame and stored in the HR_TIME_STAMP register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit time stamp associated with message buffer 0, HR_TIME_STAMP1 stores the 32-bit time stamp associated with message buffer 1, and so on.

The counter value is captured according to the TSTAMPCAP field of the Control 2 register (CTRL2). For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception. For CAN FD frames, the capture points can be the start of frame, the point in time a CAN FD frame is considered valid, or the res bit of a CAN FD frame.

The 16-bit time stamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE].

50.5.9.8 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

Please see the clock distribution chapter (module clocks table) to identify the proper clock source.

Figure 439. CAN engine clocking scheme

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The Control 1 register (CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

The CAN Bit Timing register (CBT) extends the range of the CAN bit timing variables in CTRL1. The CAN FD Bit Timing register (FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

The Enhanced Nominal CAN bit timing register (ENCBT) extends the range of CAN bit timing variables in CBT. The Enhanced Data Phase CAN bit timing register (EDCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, the bit timing nominal and data phase serial clock (Sclock) dividers must be programed in the Enhanced CAN Bit Timing Prescalers register (EPRS).

NOTE

When the CAN FD feature is enabled, always set CBT[BTF] or CTRL2[BTE] and configure the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing register (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

The PRESDIV field (as well as its extended range EPRESDIV (or ENPRESDIV) and FDPRESDIV (or EDPRESDIV) for the data phase bits of CAN FD messages) defines the prescaler value (see the equation below) that generates the serial clock (Sclock), whose period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

$$\text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) * Tq$$

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

A bit time is subdivided into three segments[1] (see Figure 441, Figure 442 and Table 375):

[1] For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

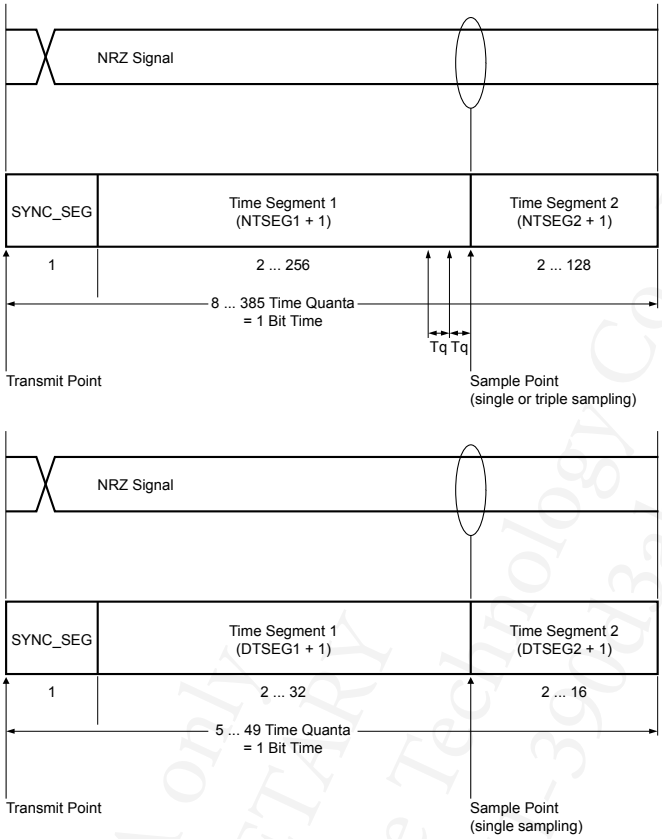

Figure 440. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting CTRL1[PROPSEG] and CTRL1[PSEG1] so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CBT[BTF] is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.

  If CTRL2[BTE] is set, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 in the range of 2 to 256 time quanta. For the data phase in CAN FD messages with BRS set, EDCBT[DTSEG1] must be used for configuring time segment 1 in the range of 2 to 32 time quanta.
- Time Segment 2: This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting CTRL1[PSEG2] (plus 1) to be 2 to 8 time quanta long. When CBT[BTF] is asserted, FlexCAN uses EPSEG2 fields of CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

  If CTRL2[BTE] is set, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 in the range of 2 to 128 time quanta. For the data phase in CAN FD messages with BRS set, EDCBT[DTSEG2] must be used for configuring time segment 2 in the range of 2 to 16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

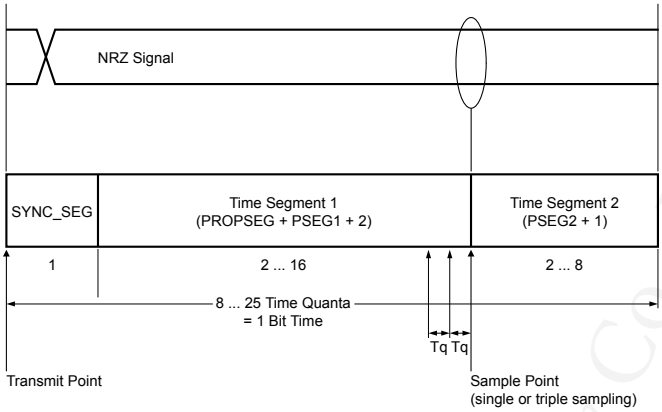

Figure 441. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

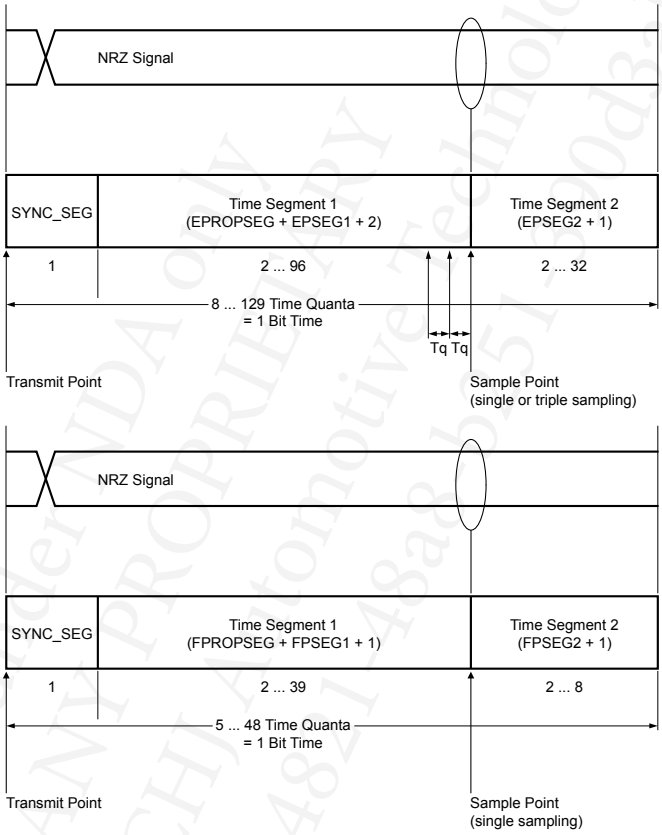

Figure 442. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 375. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.

Table continues on the next page...

Table 375. Time segment syntax (continued)

Syntax	Description
TSEG2	Corresponds to the PSEG2 value.
Transmit point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 376. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 439), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value in CTRL1[PSEG1] field.
- PSEG2 is the value in CTRL1[PSEG2] field.

- PROPSEG is the value in CTRL1[PROPSEG] field.
- PRESDIV is the value in CTRL1[PRESDIV] field.
- ENPRESDIV is the value in EPRS[ENPRESDIV] field.
- NTSEG1 is the value in ENCBT[NTSEG1] field.
- NTSEG2 is the value in ENCBT[NTSEG2] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) or the Enhanced Nominal CAN bit timing (ENCBT) register and also to the CAN FD Bit Timing register (FDCBT) or the Enhanced Nominal CAN bit timing register(ENCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

50.5.9.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

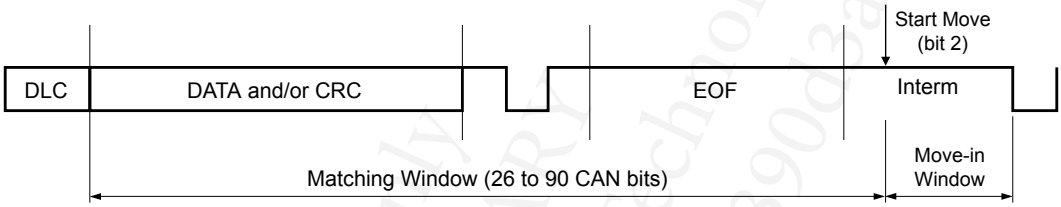

Figure 443. Matching and move-in time windows

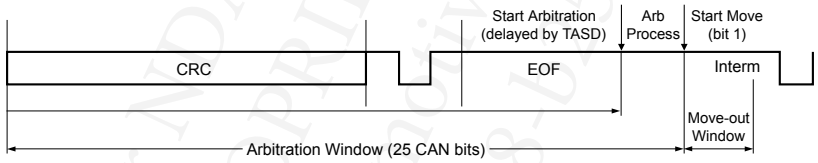

Figure 444. Arbitration and move-out time windows

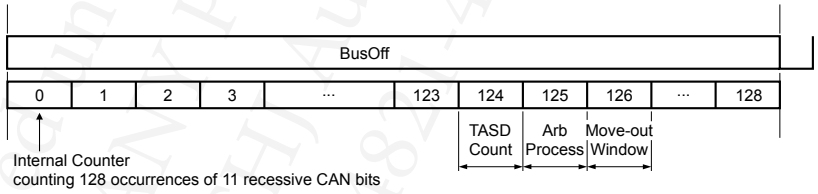

Figure 445. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

50.5.9.10 Tx arbitration start delay

CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

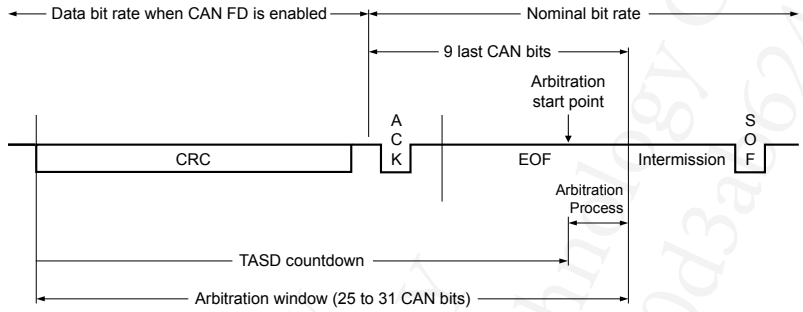

Figure 446. Optimal Tx Arbitration start point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and $(MAXMB + 1) \leq NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and $(MAXMB + 1) > NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

- MAXMB is the value in CTRL1[MAXMB].
- NMB_{END} is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].
- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] is set, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Provided by IHS Markit
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8462e5-4821-48a2-8251-39003b624c1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 377. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0
100	22	8.0
128	21	3.6

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 378. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6
128	18	1.05

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

54	22	4.0
64	21	3.33
96	20	1.54
128	18	1.05

50.5.10 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.

Table 380. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of mailboxes	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
128	0	0	49
16	1	0	16
32	1	0	17

Table continues on the next page...

Table 380. Minimum number of peripheral clocks per CAN bit for Classical CAN format (continued)

Number of mailboxes	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
64	1	0	30
96	1	0	42
128	1	0	54
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42
128	0	1	55

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT) or Enhanced Nominal CAN bit timing register (ENCBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{SYS}}{f_{CANCLK}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{SYS}}{\text{NomBitRate}}$$

where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CBT register or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 381. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29

Table continues on the next page...

Table 381. Number of fast CAN bits in a CAN FD frame (continued)

Minimum number of data bytes	DLC field	NumOfFastBits
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in ERFCR register.

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBit_A, MinNumClkFastBit_B\ )$$

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

2. The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, and Enhanced Rx FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

$$MinNumClkFastBit = Maximum\ (5.06, 6.75) = 6.75$$

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

Table 382. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced Rx FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667

Table continues on the next page...

Table 382. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced Rx FIFO disabled (continued)

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

50.5.11 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

50.5.11.1 Freeze mode

This mode is requested either by the CPU through the assertion of MCR[HALT] or when the chip is put into Debug mode. In both cases it is also necessary that MCR[FRZ] be asserted and the module not be in a low-power mode. This mode is also requested by FlexCAN through the automatic assertion of both MCR[HALT] and MCR[FRZ] when MECR[NCEFAFRZ] is set and a non-correctable error is detected in a memory read access performed by FlexCAN internal processes (see Response to errors).

The acknowledgement is obtained through the assertion by the FlexCAN of MECR[FRZ_ACK]. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off, or Idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the Error Counters register, which is read-only in other modes.
- Sets MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, the user must wait for MCR[FRZ_ACK] to be asserted before executing any other action; otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory-mapped registers are accessible.

Exiting Freeze mode is done in one of the following ways:

- CPU negates MCR[FRZ].
- The chip is removed from Debug mode and/or the HALT bit is negated.

MCR[FRZ_ACK] is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

50.5.11.2 Module Disable mode

This low-power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of MCR[MDIS], and the acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register,. The message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Disable mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

50.5.12 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

NOTE

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Legacy Rx FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "Legacy FIFO Overflow" flag; bit 6 becomes the "Legacy FIFO Warning" flag, bit 5 becomes the "Frames Available in Legacy FIFO" flag and bits 4-0 are unused. See the description of Interrupt Flags 1 register (IFLAG1) for more information.

If both Legacy Rx FIFO and DMA are enabled (MCR[RFEN] and MCR[DMA] = 1) the FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in Legacy FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register.

50.5.13 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
    1. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
    2. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0h, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0080h, and the space 0080h–008Fh is used by the one MB. The memory space 0090h–017Fh is available. The space 0180h–087Fh is reserved. The space 0880h–0883h is used by the one individual mask and the available memory in the mask registers space would be 0884h–08BFh. From 08C0h–09DFh there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.
    3. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

50.5.14 Detection and correction of memory errors

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, ranging from 080h–ADFh and from C20h–31FFh. The RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK registers need to be initialized as well. MCR[RFEN] and ERF[ERFEN] must not be set during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to five parity bits that ensure a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in two bits can be detected but not corrected (non-correctable errors). Errors in more than two bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

FlexCAN detects a noncorrectable error in the event either an all-zeros or an all-ones read occurs. See description of Error Report Syndrome register (RERRSYNR).

Memory errors are indicated to the host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address register (RERRAR), Error Report Data register (RERRDR) and Error Report Syndrome register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by MECR[ECCDIS]. When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated with the data.

To avoid accidentally changing the critical error correction configuration, this protocol must be followed to enable the update of the Memory Error Control register (MECR):

1. By default, CTRL2[ECRWRE] is zero and MECR[ECRWRDIS] is one.
2. Set CTRL2[ECRWRE].
3. Clear MECR[ECRWRDIS].
4. All writes to Memory Error Control register (MECR) must keep MECR[ECRWRDIS] cleared.
5. After configuration is done, lock the Memory Error Control register (MECR) by either setting MECR[ECRWRDIS] or clearing CTRL2[ECRWRE].

50.5.14.1 Sources of the memory access

The FlexCAN memory can be accessed by two major sources (or requestors):

- Host (CPU): the largest word accessed is 32-bit.
- FlexCAN internal processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): the largest word accessed is 64-bit.

The way that noncorrectable errors are indicated and reported depends on the source of access.

50.5.14.2 Error indication

Memory errors are indicated by flags HANCEIF, FANCEIF, and CEIF in the Error Status Register (ERRSR). Noncorrectable errors detected in memory reads requested by the host are indicated separately than the ones detected in requests by FlexCAN internal processes. FlexCAN makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases. If both noncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

A noncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked.

Each indication flag has one overrun flag in Error Status Register (ERRSR). The overrun flags do not request interrupts. Overrun flags for noncorrectable errors indicate that other errors of the same nature were detected after current error being treated; overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

This is the recommended handling sequence for error indication:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the HANCEIF, FANCEIF, and CEIF flags.

4. If the overrun flag is active:
    a. Alert application that at least one error could not be managed.
    b. Clear the overrun flag.

The FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words the interrupt and overrun flags are set simultaneously.

50.5.14.3 Error reporting

The report registers Error Report Address register (RERRAR), Error Report Data register (RERRDR), and Error Report Syndrome register (RERRSYNR) provide detailed information about the address read, raw data, and syndrome read with error, and are indicated by the flags described in Error indication. The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If either of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error; or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32-bit follows the rules described in Error indication and in the description of Error Report Address register (RERRAR).

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address register (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs, such as the Legacy Rx FIFO Structure, Enhanced RX FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by setting MECR[RERRDIS] before reading the report registers.

50.5.14.4 Response to errors

Correctable errors have no consequence on FlexCAN operation because affected data is corrected before its use by the host or FlexCAN internal processes.

For host-initiated reads, a noncorrectable error may affect the host, but does not affect FlexCAN operation.

Non-correctable errors detected on memory reads requested by the FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in processes), when a noncorrectable error occurs, an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters in Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. When MECR[NCEFAFRZ] is negated, FlexCAN continues working and a corrupted frame is received.
- During arbitration process, when a noncorrectable error occurs, either a non-highest priority Tx message buffer may be mistakenly selected for transmission or its data may be corrupted. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. When MECR[NCEFAFRZ] is negated, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out process, when a noncorrectable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] is negated, the corrupted frame is transferred from the Tx SMB to the Protocol Engine (PE) sub-block and is transmitted on the CAN bus.

- A noncorrectable error can also be detected beyond the move-out process, when Tx data is read from Tx SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus.

  To prevent the frame from being successfully received by the external nodes, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter), and transmits an error flag just after CRC delimiter as a result of self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] is negated, FlexCAN may attempt to re-transmit the same frame, as long as no other higher priority Tx MB is subsequently configured for transmission.

  In the event the noncorrectable error persists, FlexCAN eventually reaches the Bus Off state because of consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] is set and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. The assertion of MECR[NCEFAFRZ] is the only way to prevent corrupted frames from being transmitted on the CAN bus up to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

50.5.14.5 Error injection

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. The relation between the error injection addresses and the respective ones in the module memory map is shown in the description of Error Injection Address register (ERRIAR).

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by the host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, MECR[HAERRIE] and MECR[FAERRIE] must be cleared when configuring the memory injection registers.

50.6 Initialization/application information

This section provides instructions for initializing the FlexCAN module.

50.6.1 FlexCAN initialization sequence

You can reset FlexCAN in the following ways:

1. Chip level hard reset, which resets all memory-mapped registers asynchronously.
2. MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. See Table 338 to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see Freeze mode). The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
    a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
    b. Enable the warning interrupts by setting WRNEN.
    c. If required, disable frame self reception by setting SRXDIS.
    d. Enable the Legacy Rx FIFO by setting RFEN or the Enhanced Rx FIFO by setting ERFEN.
    e. If Legacy Rx FIFO or Enhanced Rx FIFO is enabled and DMA is required, set DMA.
    f. Enable the abort mechanism by setting AEN.
    g. Enable the local priority feature by setting LPRIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
    a. Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, and RJW.
    b. Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, and ERJW.
    c. Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, and FRJW.
    d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
    e. Determine the CAN FD bit rate by programming the FPRESDIV field.
    f. Determine the internal arbitration mode (LBUF).
3. All FlexCAN memory must be initialized if Error Code Correction (ECC) is enabled. See Detection and correction of memory errors.
4. Initialize the message buffers.
    a. The control and status word of all message buffers must be initialized.
    b. If Rx FIFO was enabled, the ID filter table must be initialized.
    c. Other entries in each message buffer should be initialized as required.
5. Initialize the Rx Individual Mask registers (RXIMRn).
6. Set required interrupt mask bits in
    - IMASK registers (for all MB interrupts)
    - CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)
7. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

50.7 Glossary

Active message buffer	A message buffer is *active* if it can participate in the current matching or arbitration process.
Bus interface unit	FlexCAN submodule responsible for the interface to the CPU.
Bus off	See CAN Specification.[76]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[76] and ISO International Standard.[77]

[9] Controller Area Network – CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.

CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[76]
Error frame	See CAN Specification.[76]
Error passive	See CAN Specification.[76]
Form error	See CAN Specification.[76]
Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[76]
Information processing time	See CAN Specification.[76]
Intermission	See CAN Specification.[76]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[76]
Phase buffer segment	See CAN Specification.[76]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[76]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

Chapter 51
Timestamp

51.1 Timestamping and distribution

The CAN Timestamp function enables the distribution of a common timestamp base to all CAN interfaces on the chip, which enables you to temporally correlate frames received across all CAN module instances.

CAN Timestamp supports:

- Multiple timestamp sources, selectable via software:
  - Ethernet PTP timestamp counter (32-bit)
  - PFE PTP Ethernet PTP timestamp counter (32-bit)
  - STM_7 (System Timer Module) counter output (32-bit)
- A timestamp synchronization and distribution submodule

51.2 Block diagram

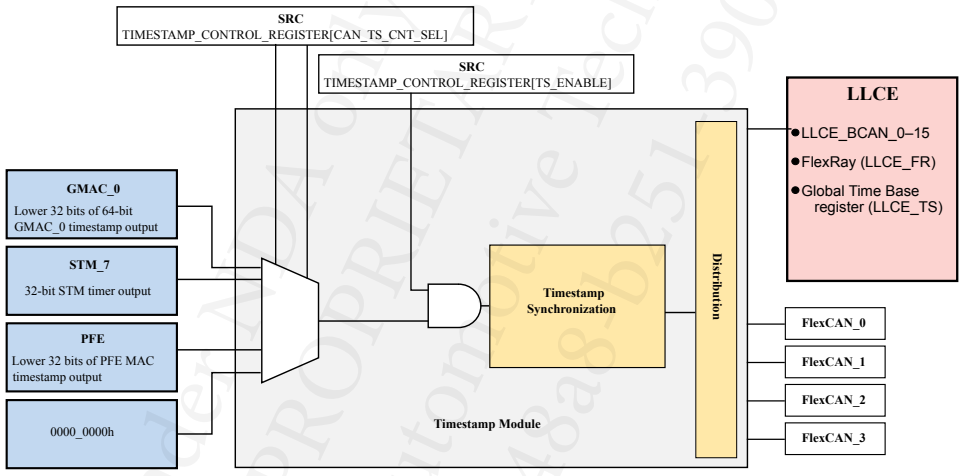

Figure 447. Timestamping connectivity diagram

The block diagram shows:

- Logic that selects the timestamp source
- Timestamping enabling logic

The timestamp logic uses the XBAR_DIV2_CLK 200 MHz clock for the timestamp clock domain to ensure the timestamp value delivered to the CAN modules (timestamp sinks) is:

- As accurate as possible
- Delivered without any missing counts

Refer to the LLCE and CAN chapters for details on how the timestamp value is used.

51.3 Timestamp synchronization controls

Configure and control CAN Timestamp via the Time Stamp Control register (TIME_STAMP_CONTROL_REGISTER) in the SRC module. See the System Resource Controller (SRC) chapter for details.

- Enable timestamp synchronization and distribution via the TS_EN field.
- Select a timestamp counter source via the CAN_TS_CNT_SEL field.

  The following table shows the available timestamp sources:

Table 383. Timestamp source selection

CAN_TS_CNT_SEL value	Timestamp source
00b	Lower 32 bits of the GMAC_0 timestamp output
01b	32-bit STM_7 timer output
10b	Lower 32 bits of the PFE GMAC timestamp output
11b	Reserved. Timestamp value is 0000_0000h

51.4 Application information

Perform the procedures in the following sections when using CAN Timestamp functions.

51.4.1 Enable timestamping

To enable CAN Timestamp:

1. Verify that all blocks related to timestamping are out of reset
2. Verify that you have enabled the required clocks
3. Select the timestamp source by setting the desired value in the SRC module's TIME_STAMP_CONTROL_REGISTER[CAN_TS_CNT_SEL] field. See Table 383.
4. Enable the timestamp synchronization submodule by writing 1 to the SRC module's TIME_STAMP_CONTROL_REGISTER[TS_EN] field.
5. Confiigure and enable the source selected in step 3 to start counting.
6. Enable the timestamp sinks (CAN modules) to send out the timestamp. Refer to the LLCE and CAN chapters for details on how to enable for each module.

51.4.2 Disable timestamping or changing the timestamp source

To disable CAN Timestamp:

1. Disable the timestamp sinks (CAN modules). Refer to the LLCE and CAN chapters for details on how to do this.
2. Disable the timestamp synchronization submodule by writing 0 to the SRC module's TIME_STAMP_CONTROL_REGISTER[TS_EN] field. This effectively pauses the timestamp output from the timestamp synchronization submodule by gating the internal clocks and causing the output timestamp flops to hold their most recent value.
3. You can now change the timestamp source, if desired, by setting the desired value in the SRC module's TIME_STAMP_CONTROL_REGISTER[CAN_TS_CNT_SEL] field. See Table 383.
4. To resume timestamping, see Enable timestamping.

NOTE

When pausing or changing timestamp sources, there is a large jump or change in the timestamp values.

Chapter 52
SerDes Subsystem

52.1 Chip-specific SerDes information

52.1.1 Mapping of SerDes signals to general purpose registers

For supporting configurability before starting of PCIe_CTRLR (PCIexpress Controller) during run mode, a few SerDes signals are mapped to general purpose registers. For debugging process, a few status signals are mapped to general purpose registers. These registers are a part of SerDes_SS register descriptions section of S32SERDESSUBSYSRM.

52.1.2 SerDes subsystem working modes

This chip implements two SerDes instances:

- SerDes_0 starts at 4040_0000.
- SerDes_1 starts at 4410_0000.

Each row below represents a valid configuration for SerDes.

NOTE
On S32G234M, only PCIe_1 and SerDes_1 are supported.

Table 384. SerDes_0 working modes

Mode	PHY lane 0	PHY lane 1	PHY Ref Clock (MHz)
PCIe only	PCIe0_X2	PCIe0_X2	100
PCIe/SGMII	PCIe0_X1	SGMII 1.25 Gbps (GMAC0 or PFE_MAC2)	100
SGMII only	SGMII 1.25 Gbps (GMAC0)	SGMII 1.25 Gbps (PFE_MAC2)	100/125 [1]

1. The SerDes subsystem's default setting is 125 MHz.

Table 385. SerDes_1 working modes

Mode	PHY lane 0	PHY lane 1	PHY Ref Clock (MHz)
PCIe only	PCIe1_X2	PCIe1_X2	100
PCIe/SGMII	PCIe1_X1	SGMII 1.25 Gbps (PFE_MAC0 or PFE_MAC1)	100
SGMII only	SGMII 1.25 Gbps (PFE_MAC0)	SGMII 1.25 Gbps (PFE_MAC1)	100/125 [1]
SGMII only	SGMII 3.125 Gbps (PFE_MAC0)	Not available	125

1. The SerDes subsystem's default setting is 125 MHz.

52.1.3 Resets required for operation

To accomplish this task...	... do this:
Start a functional reset of the chip	In the MC_RGM, write a 1 to RGM_PRST0_0[PERIPH_5_RST].
Start a reset of the SerDes subsystem	In the MC_RGM, write a 1 to RGM_PRST0_0[PERIPH_4_RST].
Finish the functional reset of the chip	In the MC_RGM, write a 0 to RGM_PRST0_0[PERIPH_5_RST].
Finish the reset of the SerDes subsystem	In the MC_RGM, write a 0 to RGM_PRST0_0[PERIPH_4_RST].

52.1.4 Register configuration for SerDes base spec

SerDes base spec electrical limits for 8Gbps operation requires specific reset values to be set for the PE0_GEN_CTRL_3[LTSSM_EN]. Configure them before the SerDes block is enabled through PE0_GEN_CTRL_3[LTSSM_EN]. These registers are described in the SerDes_SS register descriptions section of S32SERDESSUBSYSRM.

52.1.5 Linking up mode0 and SerDes

Here are the steps for linking mode0 to SerDes:

- Lift the partition reset of SerDes through RGM PRST registers
- Wait for MPLLA to get locked in PCIE_SS_PCIE_PHY_MPLLA_CTRL register
- Set equalization parameters in PORT_LOGIC_GEN3_EQ_CONTROL_OFF
- Program the BARs
- Enable link training in the PCIE_SS_PE0_GEN_CTRL_3 register

52.1.6 Unexpected behavior when enabling error injection in DMA Channel context memories of SerDes

When you enable error injection in DMA channel context memories of SerDes and perform the DMA operations, you get the errors. Even after disabling the injection, error will still be visible on the first access after disabling the error injection because the memories work in read before write fashion. During the error injection enabled stage, there is a write operation in the end that results in the error getting injected in the memory in the end.

52.1.7 Converting nonsecure accesses to secure accesses

This is the procedure to to convert nonsecure accesses to secure accesses on this chip:

1. Write 00b to XRDC.MDA_W0_*n*_DFMT1[SA].
2. Write 1b to XRDC.MDA_W0_*n*_DFMT1[VLD].

Chapter 54
Low Latency Communication Engine (LLCE)

54.1 Introduction

LLCE is a combination of cores, memory, hardware acceleration IP blocks and firmware developed by NXP.

LLCE supports the following channels:

- 16 BCAN channels
- 2 FlexRay channels (A+B)
- 4 LINFlexD channels
- 4 LPSPI channels

NOTE

This chip does not support the single wire mode for LPSPI0 and LPSPI3.

The communication hardware channels abstract the communication that is fully supported through a firmware-defined host interface. A key advantage of this approach is that it delivers an optimized host interface to reduce the load on the host cores and provides flexibility because additional firmware-defined features are added over the LLCE lifetime. Contact your local NXP representative for further details of firmware extension.

The figure below shows the high-level architecture of LLCE.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390a8b624c1

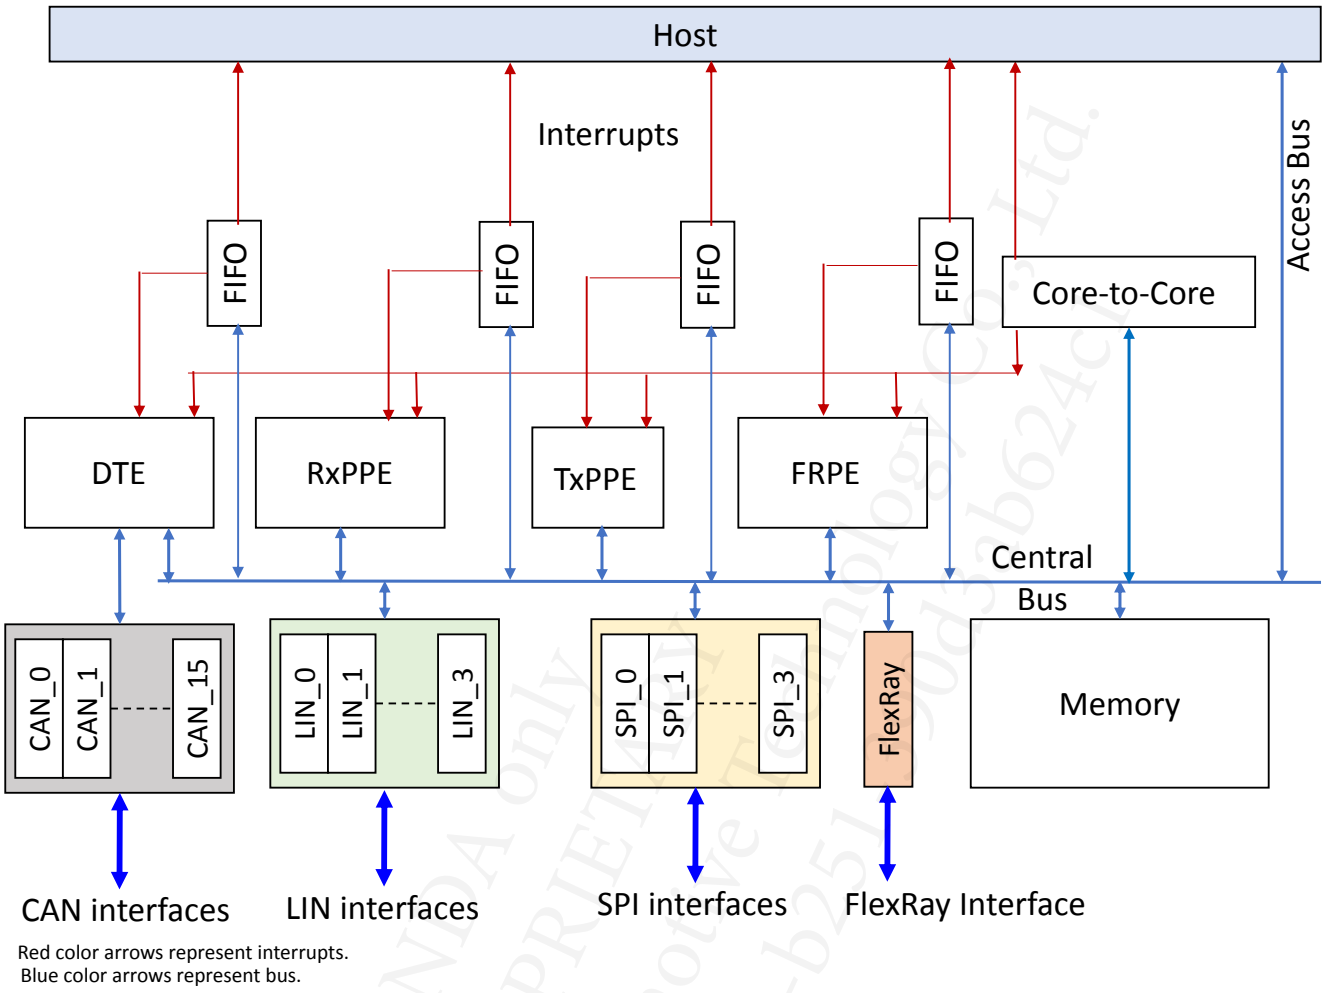

Figure 448. High-level LLCE block diagram

54.2 High-level features

- 16 BCAN interfaces fully compliant with ISO11898-1: 2015
- One FlexRay interface (2 channels) fully compliant with FlexRay communications system protocol specification, Version 2.1 Rev A
- Four LINFlexD interfaces
  - Fully compliant with LIN protocol version 1.3, 2.0, 2.1, and 2.2
  - Support master and slave mode on all channels
- Dedicated path to the HSE_H subsystem to optimize security tasks
- Global timestamping across all BCAN, FlexRay and LIN interfaces, with a global timebase that can be driven by:
  - IEEE802.1AS timebase from PFE
  - IEEE802.1AS timebase from GMAC
  - Free-running 32-bit STM counter
- Advanced BCAN and FlexRay receive filtering
- Interrupt and polled operation by the host core

- Optimized FIFO based host interface
- Abstracts communication with the host cores
- Decouples FlexRay host communication from the FlexRay schedule
- The LLCE cores can access all peripherals on the chip.

54.3 Reset and boot

LLCE is a firmware-based machine. You must load the firmware before using the LLCE. The LLCE cores boot during LLCE initialization by the host. After initialization completes, the LLCE moves into normal mode and is ready for full operation. The delivered host interface driver and LLCE firmware abstracts initialization.

54.4 Modes of operation

After initialization, all interfaces are available and operate at full performance. The abstracted host interface and firmware control communication with LLCE.

LLCE does not support low-power modes. When the chip is in Standby mode, the entire LLCE is power-gated.

54.5 Subsystem control

LLCE has the following system control features that the host configures prior to operation.

Reset control

Each of the LLCE core individually resets via LLCE_SYSRSTR. If you deassert the chip's system functional reset then all LLCE cores default to the reset state. Writing to the respective field in the LLCE_SYSRSTR allows each core to be taken out of reset. See LLCE register descriptions for details.

54.5.1 Reset control

Each of the LLCE core individually resets via LLCE_SYSRSTR. If you deassert the chip's system functional reset then all LLCE cores default to the reset state. Writing to the respective field in the LLCE_SYSRSTR allows each core to be taken out of reset. See LLCE register descriptions for details.

54.6 Host interface

All communication with LLCE is via the host interface and not directly via the individual BCAN, FlexRay, LINFlexD, and SPI communication channels. Data RAM and a number of hardware FIFO IP blocks within LLCE implement the interface. The main functional blocks of the interface are as follows:

- Hardware FIFOs: Used for transmission and reception flows. In general the FIFOs transfer indexes to the message buffers that contain the communication frames (for example, BCAN, FlexRay, and LINFlexD).
- Shared memory: Implemented with SRAM stored in LLCE. The shared memory is mostly used for exchanging message buffer content (communication frames), commands and error or status information between LLCE and the host core.
- Core2Core interrupt module: Used to generate interrupts between LLCE and the host.

The host interface implements a software architecture that transfers indexes between LLCE and the host core via the FIFOs to decrease the number of memory copy operations required for message buffers. The content of the message buffers is stored only once in the shared memory during the entire processing flow. The host core writes to and copies from LLCE shared memory.

The architecture of the host interface is shown in the following figure.

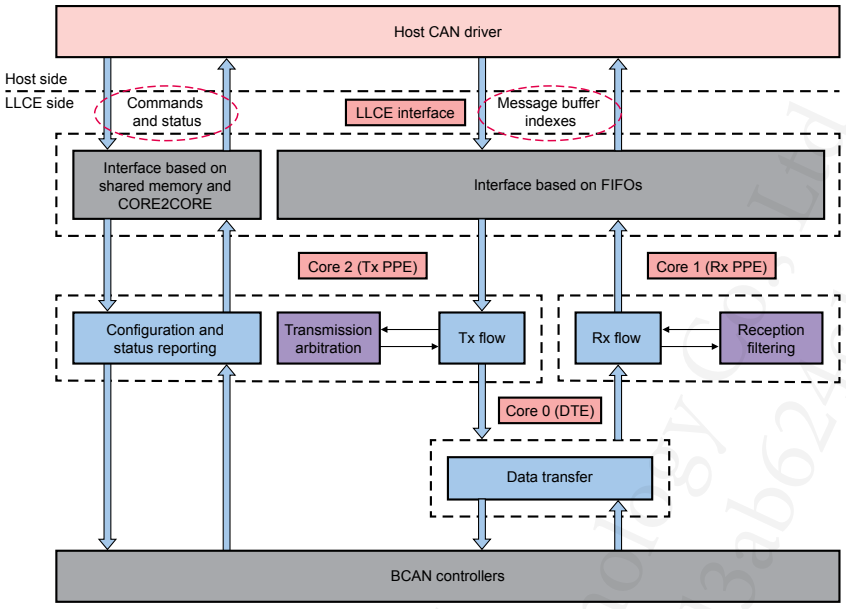

Figure 449. LLCE firmware architecture

The host and LLCE interact via data structures stored in the S32G SRAM. The following data structures exist:

- Command
- Receive message buffer
- Transmit message buffer
- Transmit acknowledge buffer
- Receive object count

The host interface is fully described in the LLCE firmware user guide.

See the LLCE firmware user guide for the following details:

- LLCE host interface
- Booting LLCE
- Initialization of the host interface
- Initialization of communication channels
- Transmission and reception
- LLCE global RAM

54.7 Clocking options

LLCE needs the following clocks to be configured correctly for full operation. See the "Clocking Overview" chapter for details.

Table 386. LLCE clocks

Clock name	Description
LLCE_SYS_CLK	This is the main LLCE clock. All cores and interconnects derive from this clock source. The source is a divided version of the XBAR_CLK that clocks the ARM Cortex-M7 cores.

Table continues on the next page...

Table 386. LLCE clocks (continued)

Clock name	Description
	LLCE_SYS_CLK runs at a maximum frequency of 200 MHz. Clocking LLCE slower than the maximum reduces its functionality.
CAN_PE_CLK[0:15]	This source clocks the protocol engine of the BCAN channels. Its source is selected from the FXOSC or output of the PERPH PLL. Each FlexCAN channel uses the same clock. For example, if you select 40 MHz FXOSC as a source, then it becomes the source for all the channels.
FLEXRAY_PE_CLK	This source clocks the protocol engine of the FlexRay channels. Its source is selected from the FXOSC or output of the PERPH PLL.
LINFLEX_CLK[0:3]	This source clocks the protocol engine of the LINFlexD channels. The LINFLEX_CLK source is LIN_BAUD_CLK, which is selected from the FXOSC or output of the PERPH PLL. To generate LINFLEX_CLK, divide LIN_BAUD_CLK by 2 within LLCE.
LPSPI_CLK[0:3]	This source clocks the LPSPI channels. The LPSPI_CLK source is PER_CLK, which is selected from the FXOSC or output of the PERPH PLL.

54.8 Global timestamping

Frames transmitted and received via the LLCE CAN and FlexRay are timestamped against a global timebase. Selection of the global timebase is configurable. See the Timestamp chapter for global timestamp sources and how they can be selected.

Also see the LLCE host interface and firmware description for supported timestamping of specific channels.

54.9 Host interface events or interrupts

The host core can generate events or interrupts on the individual LLCE cores by writing to the core2core interface. With this action, the host cores generate events or interrupts on LLCE cores 0, 1, 2, and 3. See the host interface documentation for further details.

It is also possible for the LLCE cores 0, 1, 2, and 3 to generate events or interrupts on the chip's host cores. See the interrupt map file attached to this document.

54.10 FIFO interrupts

Each LLCE host interface FIFO generates an event or interrupt on the respective host core. See the interrupt map file attached to this document.

54.11 LLCE generic FIFO

The generic FIFO handles all functionalities needed for different FIFO applications inside LLCE. Specific instances are marked with instance name as defined in LLCE block diagram. All FIFO instances have 16 entries.

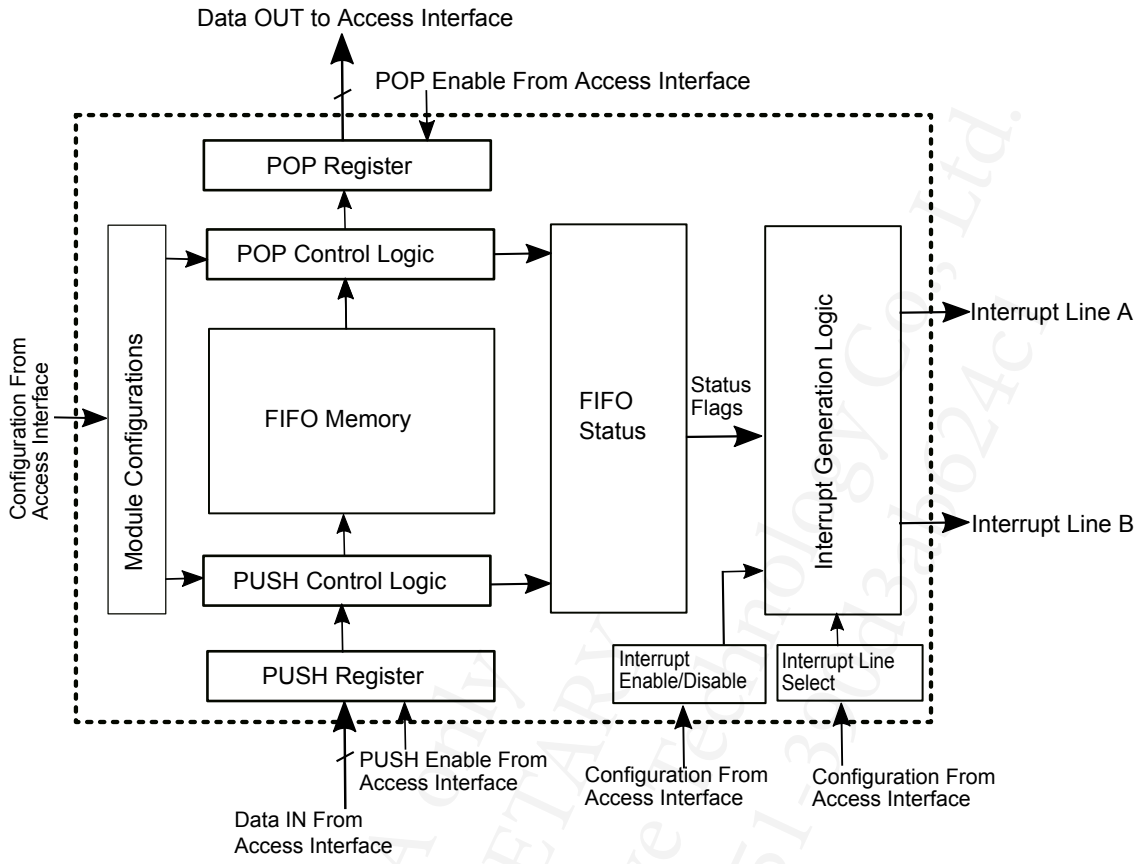

Figure 450. LLCE generic FIFO block diagram

54.11.1 Features

- FIFO full, not-full, empty, and not-empty flags
- FIFO flush control
- Consecutive Entry push operation support (back-to-back clock cycle)
- Consecutive Entry pop operation support (back-to-back clock cycle)
- Configuration of PUSH register Fixed MSB pattern
- Configurable watermark cross flag for number of filled entries
- Configurable watermark cross flag for number of empty entries
- POP operation support when automatic POP-on-read is disabled
- FIFO count status
- Control to overwrite last FIFO entry when FIFO is full
- Maskable event/error flags which can be configured to be routed to any of the two interrupt lines

54.11.2 Modes of operation

LLCE FIFO supports two operation modes:

- **FIFO run mode:** FIFO operates with full functionality.
- **FIFO disabled mode:** FIFO PUSH and POP operations are disabled. Register configurations and flush operation can still work in this mode.

54.11.3 LLCE FIFO register descriptions

54.11.3.1 LLCE FIFO registers memory map

There are multiple FIFOs used for communication between host and LLCE cores. For the base addresses of used FIFOs, see the LLCE firmware user guide.

Offset	Register	Width (In bits)	Access	Reset value
0h	FIFO Configuration Register (FCR)	32	RW	0000_0000h

Fields

Field	Function
31-28 —	Reserved
27-24 WMKEMTYL	Watermark Empty Level Number of entries for FIFO_SR[WMKEFLG] decision. This helps in bulk transfer during write operation.
23-20 —	Reserved
19-16 WMKFULLL	Watermark Full Level Number of entries for FIFO_SR[WMKFFLG] decision. This watermark helps in bulk transfer during read operation.
15-6 —	Reserved
5 RD_POP_DIS	Read when POP Disabled Writing 1 to this bit results in an entry being popped when FIFO_FCR[POPEN] is 0 and FIFO_FCR[FIFOEN] is 1. The FIFO pointers and status are updated. Writing 0 has no effect. When FIFOFCR[POPEN] = 1, writing 1 to this bit has no effect. 0b - No operation 1b - POP operation
4 FFLUSH	FIFO Flush Writing 1 to this flushes the FIFO memory content. It does not clear any set w1c status flag. Writing 0 has no effect. 0b - No operation 1b - FIFO Flush
3 PUSHEN	PUSH enable If enabled, any write to FIFO PUSH register is considered a FIFO PUSH operation and FIFO pointers/ status is updated. If disabled, FIFO logic is unaffected and only the register write takes place. 0b - PUSH Disabled 1b - PUSH Enabled
2 POPEN	POP enable If enabled, any read to FIFO POP register is taken as a FIFO POP operation and the FIFO pointers/ status is updated. If disabled, FIFO logic is unaffected and only the register read takes place. 0b - POP Disabled 1b - POP Enabled
1	Last entry overwrite enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
LENOWEN	Last FIFO entry can be overwritten when FIFO is full, when this bit is enabled. If disabled, overwrite is not allowed. 0b - Overwrite disabled 1b - Overwrite enabled
0 FIFOEN	FIFO enable This field controls the FIFO PUSH and POP operations. Register configurations and flush operation can work for both enabled and disabled values of this field. 0b - FIFO Disabled 1b - FIFO Enabled

54.11.3.3 FIFO Status Register 0 (SR0)

Offset

Register	Offset
SR0	4h

Function

The w1c bits of this register are accessible or reserved based on the programming of corresponding bits in FIFO_ILR. When the corresponding bit in FIFO_ILR is 0 then the bit is accessible to the user for w1c and read operations. When the corresponding bit in FIFO_ILR is 1 then the bit is reserved to the user. The RO bits of this register show the dynamic status of the FIFO independent of FIFO_ILR programming.

Fields

Field	Function
31-29 —	Reserved
28-24 FCOUNT	FIFO count This field gives the dynamic count of the entries present inside the FIFO.
23-18 —	Reserved
17 MSBNOMT	MSB not matching flag This bit is set when the MSB bit pattern of FIFO_PUSHR does not match the MSB bit pattern programmed inside FIFO_FMR. The bit is cleared by writing 1 into it. 0b - MSB match 1b - MSB mismatch
16 PUSHOVR	PUSH overflow Flag This bit is set when a write access is made to FIFO_PUSHR register when the FIFO is full. The bit is cleared by writing 1 into it. 0b - No PUSH overflow 1b - PUSH overflow
15 POPUND	POP underflow flag This bit is set when a read access is made to FIFO_POPR register when the FIFO is empty. The bit is cleared by writing 1 into it. 0b - No POP underflow 1b - POP underflow
14 WMKEMTY	Watermark empty flag This bit is set when FIFO_SR0[FCOUNT] goes lower than FIFO_FCR[WMKEMTY]. The bit is cleared by writing 1 into it. 0b - No Watermark Empty Event 1b - Watermark Emty Event
13 WMKFULL	Watermark Full Flag This bit is set when FIFO_SR0[FCOUNT] goes higher than FIFO_FCR[WMKFULL]. The bit is cleared by writing 1 into it. 0b - No Watermark Full Event 1b - Watermark Full Event
12	POP event flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
POPEVT	This bit stores the pop event status whenever a POP access is made to FIFO_POPR. The bit is cleared by writing 1 into it. 0b - No POP event 1b - POP event
11 FNEMTY	FIFO not empty flag This bit stores the not empty status of the FIFO when the condition occurs in the hardware. The bit is cleared by writing 1 to it. If the hardware condition that sets this bit is persisting when a w1c operation is happening, the bit is not cleared. 0b - FIFO empty 1b - FIFO not empty
10 FEMTY	FIFO empty This bit stores the empty status of the FIFO when the condition occurs in the hardware. The bit is cleared by writing 1 to it. If the hardware condition that sets this bit is persisting when a w1c operation is happening, the bit is not cleared. 0b - FIFO not empty 1b - FIFO empty
9 FNFULL	FIFO not full flag This bit stores the not full status of the FIFO when the condition occurs in the hardware. The bit is cleared by writing 1 to it. If the hardware condition that sets this bit is persisting when a w1c operation is happening, the bit is not cleared. 0b - FIFO Full 1b - FIFO not Full
8 FFULL	FIFO Full Flag This bit stores the full status of the FIFO when the condition occurs in the hardware. The bit is cleared by writing 1 to it. If the hardware condition that sets this bit is persisting when a w1c operation is happening, the bit is not cleared. 0b - FIFO not Full 1b - FIFO Full
7-2 —	Reserved
1 FEMTYD	FIFO Empy Dynamic This bit gives the dynamic empty status of the FIFO. 0b - FIFO not empty 1b - FIFO empty

54.11.3.4 FIFO Status Register 1 (SR1)

Offset

Register	Offset
SR1	8h

Function

The w1c bits of this register are accessible or reserved based on the programming of corresponding bits in FIFO_ILR. When corresponding bit in FIFO_ILR is 1 then the bit is accessible to the user for w1c operation. When corresponding bit in FIFO_ILR is 0 then the bit is reserved to the user. The RO bits of this register show the dynamic status of the FIFO independent of FIFO_ILR programming.

54.11.3.9 FIFO Fixed MSB Register (FMR0)

Offset

Register	Offset
FMR0	34h

Function

This register is configured to hold the fixed MSB bit pattern to be compared against the PUSHR MSB bit pattern. If the two bit patterns are not same, MSBNOMT bit is set in the status register and MSB bit pattern of this register is considered correct by the module.

Diagram

Fields

Field	Function
31-13 —	Reserved
12-0 ENTRFMSB	Entry Fixed MSB The fixed MSB pattern to be compared against the PUSHR MSB bit pattern. **NOTE** To change this value, FIFO needs to be flushed and there must not be any entry populated to avoid having wrong pointer value.

54.11.4 Functional description

The following sections describe the functional details of the LLCE FIFO module.

54.11.4.1 Basic push operation

Once the FIFO module has been initialized (See Programming Guidelines section), and automatic PUSH on write operation has been enabled (FIFO_FCR[PUSHEN] = 1), write into FIFO_PUSHR0 to add the entry to the FIFO memory by polling FIFO not full flag or using the interrupt indication of this flag. Once the PUSH register has been written, the FIFO write pointer increments to point to next location and module status is updated in the status register.

54.11.4.2 Mulit-word push operation

Generic FIFO supports multi-word support to write and read multiple words to and from the FIFO. When multi-word PUSH is being used, always write into PUSH register 0 at the end, after writing into PUSH register of higher index. Otherwise, incomplete data will be loaded into the memory. Once all the writes are complete, one PUSH operation is completed, the write pointer points to the next FIFO location and module status is updated in the status register.

54.11.4.3 Basic pop operation

Once the FIFO module has been initialized (See Programming Guidelines Section), and automatic POP on read operation has been enabled (FIFO_FCR[POPEN]=1), read FIFO_POPR0 to read an entry from FIFO memory by polling FIFO not empty flag or using the interrupt indication of this flag. Once the POP register has been read, the FIFO read pointer increments to point to next location and module status is updated in the status register.

54.11.4.4 Multi-word pop operation

When multi-word POP is being used, always read POP register 0 at the end, after reading POP register of higher index. Otherwise, incorrect data will be read from the FIFO. Once all the reads are complete, one POP operation is completed, the FIFO read pointer increments to point to next location and module status is updated in the status register.

54.11.4.5 Pop operation when FIFO_FCR[POPEN] is 0

There can be use cases when FIFO_FCR[POPEN] is reset to 0 so that a read access on FIFO_POPR does not result in an automatic POP operation. A POP access can still be made by writing to FIFO_FCR[RD_POP_DIS]. This is a write-only-1 bit and any write into this bit when FIFO_FCR[POPEN] = 0 qualifies a POP operation which results in an update of the FIFO status and POP register content. This operation will only work when FIFO_FCR[FIFOEN] = 1.

54.11.4.6 FIFO flush

The FIFO entries can be flushed at any time by writing 1 to FIFO_FCR[FLUSH] to completely empty the FIFO.

NOTE

W1C status flags which are set to 1 are not cleared by FIFO flush operation. They should be cleared by writing 1.

54.11.4.7 FIFO watermark operation

Generic FIFO has separate watermark indicators when the entry count is nearing full and empty levels. The application can configure the watermark levels for both the cases and use the corresponding status flags WMKFULL and WMKEMTY for bulk data transfer.

Example 1

FIFO DEPTH=16

FIFO_FCR[WMKFULLL] = 11
