FIFO_SR[WMKFULL] flag is set when FIFO_SR[FCOUNT] goes higher than 11. This flag indicates that at least 12 entries are present inside the FIFO to be read. This can help in bulk read transfer.

Example 2

FIFO DEPTH=16

FIFO_FCR[WMKEMTYL] = 5

FIFO_SR[WMKEMTY] flag is set when FIFO_SR[FCOUNT] goes lower than five. This flag indicates that at least 12 (DEPTH-FIFO_FCR[WMKEMTYL] + 1) entries are vacant inside the FIFO to be written. This can help in bulk write transfer.

54.11.4.8 Last FIFO entry overwrite operation

FIFO_FCR[LENOWEN] when set to 1 allows an entry to be added to the FIFO when it is full, overwriting the last written FIFO entry with this new incoming entry. The PUSH overflow flag, which indicates a FIFO PUSH when FIFO is full, will be set in the status register even when FIFO_FCR[LENOWEN] = 1.

54.11.4.9 Error scenarios

Scenario	Description
PUSH overflow	PUSH overflow error occurs when FIFO_PUSHR0 is written when FIFO is full as indicated by FIFO full flag of status register or FIFO full dynamic bit of status register. PUSH overflow flag is set to 1 in status register when this error condition occurs.
POP underflow	POP underflow error occurs when FIFO_POPR0 is read when FIFO is empty as indicated by FIFO empty flag of status register or FIFO empty dynamic bit of status register. POP underflow flag is set to 1 in status register when this error condition occurs.
PUSH MSB pattern mismatch	The entry pushed into FIFO_PUSHRn can have a fixed MSB pattern. This is true when memory pointers are stored inside the FIFO and not all 32 bits are used to address the memory. The FIFO hardware compares the MSB pattern of every incoming entry against a fixed MSB pattern configured in FIFO_FMRn register. In case the two patterns don't match, MSBNOMT flag is set to 1 in the status register and the MSB pattern of FIFO_FMRn is appended to entries which are read from FIFO_POPRn.

54.11.4.10 FIFO performance

Generic FIFO supports writes into the PUSH register in consecutive clock cycles. Similarly, entries can be read from the POP register in consecutive clock cycles when there are valid entries available.

54.11.5 Interrupts

The generic FIFO has two interrupt outputs, A and B. The status flags inside the status register can be programmed to be routed to either of the two interrupt lines. A value 0 in a bit of FIFO_ILR will route the corresponding flag to interrupt line A. A value 1 in a bit of FIFO_ILR will route the corresponding flag to interrupt line B.

There are two status registers implemented for software to access flags corresponding to each interrupt line with minimum latency. Core receiving interrupt A should access Status register 0 to read/clear status flags which are driving interrupt A. Flags driving interrupt A will be accessible only in FIFO_SR0 and the corresponding flag in FIFO_SR1 will read 0. Core receiving interrupt B should access Status register 1 to read/clear status flags which are driving interrupt B. Flags driving interrupt B will be accessible only in FIFO_SR1 and will read 0 in FIFO_SR0.

Interrupt line selection can be modified, dynamically, in run mode by configuring FIFO_ILR bits.

Example

When FIFO_ILR[POP_EVT] = 1 and FIFO_IER[POP_EVT] = 1, an active POP event flag is routed to interrupt line B.
The core receiving interrupt B should always access FIFO_SR1 to read and clear the status of the FIFO_SR1[POP_EVT].
FIFO_SR0[POP_EVT] will read 0 even if the event has occurred because FIFO_ILR[POP_EVT] = 1.

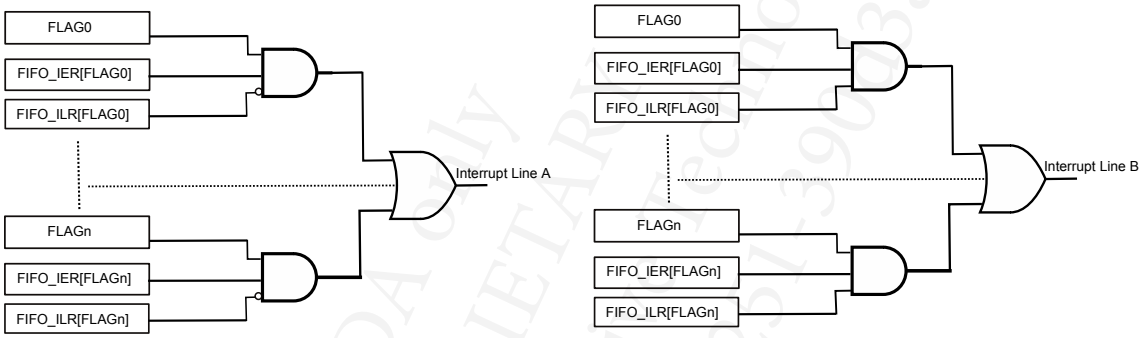

Figure 451. Interrupt generation scheme

54.11.6 Programming

- General guidelines
  1. To write into a vacant entry of the FIFO, use FIFO not full flag of the status register.
  2. To read a valid entry from the FIFO, use FIFO not empty flag of the status register.
  3. For bulk entry transfers, use watermark full and watermark empty flags of the status register See FIFO watermark operation.
- Initialization
  1. Select the interrupt line of each flag of FIFO_SR0/FIFO_SR1 register by writing into corresponding bits of FIFO_ILR register
  2. Enable the required interrupts by setting bits in the FIFO_IER register.
  3. Configure Fixed MSB pattern of FIFO_PUSHR inside FIFO_FMR register. This configuration can be changed only after flushing the FIFO.
  4. Configure the FIFO_FCR register:
     - Automatic Push operation: write 1 to FIFO_FCR[PUSHEN] (must be done for FIFO operation).
     - Automatic POP operation: write 1 to FIFO_FCR[POPEN].
     - FIFO watermark levels FIFO_FCR[WMKFULLL] and FIFO_FCR[WMKEMTYL]
     - Overwrite last entry in case of full: write 1 to FIFO_FCR[LENOWEN].

5. Select FIFO run mode: write 1 to FIFO_FCR[FIFOEN].

- FIFO RUN mode
  1. PUSH operation: Write into FIFO_PUSHR0 to add an entry to the FIFO.
  2. POP operation: Read from FIFO_POPR0 to read an entry from the FIFO.
  3. FIFO Flush: The FIFO can be flushed by writing 1 to FIFO_FCR[FFLUSH] to empty the contents of the FIFO. The flush operation does not clear w1c status flags in SR0/SR1. The status flags still should be cleared by writing 1 into them.
  4. To qualify a POP operation when FIFO_FCR[POPEN] is 0, write 1 to FIFO_FCR[RD_POP_DIS].
  5. Configuration change: The configurations done during initialization can be modified during RUN mode and the change will take effect in the next clock cycle.
  6. Select FIFO disabled mode: write 0 to FIFO_FCR[FIFOEN] to freeze the FIFO. FIFO PUSH and POP operations are disabled. Register configurations and flush operation can still work in this mode.

54.12 Core-to-Core module

Core to core communication module provides LLCE cores and HOST core the capability to indicate system events among themselves via flags and associated mask-able interrupts. Exclusive registers are provided for each core for flag bits and interrupt masking. A flag bit for a receiving core can be set by a transmitting core to indicate an event to it. Once set, the flag can be cleared by the receiving core only.

54.12.1 Block diagram

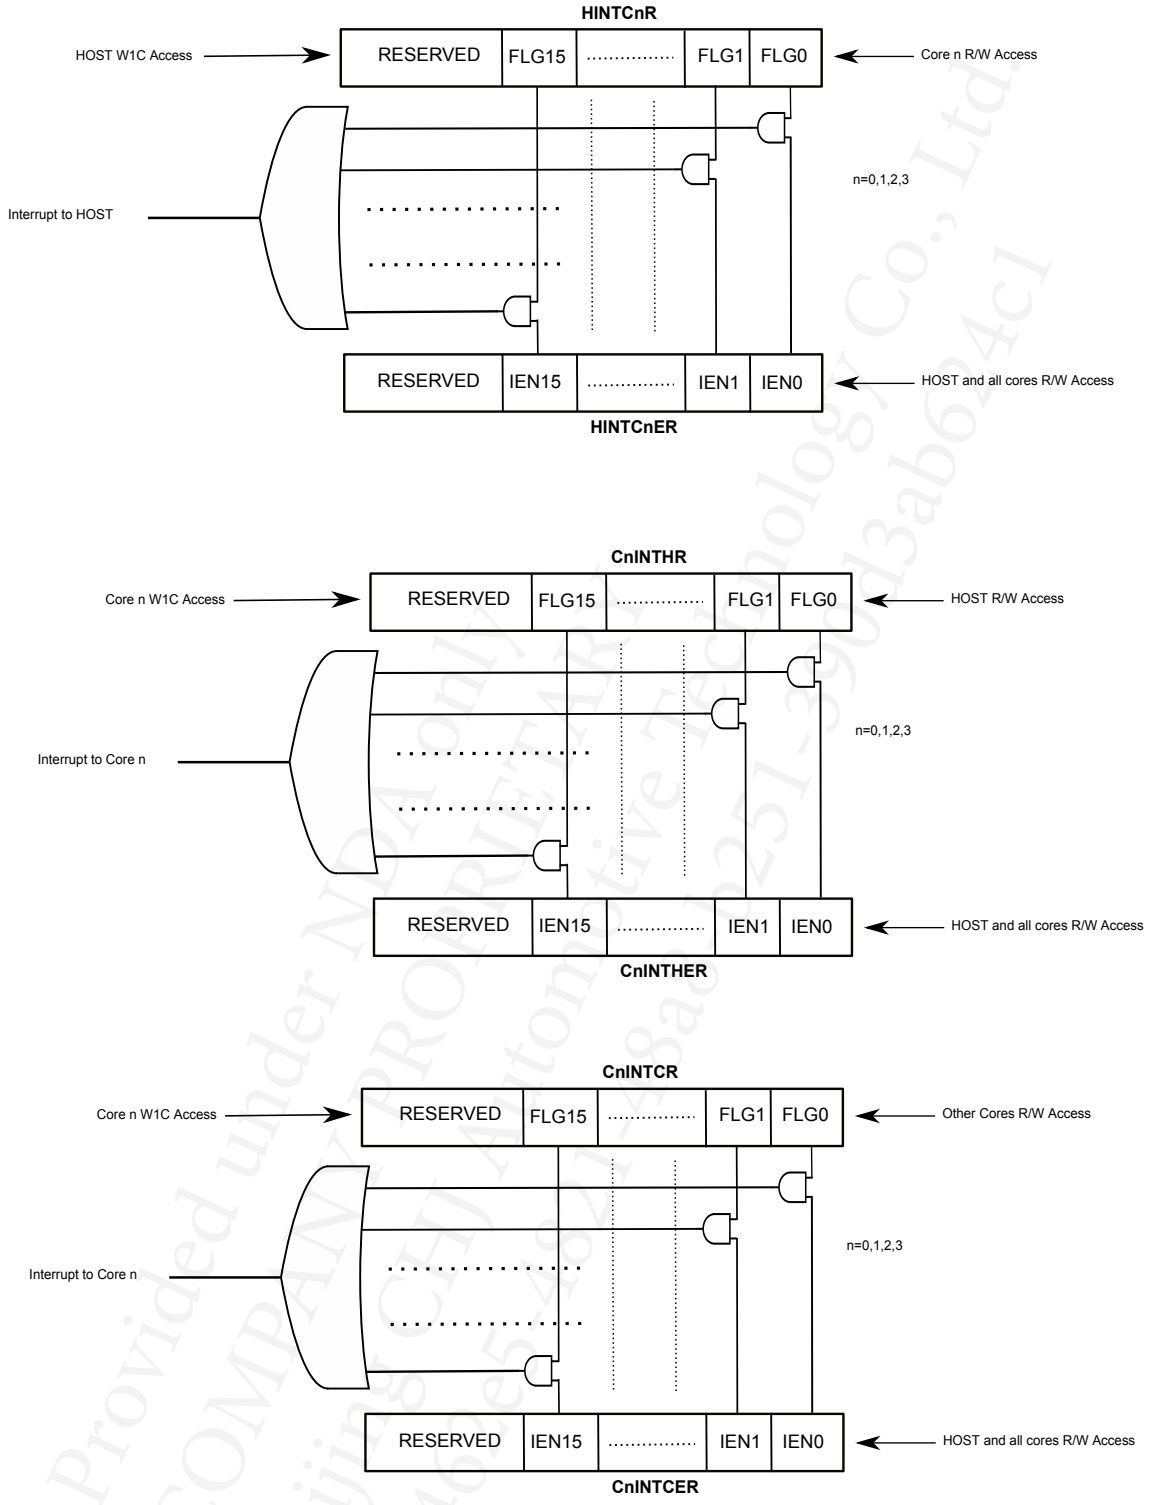

Figure 452. Core-to-core block diagram

54.12.2 Features

- Support of event communication between four LLCE cores and one host

- Interrupt to host from LLCE cores
  - Support of 16 flags with masks from each LLCE core
  - One interrupt line from each LLCE core (16 flags OR-ed after mask)
- Interrupt to LLCE cores from host
  - Support of 16 flags with masks from Host to each LLCE core
  - One interrupt line for each LLCE core (16 flags OR-ed after mask)

54.12.3 Core-to-core register descriptions

Throughout the register description the following convention is to be followed:

- Core 0 is DTE.
- Core 1 is RXPPE.
- Core 2 is TXPPE.
- Core 3 is FRPE.

The host is the core accessing through the host AHB port of LLCE.

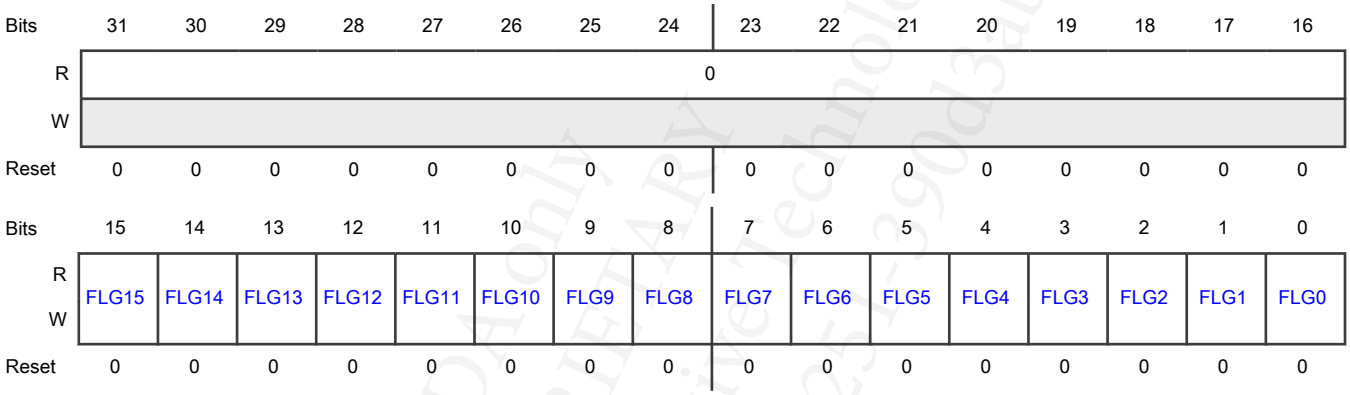
54.12.3.2 HOST interrupt from Core 0 Register (HINTC0R)



Offset

Register	Offset
HINTC0R	0h

Function

This register controls the event indication to HOST from Core 0. 16 flags can be set by Core 0 to indicate 16 separate events. All flags combine to generate a single interrupt to HOST. A flag once set, can be cleared only by HOST with w1c operation. All cores and HOST have read access to this register. Only HOST and Core 0 have write access to this register. ACCESS GUIDELINE- HOST: Write 1 to clear flag. Core 0: Write 1 to set flag.

54.12.3.7 Core 1 Interrupt From HOST Register (C1INTHR)

Offset

Register	Offset
C1INTHR	24h

Function

This register controls the event indication to Core 1 from HOST. 16 flags can be set by HOST to indicate 16 separate events. All flags combine to generate a single interrupt to Core 1. A flag once set, can be cleared only by Core 1 with w1c operation. All cores and HOST have read access to this register. Only HOST and Core 1 have write access to this register. ACCESS GUIDELINE- HOST: Write 1 to set flag. Core 1: Write 1 to clear flag.

54.12.4 Functional description

The core-to-core communication interface provides the capability for each core, including the host, to transmit and receive events via flags and maskable interrupts to each other.

The event indication between transmitting core and receiving core is facilitated by two types of registers: (symbolic notation)

1. (RxCORE)INT(TxCORE)R – Receive Core Interrupt from Transmit Core Register. This register is accessed to set or clear event flags. Transmit core sets a flag. Receive core clears the flag.
2. (RxCORE)INT(TxCORE)ER – Receive Core Interrupt from Transmit Core Enable Register. This register is accessed to enable or disable the propagation of the corresponding flag in (RxCORE)INT(TxCORE)R to interrupt line.

A flag(bit) written by Transmit core into (RxCORE)INT(TxCORE)R sets the flag in the register. A flag can be set when transmitting core wants a service from receiving core. The receiving core will be interrupted if enable bit for that flag is set in (RxCORE)INT(TxCORE)ER. Otherwise, the flag will not generate an interrupt but will remain set. Only the receiving core can reset the flag by writing 1 into the bit.

ACCESS Guidelines:

1. (RxCORE)INT(TxCORE)R can be written by only TxCORE (To set a flag) and RxCORE (To clear a flag). It can be read by all cores and HOST.
2. (RxCORE)INT(TxCORE)ER can be written and read by all cores and HOST.

Block diagram shows the interrupt generation scheme with access types.

For example, assume Core 0 wants to indicate two events to HOST. One event is required to generate an interrupt and the other required to set a flag only.

1. Write 1 to HINTC0ER[0] to generate an interrupt from the flag HINTC0R[0], keeping all other bits 0. This can be done by any core or host.
2. Core 0 sets bit HINTC0R[1] to indicate the first event to HOST. No interrupt is generated for this as it is not enabled (HINTC0ER[1]=0), only the flag is set.
3. Core 0 sets bit HINTC0R[0] to indicate the second event to HOST. This generates an interrupt to HOST along with this flag because it is enabled (HINTC0ER[0]=1).
4. The HOST, in reaction to the interrupt, reads the HINTC0R register and clears flags HINTC0R[0] and HINTC0R[1] by writing 1 to each of them after completing the requested task.
5. Flags HINTC0R[0] and HINTC0R[1] are now free to be written by Core 1 again.

Each core has its own flag/interrupt set registers and flag mask registers.

The transmitting core sets the interrupt/flag to the register of receiving core. The same physical register is read/write for transmitting core and write only one (W1C) for the receiving core. Each bit of this Flag/interrupt register can generate interrupt if enabled otherwise it is used as a flag and to be polled by receiving core.

The receiving core clears the interrupts/flags in its own Flag/interrupt register. So, the transmitting core should check the current flag status before setting it. There is no protection taken if the transmitting core clears a flag/interrupt itself before the receiving core is actually read and acted on it.

Each master has fixed Master IDs in the system. The below figure shows the decoding of master IDs to generate access protection.

Cores of LLCE have master ID values are hard coded to identify them uniquely (DTE=3, RXPPE=4, TXPPE=5, FRPE=6, Host=8).

The Core-to-Core module has five master ID input ports, each dedicated to one masters, 1 for host and 4 for four cores. The host port is fixed at value 0x8. Internal core ports are assigned to fixed indexes as below::

- Core 0 is DTE.
- Core 1 is RXPPE.
- Core 2 is TXPPE.
- Core 3 is FRPE.

Index assignment and fixed values of master IDs:

- Host master ID 8h

- Core0 master ID 3h (DTE)
- Core1 master ID 4h (RXPPE)
- Core2 master ID 5h (TXPPE)
- Core3 master ID 6h (FRPE)

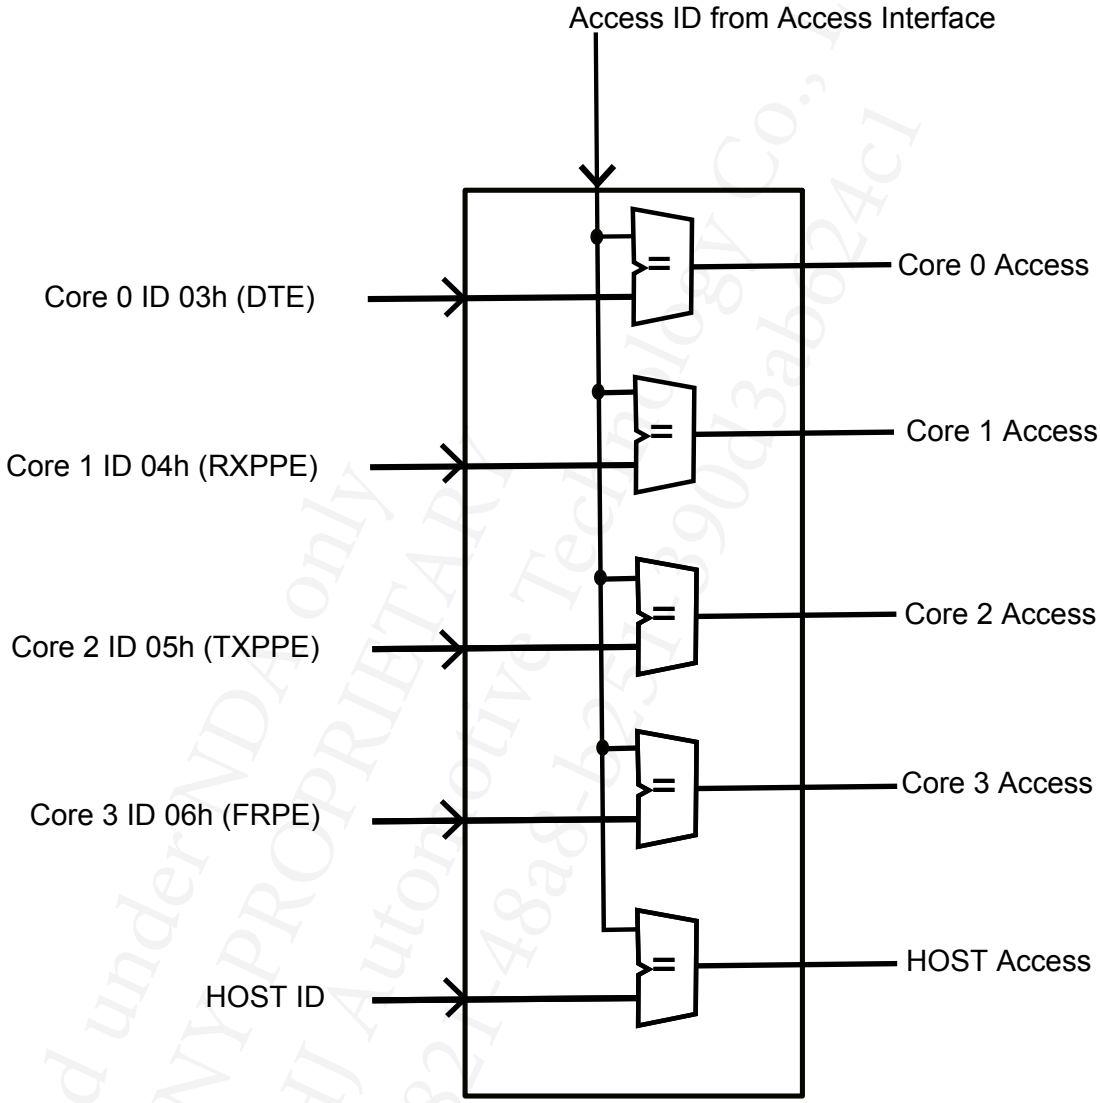

Figure 453. Master ID decoding scheme

Access protection

Access to (RxCORE)INT(TxCORE)R registers is protected against access from disallowed cores. The master ID from access interface is compared against the value of the master ID of Core 0-3 and HOST.

- Access to set the flag to a core if its ID matches TxCORE ID.
- Access to clear the flag is granted to a core if its ID matches RxCORE ID

54.13 Interrupts and status

Multiple interrupts generate from LLCE's internal modules. The interrupt logic of LLCE does concentration, keeps status, and routes them per configuration. The output goes to IRQ lines of LLCE cores and to host.

There are two modules inside LLCE:

- Interrupt concentrator module (IC)
- Interrupt routing configuration module (IRCM)

54.13.1 Interrupt concentrator (IC)

The IC takes interrupts from FIFOs and Core2Core and concentrates (OR-ed) them and present to IRCM.

Concentration occurs in two stages:

- First Level: concentration of interrupts from a single module
- Second level: concentration of interrupts from first level or directly from different modules (where first level is not required)

There are status registers for the interrupts for which second level of concentration helps in identifying the interrupting module by reading one register only. These registers are read only and corresponding status is automatically cleared when its source is cleared. The output of concentrator module goes to interrupt routing configuration module (IRCM).

54.13.2 Interrupt Routing Configuration Module (IRCM)

The IRCM module holds the configuration that defines the destinations of an interrupt coming to its input. It has a configuration register IRSPRC n (interrupt router shared peripheral routing control register) corresponding to each input. This register has as many bits as the number of destination possible for the interrupt. The number of destination for each input interrupt is fixed per its functional requirements. One input may have single or multiple destinations. In both the cases, the bit specified for a destination enables or disables the interrupt towards it. An interrupt which has multiple destination can go to all or some of the selected destinations if enabled in its register.

The destinations are:

- LLCE Core 0 (DTE)
- LLCE Core 1 (RxPPE)
- LLCE Core 2 (TxPPE)
- LLCE Core 3 (FRPE)
- Host

B line interrupts from each 8 FIFOs are captured on same status register (ICSR*) inside IC and concentrated (OR-ed) at second level to feed to IRCM.The IRCM register IRSPRC* holds the bits to route the interrupt to different locations. The below table shows the FIFO instances and corresponding registers to check the interrupt status and control the routing.

Module	Module Instances	Interrupt Concentrator Status Register	Interrupt Description (Input to IRCM)	Routing Control Register	Host	C3 (FRPE)	C2 (TxPPE)	C1 (RxPPE)	C0 (DTE)

Chapter 55
Universal Serial Bus On-The-Go Controller (USBOTG)

55.1 Chip-specific USB information

55.1.1 Chip-specific USBOTG information

Weak pulldown is required on the DIR pin of ULPI interface. In case, the external PHY is completely powered down, all the inputs need to be pulled down so that the pads should not remain floating.

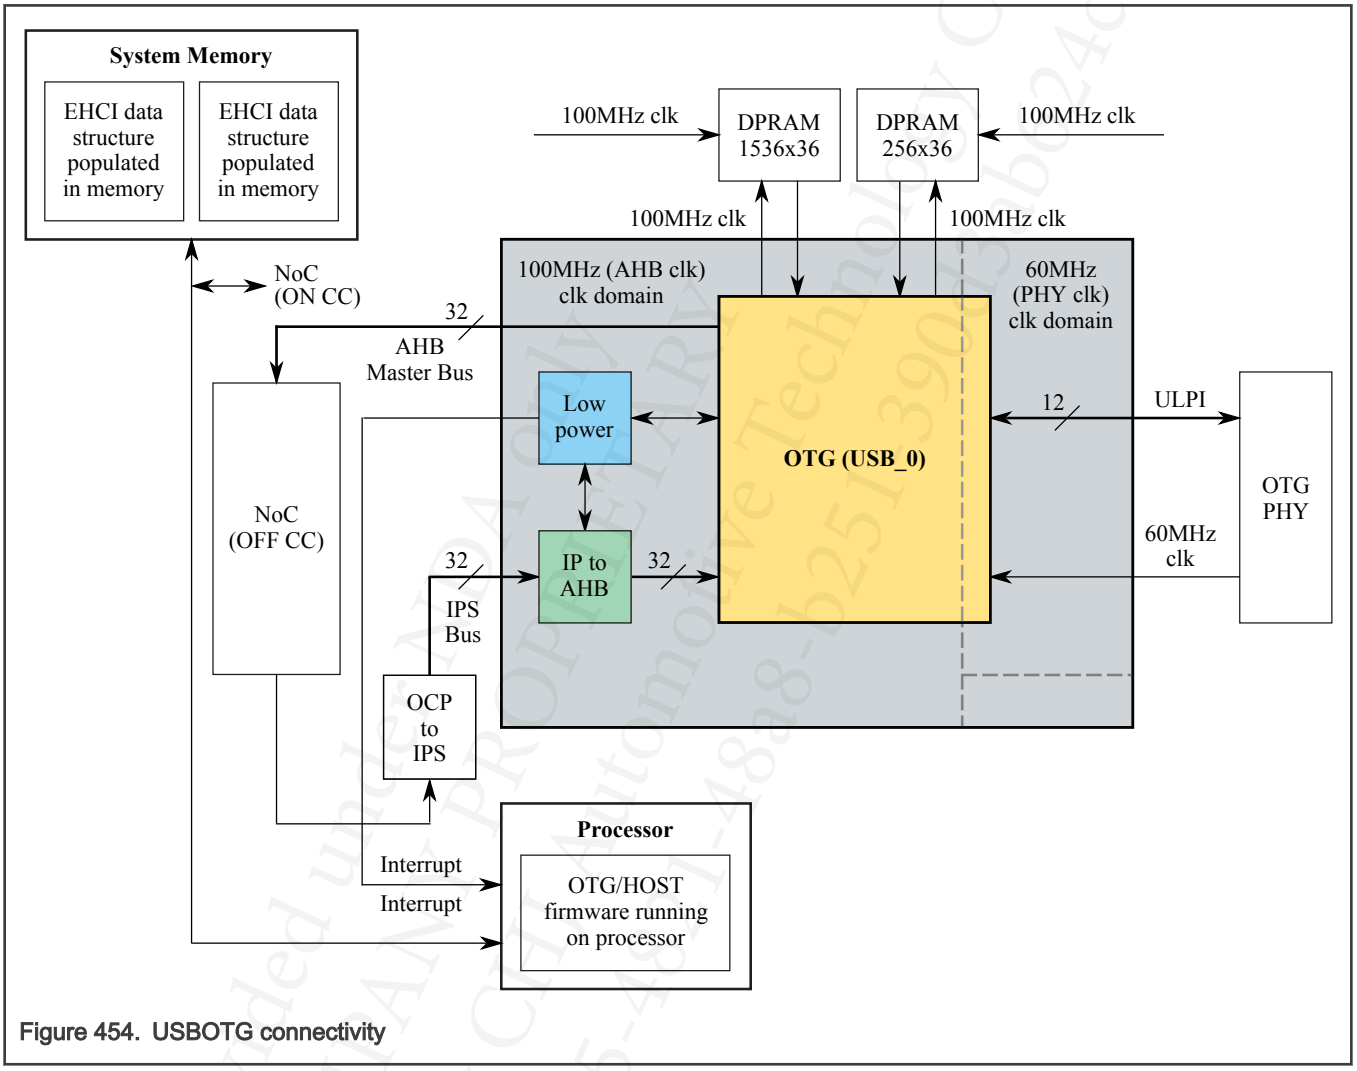

Figure 454. USBOTG connectivity

55.1.2 SBUSCFG[AHBBRST] field reset value

AHB Master Interface Burst Configuration (AHBBRST) field controls the AHB master transfer type sequence (or priority). This chip is designed to support only 011b reset value for this field. The chip operation is not guaranteed for any other programmed values.

55.2 Introduction

This chapter describes the USB high-speed (HS) OTG controller (USBOTG), which implements many industry standards. See the standards' governing specifications for more information. To use this chapter most effectively, you need to be fluent in the operation and requirements of a USB network.

See the USB implementers forum at http://www.usb.org/developers/docs for:

- *Universal Serial Bus Specification, Revision 2.0*
- *On-The-Go Supplement to the USB 2.0 Specification, Revision 1.0a*

See the Intel USB specifications at http://www.intel.com/ for:

- *Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 1.0*

See the ULPI specifications at http://www.ulpi.org for:

- *UTMI+ Specification, Revision 1.0*
- *UTMI Low Pin Interface (ULPI) Specification, Revision 1.1*

55.2.1 Overview

USBOTG is a USB 2.0-compliant serial interface engine for implementing a USB interface. The registers and data structures are based on the *Enhanced Host Controller Interface Specification for Universal Serial Bus* (EHCI) from Intel Corporation. This module can act as a host, a device, or an On-The-Go (OTG) negotiable host or device on the USB bus.

The USBOTG controller interfaces with the processor's core. The controller is configured to support host or device operations under firmware control. The ULPI (UTMI Low Pin Interface) interface supports HS, full-speed (FS), and low-speed (LS) applications.

55.2.2 Features

- Complies with USB specification rev 2.0
- USB Host mode
  - Supports EHCI
- USB Device mode
  - Supports FS/HS operation via an external ULPI transceiver
  - Supports one upstream facing port
  - Supports six programmable, bidirectional USB endpoints, including endpoint 0. See endpoint configurations in the following table:

Table 388. Endpoint configurations

Endpoint	Type	FIFO size	Data transfer	Comments
0	Bidirectional	Variable	Control	Mandatory
1-5	IN or OUT	Variable	Ctrl, int, bulk, or ISO	Optional

- Suspend mode/low-power
  - As host, firmware can suspend individual devices or the entire USB and disable chip clocks for low-power operation.
  - Device supports low-power suspend.
  - Remote wake-up is supported for host and device.
- Support for off-chip HS, FS, LS transceiver
  - External ULPI transceiver supports HS, FS, and LS operations in Host mode, and HS and FS operations in Device mode.
  - Interface uses an 8-bit, single-data-rate ULPI data bus.
  - ULPI PHY supplies a 60 MHz USB reference clock input to the USB controller.

55.2.3 Modes of operation

This module has two basic operating modes: Host and Device. Selection of an operating mode is accomplished via the USBMODE[CM] field.

Speed selection is auto-detected at connect time using enumeration procedures in the USB network. This module provides these operation modes:

- USB disabled: In this mode, the USB datapath does not accept transactions received on the USB interface.
- USB enabled: In this mode, the datapath of the USB host is enabled to accept transactions received on the USB interface.
- USB enabled, low-power modes.

55.3 External signal description

This table describes the external signal functionality of the USBOTG module.

Table 389. Signal descriptions

Signal	I/O	Description	
ULPI interface			
ULPI_CLK	I/O	60 MHz clock input from the ULPI transceiver	
ULPI_DIR	O	Direction. ULPI_DIR controls data bus direction. When PHY has data to transfer to USB port, it drives ULPI_DIR high to take ownership of the bus. When the PHY has no data to transfer, it drives ULPI_DIR low and monitors the bus for link activity. The PHY pulls ULPI_DIR high when the interface cannot accept data from the link; for example, when PHY's PLL is not stable.	
		State meaning	Asserted—PHY has data to transfer to the link. Negated—PHY has no data to transfer.
		Timing	Synchronous to ULPI_CLK
ULPI_NXT	I	Next data. PHY asserts ULPI_NXT to throttle data. When the USB port sends data to the PHY, ULPI_NXT indicates when PHY accepts the current byte. The USB port places the next byte on the data bus in the following clock cycle. When the PHY sends data to USB port, ULPI_NXT indicates when a new byte is available for USB port to consume.	
		State meaning	Asserted—PHY is ready to transfer byte. Negated—PHY is not ready.
		Timing	Synchronous to ULPI_CLK
ULPI_STP	I	Stop. ULPI_STP indicates the end of a transfer on the bus.	
		State meaning	Asserted—USB asserts this signal for one clock cycle to stop the data stream currently on the bus. If the USB port sends data to the PHY, ULPI_STP indicates the last data byte was previously on the bus. If the PHY is sending data to the USB port, ULPI_STP forces the PHY to end its transfer, deassert ULPI_DIR, and relinquish control of the data bus to the USB port. Negated—Indicates normal operation.

Table continues on the next page...

Table 389. Signal descriptions (continued)

Signal	I/O	Description	
		Timing	Synchronous to ULPI_CLK
ULPI_DATA[7:0]	I/O	Data bit *n*. ULPI_DATA*n* is bit *n* of the 8-bit, bi-directional data bus used to carry USB, register, and interrupt data between the USB port controller and the PHY.	
		State meaning	Asserted—Data bit *n* is 1. Negated—Data bit *n* is 0.
		Timing	Synchronous to ULPI_CLK

55.4 USBOTG register descriptions

There are two types of registers in the USB module: USB core registers (UOTG) and USB non-core registers (UOTGNC).

The UOTG are used to control USB core functions and are more independent of USB features. Each USB controller core has its own core registers.

The UOTGNC are additional to the UOTG and are more dependent upon USB features.

NOTE

You must preserve a register's reserved field values when writing (that is, read its reset value, then write this value back).

The UOTGNC register name prefix indicates a USB non-core register.

55.4.1 Core register descriptions

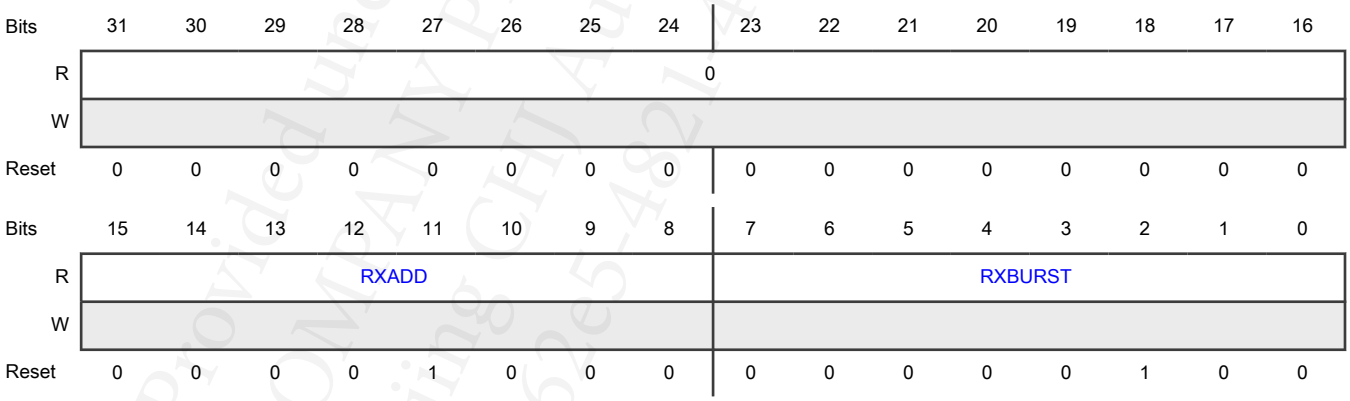
R	TXADD								TXBURST							
W																
Reset	0	0	0	0	1	0	1	1	0	0	0	0	0	1	0	0

Fields



Field	Function
31-24 —	Reserved
23-16 TXCHANADD	TX Channel Address Indicates the number of address bits required for TX channel buffer addressing. The TX buffer size is equal to $2^{TXCHANADD}$×4 bytes. For the OTG controller core, there is one TX buffer for each endpoint, therefore there are six TX buffers in all. The value of this field is configured as 8h, therefore, the buffer size is 256×4 bytes.
15-8 TXADD	TX Address Indicates the number of address bits required for TX buffer addressing. The buffer total size for all transmit endpoints is 2^{RXADD}.
7-0 TXBURST	TX Burst Size Indicates the default burst size for memory to TX buffer transfer. This is the reset value of BURSTSIZE[TXPBURST]. See BURSTSIZE for details.

55.4.1.7 RX Buffer Hardware Parameters (HWRXBUF)

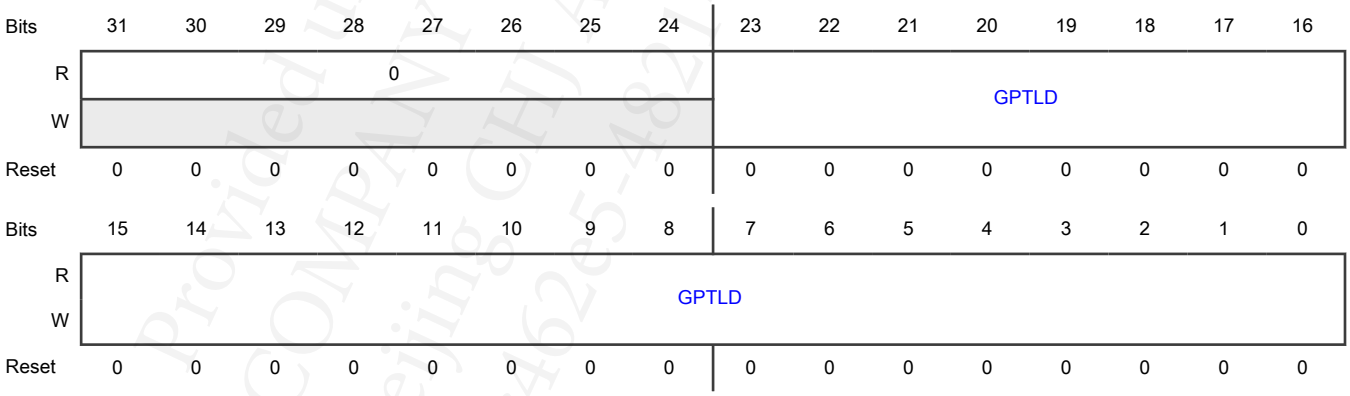
Fields

Field	Function
31-16 —	Reserved
15-8 RXADD	RX Address Indicates the number of address bits required for RX buffer addressing. The buffer total size for all receive endpoints is 2^{RXADD}. RX buffer size is equal to 2^{RXADD}×4 bytes. For the OTG controller core, there is one RX buffer shared by six endpoints. The value of this field is set to 08h, therefore, the buffer size is 256×4 bytes.
7-0 RXBURST	RX Burst size Indicates the default burst size for memory to RX buffer transfer. This is the reset value of BURSTSIZE[RXPBURST]. See BURSTSIZE for details.

55.4.1.8 General Purpose Timer Load (GPTIMER0LD - GPTIMER1LD)



Offset

Register	Offset
GPTIMER0LD	80h
GPTIMER1LD	88h

Function

Controls the load value of the count timer in GPT*n*CL. See GPTIMER0CTRL for details.

Diagram

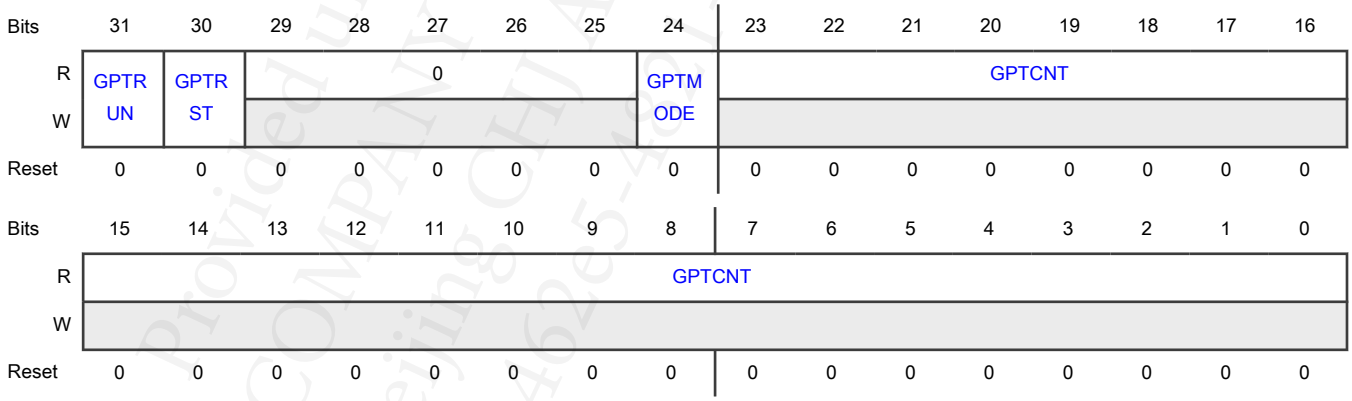
Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4625-4821-4da8-b251-390d3ab624c1

Fields

Field	Function
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value These bits are loaded to the GPTCNT bits when the GPTRST field is set to 1. This value represents the time in microseconds minus 1 for the timer duration. For example, a one millisecond timer, load 1000-1=999, or 0003E7h. **NOTE** Maximum value is FFFFFFh, or 16.777215 seconds.

55.4.1.9 General Purpose Timer Controller (GPTIMER0CTRL - GPTIMER1CTRL)

Offset



Register	Offset
GPTIMER0CTRL	84h
GPTIMER1CTRL	8Ch

Function

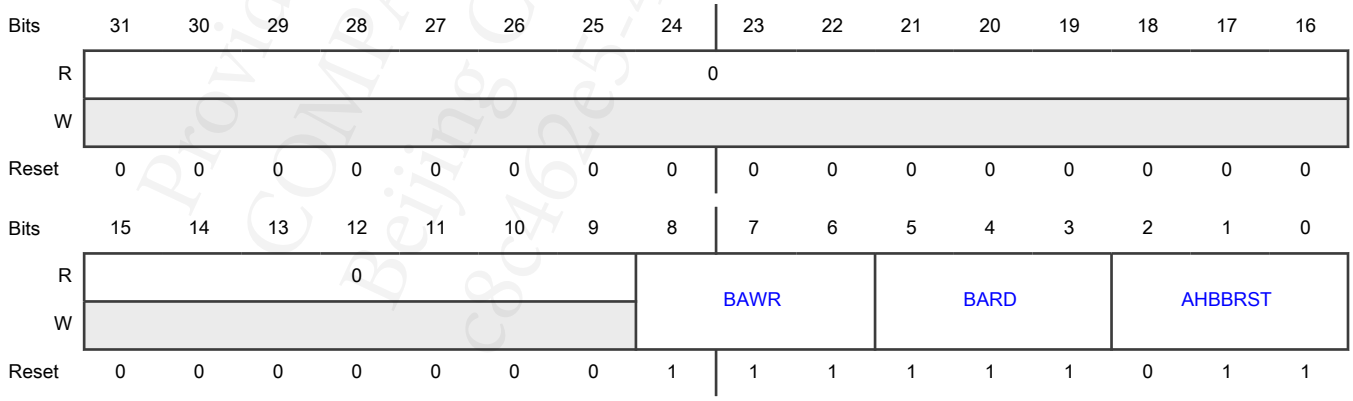
Contains the countdown timer control and a data field can be queried to determine the running count value. This timer has a granularity of 1 us and can be programmed to slightly more than 16 seconds. There are two counter modes that are described in the register table. When the timer counter value transitions to 0, an interrupt could be generated if enabled.

Interrupt status field is USBSTS[TI0]; interrupt enable field is USBINTR[TIE0].

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4e1-48a-b251-390dab624c1

Fields



Field	Function
31 GPTRUN	General Purpose Timer Run The GPTCNT bits are not affected when setting or clearing this field. 0b - Stop counting 1b - Run
30 GPTRST	General Purpose Timer Reset 0b - No action 1b - Load the counter value from GPT0LD[GPTLD]
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode In One-Shot mode, the timer counts down to 0, generates an interrupt, and stops until you reset the counter. In Repeat mode, the timer counts down to 0, generates an interrupt, and automatically reloads the counter value from the GPTLD bits to start again. 0b - One-Shot mode 1b - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Contains the count value of the countdown timer.

55.4.1.10 System Bus Configuration (SBUSCFG)

Offset

Register	Offset
SBUSCFG	90h

Diagram

Fields

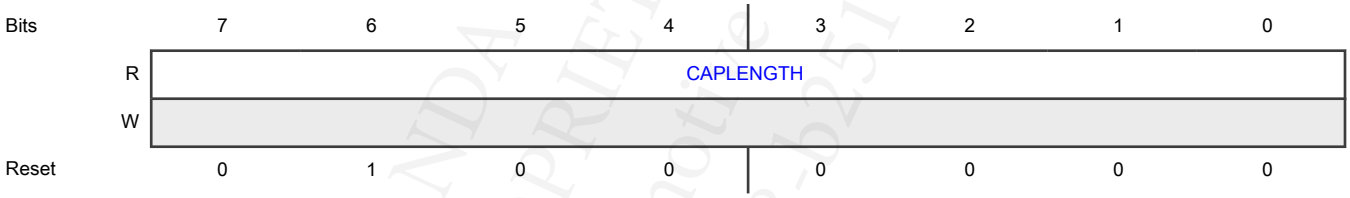
Field	Function
31-9 —	Reserved
8-6 BAWR	AMBA Burst Alignment for Writes To improve performance on system bus architectures where unaligned bursts are a problem, this mode guarantees that AMBA-AHB burst transfers never cross the burst size address boundary. Burst transfers that start unaligned are broken into smaller aligned bursts until aligned bursts of maximum size can be used. This aligns all packet data AMBA burst transfers to their respective address boundaries: • INCR16–64 byte boundary • INCR8–32 byte boundary • INCR4–16 byte boundary • SINGLE–4 byte boundary This mode only applies to packet data transfers, not data structures. When burst alignment is enabled, you can select a minimum threshold for the packet size that uses aligned bursts when being written to system memory. • 000 - Disable burst alignment • 001 - Align bursts for packets larger than 512 bytes • 010 - Align bursts for packets larger than 256 bytes • 011 - Align bursts for packets larger than 128 bytes • 100 - Align bursts for packets larger than 64 bytes • 101 - Align bursts for packets larger than 32 bytes • 110 - Align bursts for packets larger than 16 bytes • 111 - Align bursts for all packets This field configures the burst alignment only for AMBA writes.
5-3 BARD	AMBA Burst Alignment for Reads Same function as BAWR above, but for AMBA reads.
2-0 AHBBRST	AHB Master Interface Burst Configuration Controls the AHB master transfer type sequence (or priority). **NOTE** Overrides BURSTSIZE when its value is not 0. 000b - Incremental burst of unspecified length only 001b - INCR4 burst, then single transfer 010b - INCR8 burst, INCR4 burst, then single transfer 011b - INCR16 burst, INCR8 burst, INCR4 burst, then single transfer

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Reserved 101b - INCR4 burst, then incremental burst of unspecified length 110b - INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111b - INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

55.4.1.11 Capability Register Length (CAPLENGTH)



Offset

Register	Offset
CAPLENGTH	100h

Function

Indicates the offset that must be added to the register base address at the beginning of the operational register.

Diagram

Fields

Field	Function
7-0 CAPLENGTH	This field is used as an offset to be added to the register base to find the beginning of the Operational register.

55.4.1.12 Host Controller Interface Version (HCIVERSION)

Offset

Register	Offset
HCIVERSION	102h

Function

Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a3-b251-390d3ab624c1

Table continued from the previous page...

Field	Function
27-24 N_TT	Number of Transaction Translators Indicates the number of embedded transaction translators associated with the USB2.0 host controller. 0000b - Single-port host 0001b - Multi-port host
23-20 N_PTT	Number of Ports Per Transaction Translator Indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. This field is set to equal N_PORTS for Multi-Port Host, and 0000b for single-port host.
19-17 —	Reserved
16 PI	Port Indicators Indicates whether the ports support port indicator control. This field is 1b in the controller core. 0b - The ports do not support port indicator control. 1b - The port status and control registers include a read/writeable field for controlling the state of the port indicator.
15-12 N_CC	Number of Companion Controllers Indicates the number of companion controllers associated with this USB2.0 host controller. This field is 0000b in the controller core. 0000b - There is no internal companion controller and port-ownership hand-off is not supported. 0001b - There are internal companion controller(s) and port-ownership hand-offs are supported.
11-8 N_PCC	Number of Ports Per Companion Controller Indicates the number of ports supported per internal companion controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, and so on. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. This field is 0000b in the controller core.
7-5 —	Reserved
4 PPC	Port Power Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether the host controller implementation includes port power control. The value of this field affects the functionality of the port power field in each port status and control register. 0b - The ports do not have port power switches. 1b - The ports have port power switches.
3-0 N_PORTS	Number of Downstream Ports Specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational register. Valid values are in the range of 1h to Fh. The value 0h in this field is undefined. This field is always set to 0001b because the controller core is a single-port host.

55.4.1.14 Host Controller Capability Parameters (HCCPARAMS)

Offset

Register	Offset
HCCPARAMS	108h

Function

Identifies multiple mode control (time-base bit functionality) addressing capabilities.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	EECP								IST				0	ASP	PFL	ADC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Fields

Field	Function
31-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 EECP	EHCI Extended Capabilities Pointer Indicates the existence of a capabilities list. A value of 00h indicates that no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. If implemented, the pointer value must be 40h or greater to maintain the consistency of the PCI header defined for this class of device. This field has a fixed value of 00h.
7-4 IST	Isochronous Scheduling Threshold Indicates, relative to the current position of the executing host controller, where you can reliably update the isochronous schedule. When bit [7] is 0, the value of the least significant 3 bits indicates the number of microframes for which a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When IST[3] is 1, then the host software assumes that the host controller may cache an isochronous data structure for an entire frame. This field has a fixed value of 0h.
3 —	Reserved
2 ASP	Asynchronous Schedule Park Capability Supports the park feature for HS QHs in the asynchronous schedule. The feature can be disabled or enabled and set to a specific level by using USBCMD[ASPE] and USBCMD[ASP]. This field has a fixed value of 1.
1 PFL	Programmable Frame List Flag If you write 0 to this field, then the system software must use a frame list length of 1024 elements with this host controller. You must write 0 to USBCMD[FS1]. If you write 1 to this field, then the system software can specify and use a smaller frame list and configure the host controller via USBCMD[FS1]. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field has a fixed value of 1.
0 ADC	64-bit Addressing Capability This field has a fixed value of 0 and 64-bit addressing capability is not supported.

55.4.1.15 Device Controller Interface Version (DCIVERSION)

Offset

Register	Offset
DCIVERSION	120h

Function

Indicates the two-byte BCD encoding of the device controller interface version number.

Fields

Field	Function
31-24 —	Reserved
23-16 ITC	Interrupt Threshold Control The system software uses this field to set the maximum rate at which the host/device controller issues interrupts. ITC contains the maximum interrupt interval measured in microframes. Valid values are shown below. Maximum interrupt interval values are these: 00000000b - Immediate (no threshold) 00000001b - 1 microframe 00000010b - 2 microframes 00000100b - 4 microframes 00001000b - 8 microframes 00010000b - 16 microframes 00100000b - 32 microframes 01000000b - 64 microframes
15 FS1	Frame List Size See also FS0. This field is read/write only if the value of Programmable Frame List Flag in the HCCPARAMS registers is 1. Specifies the size of the frame list that controls which fields in USB Frame Index (FRINDEX) must be used for the frame list current index. **NOTE** This field is made up from USBCMD[FS1] and USBCMD[FS0]. 000 - 1024 elements (4096 bytes) 001 - 512 elements (2048 bytes) 010 - 256 elements (1024 bytes) 011 - 128 elements (512 bytes) 110 - 16 elements (64 bytes) 111 - 8 elements (32 bytes)
14 ATDTW	Add device transfer descriptor (dTD) TripWire Used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This field is set and cleared by you. This field is cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 SUTW	Setup TripWire Used as a semaphore to ensure that the setup data payload of eight bytes is extracted from a QH by the device controller driver (DCD) without being corrupted. If the setup lockout mode is off (USBMODE[SLOM] is 1), then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This field is set and cleared by you. The hardware also writes 0 to this field when a hazard is detected.
12 —	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable If HCCPARAMS[ASP] is 0, then this field defaults to 1h and is R/W. Otherwise, the field must be 0 and is RO. You use this field to enable or disable Park mode. When this field is 1, Park mode is enabled. When this field is a 0, Park mode is disabled. This field is set to 1h (the default value).
10 —	Reserved
9-8 ASP	Asynchronous Schedule Park Mode Count If HCCPARAMS[ASP] is 1, then this field defaults to 3 and is read/write. Otherwise, it defaults to 0 and is read-only. It contains a count of the number of successive transactions the host controller is allowed to execute from an HS QH on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 1 to 3. You must not write a 0 to this field when Park Mode Enable is a 1 as this results in undefined behavior. This field is set to 3h (the default value).
7 —	Reserved
6 IAA	Interrupt on Async Advance Doorbell You use this as a doorbell to tell the host controller to issue an interrupt the next time it advances the asynchronous schedule. You must write 1 to this field to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on the Async Advance status field in USB Status (USBSTS). If the Interrupt on Sync Advance Enable field in Interrupt Enable (USBINTR) is 1, then the host controller asserts an interrupt at the next interrupt threshold. The host controller clears this field to 0 after it has set the Interrupt on Sync Advance status field in USB Status (USBSTS) to 1. You must not write a 1 to this field when the asynchronous schedule is inactive; doing so yields undefined results. This field is only used in host mode. Writing 1 to this field when device mode is selected yields undefined results.

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 ASE	Asynchronous Schedule Enable Controls whether the host controller skips processing of the asynchronous schedule. Only the host controller uses this field. 0b - Do not process the asynchronous schedule 1b - Use ASYNCLISTADDR to access the asynchronous schedule
4 PSE	Periodic Schedule Enable Controls whether the host controller skips processing the periodic schedule. Only the host controller uses this field. 0b - Do not process the periodic schedule 1b - Use PERIODICLISTBASE to access the periodic schedule
3-2 FS0	FS0 See description at FS1.
1 RST	Controller Reset You use this field to reset the controller. It is cleared to 0 by the Host/Device controller when the reset process is complete. You cannot terminate the reset process early by writing a 0 to this register. Host operation mode: When you write 1 to this field, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial value. Any transaction currently in progress on the USB is immediately terminated. A USB reset is not driven on downstream ports. You must not write 1 to this field when USBSTS[HCH] is 0. Attempting to reset an actively running host controller results in undefined behavior. Device operation mode: When you write 1 to this field, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values. Writing 1 to this field, when the device is in the attached state, is not recommended because the effect on an attached host is undefined. To ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints must be flushed, and USBCMD[RS] must be written to 0. The reset value of this field is gated with the reset state machine. If the PHY clock is not up and running, the read value of this field is 1.
0 RS	Run/Stop Host Operation mode: When the value of this field is 1, the controller proceeds with the execution of the schedule. The controller continues execution as long as this field is set to 1. When this field is cleared to 0, the host controller completes the current transaction on the USB and then halts. The HC Halted field in the status register indicates when the controller has finished the transaction and has entered the stopped state. You must not write a 1 to this field unless the controller is in the Halted state (that is, USBSTS[HCH] is a 1). Device Operation mode: Writing a 1 to this field causes the controller to enable a pull-up on D+ and initiate an attach event. This control field is not directly connected to the pull-up enable, as the pull-up becomes

Table continues on the next page...

Table continued from the previous page...

Field	Function
	disabled upon transitioning into HS mode. You must use this field to prevent an attach event before the controller has been properly initialized. Writing a 0 to this field causes a detach event. 0b - Stop 1b - Run

55.4.1.18 USB Status (USBSTS)

Offset

Register	Offset
USBSTS	144h

Function

Indicates various states of the host/device controller and any pending interrupts. The register does not indicate status resulting from a transaction on the serial bus.

Diagram

Fields

Field	Function
31-26 —	Reserved
25 TI1	General Purpose Timer Interrupt 1 This field is set to 1 when the counter in the GPT1CL register transitions to 0.
24	General Purpose Timer Interrupt 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
TI0	This field is set to 1 when the counter in the GPT0CL register transitions to 0.
23-20 —	Reserved
19 UPI	USB Host Periodic Interrupt The host controller writes 1 to this field when the cause of an interrupt is a completion of a USB transaction in which the transfer descriptor (TD) has an interrupt on complete (IOC) field set to 1 and the TD was from the periodic schedule. This field is also set to 1 by the host controller when a short packet is detected and the packet is on the periodic schedule. A short packet occurs when the actual number of bytes received is less than expected. This field is not used by the device controller and is always 0.
18 UAI	USB Host Asynchronous Interrupt The host controller writes 1 to this field when the cause of an interrupt is completion of a USB transaction in which the TD has an IOC field set to 1 and the TD originates from the asynchronous schedule. This field is also set to 1 by the host when a short packet is detected and the packet is on the asynchronous schedule. A short packet occurs when the actual number of bytes received is less than expected. This field is not used by the device controller and is always 0.
17 —	Reserved
16 NAKI	NAK Interrupt This field is set to 1 by hardware when, for a particular endpoint, both the TX/RX Endpoint NAK fields (ENDPTNAK[EPTN] and ENDPTNAK[ERTN]) and the corresponding TX/RX Endpoint NAK Enable fields (ENDPTNAKEN[EPTNE] and ENDPTNAKEN[EPRNE]) are 1. This field is automatically cleared to 0 by hardware when all Enabled TX/RX Endpoint NAK fields are cleared to 0.
15 AS	Asynchronous Schedule Status Reports the current real status of the asynchronous schedule. When cleared to 0, the asynchronous schedule status is disabled; if set to 1, the status is enabled. The host controller is not required to immediately disable or enable the asynchronous schedule when you transition USBCMD[ASE]. When this field and USBCMD[ASE] are the same value, the asynchronous schedule is either enabled (1) or disabled (0). This field is only used in the host operation mode.
14 PS	Periodic Schedule Status Reports the current real status of the periodic schedule. When cleared to 0, the periodic schedule is disabled, and if set to 1 the status is enabled. The host controller is not required to immediately disable or enable the periodic schedule when you transition the Periodic Schedule Enable field in USB Command (USBCMD). When this field and the Periodic Schedule Enable field are the same value, the periodic schedule is either enabled (1) or disabled (0).

Table continues on the next page...

Table continued from the previous page...

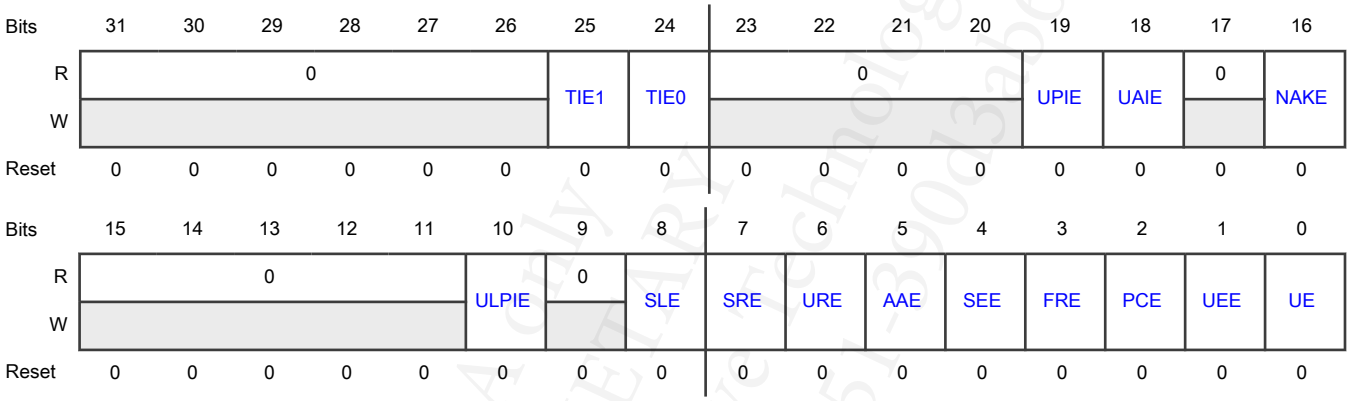
Field	Function
	This field is only used in the host operation mode.
13 RCL	Reclamation This status field is used to detect an empty asynchronous schedule. It is only used in the host operation mode.
12 HCH	HC Halted This field is a 0 whenever the Run/Stop field is a 1. The controller sets this field to 1 after it has stopped executing because of the Run/Stop field being cleared to 0, either by you or by the controller hardware (for example, on an internal error). This field is only used in the host operation mode. The OTG core does not operate as a host by default. See USBMODE[CM].
11 UALTI	ULPI alt_int Interrupt This interrupt field is set to 1 when an RXCMD is received through the ULPI interface with bit 7 set (alt_int). The alt_int itself is set when an unmasked event occurs on any bit in the Carkit Interrupt Latch register, in the ULPI PHY. You must read the Carkit Interrupt Latch register (Read to Clear) through the ULPI Viewport to check the source of the interrupt.
10 ULPII	ULPI Interrupt This field is set to 1 by hardware when there is an event completion in the ULPI viewport. This field is usable only if the controller supports ULPI interface mode.
9 —	Reserved
8 SLI	DC Suspend When a controller enters a suspend state from an active state, the value of this field is 1. The device controller clears the field to 0 upon exiting from a suspend state. This field is only used in device operation mode.
7 SRI	SOF Received When the device controller detects a start-of-(micro)frame, this field is set to 1. When a SOF is extremely late, the device controller automatically sets this field to 1 to indicate that an SOF was expected. Therefore, this field is set roughly every 1 ms in device FS mode and every 125 ms in HS mode, and is synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this field is set to 1 at an interval of 1 ms during the prelude to connect and chirp. In host mode, this field is set every 125 µs and can be used by the host controller driver as a time base. You write a 1 to this field to clear it.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 URI	USB Reset Received When the device controller detects a USB Reset and enters the default state, this field is set to 1. You can write a 1 to this field to clear the USB Reset Received status field to 0. This field is only used in device operation mode.
5 AAI	Interrupt on Async Advance You can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 to USBCMD[IAA]. This status field indicates the assertion of that interrupt source. This field is only used in host operation mode.
4 SEI	System Error This field is set to 1 when an error is seen in response to a read on the system interface.
3 FRI	Frame List Rollover The host controller sets this field to 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in USBCMD[FS1]) is 1024, USB Frame Index (FRINDEX) rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the host controller sets this field to 1 every time FHINDEX [12] toggles. This field is only used in host operation mode.
2 PCI	Port Change Detect The host controller sets this field to 1 when, on any port, a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume field is set as the result of a J-K transition on the suspended port. The device controller sets this field to 1 when the port controller enters the FS or HS operational state. When the port controller exits the FS or HS operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received and the DCSuspend fields, respectively.
1 UEI	USB Error Interrupt When completion of a USB transaction results in an error condition, this field is set to 1 by the host/device controller. This field is set to 1, along with the USBSTS[UI] field, if the TD on which the error interrupt occurred also had its IOC field set to 1. The device controller detects resume signaling only.
0 UI	USB Interrupt Set by the host/device controller when the cause of an interrupt is a completion of a USB transaction where the TD has an IOC field set to 1. This field is also set by the host/device controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

55.4.1.19 Interrupt Enable (USBINTR)



Offset

Register	Offset
USBINTR	148h

Function

Enables interrupts to software. An interrupt is generated when a field is 1 and the corresponding interrupt source is active. USB Status (USBSTS) still shows interrupt sources even if they are disabled by the USBINTR, allowing you to poll interrupt events.

Diagram

Fields

Field	Function
31-26 —	Reserved
25 TIE1	General Purpose Timer 1 Interrupt Enable When this field is 1 and USBSTS[TI1] is 1, the controller issues an interrupt.
24 TIE0	General Purpose Timer 0 Interrupt Enable When this field is 1 and USBSTS[TI0] is 1, the controller issues an interrupt.
23-20 —	Reserved
19 UPIE	USB Host Periodic Interrupt Enable When this field is 1 and USBSTS[UPI] is 1, the host controller issues an interrupt at the next interrupt threshold.
18	USB Host Asynchronous Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
UAIE	When this field is 1 and USBSTS[UAI] is 1, the host controller issues an interrupt at the next interrupt threshold.
17 —	Reserved
16 NAKE	NAK Interrupt Enable When this field is 1 and USBSTS[NAKI] is 1, the controller issues an interrupt.
15-11 —	Reserved
10 ULPIE	ULPI Interrupt Enable When this field is 1 and USBSTS[ULPII] is 1, the controller issues an interrupt. This field is usable only if the controller supports ULPI interface mode.
9 —	Reserved
8 SLE	Sleep Interrupt Enable When this field is 1 and USBSTS[SLI] is 1, the controller issues an interrupt. This field is only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this field is 1 and USBSTS[SRI] is 1, the controller issues an interrupt.
6 URE	USB Reset Interrupt Enable When this field is 1 and USBSTS[URI] is 1, the controller issues an interrupt. This field is only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this field is 1 and USBSTS[AAI] is 1, the controller issues an interrupt. This field is only used in host operation mode.
4 SEE	System Error Interrupt Enable When this field is 1 and USBSTS[SEI] is 1, the controller issues an interrupt.
3 FRE	Frame List Rollover Interrupt Enable When this field is 1 and USBSTS[FRI] is 1, the controller issues an interrupt. This field is only used in host operation mode.
2	Port Change Detect Interrupt Enable

Table continues on the next page...

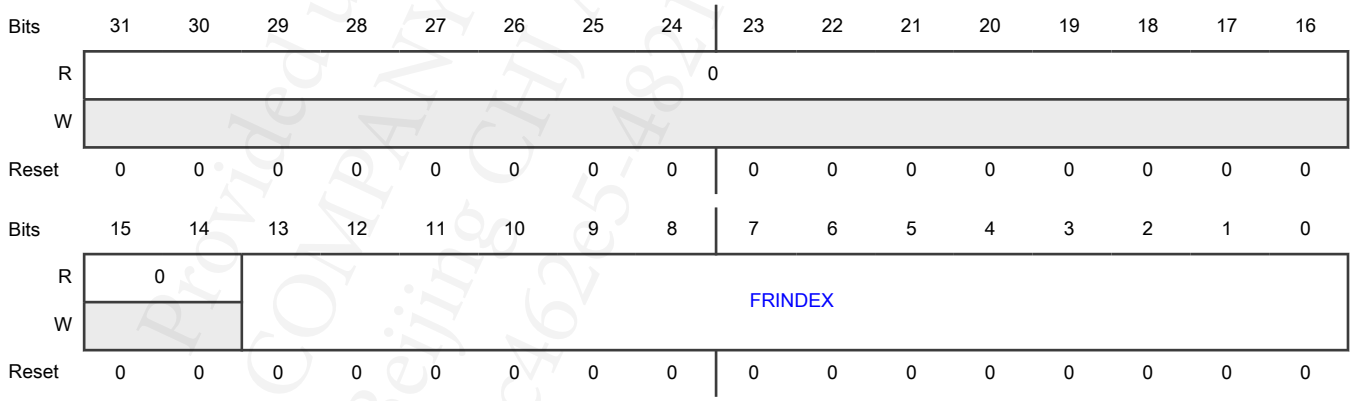
Table continued from the previous page...

Field	Function
PCE	When this field is 1 and USBSTS[PCI] is 1, the controller issues an interrupt.
1 UEE	USB Error Interrupt Enable When this field is 1 and USBSTS[UEI] is 1, the controller issues an interrupt.
0 UE	USB Interrupt Enable When this field is 1 and USBSTS[UI] is 1, the controller issues an interrupt.

55.4.1.20 USB Frame Index (FRINDEX)

Offset

Register	Offset
FRINDEX	14Ch



Function

Used by the host controller to index the periodic frame list. The register updates every 125 µs (once each microframe). Bits [N:3] are used to select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list that you set in USBCMD[FS1].

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the host controller is in the Halted state as indicated by USBSTS[HCH]. A write to this register while USBCMD[RS] is set to 1 produces undefined results. Writes to this register also affect the SOF value.

In Device mode, this register is read-only, and the device controller updates it using the frame number indicated by the SOF marker. Whenever the USB receives and SOF, FRINDEX [13:3] is checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] becomes 0 (that is, SOF for a 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] is incremented (that is, SOF for a 125 µs microframe.).

Diagram

Fields

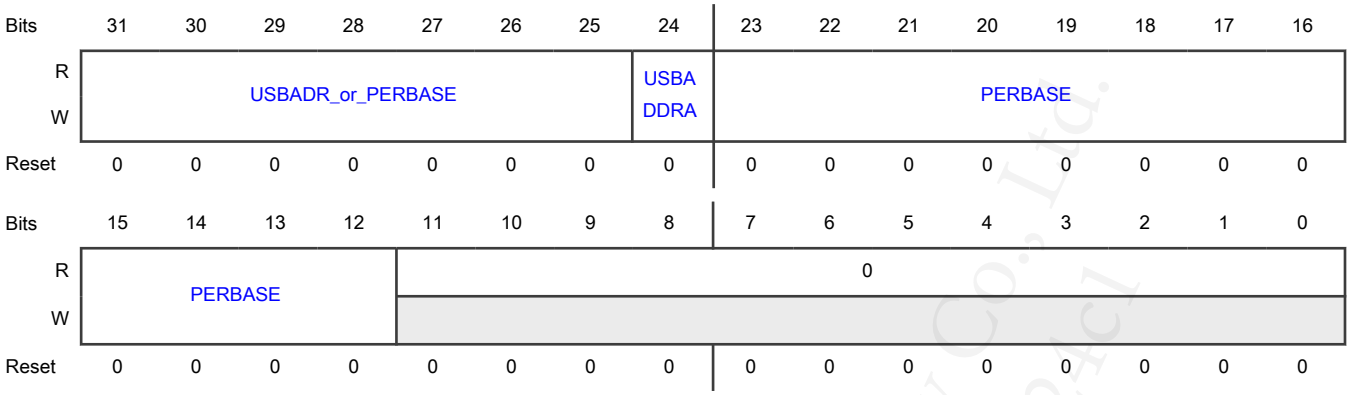
Field	Function
31-14 —	Reserved
13-0 FRINDEX	Frame Index In this field, the value increments at the end of each time frame (microframe). Bits [N:3] are used for the Frame List current index. This means that each location of the frame list is accessed eight times (frames or microframes) before moving to the next index. The following illustrates values of N, based on the value of USBCMD[FS1], when used in Host mode. In Device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current microframe. USBCMD [Frame List Size] Number Elements N 00000000000000b - (1024) 12 00000000000001b - (512) 11 00000000000010b - (256) 10 00000000000011b - (128) 9 00000000000100b - (64) 8 00000000000101b - (32) 7 00000000000110b - (16) 6 00000000000111b - (8) 5

55.4.1.21 Frame List Base Address or Device Address (PERIODICLISTBASE_or_DEVICEADDR)

Offset

Register	Offset
PERIODICLISTBASE_or_DEVICEADDR	154h

Function



PERIODICLISTBASE - For host controller only:

Contains the beginning address of the periodic frame list in the system memory. The host controller device (HCD) loads this register prior to starting the schedule execution by the host controller. The memory structure referenced by this physical memory pointer is assumed to be 4 KB aligned. The contents of this register are combined with the ones of USB Frame Index (FRINDEX) to enable the host controller to step through the periodic frame list in sequence.

DEVICEADDR - For device controller only:

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. You must reprogram the address after receiving a SET_ADDRESS descriptor.

Diagram

Fields

Field	Function
31-25 USBADR_or_PERBASE	Device Address (For Device mode) or PERBASE (For Host mode) Device mode: These bits correspond to the USB device address. Host mode: See the PERBASE description.
24 USBADDRA	Device Address Advance (For Device mode) or Reserved (For Host mode) Device mode: When this field is 0, any writes to USBADR are instantaneous. When this field is written to 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and generates an ACK response, USBADR is loaded from the holding register. Hardware automatically clears this field to 0 on the following conditions: • IN generates an ACK to endpoint 0 (USBADR is updated from the hidden register). • OUT/SETUP occurs to endpoint 0 (USBADR is not updated). • Device Reset occurs (USBADR is reset to 0). **NOTE** • After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism ensures that this specification is met when the DCD cannot execute a write of the device address within 2 ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR is programmed instantly at the correct time and meet the 2 ms USB requirement. • This field is reserved for Host mode operation.
23-12 PERBASE	PERBASE (For Host mode) or Reserved (for Device mode) Periodic List Base Address Corresponds to memory address signals [31:12].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is only used by the host controller. **NOTE** This field is reserved for Device mode operation.
11-0 —	Reserved

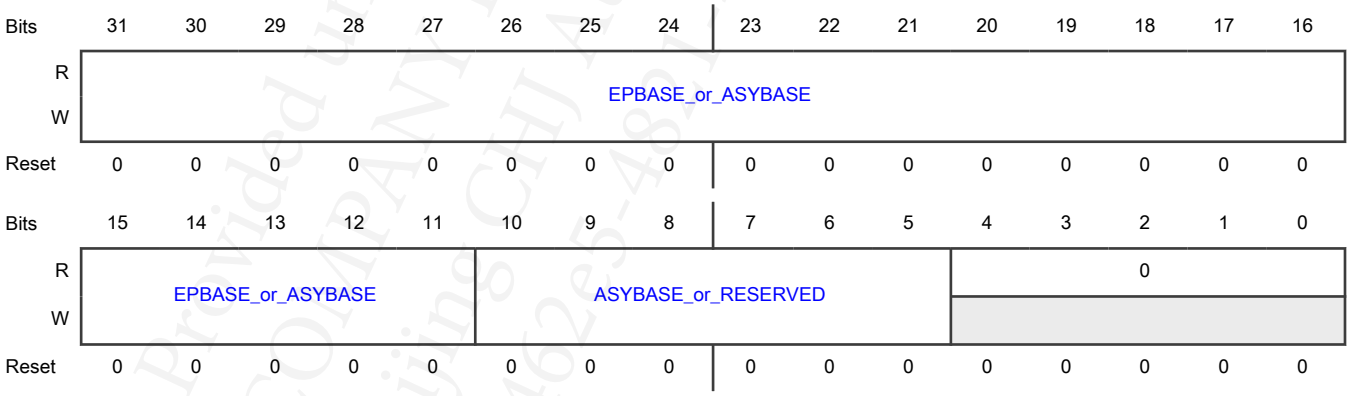
55.4.1.22 Next Asynchronous Address or Endpoint List Address (ASYNCLISTADDR_or_ENDPOINTLISTADDR)

Offset

Register	Offset
ASYNCLISTADDR_or_ENDPOINTLISTADDR	158h

Function

Next asynchronous address - for host controller only:



Contains the address of the next asynchronous QH to be executed by the host. You cannot modify bits [4:0] of this register, and when you read them they always return 0s.

Endpoint list address - for device controller only:

In Device mode, this register contains the address of the top of the endpoint list in system memory. You cannot modify bits [10:0] of this register, and when you read them they always return 0s.

The memory structure referenced by this physical memory pointer is assumed to be 64 bytes.

Diagram

Fields

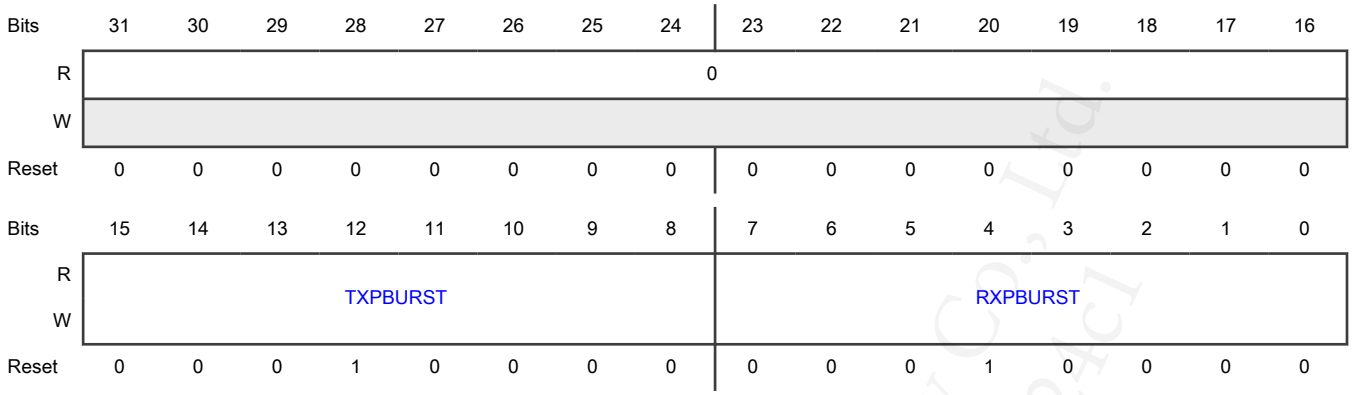
Field	Function
31-11 EPBASE_or_ASYBASE	Endpoint List Pointer (Low) (for Device mode) or Link Pointer Low (LPL) (for Host mode) Device mode: These bits correspond to memory address signals [31:11]. This field references a list of up to 32 QH (that is, one QH per endpoint and direction). Host mode: See the ASYBASE description.
10-5 ASYBASE_or_RESERVED	Link Pointer Low (LPL) (for Host mode) or Reserved (for Device mode) Host mode: These bits correspond to memory address signals [31:5]. This field may only reference a QH. **NOTE** This field is reserved for Device mode operation.
4-0 —	Reserved

55.4.1.23 Programmable Burst Size (BURSTSIZE)

Offset

Register	Offset
BURSTSIZE	160h

Function



Controls the burst size used during data movement on the AHB master interface. The register is ignored if SBUSCFG[AHBBRST] is a non-zero value.

NOTE

The AHB maximum burst length is 16 beats. Each beat can be 4 bytes; therefore, the maximum burst supported on the AHB is 64 bytes.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.
c8c462e5-4811-48a8-b251-390a3a624c1

Diagram

Fields

Field	Function
31-16 —	Reserved
15-8 TXPBURST	Programmable TX Burst Size HWTXBUF[TXBURST] determines the default value. This field represents the maximum burst length in 32-bit words while moving data from system memory to the USB bus.
7-0 RXPBURST	Programmable RX Burst Size HWRXBUF[RXBURST] determines the default value. This field represents the maximum burst length in 32-bit words while moving data from the USB bus to system memory.

55.4.1.24 TX FIFO Fill Tuning (TXFILLTUNING)

Offset

Register	Offset
TXFILLTUNING	164h

Function

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include how much data to post into the FIFO and an estimate of the length the operation should take in the target system.

Definitions:

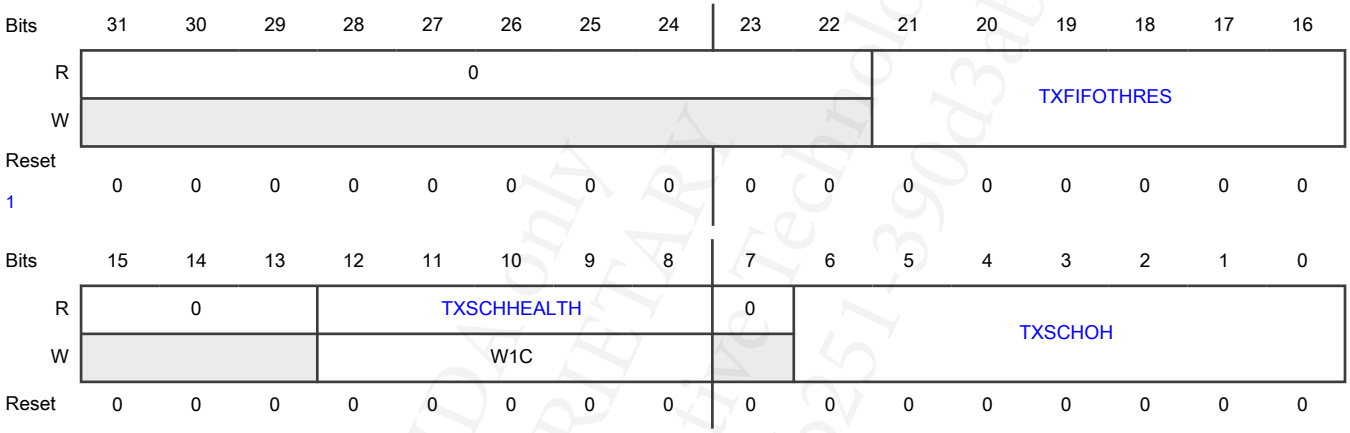
T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4e5-4821-48ac-b251-390d3ab624c1

T_s = Total Packet Flight Time (send-only) packet



$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, the host controller checks to ensure T_p remains before the end of the (micro)frame. If so, it proceeds to pre-fill the TX FIFO. If at any time during the pre-fill operation the time remaining the [micro]frame is < T_s, then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller eventually recovers, a mark is made to the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that begins after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus must be minimized (not necessarily eliminated). Back-offs can be minimized with use of the TSCHHEALTH (T_{ff}) described below.

Diagram

1. Reset value is implementation-dependent.

Fields

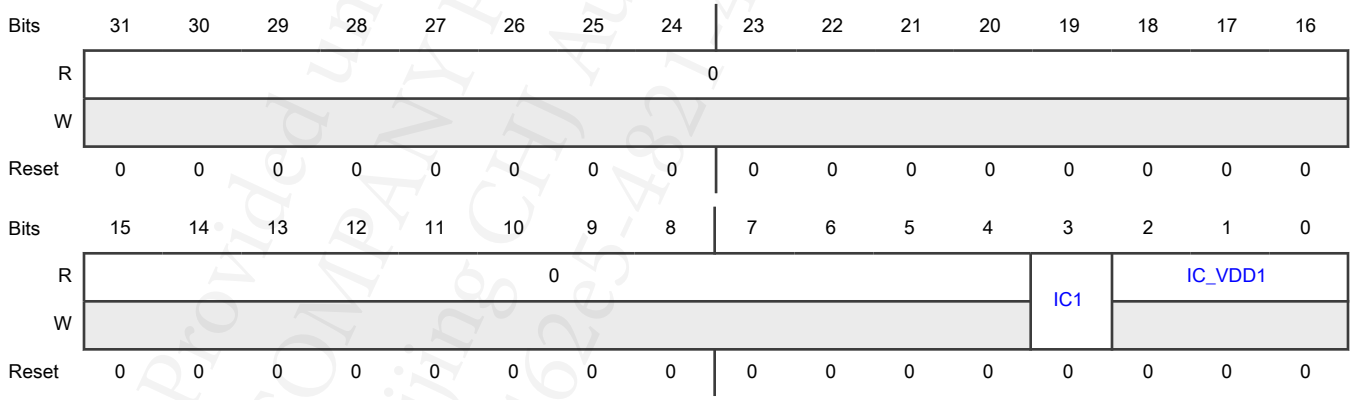
Field	Function
31-22 —	Reserved
21-16 TXFIFOTHRES	FIFO Burst Threshold Controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on the bus. The minimum value is two, and this value must be as small as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth for which the FIFO may underrun because the data transferred from the latency FIFO to the USB occurs before it can be refreshed from system memory. This value is ignored if USBMODE[SDIS] is 1.
15-13 —	Reserved
12-8	Scheduler Health Counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXSCHHEALTH	Increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. The maximum value for this counter is 31, and writing to this register clears the counter.
7 —	Reserved
6-0 TXSCHOH	Scheduler Overhead This field adds a fixed offset to the schedule time estimator described above as T_{ff}. As an approximation, the value chosen for this register must limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a high-usage bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in HS mode. The time unit represented in this register is 6.333 µs when a device is connected in LS/FS mode.

55.4.1.25 IC_USB Enable and Voltage Negotiation (IC_USB)



Offset

Register	Offset
IC_USB	16Ch

Function

Enables and controls the IC-USB FS or LS transceiver.

Diagram

Fields

Field	Function
31-4 —	Reserved
3 IC1	Inter-Chip Transceiver Enable Enables the inter-chip transceiver. To enable the IC-USB interface, the PTS bits in the PORTSC1 register also need to be set correspondingly. See PORTSC1. **NOTE** If IC1 is enabled, IOMUX must set the DP/DM pad into loopback mode.
2-0 IC_VDD1	Indicates which voltage is being supplied to the peripheral. The field is set to 000b in the case of a device controller. 000b - No voltage 001b - 1.0 V 010b - 1.2 V 011b - 1.5 V 100b - 1.8 V 101b - 3.0 V 110b - Reserved 111b - Reserved

55.4.1.26 ULPI Register Access (ULPI_VIEWPORT)

Offset

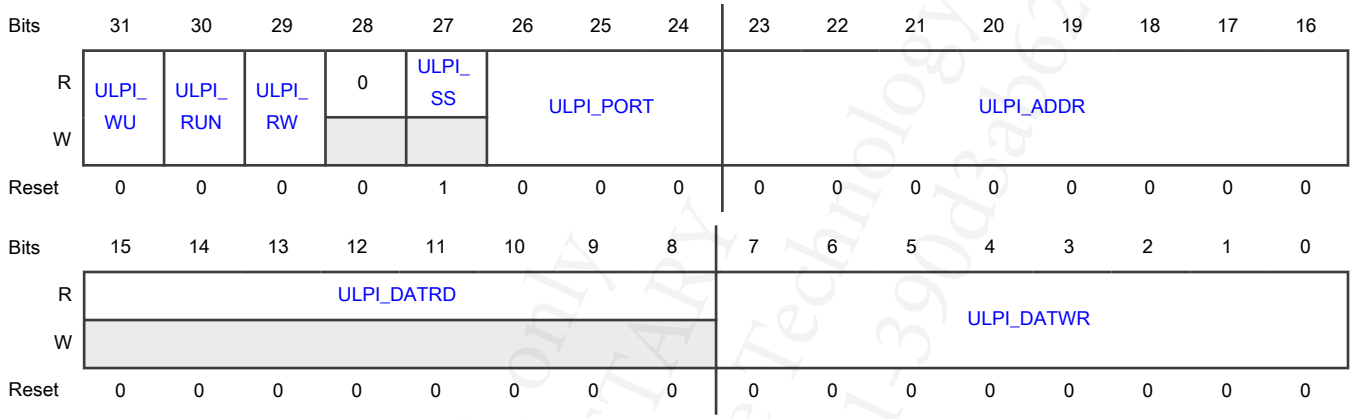
Register	Offset
ULPI_VIEWPORT	170h

Function

Provides indirect access to the ULPI PHY register set. Although the controller modules perform access to the ULPI PHY register set, there may be circumstances for which you need direct access.

CAUTION

Writes to the ULPI through the ULPI viewport can substantially harm standard USB operations. No usage model has been defined in which you should need to execute writes directly to the ULPI. Executing read operations though the ULPI viewport must have no harmful side effects to standard USB operations. Also, if the ULPI interface is not enabled, this register is always read-cleared.



There are two operations that can be performed with the ULPI viewport: wake-up and read/write. The wake-up operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wake-up operation is required before accessing the registers when the ULPI interface is operating in low-power mode, serial mode, or carkit mode. The ULPI state can be determined by reading the sync state field (ULPI_VIEWPORT[ULPI_SS]). If this field is 1, then the ULPI

interface is running in normal operating mode and can accept read/write operations. If ULPI_VIEWPORT[ULPI_SS] becomes 0, then read/write operations are not executed. Undefined behavior results if a read or write operation is performed when ULPI_VIEWPORT[ULPI_SS] becomes 0. To execute a wake-up operation, you write all 32-bits of the ULPI VIEWPORT where ULPI_VIEWPORT[ULPI_PORT] is constructed appropriately, the ULPI_WU field is set to 1, and ULPI_VIEWPORT[ULPI_RUN] is cleared to 0. You must poll this register until the ULPI_WU field is cleared to 0 in order for the operation to complete.

To execute a read or write operation, you must write to all 32-bits of this register, where ULPI_DATWR, ULPI_ADDR, ULPI_PORT, and ULPI_RW fields are constructed appropriately and the ULPI_RUN field is 1. Poll the register until ULPI_RUN becomes 0 in order for the operation to complete. For read operations, ULPI_DATRD is valid after ULPI_RUN becomes 0.

The polling method above can be replaced with interrupts using the ULPI interrupt defined in USB Status (USBSTS) and Interrupt Enable (USBINTR). When a wake-up or read/write operation completes, the ULPI interrupt is set.

Diagram

Fields

Field	Function
31 ULPI_WU	ULPI Wake-Up Writing a 1 to this field begins the wake-up operation. This field is automatically cleared to 0 after the wake-up is complete. After this field is set to 1, it cannot be cleared to 0 by you. **NOTE** The driver must never execute a wake-up and a read/write operation at the same time.
30 ULPI_RUN	ULPI Run Writing this field to 1 begins a read/write operation. This field is automatically cleared to 0 after the read/write is complete. After this field is set to 1, it cannot be cleared to 0 by you. **NOTE** The driver must never execute a wake-up and a read/write operation at the same time.
29 ULPI_RW	ULPI Read/Write Selects between running a read or write operation to the ULPI. 0b - Read 1b - Write

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 —	Reserved
27 ULPI_SS	ULPI Sync State Represents the state of the ULPI interface. Before reading this field, the ULPI_PORT field must be set accordingly if used with the multi-port host. Otherwise, this field must always remain 0. 0b - Any other state (that is, carkit, serial, low-power) 1b - Normal sync state
26-24 ULPI_PORT	ULPI Port Number For wake-up or read/write operations, this value selects the port number to which the ULPI PHY is attached. Valid values are 0 and 1.
23-16 ULPI_ADDR	ULPI Data Address When a read or write operation is commanded, the address of the operation is written to this field.
15-8 ULPI_DATRD	ULPI Data Read After a read operation completes, the result is placed in this field.
7-0 ULPI_DATWR	ULPI Data Write When a write operation is commanded, the data to be sent is written to this field.

55.4.1.27 Endpoint NAK (ENDPTNAK)

Offset

Register	Offset
ENDPTNAK	178h

Function

This status register indicates whether the device has sent NAK on the corresponding endpoint.

Provided under NDA only

55.4.1.30 Port Status and Control (PORTSC1)

Offset

Register	Offset
PORTSC1	184h

Function

Host controller

A host controller could implement one to eight of these port status and control registers. The number is determined by the N_PORTs bits in the HCSPARAMS register (see HCSPARAMS). You can read this parameter register to determine how many ports need service.

Both of the controller cores are single-port hosts, so there is only one port status and control register for each controller core.

This register is only reset by power-on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, the device controller state remains until port power is supplied (by you).

A device controller has only port register one (PORTSC1) and it does not support power control. Port control in Device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate Test mode or force signaling, and allows you to put the PHY into low-power Suspend mode and disable the PHY clock.

Provided under NDA

Fields

Field	Function
31-30 PTS1	Parallel Transceiver Select This field consists of PTS1 and PTS0. **NOTE** All USB port interface modes are listed in this field description, but not all are supported. For the feature details of each controller core, see Features. The behavior is unknown when an unsupported interface mode is selected. 000 UTMI/UTMI+ 001 Reserved 010 ULPI 011 Serial/USB 1.1 PHY/IC-USB (FS only) 100 HSIC 101 Reserved 110 Reserved 111 Reserved
29 STS	Serial Transceiver Select The serial interface engine can be used in combination with the UTMI+/ULPI physical interface to provide FS or LS signaling instead of the parallel interface signals. When this field is 1, the serial interface engine is used instead of the parallel interface signals. This field has no effect unless the PTS field is configured to select the UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB uses the serial interface engine for FS or LS signaling regardless of this field's value. 0b - Parallel interface signals selected 1b - Serial interface engine selected
28	Parallel Transceiver Width

Table continues on the next page...

Table continued from the previous page...

Field	Function
PTW	This field has no effect if serial interface engine is used. These register bits are implementation-dependent. 0b - Select the 8-bit UTMI interface [60MHz] 1b - Select the 16-bit UTMI interface [30MHz]
27-26 PSPD	Port Speed Indicates the speed at which the port is operating. 00b - FS 01b - LS 10b - HS 11b - Undefined
25 PTS0	PTS0 See the description in PTS1.
24 PFSC	Port Force FS Connect When this field is set to 1, the port is forced to only connect at FS, It disables the chirp sequence that allows the port to identify itself as FS. 0b - Normal operation 1b - Forced to FS
23 PHCD	PHY Low Power Suspend - Clock Disable When this field is 1, the PHY clock is disabled. Reading this field indicates the status of the PHY clock. **NOTE** The PHY clock cannot be disabled if it is being used as the system clock. In Device mode, the PHY can be put into low-power Suspend mode when the device is not running (USBCMD Run/Stop=0) or the host has signaled suspend (PORTSC1 SUSPEND=1). PHY Low Power Suspend is cleared automatically when the host initials resume. Before forcing a resume from the device, the DCD must clear this field. In Host mode, the PHY can be put into low-power Suspend mode when the downstream device has been put into Suspend mode or when no downstream device is connected. Low-power Suspend mode is completely under your control. 0b - Enable PHY clock 1b - Disable PHY clock
22 WKOC	Wake on Over-current Enable Writing this field to 1 enables the port to be sensitive to over-current conditions as wake-up events. This field is 0 if PORTSC1 is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 WKDS	Wake on Disconnect Enable Writing this field to 1 enables the port to be sensitive to device disconnects as wake-up events. This field is 0 if PORTSC1 is 0 or is in Device mode.
20 WKCN	Wake on Connect Enable Writing this field to a 1 enables the port to be sensitive to device connects as wake-up events. This field is 0 if PORTSC1 is 0 or is in Device mode.
19-16 PTC	Port Test Control The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS, FS, or LS} values forces the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE allows the port state machines to progress normally from that point. **NOTE** LS operations are not supported as a peripheral device. Any value other than 0h indicates that the port is operating in Test mode. 0000b - TEST_MODE_DISABLE 0001b - J_STATE 0010b - K_STATE 0011b - SE0 (host) / NAK (device) 0100b - Packet 0101b - FORCE_ENABLE_HS 0110b - FORCE_ENABLE_FS 0111b - FORCE_ENABLE_LS 1000-1111b - Reserved
15-14 PIC	Port Indicator Control Writing to this field has no effect if HCSPARAMS[PI] is 0. See "USB Specification Revision 2.0" for a description on how these fields are to be used. This field is 0 if port power is 0. Field-value encoding: 00b - Port indicators are off 01b - Amber 10b - Green 11b - Undefined
13	Port Owner

Table continues on the next page...

Table continued from the previous page...

Field	Function
PO	This field unconditionally goes to 0 when the configured field in Configure Flag (CONFIGFLAG) makes a 0 to 1 transition. This field unconditionally goes to 1 whenever the Configured field is 0. You use this field to release ownership of the port to a selected host controller (if the attached device is not an HS device). You write 1 to this field when the attached device is not an HS device. A 1 in this field means that an internal companion controller owns and controls the port. Port owner hand-off is not supported, therefore this field is always 0.
12 PP	Port Power The function of this field depends on the value of HCSPARAMS[PPC]. The behavior is as follows: PPC PP Operation 0 1b - Read Only. The host controller does not have port power control switches. Each port is hard-wired to power. 1 1b/0b - Read/Write. Host/OTG controller requires port power control switches. This field represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals 0), the port is non-functional and does not report attaches, detaches, and so on. When an over-current condition is detected on a powered port and PPC is 1, the PP field in each affected port may be transitioned by the host controller driver from 1 to 0 (removing power from the port).
11-10 LS	Line Status Reflects the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the DCD is not necessary. The encoding of the bits [11:10] are: 00b - SE0 01b - K-state 10b - J-state 11b - Undefined
9 HSP	HS Port When the field is 1, the host/device connected to the port is in HS mode; when this field is 0, the host/device connected to the port is not in HS mode. **NOTE** HSP is redundant with PSPD (bit 27, 26) but is retained for compatibility.
8 PR	Port Reset In Host mode, this field is R/W. When you write 1 to this field, the bus reset sequence begins as defined in USB Specification Revision 2.0. This field automatically changes to 0 after the reset sequence is completed. This behavior is different from

Table continues on the next page...

Table continued from the previous page...

Field	Function
	the EHCI in which the host controller driver is required to clear this field to 0 after the reset duration is timed in the driver. In Device mode, this field is read-only. Device reset from the USB bus is also indicated in USB Status (USBSTS). This field is 0 if PORTSC1[PP] is 0. 0b - Port is not in Reset 1b - Port is in Reset
7 SUSP	Suspend 1 - Port is in suspend state 0 - Port is not in suspend state In Host mode: Read/Write PORTSC1[PE] and PORTSC1[SUSP] of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x - Disabled 10 - Enabled 11 - Suspended When in the Suspend state, the downstream propagation of data is blocked on this port except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this field was written to 1. In the Suspend state, the port is sensitive to resume detection. The field status does not change until the port is suspended, and there may be a delay in suspending a port if there is a transaction currently in progress. The host controller unconditionally clears this field to 0 when you set the Force Port Resume field to 0. The host controller ignores a write of 0 to this field. If the host software sets this field to 1 when the port is not enabled (that is, the Port enabled field is 0), the results are undefined. This field is 0 if PORTSC1[PP] is 0 in Host mode. In Device mode: Read Only In Device mode, this field is a read-only status field.
6 FPR	Force Port Resume In Host mode: You set this field to 1 to drive resume signaling. The host controller sets this field to 1 if a J-to-K transition is detected while the port is in the Suspend state. When this field transitions to a 1 because a J-to-K transition is detected, the Port Change Detect field in the USBSTS register is also set to 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field automatically changes to 0 after the resume sequence is completed. This behavior is different from EHCI, in which the host controller driver is required to set this field to 0 after the resume duration is timed in the driver. When the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (FS, 'K') is driven on the port as long as this field remains 1. This field remains 1 until the port has switched to HS idle. Writing 0 has no effect because the port controller times the resume operation to clear the field when the port control state switches to HS or FS idle. This field is 0 if PORTSC1[PP] is 0 in Host mode. This field is not EHCI-compatible. In Device mode: After the device has been in the Suspend state for 5 ms or more, you must set this field to 1 to drive resume signaling before clearing. The Device Controller sets this field to 1 if a J-to-K transition is detected while the port is in the Suspend state. The field is cleared to 0 when the device returns to normal operation. Also, when this field transitions to a 1 because a J-to-K transition detected, USBSTS[PCI] is also set to 1. Field values: 0b - No resume (K-state) detected/driven on port 1b - Resume detected/driven on port
5 OCC	Over-Current Change This field is set to 1 by hardware when there is a change to Over-current Active. You can clear this field to 0 by writing 1 to it.
4 OCA	Over-Current Active Automatically transitions from 1 to 0 when the over-current condition is removed. 0b - This port does not have an over-current condition 1b - This port presently has an over-current condition
3 PEC	Port Enable/Disable Change In Host mode: For the root hub, this field is set to 1 only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). You clear this field to 0 by writing 1 to it. This field is 0 if PORTSC1[PP] is 0. In Device mode: The device port is always enabled, so this field is always 0. 0b - No change 1b - Port enabled/disabled status has changed

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 PE	Port Enabled/Disabled In Host mode: Ports can only be enabled by the host controller as a part of the reset and enable. You cannot enable a port by writing 1 to this field. Ports can be disabled by a disconnect event or other fault condition, or by the host software. The field status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled (0), downstream propagation of data is blocked except for reset. This field is 0 if PORTSC1[PP] is 0 in host mode. In Device mode: The device port is always enabled, so this field is always 1. 0b - Disabled 1b - Enabled
1 CSC	Connect Status Change In Host mode: Indicates that a change has occurred in the port's Current Connect Status. The host/device controller sets this field for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, if the insertion status changes twice before the system software has cleared the changed condition, the hub hardware is setting an already-set field (that is, the field remains set). You clear this field to 0 by writing a 1 to it. This field is 0 if PORTSC1[PP] is 0 in Host mode. In Device mode: This field is undefined in device controller mode.
0 CCS	Current Connect Status In Host mode: 0 = No device is present 1 = Device is present on port This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change field (bit 1) to be set to 1. This field is 0 if PORTSC1[PP] is 0 in Host mode. In Device mode: A value of 1 in this field indicates that the device successfully attached and is operating in either HS or FS as indicated by the HS Port field in this register. A 0 indicates that the device did not attach successfully or you forcibly disconnected it by writing a 0 to USBCMD[RS]. It does not identify the device being disconnected or suspended.

55.4.1.31 OTG Status Control (OTGSC)

Offset

Register	Offset
OTGSC	1A4h

Function

This register has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status inputs (bits 14:0 of this register) or cause an OTG interrupt.

Also see USBMODE.

Table continued from the previous page...

Field	Function
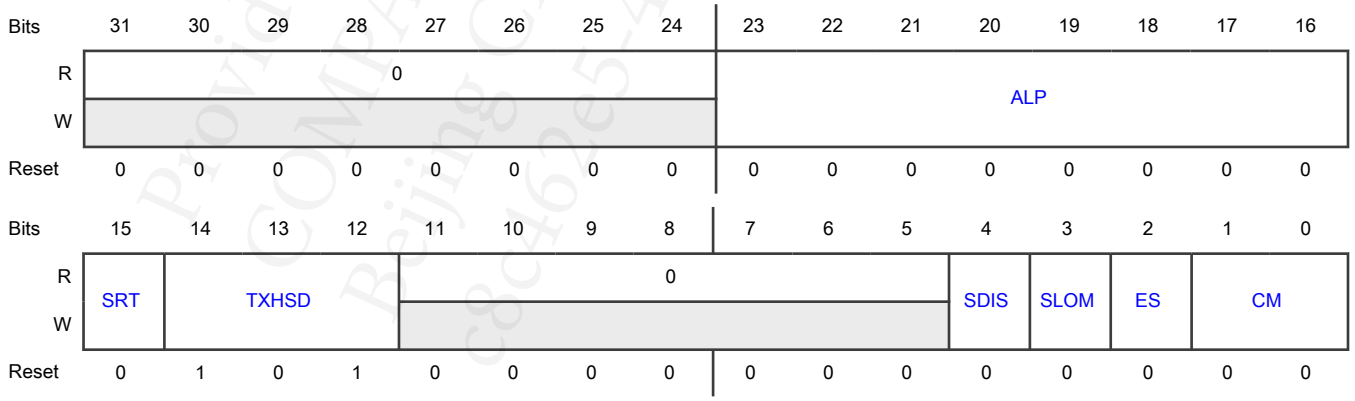
IDPU	Provides control over the ID pull-up resistor. When this field is 0, the ID input is not sampled. 0b - Pull-up resistor is off 1b - Pull-up resistor is on (default)
4 DP	Data Pulsing Writing 1 to this field causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination This field must be set when the OTG device is in device mode; this controls the pulldown on DM.
2 HAAR	Hardware Assist Auto-Reset 0b - Disabled 1b - Enable automatic reset after connect on host port
1 VC	VBUS Charge Writing 1 to this field causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS Discharge Writing 1 to this field causes VBus to discharge through a resistor.

55.4.1.32 USB Device Mode (USBMODE)



Offset

Register	Offset
USBMODE	1A8h

Function

Configures various features of the USB controller as given in the field descriptions below.

Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
ca246e54-821-48a8-b251-320d3ab6241

Fields

Field	Function
31-24 —	Reserved
23-16 ALP	Auto Low Power Includes one bit per port. To enable or disable this automation for a port, you must write the corresponding bit: 16 + port number - 1. When you enable this field, the PHY is put into low-power when in Suspend (PORTSCx[SUSP]), even if PORTSCx[PHCD] is not set to 1.
15 SRT	Shorten Reset Time When the controller is in Host mode, this field enables a bypass of the Chirp J/K reset handshake, saving 6-7 ms in simulation time for each reset sequence. This field should only be used for initial system integration simulations, and must always be cleared for normal operation.
14-12 TXHSD	Tx to Tx HS Delay
11-5 —	Reserved
4 SDIS	Stream Disable Mode Device mode: Writing 1 to this field disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double-buffering scheme is disabled to prevent overruns/underruns in bandwidth-limited systems. Note: In HS mode, all packets received are responded to with a NYET handshake when stream disable is active. Host mode: Writing 1 to this field ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING to characterize the adjustments needed for the scheduler when using this feature. **NOTE** The use of this feature substantially limits overall USB performance.
3 SLOM	Setup Lockout Mode In Device mode, controls the behavior of the setup lock mechanism. 0b - Setup lockouts on (default) 1b - Setup lockouts off (DCD requires use of Setup Data Buffer Tripwire in USBCMD)

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 ES	Endian Select Controls the byte alignment of the transfer buffers to match the host microprocessor. The fields in the microprocessor interface and the data structures are unaffected by the value of this field because they are based on the 32-bit word. Bit Meaning 0b - Little Endian 1b - Big Endian
1-0 CM	Controller Mode Controller mode is defaulted to the proper mode for host-only and device-only implementations. For those designs that contain both host and device capability, the controller defaults to an idle state and must be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, you must reset the controller by writing to USBCMD[RST] before reprogramming this register. 00b - Idle 01b - Reserved 10b - Device Controller 11b - Host Controller

55.4.1.33 Endpoint Setup Status (ENDPTSETUPSTAT)

Offset

Register	Offset
ENDPTSETUPSTAT	1ACh

Function

For every setup transaction that is received, a corresponding bit in this register is set to 1.

55.4.1.39 Endpoint Control (ENDPTCTRL1 - ENDPTCTRL5)

Offset

Register	Offset
ENDPTCTRL1	1C4h
ENDPTCTRL2	1C8h
ENDPTCTRL3	1CCh
ENDPTCTRL4	1D0h
ENDPTCTRL5	1D4h

Function

There is an ENDPTCTRLn register for each endpoint in a device.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (for example, bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint/direction.

2 PWRFLT	Vbus Power Fault Polarity Control This field controls the polarity of power fault. Write to this field to reverse the polarity. See CR[PWRFLTDF] to learn impact of writing to this field. 1b - Reverse the polarity of Power fault
1 CORE_IE	Enable Interrupt from Core This field enables or disables interrupts from the core. 0b - Disable 1b - Enable
0 WAKEUP_IE	USB Wake-Up Interrupt Enable This field enables or disables the wake-up interrupt. You must disable this field after receiving a wake-up interrupt and enable it again prior to going into Suspend mode. 0b - Disable 1b - Enable

55.5 Functional description

These sections describe the functionality of the various building blocks of the USB.

55.5.1 USB dual role device/host controller

The OTG controller is an instantiation of EHCI-compatible USB core that supports HS, FS, and LS operations.

The USBOTG core USB signals do not connect directly to the OTG I/O pins. Instead, the signals pass through the Serial and ULPI Mux to allow for additional functionality on the OTG port. The OTG controller is configured for operation with a parallel

ULPI transceiver (HS, FS, or LS). The selection between transceiver types is software programmable. The block defaults to Serial mode.

The USB controller core supports HS, FS, and LS operations in Host mode, and HS and FS operations in Device mode.

55.5.1.1 Host mode

The controller supports the direct connection of a HS, FS, or LS device (without an external hub). Although there is no separate transaction translator block in the system, the transaction translator function, normally associated with a USB 2.0 HS hub, is implemented within the DMA and protocol engine blocks to support connection to FS and LS devices.

55.5.1.2 Peripheral (Device) mode

- Up to six bidirectional endpoints
- HS or FS operation
- Remote wake-up capable

55.5.2 System interface

The system interface block contains all the control and status registers to allow a core to interface with the module. These registers allow the processor to control the configuration and ascertain the capabilities of the module, and they control the module's operation.

55.5.3 DMA engine

This module contains a local DMA engine. It is responsible for moving all of the data transferred over the USB between the module and system memory.

The DMA controllers must access control information and packet data from system memory. Control information is contained in linked list-based queue structures. The DMA controllers have state machines that are able to parse all of the data structures defined in the EHCI specification. In Host mode, the data structures are EHCI compliant and represent queues of transfers performed by the host controller, including the split-transaction requests that allow an EHCI controller to direct packets to FS and LS devices.

55.5.4 FIFO RAM controller

The FIFO RAM controller is used for context information and to control FIFOs between the protocol engine and the DMA controller. These FIFOs decouple the system processor/memory bus requests from the extremely tight timing required by USB.

In Host mode, a single data channel is maintained in each direction through the buffer memory, and the USB host modules use 1024-byte transmit buffers and 1024-byte receive buffers.

55.5.5 USB power control block

The USB controller supports suspend and wake-up functionality. The power control block allows for placing the transceiver in low-power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of low-power mode when needed. Additionally, the power control block can wake-up the platform from Sleep mode by generating an interrupt.

55.5.5.1 Entering low-power Suspend mode

This mode is always entered when the controlling driver software sets the appropriate field in the USB core register, Port Status and Control (PORTSC1). After the controller is suspended, the clocks to the USB can be stopped.

55.6 Wake-up events

The power control block monitors the USB bus when the USB core is in the suspend state. Depending on whether the core is in Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt

(asynchronous) can be generated to the platform if the value of the related wake-up interrupt enable field is 1. This interrupt also reactivates the platform clocks if they were stopped during the suspend.

55.6.1 Host mode events

The host controller wakes up on the following events:

- Remote wake-up request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when J-K transition on DM/DP line is detected.

- Wake-up on over-current

If wake-up on over-current is enabled (the value of PORTSC1[WKOC] is 1), the power control block sends a wake-up request to the USB core when an over-current event is detected.

- Wake-up on disconnect

If wake-up on disconnection is enabled (the value of PORTSC1[WKDS] is 1), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-up on connect

If wake-up on connection is enabled (the value of PORTSC1[WKCN] is 1), the power control sub-block sends a wake-up request to the USB core when a connection event is detected (SE0-J/SE0-K transition on DM/DP line).

55.6.2 Device mode events

When the OTG controller is configured for peripheral operation, the power control block sends a wake-up request to the USB core when any non-idle state is detected on the USB bus.

55.7 Interrupts

55.7.1 USB core interrupts

Each USB core uses one dedicated vector in the interrupt table. The vector number associated with each core can be found in the interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB cores.

55.7.2 USB wake-up interrupts

Each USB core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but each one uses the same vector as the corresponding USB controller core's interrupt. These interrupts are generated by the power control blocks, which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and platform clocks are disabled, such that a wake-up condition on the USB bus can reactivate the platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, you must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the platform clock. You must then wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low-power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB Suspend mode.

55.8 Data structures

55.8.1 Device data structures

This section defines the interface data structures used to communicate control, status, and data between DCD software and the device controller. The interface consists of multiple dQH and TD instances.

NOTE

You must ensure that data structures do not span a 4 KB page boundary.

The USB OTG uses an array of device endpoint QHs to organize device transfers. As shown in the following figure, there are two endpoint QHs in the array for each device endpoint—one for IN and the other for OUT. ENDPOINTLISTADDR provides a pointer to the first entry in the array.

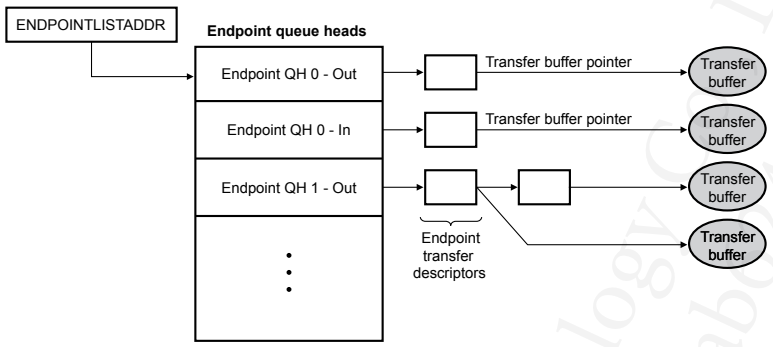

Figure 455. End point QH head organization

55.8.1.1 Endpoint dQH

All transfers are managed in the endpoint dQH. The dQH is a 48-byte data structure, but must align on 64-byte boundaries. During priming of an endpoint, the dTD copies into the overlay area of the dQH, which starts at the NextTD pointer and continues through the end of the buffer pointers entries. After a transfer is complete, the dTD status updates to the CurrentTD pointer. When a packet is in progress, the overlay area of the dQH acts as a staging area for the dTD, so the device controller can access needed information with minimal latency.

The following table shows the endpoint QH structure.

Table 390. Endpoint QH layout

31–30	29	28–27	26–16	15	14–10	9–0	offset
Mult	ZLT	0	Maximum Packet Length	IOS	0	0	00h

55.8.1.1.1 Endpoint capabilities and characteristics (offset = 0h)

This entry specifies static information about the endpoint. In other words, this information does not change over the lifetime of the endpoint. DCD software must not attempt to modify this information when the corresponding endpoint is enabled.

Table 391. Endpoint capabilities and characteristics

Field	Description
31-30 Mult	Multiple packet select This field indicates the number of packets executed per transaction description: 00 Execute N transactions as demonstrated by the USB variable length packet protocol, where N is computed using the Maximum Packet Length field (dQH) and the Total Bytes field (dTD) 01 Execute 1 transaction 10 Execute 2 transactions 11 Execute 3 transactions
	NOTE Non-ISO endpoints must set Mult equal to 00. ISO endpoints must set Mult equal to 01, 10, or 11 as needed.
29 ZLT	Zero length termination select. This field is ignored in isochronous transfers. Clearing this bit enables the hardware to automatically append a zero-length packet when the following conditions are true: • The packet transmitted equals the value of the Maximum Packet Length field • The dTD has exhausted the Total Bytes field After this, the dTD retires. When the device is receiving packets, if the last packet length received equals the maximum packet length, and the value of the Total Bytes field is zero, it waits for a zero-length packet from the host to retire the current dTD. Setting this field disables the zero-length packet. When the device is transmitting, the hardware does not append any zero-length packet. When receiving, it does not require a zero-length packet to retire

Table continues on the next page...

Table 391. Endpoint capabilities and characteristics (continued)

Field	Description
	a dTD, the last packet of which was equal to the maximum packet length. The dTD is retired as soon as the value of the Total Bytes field becomes zero, or a short packet is received. 0 Enable zero-length packet (default) 1 Disable the zero-length packet
	NOTE Each transfer is defined by one dTD, so the zero-length termination is for each dTD. In some software application cases, the logic transfer does not fit into only one dTD, so it does not make sense to add a zero-length termination packet each time a dTD is consumed. For those cases, it is recommended that the ZLT feature be disabled and the software used to generate the zero-length termination.
28-27	Reserved
26-16 Maximum Packet Length	This field directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value for this field is 400h (1024).
15 IOS	Interrupt on setup. This field, used on control type endpoints, indicates if USBSTS[UI] is set in response to a setup being received.
14-0	Reserved

55.8.1.1.2 Transfer overlay (offset = 8h-20h)

The seven entries in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then the device controller does not read the associated endpoint.

After an endpoint is configured, the dTD is copied into this QH overlay area by the device controller. Until a transfer expires, you must not write the QH overlay area or the associated TD. When the transfer is complete, the device controller writes the results back to the original TD and advances the queue.

See Endpoint dTD for a description of the overlay fields.

55.8.1.1.3 Current dTD Pointer (offset = 0h)

The current dTD pointer is used by the controller to locate the transfer in progress. This entry is for device controller (hardware) use only and must not be modified by DCD software.

Table 392. Current dTD pointer

Field	Description
31-5 Current dTD Pointer	This field is a pointer to the dTD that is represented in the transfer overlay area, and is updated by the device controller to the next dTD pointer during endpoint priming or queue advance.
4-0	Reserved

55.8.1.1.4 Setup buffer (offset = 28h-2Ch)

The setup buffer is a dedicated storage for the 8-byte data that follows a setup PID. See Control endpoint operation for information on the procedure for reading the setup buffer.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX QH receives setup data packets.

Table 393. Multiple mode control

Offset	Field	Description
28h	31-0 Setup buffer 0	Setup buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller software reads.
2Ch	31-0 Setup buffer 1	Setup buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller software reads.

55.8.1.2 Endpoint dTD

The dTD describes to the device controller the location and quantity of data for a given transfer.

NOTE

The DCD software must not attempt to modify any field in an active dTD except the next dTD pointer.

Table 394. Endpoint dTD

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

Table 394. Endpoint dTD (continued)

Buffer Pointer (Page 4)	0	0	0	0	0	0	0	0	0	0	0	0	0	18h

Device controller read/write; all others read-only.

55.8.1.2.1 Next dTD pointer (offset = 0h)

The Next dTD pointer is used to point the device controller to the next dTD in the linked list.

Table 395. Next dTD pointer

Field	Description
31-5 Next dTD Pointer	This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0 T	Terminate. This field indicates to the device controller that no more valid entries exist in the queue. 0 - Pointer is valid (points to a valid transfer element descriptor) 1 - Pointer is invalid

55.8.1.2.2 dTD token (offset = 4h)

The dTD token is used to specify attributes for the transfer including the number of bytes to read or write and the status of the transaction.

Table 396. dTD token

Field	Description
31	Reserved
30-16 Total Bytes	This field specifies the total number of bytes moved with this TD. This field decrements by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value that you may store in the field is 5*4 K(5000h). This is the maximum number of bytes that five-page pointers can access. Although possible to create a transfer up to 20 KB, this assumes the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16 K**. Therefore, the maximum recommended transfer is 16 KB (4000h). **NOTE** Larger transfer sizes can be supported, but require disabling ZLT and using multiple dTDs. If the value of the field is 0 when the host controller fetches this TD (and the active bit is 1), the device controller executes a zero-length transaction and retires the TD.

Table continues on the next page...

Table 396. dTD token (continued)

Field	Description
	For IN transfers, Total Bytes to Transfer need not be an even multiple of the maximum packet length. If you build such a TD for an IN transfer, the last transaction is always less than the maximum packet length. For OUT transfers, total bytes must be evenly divisible by the maximum packet length.
15 IOC	Indicates whether USBSTS[UI] is set in response to the device controller being finished with this dTD.
14-12	Reserved
11-10 MultO	Multiplier Override. This field can possibly transmit ISOs (ISO-IN) to override the multiplier in the QH. This field must be 0 for all packet types that are not transmit-ISO. For example, if QH.MULT equals 3, maximum packet size equals 8, total bytes equals 15, and MultO equals 0 [default], then three packets are sent: {Data2(8); Data1(7); Data0(0)}. If QH.MULT equals 3, maximum packet size equals 8, total bytes equals 15, and MultO equals 2, then two packets are sent: {Data1(8); Data0(7)}. For maximum efficiency, you must compute MultO equals greatest integer of (total bytes / maximum packet size) except for the case when total bytes equals 0; then MultO must be 1. **NOTE** Non-ISO and Non-TX endpoints must set MultO to 0.
9-8	Reserved
7-0 Status	The device controller communicates individual command execution states back to the DCD software. This field contains the status of the last transaction performed on this dTD. The bit encodings are as follows.

Bit	Status field description
7	Active. Set by you to enable the execution of transactions by the device controller.
6	Halted. Set by the device controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this dTD. Any time a transaction results in the halted bit being set, the active bit is also cleared.
5	Data Buffer Error. Set by the device controller during status update to indicate that the device controller is unable to maintain the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (underrun).
4	Reserved

Table continues on the next page...

Table 396. dTD token (continued)

Field	Description	
	3	Transaction Error. Set by the device controller during status update in case the device did not receive a valid response from the host (time-out, CRC, bad PID).
	2-0	Reserved

55.8.1.2.3 dTD buffer page pointer list (offset = 8h-18h)

The buffer page pointer list (belonging to a device element TD) is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

Table 397. Buffer page pointer list

Field	Description
31-12 Buffer Pointer	Selects the page offset in memory for the packet buffer. Non-virtual memory systems typically set the buffer pointers to a series of incrementing integers.
0;11-0 Current Offset	Offset into the 4 KB buffer where the packet begins.
1;10-0 Frame Number	Written by the device controller to indicate the frame number in which a packet finishes. Typically correlates relative completion times of packets on an ISO endpoint.

55.8.2 Host data structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the enhanced host controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of the following:

- Periodic schedule
- Periodic frame list
- Asynchronous schedule
- iTDs
- siTDs
- Queue heads
- Queue element transfer descriptors

The following table shows the functions of data structures.

Table 398. Data structure functions

Data structure	Function
Periodic frame list	Root of all periodic (isochronous and interrupt transfer type) transfers for the host controller

Table continues on the next page...

Table 398. Data structure functions (continued)

Data structure	Function
Asynchronous list	Root for all the bulk and control transfers
iTDs	Manage isochronous data streams
siTDs	Manage isochronous split-transaction data streams
Queue heads, queue element transfer descriptors	Manage all interrupt, control, and bulk data streams

These data structures are optimized to reduce the total memory footprint of the schedule and to reduce the average number of memory accesses needed to execute a USB transaction.

Note that you must ensure that no interface data structure reachable by the EHCI host controller spans a 4 KB page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

55.8.2.1 Periodic frame list

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the PERIODICLISTBASE address register and USB Frame Index (FRINDEX) register. The periodic schedule is based on an array of pointers called the periodic frame list. The PERIODICLISTBASE address register is combined with the USB Frame Index (FRINDEX) register to produce a memory pointer into the frame list. The periodic frame list implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

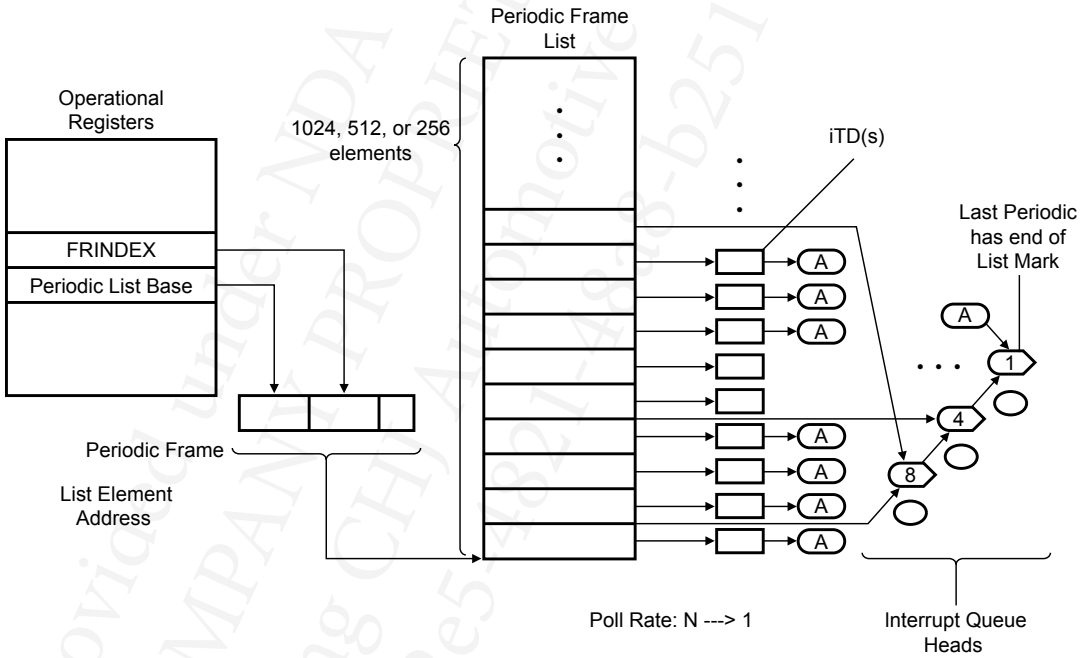

Figure 456. Periodic schedule organization

Split-transaction interrupt, bulk, and control are also managed using QHs and queue element transfer descriptors.

The Periodic frame list is a 4 KB page-aligned array of frame list link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to the system software via the Host Controller Capability Parameters (HCCPARAMS) register.

Table 399. Frame list length

Programmability	Number of elements
No	1024
Yes	Selectable by system software to be 256, 512, or 1024 elements

An implementation must support all three of the above sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into USBCMD[FS1].

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current microframe. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the frame list element pointer.

Table 400. Format of frame list element pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link pointer																											0		Typ			03-00 h

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced objects may be isochronous transfer descriptors for HS devices, siTDs (for FS isochronous endpoints), or a QH (used to support HS, FS, and LS interrupts). System software must not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to indicate to the host controller the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When the value of this field is 1, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer; the value encodings are shown below.

Table 401. Typ field value definitions

Value	Meaning
00b	Isochronous transfer descriptor (iTD)
01b	QH
10b	Split transaction isochronous transfer descriptor (siTD)
11b	Frame span traversal node (FSTN)

55.8.2.2 Asynchronous list QH pointer

The asynchronous transfer list (based at the ASYNCLISTADDR register) is where all of the control and bulk transfers are managed. Host controllers use the list based at ASYNCLISTADDR only when the periodic list is empty or disabled.

Preliminary Information
COMPANY CONFIDENTIAL

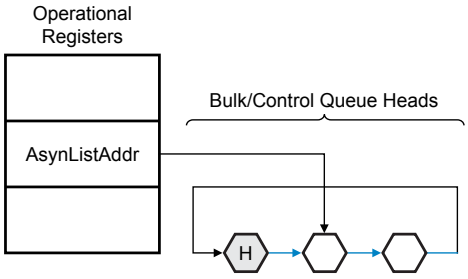

Figure 457. Asynchronous schedule organization

The asynchronous list is a simple circular list of QHs. ASYNCLISTADDR is a pointer to the next QH. This implements a round-robin service for all QHs linked into the asynchronous list.

55.8.2.3 iTD

The format of an iTD is shown in the table below.

This structure is used only for HS isochronous endpoints. All other transfer types must use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 402. iTD

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

These fields may be modified by the host controller if the I/O field indicates an OUT.

55.8.2.3.1 Next link pointer

The first DWord of an iTD is a pointer to the next schedule data structure. The following table describes the Next Schedule Element pointer field.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390da4b624c1

Table 403. Next schedule element pointer

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another iTD, siTD, or QH.
4-3 Reserved	This field is reserved and its value has no effect on operation. You must initialize this field to zero.
2-1 QH/(s)iTD Select (Typ)	This field indicates to the host controller whether the item referenced is an iTD, siTD, or a QH. This allows the host controller to perform appropriate processing on the item after it is fetched. Value encodings are given below. 00b - iTD 01b - QH 10b - siTD 11b - Frame span traversal node (FSTN)
0 Terminate (T)	1b - Link Pointer field is invalid. 0b - Link Pointer field is valid.

55.8.2.3.2 iTD transaction status and control list

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions)
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list to execute a transaction on the USB.

The following table describes the iTD Transaction Status and Control fields.

Table 404. iTD transaction status and control

Bit	Description	
31-28 Status	Records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to 1 by you to enable the execution of an isochronous transaction by the host controller. When the transaction associated with this descriptor is completed, the host controller sets this bit to 0 to indicate that a transaction for this element should not be executed when it is next encountered in the schedule.

Table continues on the next page...

Table 404. iTD transaction status and control (continued)

Bit	Description	
	30	Data Buffer Error. Set to 1 by the host controller during status update to indicate that the host controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to 1 by the host controller during status update when "babble" is detected during the transaction generated by this descriptor.
	28	Transaction Error (XactErr). Set to 1 by the host controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, and so on). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT transaction, this field is the number of data bytes that the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN transaction, this is the initial value of the endpoint to deliver. During status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0-zero length data, 1-one byte, 2-two bytes, and so on). The maximum value this field may contain is C00h (3072).	
15 IOC	If the value of this field is 1, it specifies that when this transaction completes, the host controller should issue an interrupt at the next interrupt threshold.	
14-12 Page Select (PG)	You configure the value of this field to indicate which of the buffer page pointers in the offset field in this slot must be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. The field is concatenated onto the buffer page pointer indicated in the PG field to produce the starting buffer address for this transaction.	

55.8.2.3.3 iTD buffer page pointer list (plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 KB aligned) to the data buffer for this TD. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) = 24576 bytes to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 KB aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 405. iTD buffer pointer page 0 (plus)

Field	Description
31-12	This is a 4 KB aligned pointer to physical memory that corresponds to memory address bits [31:12].

Table continues on the next page...

Table 405. iTD buffer pointer page 0 (plus) (continued)

Field	Description
Buffer Pointer (page 0)	
11-8 Endpoint Number (Endpt)	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7 Reserved	This field is reserved for future use and you must initialize it to 0.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 406. iTD buffer pointer page 1 (plus)

Field	Description
31-12 Buffer Pointer (page 1)	This is a 4 KB aligned pointer to physical memory that corresponds to memory address bits [31:12].
11 Direction (I/O)	This field encodes whether the HS transaction should use an IN or OUT PID. 0 - OUT 1 - IN
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per microframe). The field is used with the Multi field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. You must not set a value larger than 1024 (400h). Any larger value yields undefined results.

Table 407. iTD buffer pointer page 2 (plus)

Field	Description
31-12 Buffer Pointer	This is a 4 KB aligned pointer to physical memory that corresponds to memory address bits [31:12].
11-2 Reserved	This field is reserved for future use and must be set to 0.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that are executed per transaction description (per microframe). The valid values are: 00b - Reserved—must always be zero 01b - One transaction to be issued for this endpoint per microframe 10b - Two transactions to be issued for this endpoint per microframe 11b - Three transactions to be issued for this endpoint per microframe

Table 408. iTD buffer pointer pages 3-6

Field	Description
31-12 Buffer Pointer	This is a 4 KB aligned pointer to physical memory that corresponds to memory address bits [31:12].
11-0 Reserved	This field is reserved for future use and must be set to 0.

55.8.2.4 siTD

All FS isochronous transfers through the internal transaction translator are managed using the siTD data structure, which satisfies the operational requirements for managing the split transaction protocol.

The following table shows the siTD.

Table 409. siTD

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Back Pointer																											0				T	1B-18h

	Host controller read/write		Host controller read only

55.8.2.4.1 Next link pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the next link pointer fields.

Table 410. Next link pointer

Field	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. This field must be written to zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the host controller whether the item referenced is an iTD/siTD or a QH. This allows the host controller to perform the proper type of processing on the item after it is fetched. Value encodings are: 00b - iTD 01b - QH 10b - siTD 11b - FSTN
0	Terminate (T) 1b - Link pointer field not valid 0b - Link pointer valid

55.8.2.4.2 siTD endpoint capabilities/characteristics

DWords 1 and 2 specify static information about the FS endpoint, the addressing of the parent companion controller, and microframe scheduling control.

The tables below describe the endpoint and transaction translator characteristics, and microframe schedule control fields.

Table 411. Endpoint and transaction translator characteristics

Field	Description
31	Direction (I/O). This field encodes whether the FS transaction should be an IN or OUT. 0 - OUT 1 - IN
30-24	Port number. This field is the port number of the recipient transaction translator.
23	This field is reserved and must be set to 0.
22-16	Hub address. This field holds the device address of the companion controller's hub.
15-12	This field is reserved and must be set to 0.
11-8	Endpoint number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	This field is reserved for future use and must be set to 0.
6-0	Device address. This field selects the specific device serving as the data source or sink.

Table 412. Microframe schedule control

Field	Description
31-16	This field is reserved for future use and must be set to 0.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the Active and SplitX state fields in the Status byte) is used to determine during which microframes the host controller must execute complete-split transactions. When the criteria for using this field is met, an all-zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position for which the mFrame C-Mask field is a 1, then this siTD is a candidate for transaction execution. There may be more than one bit set in this mask.
7-0	Split Start Mask (mFrame S-mask). This field (along with the Active and SplitX state fields in the Status byte) is used to determine during which microframes the host controller must execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position for which the mFrame S-mask field is a 1, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list, has undefined results.

55.8.2.4.3 siTD transfer state

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 413. siTD transfer status and control

Bit	Description
31	IOC When the host controller determines that the split transaction is complete, it asserts a hardware interrupt at the next interrupt threshold. 0 - Do not interrupt when transaction is complete. 1 - Do interrupt when transaction is complete.
30	Page Select (P). Used to indicate which data page pointer must be concatenated with the CurrentOffset field to construct a data buffer pointer. 0 - Selects Page 0 pointer 1 - Selects Page 1 pointer The host controller is not required to write this field back when the siTD is retired (Active bit transitioned from a one to a zero).
29-26	This field is reserved for future use and must be set to zero.
25-16	Total Bytes to Transfer. You initialize this field to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh).
15-8	µFrame Complete-Split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.

Table continues on the next page...

Table 413. siTD transfer status and control (continued)

Bit	Description	
7-0	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit number	Definition
	7	Active. You set this bit to 1 to enable the execution of an isochronous split transaction by the host controller.
	6	ERR. The host controller writes a 1 to this bit when an ERR response is received from the companion controller.
	5	Data Buffer Error. The host controller writes a 1 to this bit during status update to indicate that the host controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the host controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
	4	Babble Detected. The host controller writes a 1 to this bit during status update when "babble" is detected during the transaction generated by this descriptor.
	3	Transaction Error (XactErr). The host controller writes a 1 to this bit during status update in the case for which the host did not receive a valid response from the device (Timeout, CRC, Bad PID, and so on). This bit is set only for IN transactions.
	2	Missed Microframe. The host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction.
	1	Split Transaction State (SplitXstate). The bit encodings are: 00b - Do Start Split. This value directs the host controller to issue a Start Split transaction to the endpoint when a match is encountered in the S-mask. 01b - Do Complete Split. This value directs the host controller to issue a Complete Split transaction to the endpoint when a match is encountered in the C-mask.
	0	Reserved—must always be zero.

55.8.2.4.4 siTD buffer pointer list (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 KB (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Provided by IHS Markit
COMPANY CONFIDENTIAL
Beijing CHX Xinyuan Tech Co., Ltd.
c8c462e6-4821-4a3-b23-3900d6b6041

Table 414. Buffer page pointer list (plus)

Field	Description	
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 KB page-aligned, physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. This field P specifies the current active pointer.	
11-0	Page 0: Current Offset. The 12 least significant bits of the Page 0 pointer is the current byte offset for the current page pointer (as selected with the page indicator bit (P field)). The host controller is not required to write this field back when the siTD is retired (Active bit transitioned from a 1 to a 0). The least significant bits of Page 1 pointer are split into three sub-fields. Page 1:	
	Field	Description
	11-5	Reserved
	4-3	Transaction Position (TP). This field is used with T-Count to determine whether to send All, Begin, Mid, or End with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: 00b - All. The entire FS transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b - Begin. This is the first data payload for a FS transaction that is greater than 188 bytes. 10B - Mid. This is the middle payload for a FS OUT transaction that is larger than 188 bytes. 11b - End. This is the last payload for a FS OUT transaction that was larger than 188 bytes.
	2-0	Transaction Count (T-Count). You initialize this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

55.8.2.4.5 siTD back link pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

.

Table 415. siTD back link pointer

Field	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to an siTD.
4-1	Reserved—must always be zero."
0	Terminate (T) 1 - siTD Back Pointer field is invalid 0 - siTD Back Pointer field is valid

55.8.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a QH. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes. The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal usage of on-chip buses, it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a QH.

The following table shows the QH data structure.

Table 416. QH data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Alternate Next qTD Pointer																											0				T	07-04h
DT	Total Bytes to Transfer															IOC	C_Page			Cerr		PID code		Status								0B-08h
Buffer Pointer (Page 0)																				Current Offset												0F-0Ch
Buffer Pointer (Page 0)																				-												13-10h
Buffer Pointer (Page 0)																				-												17-14h

Table continues on the next page...

Table 416. QH data structure (continued)

		4h
Buffer Pointer (Page 0)	-	1B-18h
Buffer Pointer (Page 0)	-	1F-1Ch

	Host controller read/write		Host controller read only.

qTDs must be aligned on 32-byte boundaries.

55.8.2.5.1 Next qTD pointer

The first DWord of an element TD is a pointer to another transfer element descriptor. The following table describes Next qTD pointer fields.

Table 417. qTD next element transfer pointer (DWord 0)

Field	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T) 1 - Pointer is invalid 0 - Pointer is valid (points to a valid transfer element descriptor) This bit indicates to the host controller that there are no more valid entries in the queue.

55.8.2.5.2 Alternate next qTD pointer

The second DWord of a qTD is used to support hardware-only advance of the data stream to the next TD on short packet. To be more explicit, the host controller always uses this pointer when the current qTD is retired because of a short packet. The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Freescale Semiconductor Inc. NDA only
COMPANY PROPRIETARY
Beijing CAT Automotive Technology Co., Ltd.
c8c40e5-4921-483-b251-39003ab6246d

Table 418. TD alternate next element transfer pointer (DWord 1)

Field	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). This bit indicates to the host controller that there are no more valid entries in the queue. 1 - Pointer is invalid 0 - Pointer is valid (points to a valid transfer element descriptor)

55.8.2.5.3 qTD token

The third DWord of a qTD contains most of the information that the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the QH).

NOTE

The field descriptions forward reference fields defined in the QH. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD token fields.

Table 419. TD token (DWord 2)

Field	Description
31 Data Toggle	This is the data toggle sequence field. The use of this field depends on the setting of the Data Toggle Control field in the QH.
30-16 Total Bytes to Transfer	This field specifies the total number of bytes to be moved with this TD. The field is decremented by the number of bytes actually moved during the transaction only on the successful completion of the transaction. The maximum value that you may store in this field is 5 * 4 KB (5000h). This is the maximum number of bytes five page pointers can access. If the value of this field is 0 when the host controller fetches this TD (and the value of the Active field is 1), the host controller executes a zero-length transaction and retires the TD. It is not a requirement for OUT transfers that this field be an even multiple of QH.Maximum Packet Length. If you build such a TD for an OUT transfer, the last transaction is always less than QH.Maximum Packet Length. Although it is possible to create a transfer up to 20 KB, it is required that the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16 KB**. Therefore, the maximum recommended transfer is 16 KB (4000h).
15 IOC	If the value of this bit is 1, it specifies that when this qTD is completed, the host controller must issue an interrupt at the next interrupt threshold.
14-12 Current Page (C_Page)	This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0h to 4h. The host controller is not required to write this field back when the qTD is retired.

Table continues on the next page...

Table 419. TD token (DWord 2) (continued)

Field	Description
11-10 Error Counter (CERR)	This field is a 2-bit down counter that keeps track of the number of consecutive errors detected when executing this qTD. If this field is programmed with a non-zero value during set-up, the host controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from 1 to 0, the host controller: • Marks the qTD inactive • Writes the Halted bit to 1 • Writes the error status bit for the error that caused this field to decrement to 0 An interrupt is generated if the the value of the USB Error Interrupt Enable field in the USBINTR register is 1. If HCD writes a 0 to this field during set-up, the host controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the QH overlay area, not to the qTD. Transaction Error - Decrement Data Buffer Error - No decrement[3] Stalled - No decrement[1] Babble Detected - No decrement[1] No Error - No decrement[2]

Error	Decrement counter
1	Detection of Babble or Stall automatically halts the QH. Thus, count is not decremented.
2	If the EPS field indicates an HS device or the QH is in the asynchronous schedule (and PIDCode indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller must reset CERR to extend the total number of errors for this transaction. For example, CERR must be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b. See Split transaction interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the QH is in the periodic schedule. See Asynchronous—do complete split for CERR adjustment rules when the EPS field indicates a FS or LS device, the QH is in the asynchronous schedule and the PIDCode indicates a SETUP.
3	Data buffer errors are host problems; these do not count against the device's retries.

NOTE

You must not write 0 to CERR when the EPS field is programmed with a value indicating an FS or LS device. This combination could result in an undefined behavior.

Table continues on the next page...

Table 419. TD token (DWord 2) (continued)

Field	Description	
9-8 PID Code	This field is an encoding of the token, which must be used for transactions associated with this TD. The encodings are described as follows.	
	00b	OUT token generates token (E1H)
	01b	IN token generates token (69H)
	10b	SETUP token generates token (2DH) (undefined if endpoint is an interrupt, the QH is non-zero) transfer type
	11b	Reserved
7-0 Status	This field is used by the host controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are described as follows:	
	Bit	**Status field description**
	7	Active. You write 1 to this bit to enable the execution of transactions by the host controller.
	6	Halted. The host controller writes a 1 to this field during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time a transaction results in the Halted field being set to a 1, the Active field is also set to 0.
	5	Data Buffer Error. The host controller writes a 1 to this field during status updates to indicate that the host controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the host controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller writes this field to a 1, then it remains a 1 for the duration of the transfer.
	4	Babble Detected. The host controller writes a 1 to this field during status update when "babble" is detected during the transaction. In addition to writing a 1 to this field, the host controller writes a 1 to the Halted field. Because "babble" is considered a fatal error for the transfer, writing a 1 to the Halted field ensures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). The host controller writes a 1 to this field during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, and so on). If the host controller writes a 1 to this field, then it remains a 1 for the duration of the transfer.
	2	Missed Microframe. This field is ignored unless the QH.EPS field indicates an FS or LS endpoint and the QH is in the periodic list. The host controller writes a 1 to this field when it detects that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller writes a 1 to this field, then it remains a 1 for the duration of the transfer.

Table continues on the next page...

Table 419. TD token (DWord 2) (continued)

Field	Description	
	1	Split Transaction State (SplitXstate). The host controller ignores this field unless the QH.EPS field indicates a FS or LS endpoint. With an FS or LS device, the host controller uses this field to track the state of the split-transaction. The functional requirements of the host controller for managing this state field and the split transaction protocol depend on whether the endpoint is in the periodic or asynchronous schedule. Following are the bit encodings: 0b - Do Start Split. This value directs the host controller to issue a start split transaction to the endpoint. 1b - Do Complete Split. This value directs the host controller to issue a complete split transaction to the endpoint.
	0	Ping State (P)/ERR. If the QH.EPS field indicates an HS device and the PID_Code indicates an OUT endpoint, then this is the state field for the Ping protocol. The bit encodings are: 0b - Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b - Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the QH.EPS field does not indicate an HS device, then this field is used as an error indicator field. The host controller writes this field to a 1 whenever a periodic split-transaction receives an ERR handshake.

55.8.2.5.4 qTD buffer page pointer list

The last five DWords of a qTD form an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes the Current Offset field to the starting offset into the current page, where this page is selected through the value in the C_Page field.

The following table describes the qTD buffer pointer(s) (DWords 3-7) fields.

Table 420. qTD buffer pointer(s) (DWords 3-7)

Field	Description
31-12	Buffer Pointer List. Each element in the list is a 4 KB page-aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 KB page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4 KB buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page, advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example, page 0). The host controller must ignore all of the reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. You must ensure the reserved fields are initialized to 0.

55.8.2.6 QH

The following table shows the QH structure layout.

Table 421. QH structure layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

55.8.2.6.1 QHLP

The first DWord of a QH contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a QH or one of the isochronous transfer descriptors. It must not reference a qTD.

The following table describes the QH DWord 0 fields.

Table 422. QH DWord 0

Field	Description
31-5	QHLP. This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD, or a QH. This allows the host controller to perform the proper type of processing on the item after it is fetched. Value encodings are: 00b - iTD 01b - QH 10b - siTD 11b - FSTN
0	Terminate (T). If the QH is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the QH is in the asynchronous schedule. You must ensure that QHs reachable by the host controller always have valid horizontal link pointers. 1 - Last QH (pointer is invalid). 0 - Pointer is valid.

55.8.2.6.2 QH endpoint capabilities/characteristics

The second and third DWords of a QH specify static information about the endpoint. This information does not change over the lifetime of the endpoint. There are three types of information in this region:

- Endpoint characteristics: These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint capabilities: These are adjustable parameters of the endpoint. They affect how the endpoint data stream is managed by the host controller.
- Split transaction characteristics: This data structure is used to manage FS and LS data streams for bulk, control, and interrupt via split transactions to USB2.0 hub transaction translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: QH DWord 1 fields.

Beijing Lomotive Technology Co., Ltd.
c8c46e2e-4821-4a8-b21-390d3a16241
Product under NDA only
COMPANY PROPRIETARY

Table 423. Endpoint characteristics: QH DWord 1

Field	Description	
31-28	Nak Count Reload (RL). This field contains a value that is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the QH.EPS field indicates the endpoint is not a HS device, and the endpoint is a control endpoint, then you must set this bit to 1. Otherwise, you must always set this bit to 0.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 400h (1024).	
15	Head of Reclamation List Flag (H). This bit is set by system software to mark a QH as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller must obtain the initial data toggle on an overlay transition. 0b - Ignore DT bit from incoming qTD. The host controller preserves the DT bit in the QH. 1b - Initial data toggle from the incoming qTD DT bit. Host controller replaces the DT bit in the QH from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	**Meaning**
	00b	FS (12 Mbits/sec)
	01b	LS (1.5 Mbits/sec)
	10b	HS (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by the system software to request that the host controller set the Active bit to 0. See Rebalancing the periodic schedule for full operational details. This field is only valid when the QH is in the periodic schedule and the EPS field indicates a FS and LS endpoint. Writing 1 to this field when the QH is in the asynchronous schedule or the EPS field indicates a HS device and yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the endpoint capabilities: QH DWord 2 field descriptions.

Preliminary Information
COMPANY CONFIDENTIAL
Beijing C.A.R Automotive Technology Co., Ltd.
c8c462e2-2201-4ba8-b251-390da1624c

Table 424. Endpoint capabilities: QH DWord 2

Field	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that you properly initialize this field (regardless of the location of the QH in the schedules or other run-time parameters). The valid values are: 00b - Reserved. A 0 in this field yields undefined results. 01b - One transaction to be issued for this endpoint per microframe 10b - Two transactions to be issued for this endpoint per microframe 11b - Three transactions to be issued for this endpoint per microframe
29-23	Port Number. This field is ignored by the host controller unless the EPS field indicates a FS or LS device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address Hub Addr below), below which the FS or LS device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the EPS field indicates a FS or LS device. The value is the USB device address of the USB 2.0 Hub below which the FS or LS device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (μFrame C-Mask). This field is ignored by the host controller unless the EPS field indicates this device is a LS or FS device and this QH is in the periodic list. This field (along with the Active and SplitX-state fields) is used to determine during which microframes the host controller must execute a complete-split transaction. When the criteria for using this field are met, the value 00h in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of USB Frame Index (FRINDEX). If the USB Frame Index (FRINDEX) bits decode to a position where the value of μFrame C-Mask field is 1, then this QH is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (μFrame S-mask). This field is used for all endpoint speeds. You must set this field to 00h when the QH is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of USB Frame Index (FRINDEX) as an index into a bit position in this bit vector. If the μFrame S-mask field has a 1 at the indexed bit position then this QH is a candidate for transaction execution. If the EPS field indicates the endpoint is a HS endpoint, then the transaction executed is determined by the PID_Code field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the EPS field indicates this is either a FS or LS device. A value of 00h in this field, in combination with existing in the periodic frame list, has undefined results.

55.8.2.6.3 Transfer overlay-QH

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the QHLP the next QH. The host controller never follows the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a QH contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the Current qTD Link Pointer field descriptions.

Table 425. Current qTD link pointer

Field	Description
31-5	Current Element Transaction Descriptor Link Pointer. Contains the address of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). The host controller ignores these bits when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a QH are the transaction overlay area. This has the same base structure as a qTD. The QH uses the reserved fields of the page pointers to implement tracking of the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the host-controller rules for bits in overlay.

Table 426. Host-controller rules for bits in overlay (DWords 5, 6, 8 and 9)

DWord	Field	Description
5	4-1	Nak Counter (NakCnt)µRW. The host controller decrements this value whenever a transaction for the endpoint associated with this QH results in a Nak or Nyet response. This counter is reloaded from RL before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	Data Toggle. Controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	IOC. Is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). Is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the EPS field indicates a HS endpoint, then you must preserve this field during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). Is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). Is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. You must ensure that the S-bytes field in a qTD is zero before activating the qTD. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

55.8.2.7 Periodic FSTN

This data structure is to be used only for managing FS and LS transactions that span a host-frame boundary.

See Host controller operational model for FSTNs for full operational details. You must not use an FSTN in the asynchronous schedule. An FSTN in the asynchronous schedule results in undefined behavior. You must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	Normal Path Link Pointer																											0		Typ		T	03-00h
	Back Path Link Pointer																											0		Typ		T	07-04h

Table 427. FSTN structure layout

	Host controller read/write		Host controller read only

55.8.2.7.1 FSTN normal path pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 428. FSTN normal path pointer field descriptions

Field	Description
31-5	Normal Path Link Pointer (NPLP). Contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). Indicates to the host controller whether the item referenced is an iTD/siTD, a QH, or an FSTN. This allows the host controller to perform the proper type of processing on the item after it is fetched. Value encodings are: 00b - iTD 01b - QH 10b - siTD 11b - FSTN
0	Terminate (T) 1 - Link Pointer field is not valid. 0 - Link Pointer is valid.

55.8.2.7.2 FSTN back path link pointer

The second DWord of an FTSN node contains a Link Pointer to a QH. If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. You must set its Typ field to indicate the target data structure is a QH. If the T-bit in this pointer is set to one, then this FSTN is the Restore Indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 429. FSTN back path link pointer field descriptions

Field	Description
31-5	Back Path Link Pointer (BPLP). Contains the address of a QH. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. You must ensure this field is set to indicate the target data structure is a QH. Any other value in this field yields undefined results.
0	Terminate (T). 1 - Link Pointer field is not valid; that is, the host controller must not use bits [31:5] as a valid memory address. This value also indicates that this FSTN is a Restore Indicator. 0 - Link Pointer is valid; that is, the host controller may use bits [31:5] as a valid memory address. This value also indicates that this FSTN is a Save-Place Indicator.

55.9 Device mode operation

The function of the device operation is to transfer a request to and from the Universal Serial Bus (USB). The device controller performs data transfers using a set of linked list transfer descriptors pointed to by a QH. The next sections explain the use of the device controller from the DCD point-of-view and further describes how specific USB events relate to status changes in the device controller programmer's interface.

55.9.1 Port state and control

From a chip or system reset, the USB OTG module enters the Powered state. A transition from the Powered state to the Attach state occurs when USBCMD[RS] is 1. After receiving a reset on the bus, the port enters the DefaultFS or DefaultHS state in accordance with the protocol reset described in Appendix C.2 of the *Universal Serial Bus Specification, Revision 2.0*. The next figure depicts the states of a USB 2.0 device.

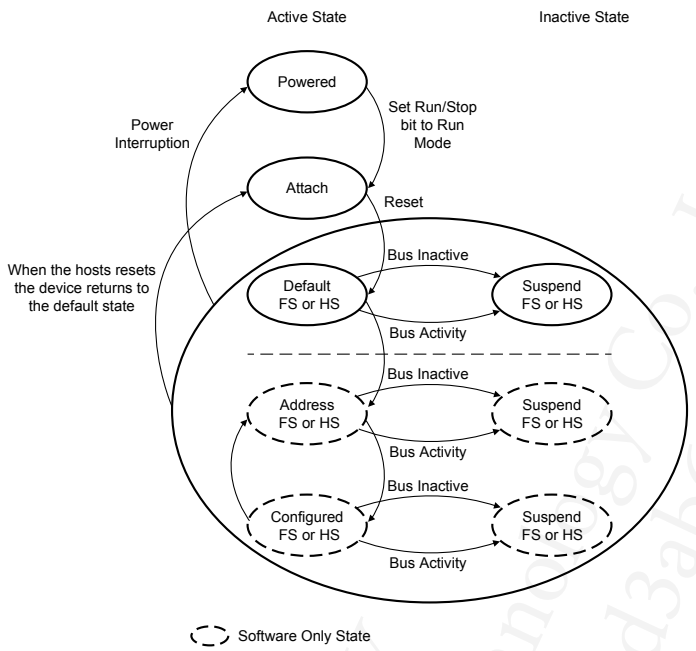

Figure 458. USB 2.0 device states

States Powered, Attach, Default FS or HS, and Suspend FS or HS are implemented in the USB OTG, and they are communicated to the DCD using the following status fields:

Table 430. Device controller state information fields

Field	Register
DC Suspend (SLI)	USBSTS
USB Reset Received (URI)	USBSTS
Port Change Detect (PCI)	USBSTS
HS Port (PSPD)	PORTSCn

The DCD software must maintain a state variable to differentiate between the Default FS or HS state and the Address/Configured states. Change of state from Default to the Address and Configured states is part of the enumeration process described in the Device Framework section of the USB 2.0 specification.

As a result of entering the Address state, the DCD must program the Device Address Register (DEVICEADDR).

Entry into the configured state indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRL*n* registers and initializing the associated queue heads.

55.9.2 Bus reset

The host uses a bus reset to initialize downstream devices. When a bus reset is detected, the USB OTG controller does the following:

1. Renegotiates its attachment speed.
2. Resets the device address to 0.

3. Notifies the DCD by interrupt (assuming the USB reset interrupt enable (USBINTR[URE]) is 1).

After a reset is received, all endpoints (except endpoint 0) are disabled and the device controller cancels any primed transactions. The concept of priming is clarified below, but when a reset is received, the DCD must perform the following:

1. Clear all setup token semaphores by reading Endpoint Setup Status (ENDPTSETUPSTAT) and writing the same value back to this register.
2. Clear all the endpoint complete status bits by reading Endpoint Complete (ENDPTCOMPLETE) and writing the same value back to this register.
3. Cancel all primed status by waiting until all bits in Endpoint Initialization (ENDPTPRIME) are 0 and then writing 000F_000Fh to Endpoint De-Initialize (ENDPTFLUSH).
4. Read PORTSCn[PR] and make sure it remains active. A USB reset occurs for a minimum of 3 ms and the DCD must reach this point in the reset clean-up before the end of the reset occurs; otherwise, a hardware reset of the device controller is recommended (rare).
    a. Writing a 1 to USBCMD[RST] can perform a hardware reset.

NOTE

A hardware reset causes the device to detach from the bus by writing 0 to USBCMD[RS]. Therefore, the DCD must completely re-initialize the USB OTG after a hardware reset.

5. Free all allocated dTDs because the device controller no longer executes them. If this is the first time the DCD processes a USB reset event, it is likely no dTDs have been allocated.
6. At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a port change detect is indicated.
7. After a port change detect, the device has reached the default state and the DCD can read PORTSCn to determine if the device operates in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration (see the "Device Framework" chapter of the USB specification).

55.9.3 Suspend/resume

To conserve power, the USB OTG module automatically enters the Suspended state when no bus traffic is observed for a specified period. When suspended, the module maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend any time they are powered, regardless of whether they are assigned a non-default address, are configured, or neither. Bus activity may cease because the host enters a Suspend mode of its own. In addition, a USB device also enters the Suspended state when the hub port it is attached to is disabled.

The USB OTG module exits Suspend mode when there is bus activity. It may also request the host to exit Suspend mode or selectively suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. The USB OTG is capable of remote wake-up signaling. When the USB OTG is reset, remote wake-up signaling must be disabled.

55.9.3.1 Suspend operational model

The USB OTG moves into the Suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the Suspend state, an interrupt notifies the DCD (assuming that the device controller suspend interrupt is enabled, by writing 1 to USBINTR[SLE]). When you write 1 to PORTSCn[SUSP], the device controller is suspended.

DCD response when the device controller is suspended is application-specific and may involve switching to a low-power operation. See the USB 2.0 specification for information on the bus power limits in the Suspend state.

55.9.3.2 Resume

If the USB OTG is suspended, its operation resumes when any non-idle signaling is received on its upstream-facing port. In addition, the USB OTG can signal the system to resume operation by forcing resume signaling to the upstream port. Writing 1 to PORTSCn[FPR] when the device is in the Suspend state sends resume signaling upstream. Sending a resume signal to an

upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one or more devices) back to the active condition.

NOTE

Before the use of resume signaling, the host must enable it by using the set feature command defined in the "Device Framework" chapter of the USB 2.0 specification.

55.9.4 Managing endpoints

The USB 2.0 specification defines an endpoint (also called a device endpoint or an address endpoint) as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The combination of the endpoint number and the endpoint direction specifies endpoint address.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints that are supported by USB include bulk, interrupt, and isochronous. Each endpoint type has specific behavior related to packet response and error managing. See the USB 2.0 specification for more details.

The USB OTG supports up to six endpoint-specified numbers. The DCD can enable, disable, and configure each endpoint except endpoint 0.

Each endpoint direction is essentially independent and can have differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0, for example, is always a control endpoint and uses both directions.

Each endpoint direction requires a QH allocated in memory. If the maximum is six endpoint numbers (one for each endpoint direction used by the device controller), 12 QHs are required. The operation of an endpoint and use of QHs are described later in this document.

55.9.4.1 Endpoint initialization

After a hardware reset, all endpoints except endpoint 0 are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to the appropriate ENDPTCTRL*n* register. Each register is split into an upper and lower half. The lower half of the register configures the receive or OUT endpoint, and the upper half configures the corresponding transmit or IN endpoint. Control endpoints must have the same configuration in the upper and lower halves of the register; otherwise, behavior is undefined. The next table shows how to construct a configuration word for endpoint initialization.

Table 431. Device controller endpoint initialization

Field	Value
Data Toggle Reset (TXR, RXR)	1 - Synchronize the data PIDs
Data Toggle Inhibit (TXI, RXI)	0 - PID sequencing disabled
Endpoint Type (TXT, RXT)	00 - Control 01 - Isochronous 10 - Bulk 11 - Interrupt
Endpoint Stall (TXS, RXS)	0 - Not stalled

55.9.4.2 Stalling

There are two occasions for which the USB OTG may need to return a STALL response to the host:

- The functional stall is a condition set by the DCD as described in the USB 2.0 Device Framework chapter. A functional stall is used only on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRL*n* register associated with the given endpoint and the given direction. In a functional stall condition, the device controller continues to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.
- A protocol stall, unlike a functional stall, is used on control endpoints and automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD must enable the stall bits as a pair (TXS and RXS bits). A single write to the ENDPTCTRL*n* register can ensure both stall bits are set at the same instant.

NOTE

Any write to the ENDPTCTRL*n* register during operational mode must preserve the endpoint type field (perform a read-modify-write).

Table 432. Device controller stall response matrix

USB packet	Endpoint stall bit	Effect on stall bit	USB response
SETUP packet received by a non-control endpoint	N/A	None	STALL
IN/OUT/PING packet received by a non-control endpoint	1	None	STALL
IN/OUT/PING packet received by a non-control endpoint	0	None	ACK/NAK/NYET
SETUP packet received by a control endpoint	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	1	None	STALL
IN/OUT/PING packet received by a control endpoint	0	None	ACK/NAK/NYET

55.9.4.3 Data toggle

Data toggle maintains data coherency between host and device for any given data pipe. See the USB 2.0 specification for more information on data toggle.

55.9.4.3.1 Data toggle reset

The DCD may reset the Data Toggle state bit and cause the data toggle sequence to reset in the device controller by setting the Data Toggle reset field in the ENDPTCTRL*n* register. This must only happen when configuring or initializing an endpoint or returning from a STALL condition.

55.9.4.3.2 Data toggle inhibit

This feature is for test purposes only and must never be used during normal device controller operation.

Setting the Data Toggle Inhibit bit causes the USB OTG module to ignore the data toggle pattern normally sent and accepts all incoming data packets regardless of the data toggle state.

In normal operation, the USB OTG checks the DATA0/DATA1 bit against the Data Toggle to determine if the packet is valid. If the data PID does not match the Data Toggle state bit maintained by the device controller for that endpoint, the data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the USB OTG from re-sending the same packet, the device controller responds to the error packet by acknowledging it with an ACK or NYET response.

55.9.5 Packet transfers

The host initiates all transactions on the USB bus, and in turn the device must respond to any request from the host within the turnaround time stated in the USB 2.0 specification.

A USB host sends requests to the USB OTG in an order that cannot be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, expect the host to send IN requests to that endpoint. This USB OTG module prepares packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host-initiated transactions on the bus is referred to as priming the endpoint. This term appears throughout the documentation to describe the USB OTG operation so the DCD is built properly. In addition, the term flushing describes the action of clearing a packet queued for execution.

55.9.5.1 Priming transmit endpoints

Priming a transmit endpoint causes the device controller to fetch the dTD for the transaction pointed to by the dQH. After the dTD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to manage a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO splits into virtual channels so the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of "primed" is indicated in Endpoint Status (ENDPTSTAT). For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of HS USB.

55.9.5.2 Priming receive endpoints

Priming receives endpoints identical to priming of transmit endpoints from the point of view of the DCD. The major difference in the operational model at the device controller is no data movement of the leading packet data because the data is to be received from the host.

As part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

55.9.5.3 Interrupt/bulk endpoint operation

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes handshake with a NAK unless the endpoint is primed. After the endpoint is primed, data delivery commences.

A dTD is retired by the device controller when the packets described in the TD are completed. Each dTD describes N packets to transfer according to the USB variable length transfer protocol. The formula below and the next table describe how the device controller computes the number and length of the packets sent/received by the USB, which varies according to the total number of bytes and maximum packet length. See Endpoint capabilities and characteristics (offset = 0h) for details on the ZLT bit.

With zero-length termination (ZLT) cleared:

N = INT(number of bytes/maximum packet length) + 1

With zero-length termination (ZLT) set:

N = MAXINT(number of bytes/maximum packet length)

Table 433. Variable length transfer protocol example (ZLT=0)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	-
512	256	3	256	256	0
512	512	2	512	0	-

Table 434. Variable length transfer protocol example (ZLT=1)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	-
512	256	2	256	256	-
512	512	1	512	-	-

TX-dTD is complete when:

- All packets described in the dTD successfully transmit. Total bytes in dTD equal 0 when this occurs.

RX-dTD is complete when:

- All packets described in the dTD are successfully received. Total bytes in dTD equal 0 when this occurs.
- A short packet (number of bytes < maximum packet length) was received.

  This is a successful transfer completion; DCD must check the total bytes field in the dTD to determine the number of bytes remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) or (total bytes received > total bytes specified).

  This is an error condition. The device controller discards the remaining packets and sets the buffer error bit in the dTD. In addition, the endpoint flushes and the USBERR interrupt becomes active.

NOTE

Disabling zero-length packet termination allows transfers larger than the total bytes field spanning across two or more dTDs.

Upon successful completion of the packet(s) described by the dTD, the active bit in the dTD is cleared and the next pointer is followed when the terminate bit is clear. When the terminate bit is set, the USB OTG flushes the endpoint/direction and ceases operations for that endpoint/direction.

Upon unsuccessful completion of a packet (see long packet above), the dQH remains pointing to the dTD in error. To recover from this error condition, DCD must properly re-initialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors, such as a missing handshake or CRC error, are retried automatically by the device controller. There is no required interaction with the DCD for managing such errors.

Table 435. Interrupt/bulk endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error[1]	N/A
Out	STALL	NAK	Receive + NYET/ACK[2]	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. Force bit stuff error
2. NYET/ACK - NYET; or, if the TD has packets remaining according to the USB variable length protocol, then ACK.

55.9.6 Control endpoint operation

55.9.6.1 Setup phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase.

Setup packet managing:

- Disable setup lockout by writing 1 to USBMODE[SLOM] at initialization. Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the setup lockout mode cleared results in a potential compliance issue.

- After receiving an interrupt and inspecting Endpoint Setup Status (ENDPTSETUPSTAT) to determine a setup packet was received on a particular pipe:
  1. Write 1 to clear the corresponding field in Endpoint Setup Status (ENDPTSETUPSTAT).
  2. Set the setup tripwire field (USBCMD[SUTW]).
  3. Duplicate contents of dQH.SetupBuffer into a local software byte array.
  4. Read USBCMD[SUTW]. If set to 1, continue; if cleared to 0, go to step 2.
  5. Clear USBCMD[SUTW].
  6. Poll Endpoint Setup Status (ENDPTSETUPSTAT) until it clears to 0.
  7. Process the setup packet using the local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet, status and/or handshake phases may remain pending from a previous control sequence. These must be flushed and de-allocated before linking a new status and/or handshake dTD for the most recent setup packet.

55.9.6.2 Data phase

Following the setup phase, the DCD must create a dTD for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet is not received by reading Endpoint Setup Status (ENDPTSETUPSTAT) immediately, verifying that the prime had completed. A prime completes when the associated field in Endpoint Initialization (ENDPTPRIME) is cleared to 0 and the associated field in Endpoint Status (ENDPTSTAT) is set to 1. If Endpoint Initialization (ENDPTPRIME) goes to 0 and Endpoint Status (ENDPTSTAT) is not set to 1, the prime fails. This can only happen

because of improper setup of the dQH, dTD, or a setup arriving during the prime operation. If a new setup packet is indicated after Endpoint Initialization (ENDPTPRIME) is cleared to 0, then the TD can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller automatically clears the prime status (Endpoint Status (ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

Error managing of data phase packets is the same as for bulk packets described previously.

55.9.6.3 Status phase

Similar to the data phase, the DCD must create a TD (with byte length equal to 0) and prime the endpoint for the status phase. The DCD must also perform the same checks of Endpoint Setup Status (ENDPTSETUPSTAT) as described above in the data phase.

NOTE

Error managing of status phase packets is the same as bulk packets described previously.

55.9.6.4 Control endpoint bus response matrix

The next table shows the device controller response to packets on a control endpoint according to the device controller state.

Table 436. Control endpoint bus response matrix

Token type	Endpoint state					Setup lockout
	Stall	Not primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR[1]	
In	STALL	NAK	Transmit	BS Error[2]	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK[3]	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

1. SYSERR - System error must never occur when the latency FIFOs are correctly sized and the DCD is responsive.
2. Force bit stuff error.
3. NYET/ACK - NYET; or, if the TD has packets remaining according to the USB variable length protocol, then ACK.

55.9.7 Isochronous endpoint operation

Isochronous endpoints are used for real-time scheduled delivery of data, and their operational model is significantly different than the host throttled bulk, interrupt, and control data pipes. Real time delivery by the USB OTG is accomplished by:

- Exactly MULT packets per (micro)frame are transmitted/received.

NOTE

MULT is a 2-bit field in the dQH. Isochronous endpoints do not use the variable length packet protocol.

- NAK responses are not used. Instead, zero-length packets are sent in response to an IN request to unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If ISO-dTD remains active after that frame, ISO-dTD holds ready until executed or canceled by the DCD.

The USB OTG in Host mode uses the periodic frame list to schedule data exchanges to isochronous endpoints. The operational model for Device mode does not use such a data structure. Instead, the same dTD used for control/bulk/interrupt endpoints is also used for isochronous endpoints. The difference is in the managing of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint becomes primed only after a SOF is received. After the DCD writes the prime bit, the prime bit clears as usual to indicate to you that the device controller completed priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD, but occurs so the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. After an ISO transaction is started in a (micro)frame, it retires the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, and the device controller retires the current ISO-dTD and moves to the next ISO-dTD.

Fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction stays primed indefinitely. This means you must discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error managing. When a CRC error occurs on a received packet, the packet is not retried as is done for bulk and control endpoints. Instead, the CRC is noted by setting the transaction error bit and the data is stored as usual for you to sort out.

- TX packet retired:
  - MULT counter reaches zero.
  - Fulfillment error (Transaction Error bit is 1):
    - # packets occurred > 0 AND # packets occurred < MULT

    NOTE

    For TX-ISO, MULT counter can be loaded with a lesser value in the dTD multiplier override field. If the multiplier override field is 0, the MULT counter initializes to the multiplier in the QH.
- RX packet retired:
  - MULT counter reaches zero.
  - Non-MDATA data PID is received.
  - Overflow error (Buffer Error bit is 1):
    - Packet received is > maximum packet length.
    - Packet received exceeds total bytes allocated in dTD.
  - Fulfillment error (Transaction Error bit is 1):
    - # packets occurred > 0 AND # packets occurred < MULT
  - CRC error (Transaction Error bit is 1)

    NOTE

    For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation, DCD must ensure the dTD linked list is out ahead of the device controller by at least two (micro)frames.

55.9.7.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro)frame number (USB Frame Index (FRINDEX)) can act as a marker. To cause a packet transfer to occur at a specific (micro)frame number (N), the DCD must interrupt on SOF during frame N-1. When USB Frame Index (FRINDEX) equals N-1, the DCD must write the prime bit. The USB OTG primes the isochronous endpoint in (micro)frame N-1 so the device controller executes delivery during (micro)frame N.

CAUTION

Priming an endpoint towards the end of (micro)frame N-1 does not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if the device controller does not have enough time to complete the prime before the SOF for packet N is received.

55.9.7.2 Isochronous endpoint bus response matrix

Table 437. Isochronous endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL[1] packet	NULL packet	Transmit	BS error[2]	N/A
Out	Ignore	Ignore	Receive	N/A	Drop packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. Zero length packet
2. Force bit stuff error

55.9.8 Managing QHs

The dQH points to the linked list of transfer tasks, each depicted by the dTD. An area of memory pointed to by ENDPOINTLISTADDR register contains a group of every dQH in a sequential list (see the next figure). The even elements in the dQH list receive endpoints (OUT/SETUP) and the odd elements transmit endpoints (IN/INTERRUPT). dTDs are linked head to tail starting at the QH and ending at a terminate bit. After the dTD retires, it is no longer part of the linked list from the QH. Therefore, you are required to track all transfer descriptors because pointers no longer exist within the QH after the dTD is retired (see Software link pointers).

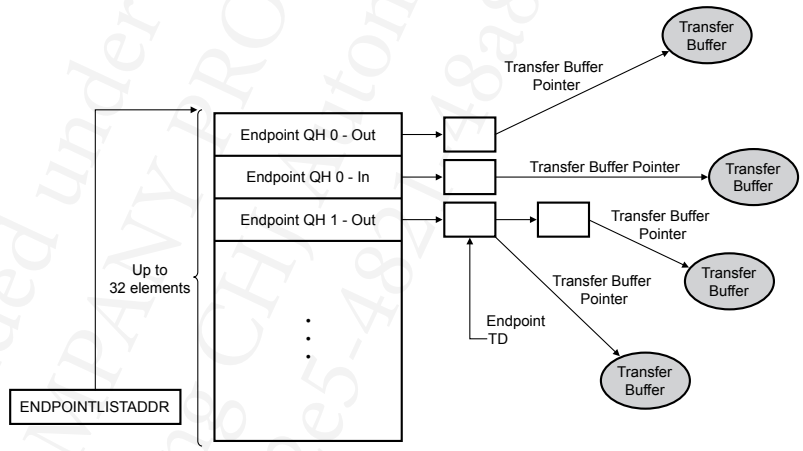

Figure 459. Endpoint QH diagram

In addition to current and next pointers and the dTD overlay examined in Packet transfers, the dQH also contains the following parameters for the associated endpoint:

- Multiplier
- Maximum packet length

- Interrupt on setup

The next section includes a demonstration of complete initialization of the dQH including these fields.

55.9.8.1 QH initialization

One dQH pair must be initialized for each active endpoint. To initialize a dQH:

1. Write to the wMaxPacketSize field as required by the USB specification chapter 9 or application-specific protocol.
2. Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required for bandwidth with the USB specification chapter 9 protocol. In FS mode, the multiplier field can only be 1 for ISO endpoints.
3. Set the next dTD terminate bit field.
4. Clear the active bit in the status field.
5. Clear the halt bit in the status field.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

55.9.8.2 Setup transfers operation

As discussed in Control endpoint operation, setup transfers require special treatment by the DCD. A setup transfer does not use a dTD, but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD must manage the setup transfer by:

1. Copying setup buffer contents from dQH-RX to the software buffer.
2. Acknowledging setup backup by writing a 1 to the corresponding field in Endpoint Setup Status (ENDPTSETUPSTAT).

NOTE

The acknowledge must occur before continuing to process the setup packet. After acknowledge occurs, DCD must not attempt to access the setup buffer in dQH-RX. Only the local software copy should be examined.

3. Checking for pending data or status dTDs from previous control transfers and flushing any that exist as discussed in Flushing/de-priming an endpoint.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

4. Decoding the setup packet and prepare data phase (optional) and status phase transfer as required by the USB specification chapter 9 or application-specific protocol.

55.9.9 Managing transfers with transfer descriptors

55.9.9.1 Software link pointers

It is necessary for the DCD software to maintain head and tail pointers for the linked list of dTDs for each respective QH. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD executed. The operations described in the next section for managing dTDs assumes the DCD can reference the head and tail of the dTD linked list.

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the head and tail pointers, but the DCD must continue maintaining the pointers.

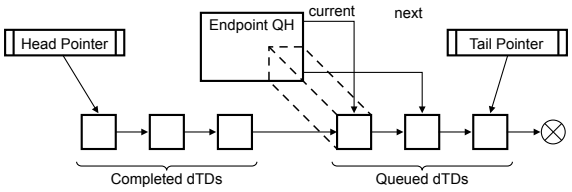

Figure 460. Software link pointers

NOTE

Check the status of each dTD to determine completed status.

55.9.9.2 Building a TD

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. You use the following procedure for building dTDs.

First, you allocate a 32-byte dTD block of memory aligned to 32-byte boundaries. The last 5 bits of the address must equal 00000.

Then, you need to do the following:

1. Initialize the first 7 entries (28 bytes) to 0.
2. Set the terminate field.
3. Fill in total bytes with transfer size.
4. Set the IOC field if desired.
5. Initialize the Status field with the Active field set to 1, and all remaining status bits cleared to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointers.

55.9.9.3 Executing a TD

To safely add a dTD, the DCD must follow this procedure that manages the event where the device controller reaches the end of the dTD list. At the same time, a new dTD is added to the end of the list.

The DCD needs to determine whether the linked list is empty by checking the DCD driver to see if the pipe is empty (the internal representation of the linked list must indicate if any packets are outstanding).

Case 1: Linked list is empty.

1. Write the dQH next pointer AND dQH terminate bit to 0 as a single 32-bit operation.
2. Clear the active and halt bits in the dQH (in case set from a previous error).
3. Prime the endpoint by writing 1 to the correct bit position in Endpoint Initialization (ENDPTPRIME).

Case 2: Linked list is not empty.

1. Add the dTD to the end of the linked list.
2. Read the correct prime bit in Endpoint Initialization (ENDPTPRIME); if 1, then we are done.
3. Write 1 to USBCMD[ATDTW].
4. Read the correct status bit in Endpoint Status (ENDPTSTAT), and store it in a temporary variable for later.
5. Read USBCMD[ATDTW]:

   If it is 0, go to step 3.

   If it is 1, continue to step 6.

6. Write 0 to USBCMD[ATDTW].
7. If the status bit read in step 4 is 1, then DONE.
8. If the status bit read in step 4 is 0, then go to step 1 in case 1.

55.9.9.4 Transfer completion

After a dTD is initialized and the associated endpoint is primed, the device controller executes the transfer upon the host-initiated request. The DCD is notified with a USB interrupt if the IOC field was set, or alternatively, the DCD can poll the endpoint complete register to determine when the dTD was executed. After a dTD is executed, the DCD can check the status bits to determine success or failure.

CAUTION

Multiple dTDs can be completed in a single endpoint complete notification. After clearing the notification, the DCD must search the dTD linked list and retire all finished (active bit cleared) dTDs.

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction error = 0
- Data buffer error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in Device error matrix.

In addition to checking the status bit, the DCD must read the transfer bytes field to determine the actual bytes transferred. When a transfer is complete, the total bytes transferred decrements by the actual bytes transferred. For transmit packets, a packet is only complete after the actual bytes reaches zero. However, for receive packets, the host may send fewer bytes in the transfer according to the USB variable length packet protocol.

55.9.9.5 Flushing/de-priming an endpoint

It is necessary for the DCD to flush or de-prime endpoints during a USB device reset or during a broken control transfer. There may also be application-specific requirements to stop transfers in progress. The DCD can use this procedure to stop a transfer in progress:

1. Set the corresponding bit(s) in Endpoint De-Initialize (ENDPTFLUSH).
2. Wait until all bits in Endpoint De-Initialize (ENDPTFLUSH) are cleared to 0.

   NOTE

   This operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.

3. Read Endpoint Status (ENDPTSTAT) to ensure that, for all endpoints commanded to be flushed, the corresponding bits are now cleared. If the corresponding bits are set after step #2 has finished, the flush failed as described below:

   In very rare cases, a packet is in progress to the particular endpoint when commanded to flush using Endpoint De-Initialize (ENDPTFLUSH). A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint successfully flushes.

55.9.9.6 Device error matrix

The following table summarizes packet errors not automatically managed by the USB OTG module.

Table 438. Device error matrix

Error	Direction	Packet type	Data buffer error bit	Transaction error bit
Data buffer overflow	RX	Any	1	0
ISO packet error	RX	ISO	0	1
ISO fulfillment error	Both	ISO	0	1

The device controller manages all errors on bulk/control/interrupt endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated.

Table 439. Error descriptions

Overflow	Number of bytes received exceeded the maximum packet size or total buffer length. **NOTE** This error also sets the halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, those are not executed.
ISO packet error	CRC error on received ISO packet. Contents are not guaranteed to be correct.
ISO fulfillment error	Host failed to complete the number of packets defined in the dQH Mult field within the given (micro)frame. For scheduled data delivery, the DCD may need to readjust the data queue because a fulfillment error causes the device controller to cease data transfers on the pipe for one (micro)frame. During the dead (micro)frame, the device controller reports an error on the pipe and primes for the following frame.

55.9.10 Servicing interrupts

The interrupt service routine programmer must understand that there are high-frequency, low-frequency, and error operations to order accordingly.

55.9.10.1 High frequency interrupts

In particular, high frequency interrupts must be managed in the following order. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 440. Interrupt managing order

Execution order	Interrupt	Action
1a	USB interrupt[1] ENDPTSETUPSTAT	Copy the contents of the setup buffer and acknowledge the setup packet (as indicated in Managing QHs). Process the setup packet according to USB specification chapter 9 or application-specific protocol.
1b	USB interrupt ENDPTCOMPLETE	Manage completion of the dTD as indicated in Managing QHs.
2	SOF interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts stack up on any call to the interrupt service routine and during the interrupt service routine.

55.9.10.2 Error interrupts

Error interrupts are the least frequent and should be placed last in the interrupt service routine.

Table 441. Error interrupt events

Interrupt	Action
USB error interrupt	This error is redundant because it combines USB interrupt and an error status in the dTD. The DCD more aptly manages packet-level errors by checking the dTD status field upon receipt of USB interrupt (with Endpoint Complete (ENDPTCOMPLETE)).
System error	Unrecoverable error. Immediate reset of module; free transfer buffers in progress and restart the DCD.

55.10 Host mode operation

The EHCI specification defines the general operational model for a USB module in Host mode. The EHCI specification describes the register-level interface for a host controller for USB Revision 2.0. It includes a description of the hardware/software interface between system software and host controller hardware. The next section has information about the initialization of the USB modules; however, full details of the EHCI specification are beyond the scope of this document.

55.10.1 Servicing interrupts

The interrupt service routine programmer must understand that there are high-frequency, low-frequency, and error operations to order accordingly.

55.10.1.1 High frequency interrupts

In particular, high frequency interrupts must be managed in the following order. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 442. Interrupt managing order

Execution order	Interrupt	Action
1a	USB interrupt[1] ENDPTSETUPSTAT	Copy the contents of the setup buffer and acknowledge the setup packet (as indicated in Managing QHs). Process the setup packet according to USB specification chapter 9 or application-specific protocol.
1b	USB interrupt ENDPTCOMPLETE	Manage completion of the dTD as indicated in Managing QHs.
2	SOF interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely multiple interrupts stack up on any call to the interrupt service routine and during the interrupt service routine.

55.10.1.2 Low frequency interrupts

The low frequency events include the following interrupts. These interrupts can be managed in any order because they do not occur often in comparison to the high-frequency interrupts.

Table 443. Low frequency interrupt events

Interrupt	Action
Port change	Change software state information.
Sleep enable (Suspend)	Change software state information. Low-power managing as necessary.
Reset received	Change software state information. Abort pending transfers.

55.10.1.3 Error interrupts

Error interrupts are the least frequent and should be placed last in the interrupt service routine.

Table 444. Error interrupt events

Interrupt	Action
USB error interrupt	This error is redundant because it combines USB interrupt and an error status in the dTD. The DCD more aptly manages packet-level errors by checking the dTD status field upon receipt of USB interrupt (with Endpoint Complete (ENDPTCOMPLETE)).
System error	Unrecoverable error. Immediate reset of module; free transfer buffers in progress and restart the DCD.

55.10.2 Managing isochronous transfers using iTDs

The structure of an iTD is presented in iTD. The four distinct sections to an iTD are:

- Next link pointer - This first field is for schedule linkage purposes only.
- Transaction description array - This area is an eight-element array. Each element represents control and status information for one microframe's worth of transactions for a single HS isochronous endpoint.
- The buffer page pointer array - This is a 7-element array of physical memory pointers to data buffers. These are 4 KB aligned pointers to physical memory.
- Endpoint capabilities - This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size, and high-bandwidth multiplier.

55.10.2.1 Host controller operational model for iTDs

The host controller uses USB Frame Index (FRINDEX) register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to USB Frame Index (FRINDEX) register bits [2:0]. Therefore, each transaction descriptor corresponds to one microframe. Each iTD can span eight microframes worth of transactions.

When the host controller fetches an iTD, it uses USB Frame Index (FRINDEX) register bits [2:0] to index into the transaction description array.

If the value of the Active field in the Status field of the indexed transaction description is set to 0, the host controller ignores the iTD and follows the next pointer to the next schedule data structure.

When the value of the indexed Active field is 1, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if the PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses

the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the Active field to 0 and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction description's PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs, the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of bus transactions of maximum packet size for the endpoint in the current microframe. In other words, the Mult field represents a T-Count for the endpoint in the current microframe. If the Mult field is 0, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers:

- The value of the Transaction X Length field represents the total bytes to be sent during the microframe.
- You must set the Mult field to be consistent with Transaction X Length and Maximum Packet Size.
- The host controller:
  - Sends the bytes in portions that are of Maximum Packet Size
  - Decrements its local copy of Transaction X Length by Maximum Packet Size after each transaction
  - Always sends a number of bytes that are of Maximum Packet Size or Transaction X Length, whichever is less
  - Advances the transfer state in the transfer description
  - Updates the appropriate record in the iTD
  - Moves to the next schedule data structure
- The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers:

- The host controller issues Mult transactions.
- It is assumed that you have properly initialized the iTD to accommodate all of the possible data.
- During each IN transaction, the host controller:
  - Must use the maximum packet size during each IN transaction to detect packet babble errors
  - Keeps the sum of bytes received in the Transaction X Length field
- After all transactions for the endpoint have completed for the microframe, Transaction X Length contains the total number of bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size:
  - Less data than was allowed for was received from the associated endpoint.
  - This short packet condition does not write 1 to USBSTS[UI].
  - The host controller will not detect this condition.
- If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less):
  - The host controller sets the Babble Detected field to 1 and sets the Active field to 0.
  - Note that the host controller is not required to update the iTD Transaction X Length field in this error scenario.
- If the value of the Mult field is greater than 1, then the host controller automatically executes the value of Mult transactions. The host controller does not execute all Mult transactions if:
  - The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (run out of data), or

— The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of microframe may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next microframe. See Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

55.10.2.2 Software operational model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N microframes. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates how a client buffer is mapped by system software to the periodic schedule (that is, the periodic frame list and a set of iTDs).

- On the right side of this figure is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer must be used with each bus transaction.
- In the middle are the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one microframe's worth of transactions. The EHCI controller does not provide per-transaction results within a microframe. It treats the per-microframe transactions as a single logical transfer.
- On the left is the host controller's Frame List. System software establishes references from the appropriate locations in the Frame List to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer.

System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

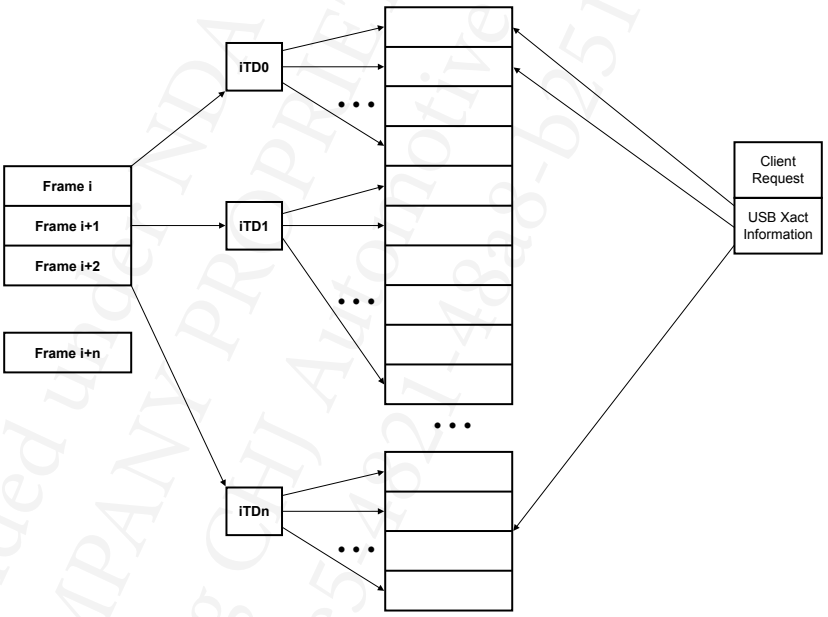

Figure 461. Example association of iTDs to client request buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the Transaction Offset field. The result is a starting buffer address for the transaction. As the host controller

moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page 0. USB 2.0 isochronous endpoints can specify a period greater than one. You can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the Frame List) and by setting appropriate transaction description elements active bits to 1.

55.10.2.2.1 Periodic scheduling threshold

HCCPARAMS[IST] is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

Each of the iTD and siTD data structures describe 8 microframes of transactions. The host controller is allowed to cache one (or more) of these data structures to reduce memory traffic. Three basic caching models account for the fact that the isochronous data structures span eight microframes. Those are:

- No caching
- Microframe caching
- Frame caching

When you add new isochronous transactions to the schedule, it always performs a read of USB Frame Index (FRINDEX) to determine the frame and microframe the host controller is currently executing. Of course, there is no information about where in the microframe the host controller is, so a constant uncertainty-factor of one microframe must be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per microframe) but always dumps any accumulated schedule state at the end of the microframe. At the appropriate time relative to the beginning of every microframe, the host controller always begins schedule traversal from the frame list. You can use the value of USB Frame Index (FRINDEX) (plus the constant uncertainty-factor of one microframe) to determine the approximate position of the executing host controller. When no caching is selected, you can add an isochronous transaction as near as two microframes in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (eight microframes). You use the value of USB Frame Index (FRINDEX) (plus the constant uncertainty-factor of one microframe) to determine the current microframe/frame (assume modulo 8 arithmetic in adding the constant 1 to the microframe number). For any current frame N, if the current microframe is 0 to 6, then you can safely add isochronous transactions to frame N + 1. If the current microframe is 7, then you can add isochronous transactions to frame N + 2.

Microframe caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of microframes indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of two microframes worth of state (the current microframe, plus the next frame) on-chip. On each microframe boundary, the host controller releases the current microframe state and begins accumulating the next microframe state.

55.10.3 Managing control/bulk/interrupt transfers through QHs

This section presents an overview of how the host controller interacts with queuing data structures.

QHs use the qTD structure. One QH is used to manage the data stream for one endpoint. The QH structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see the Overlay area, defined in QH). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a transfer.

The general processing model for the host controller's use of a QH is this:

1. Read a QH
2. Execute a transaction from the overlay area
3. Write back the results of the transaction to the overlay area
4. Move to the next QH

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the QH's Status field. The Status field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the QH Status field are "sticky" until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so that no additional bus transactions occur for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a QH traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a QH. The host controller must be able to advance the queue from the Fetch QH state in order to avoid all hardware/software race conditions. This simple mechanism allows you to simply link qTDs to the QH and activate them, then the host controller can always find them if/when they are reachable. The figure below illustrates the host controller QH traversal state machine.

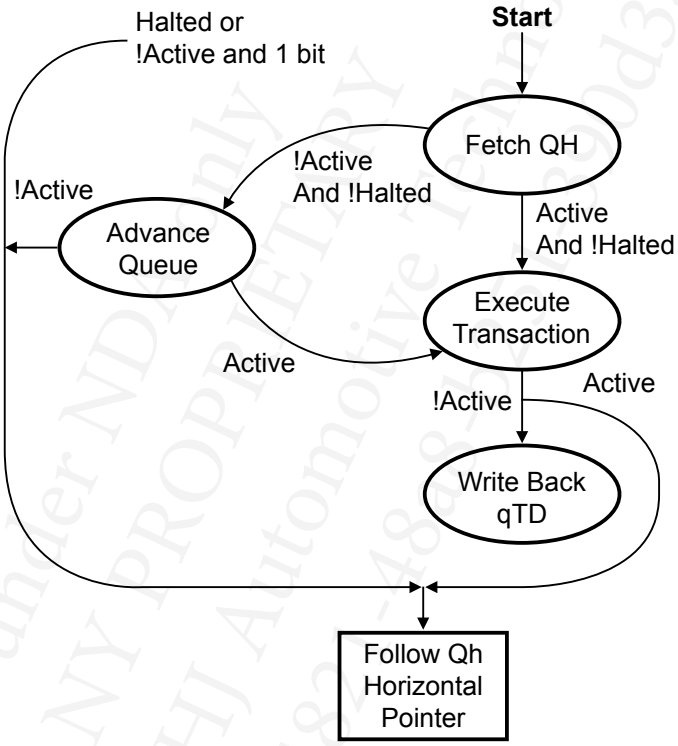

Figure 462. Host controller QH traversal state machine

This traversal state machine applies to all QHs, regardless of transfer type or whether split transactions are required. The following sections describe each state, and each state description describes the entry criteria. The Execute Transaction state (see Execute transaction) describes the basic requirements for all endpoints. Split transactions for asynchronous transfers and Split transaction interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to placing a QH into either the periodic or asynchronous list, you must ensure the QH is properly initialized. At a minimum, the QH must be initialized to the following (see section QH for layout of a QH):

Valid static endpoint state:

- For the very first use of a QH, you may zero-out the QH transfer overlay, then set the next qTD pointer field value to reference a valid qTD.

55.10.3.1 Fetch QH

A QH can be referenced from the physical address stored in ASYNCLISTADDR. Additionally, it may be referenced from the Next LinkPointer field of an iTD, siTD, FSTN, or another QH. If the referencing link pointer has the Typ field set to indicate a QH, it is assumed to reference a QH structure as defined in Table 421.

When in this state, the host controller performs operations to implement empty schedule detection and Nak Counter reloads. After the QH has been fetched, the host controller checks the following conditions for empty schedule detection:

- The QH is not an interrupt QH (that is, S-mask is 0).
- The H-bit is 1.
- USBSTS[RCL] is 0.

When the above criteria are met, the host controller stops traversing the asynchronous list. When the criteria are not met, the host controller continues schedule traversal. If the QH is not an interrupt and the H-bit is one and USBSTS[RCL] is 1, then the host controller writes USBSTS[RCL] to 0 before completing this state. The operations for reloading of the Nak Counter are described in detail in the Operational Model for Nak Counter. For details, see the standard documentation of *Enhanced Host Controller Interface Specification for Universal Serial Bus (EHCI)* available at intel.in.

This state is complete when the QH has been read on-chip.

55.10.3.2 Advance queue

To advance the queue, the host controller must find the next qTD, adjust the pointers, perform the overlay, and write the results back to the QH.

This state is entered from the FetchQHD state if the overlay Active and Halt bits are set to 0. Upon entry into this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD, and then determines whether or not to perform an overlay.

NOTE

If the I-bit is 1 and the Active field is 1, the host controller immediately skips processing of this QH, exits this state, and uses the horizontal pointer to the next schedule data structure. If the Bytes to Transfer field is not 0 and the T-bit in the Alternate Next qTD Pointer is set to 0, then the host controller uses the Alternate Next qTD Pointer. Otherwise, the host controller uses the NextqTD Pointer. If NextqTD Pointer's T-bit is set to 1, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer, the host controller fetches the referenced qTD. If the fetched qTD has its Active field set to 1, the host controller moves the pointer value used to reach the qTD (next or alternate next) to the Current qTD Pointer field, then performs the overlay. If the fetched qTD has its Active field set to 0, the host controller aborts the queue advance and follows the QH's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the Data Toggle (DT) field in the overlay area depends on the value of the Data Toggle Control (DTC) field (see Table 423).
- If the EPS field indicates the endpoint is a HS endpoint, the Ping state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- C-prog-mask field is set to 0 (field from incoming qTD is ignored, as is the current contents of the overlay area).
- Frame Tag field is set to 0 (field from incoming qTD is ignored, as is the current contents of the overlay area).
- NakCnt field in the overlay area is loaded from the RL field in the QH's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the QH.

55.10.3.3 Execute transaction

The host controller enters this state from the Fetch QH Head state only if the Active field in Status field of the QH is set to 1.

Upon entry to this state, the host controller executes a few pre-operations, then checks pre-condition criteria before committing to executing a transaction for the QH.

The pre-operations performed and the pre-condition criteria depend on whether the QH is an interrupt endpoint. The host controller can determine that a QH is an interrupt QH when the QH's S-mask field contains a non-zero value. It is your responsibility to ensure the S-mask field is appropriately initialized based on the transfer type. There are other criteria that must be met if the EPS field indicates that the endpoint is a LS or FS endpoint; see Split transactions for asynchronous transfers and Split transaction interrupt.

55.10.3.3.1 Interrupt transfer pre-condition criteria

If the QH is for an interrupt endpoint (for example, non-zero S-mask field), then the FRINDEX[2:0] field must identify a bit in the S-mask field that has 1 in it.

For example, an S-mask value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met, then the host controller considers this QH for a transaction.

55.10.3.3.2 Asynchronous transfer pre-operations and pre-condition criteria

If the QH is not for an interrupt endpoint (for example, 0 in the S-mask field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

- Check the Nak Counter reload state. It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Regardless of whether or not the NakCnt field has been reloaded, the host controller checks the value of the NakCnt field in the QH. If NakCnt is non-zero, or if the Reload Nak Counter field is 0, then the host controller considers this QH for a transaction.

55.10.3.3.3 Transfer type independent pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter qHTransactionCounter is loaded from the QH's Mult field. A host controller implementation is allowed to ignore this for QHs on the asynchronous list. It is mandatory for interrupt QHs. You must ensure that the Mult field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the microframe to complete this transaction. If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of qHTransactionCounter for an interrupt endpoint is 0, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets USBSTS[RCL] to 1 and then begins executing one or more transactions using the endpoint information in the QH. The host controller iterates qHTransactionCounter times in this state executing transactions. After each transaction is executed, qHTransactionCounter is decremented by 1. The host controller exits this state when one of the following events occurs:

- The qHTransactionCounter decrements to 0.
- The endpoint responds to the transaction with any handshake other than an ACK,[4].
- The transaction experiences a transaction error.
- The Active field in the QH goes to 0.

- There is not enough time remaining in the microframe to execute the next transaction.

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally retry the transaction immediately if it fails.

The results of each transaction are recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance the QH's transfer state, the Total Bytes to Transfer field is decremented by the number of bytes moved in the transaction, the Data Toggle field (DT) is toggled, the current page offset is advanced to the next appropriate value (for example, advanced by the number of bytes successfully moved), and the C_Page field is updated to the appropriate value (if necessary). See Buffer pointer list use for data streaming with qTDs.

NOTE

The Total Bytes to Transfer field may be 0 when all the other criteria for executing a transaction are met. When this occurs, the host controller executes a zero-length transaction to the endpoint. If the PID_Code field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, sets the babble and halted fields in the Status field, sets the Active field to 0, writes the results back to the source qTD, and then exits this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example, not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement qHTransactionCounter). It is recommended (but not required) that the host controller continue executing transactions for this endpoint if the resultant value of qHTransactionCounter is greater than 1.

If the response to the IN bus transaction is a Nak (or Nyet) and RL is non-zero, NakCnt is decremented by 1. If RL is 0, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of CErr did not change). You must set the RL field to 0 if the QH is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly NakCnt), the host controller writes back the results of the transaction to the QH's overlay area in main memory.

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is MaximumPacket Size. The number of bytes moved during an OUT transaction is either Maximum Packet Length bytes or Total Bytes to Transfer, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The CErr field is decremented by 1 and the status field is updated to reflect the type of error observed.

The following events will cause the host controller to clear the Active field to 0 in the QH's overlay status field. When the Active field transitions from 1 to 0, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the Active field to 0) determines the next state.

- The CErr field decrements to 0. When this occurs, the Halted field is set to 1 and Active is set to 0. This results in the hardware not advancing the queue and the pipe halts. You must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the Halted field is set to 1 and the Active field is set to 0. This results in the hardware not advancing the queue and the pipe halts. You must intercede to recover.
- The Total Bytes to Transfer field is 0 after the transaction completes.
  - For a zero length transaction, it was 0 before the transaction was started. When this condition occurs, the Active field is set to 0.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the Maximum Packet Length. When this occurs, the Active field is set to 0 and a short-packet condition exists. The short-packet condition is detected during the Advance Queue state. See Split transactions for additional rules for managing LS and FS transactions.

With the exception of a NAK response (when the value of the RL field is 0), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a HS endpoint, the QH

information written back includes the following fields at a minimum: The PID Code field indicates an IN and the device sends more than the expected number of bytes (for example Maximum Packet Length or Total Bytes to Transfer bytes, whichever is less) (for example, a packet babble). This results in the host controller setting the Halted field to 1.

- NakCnt, DT, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a LS or FS device, the QH information written back also includes these fields:

- C-prog-mask, FrameTag and S-bytes

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

55.10.3.3.4 Halting a QH

A halted endpoint is defined only for the transfer types that are managed through QHs (control, bulk and interrupt). The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a QH), the host controller halts the QH and sets the USBSTS[UEI] status field to 1. To halt the QH, the Active field is set to 0 and the Halted field is set to 1. There may be other error status fields that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a Halt condition (for example, no updates necessary for Total Bytes to Transfer, C_Page, Current Offset, and DT). The host controller must update CErr as appropriate. When a QH is halted, USBSTS[UEI] is set to 1. If the USBINTR[UEE] is set to 1, a hardware interrupt is generated at the next interrupt threshold.

55.10.3.3.5 Asynchronous Schedule Park mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a HS QH in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on QHs or other data structures in the Periodic schedule. This feature is similar in intent to the Mult feature that is used in the Periodic schedule. Where the Mult feature is a characteristic that is tunable for each endpoint, park-mode is a policy that is applied to all HS QHs in the Asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same QH before moving to the next QH in the Asynchronous List. This feature allows the host controller to attain better bus usage for those devices that are capable of moving data at maximum rate, and at the same time provide a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the Asynchronous Schedule Park Capability field in the USB_n_HCCPARAMs register to 1. This information keys system software that the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a 1 to the Asynchronous Schedule Park Mode Enable field.

When park-mode is not enabled (for example, when the Asynchronous Schedule Park Mode Enable field in the USB_n_USBCMD register is 0), the host controller must not execute more than one bus transaction per HS QH, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a QH whose EPS field indicates an LS or FS device (for example, only one bus transaction is allowed from each LS or FS QH per traversal of the asynchronous schedule). Park-mode may only be applied to QHs in the asynchronous schedule whose EPS field indicates that it is an HS device.

The host controller must apply park mode to QHs whose EPS field indicates a HS endpoint. The maximum number of consecutive bus transactions a host controller may execute on a HS QH is determined by the value in the Asynchronous Schedule Park Mode Count field in the USB_n_USBCMD register. You must not set the Asynchronous Schedule Park Mode Enable field to 1 and also set the Asynchronous Schedule Park Mode Count field to 0; the resulting behavior is not defined. A behavioral example describes

the operational requirements for the host controller implementing park-mode. How the host controller manages the bus transaction as defined in Execute transaction is not affected by this feature. It only affects how many consecutive bus transactions for the current QH can be executed. All boundary conditions, error detection, and reporting apply as usual. This feature is similar in concept to the use of the Mult field for high-bandwidth interrupts for QHs in the periodic schedule.

The host controller effectively loads an internal down-counter PM-Count from Asynchronous Schedule Park Mode Count when the Asynchronous Schedule Park Mode Enable field is 1, and a HS QH is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, PM-Count is decremented. The host controller may continue to execute bus transactions from the current QH until PM-Count goes to 0, an error is detected, the buffer for the current transfer is exhausted, or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that affect whether the host controller continues with another bus transaction for the current QH.

Table 445. Actions for park mode, based on endpoint response and residual transfer state

PID	Endpoint response	Transfer state after transaction		Action
		PM-Count	Bytes to transfer	
IN	DATA[0,1] with maximum packet-sized data	Not zero	Not zero	Allowed to perform another bus transaction[1,2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH
	DATA[0,1] with short packet	Don't care	Don't care	Retire qTD and move to next QH
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH
OUT	ACK	Not zero	Not zero	Allowed to perform another bus transaction[2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH
	NYET, NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not zero	Not zero	Allowed to perform another bus transaction [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current HS QH (if PM-Count is not 0), if a PID mismatch is detected (for example, expected DATA1 and received DATA0, or vice-versa).
2. This specification does not require that the host controller execute another bus transaction when PM-Count is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

55.10.3.4 Write back qTD

This state is entered from the Execute Transaction state when the Active bit is set to 0.

The source data for the write-back is the transfer results area of the QH overlay area (see Table 445).

The host controller uses the Current qTD Pointer field as the target address for the qTD.

The QH transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as "qTD Retirement". The fields that must be written back to the source qTD include Total Bytes to Transfer, Cerr, and Status.

The duration of this state depends on when the qTD write-back is committed.

55.10.3.5 Follow QH horizontal pointer

The host controller must use the horizontal pointer in the QH to the next schedule data structure when any of the following conditions exist:

- If the Active bit is 1 on exit from the Execute Transaction state
- When the host controller exits the Write Back qTD state
- If the Advance Queue state fails to advance the queue because the target qTD is not active
- If the Halted bit is 1 on exit from the fetch QH state

There is no functional requirement for the host controller to wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

55.10.3.6 Buffer pointer list use for data streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be virtually contiguous. This means that, if it spans more than one physical page, the buffer must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 KB chunk beyond the first page, each buffer portion matches to a full 4 KB page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 KB. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD manages a 16 KB buffer with any starting buffer alignment.

The host controller uses the C_Page field as an index value to determine which buffer pointer in the list must be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing C_Page and pulling the next page pointer from the list. You must ensure there are sufficient buffer pointers to move the amount of data specified in the Bytes to Transfer field.

The following figure illustrates a nominal example of how system software would initialize the buffer pointers list and the C_Page field for a transfer size of 16383 bytes. C_Page is set to 0. The upper 20 bits of page 0 references the start of the physical page. Current Offset (the lower 12 bits of QH Dword 7) holds the offset in the page; for example, 2049 (that is, 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 KB page.

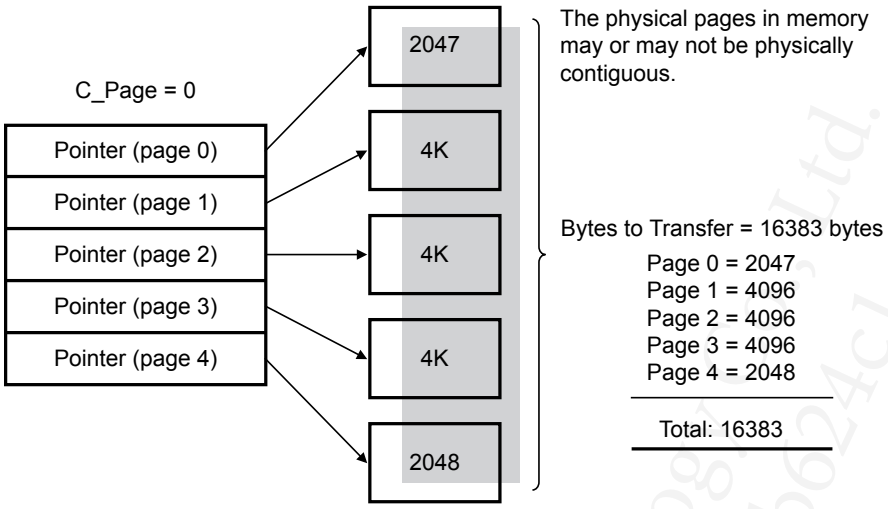

Figure 463. Example mapping of qTD buffer pointers to buffer pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because C_Page is set to 0) and concatenates the Current Offset field. The 512 bytes are moved during the transaction, and current offset and total bytes to transfer are adjusted by 512 and written back to the QH working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments C_Page (to 1) and uses the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and Current Offset has rolled to 1, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is, C_Page) when necessary. The three conditions for how the host controller manages C_Page are:

- The current transaction does not span a page boundary. The value of C_Page is not adjusted by the host controller.
- The current transaction spans a page boundary. The host controller must detect the page cross condition and advance to the next buffer when streaming data to and from the USB.
- The current transaction completes on a page boundary (that is, the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment C_Page before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to C_Page is to increment by 1.

55.10.3.7 Adding interrupt QHs to the periodic schedule

The link path(s) from the periodic frame list to a QH establishes in which frames a transaction can be executed for the QH. QHs are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a QH's S-Mask to indicate which microframe within a 1 ms period a transaction must be executed for the QH. You must ensure that all QHs in the periodic schedule have S-Mask set to a non-zero value. An S-mask with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of QH linking and S-Mask values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 446. Example periodic reference patterns for interrupt transfers with 2 ms poll rate

Frame # reference sequence	Description
0, 2, 4, 6, 8, and so on S-Mask = 01h	A QH for the bInterval of 2 ms (16 microframes) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the S-Mask field in the QH is set to 01h, indicating that the transaction for the endpoint must be executed on the bus during microframe 0 of the frame.
0, 2, 4, 6, 8, and so on S-Mask = 02h	Another example of a QH with a bInterval of 2 ms is linked into the periodic frame list at exactly the same interval as the previous example. However, the S-Mask is set to 02h indicating that the transaction for the endpoint must be executed on the bus during microframe 1 of the frame.

55.10.3.8 Managing transfer complete interrupts from queue heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an IOC field that has a value of 1, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (such as a control transfer), the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOCs to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be reused in a timely manner.

55.10.4 Split transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with FS and LS devices, connected below USB 2.0 hub, using the split transaction protocol.

See the USB 2.0 Specification for the complete definition of the split transaction protocol. FS and LS devices are enumerated identically as HS devices, but the transactions to the FS and LS endpoints use the split-transaction protocol on the HS bus. The split transaction protocol is an encapsulation of (or wrapper around) the FS or LS transaction. The HS wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator, below which the FS or LS device is attached.

The EHCI interface uses dedicated data structures for managing FS isochronous data streams (see siTD). Control, bulk, and interrupt are managed using the queuing data structures (see QH). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the LS or FS host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

55.10.4.1 Split transactions for asynchronous transfers

A QH in the asynchronous schedule with an EPS field indicating a FS or LS device indicates to the host controller that it must use split transactions to stream data for this QH.

All FS bulk, full- and LS control are managed through QHs in the asynchronous schedule.

You must initialize the QH with the appropriate device address and port number for the transaction translator that is serving as the FS/LS host controller for the links connecting the endpoint. You must also initialize the split transaction state field (SplitXState) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the Control Transfer Type (C) field in the QH to 1. If this is not a control transfer type endpoint, you must initialize the C field to be 0. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the C field is 0, the split transaction token's ET field is set to indicate a bulk endpoint. When the C field is 1, the split transaction token's ET field is set to indicate a control endpoint. See the USB Specification Revision 2.0 chapter for details.

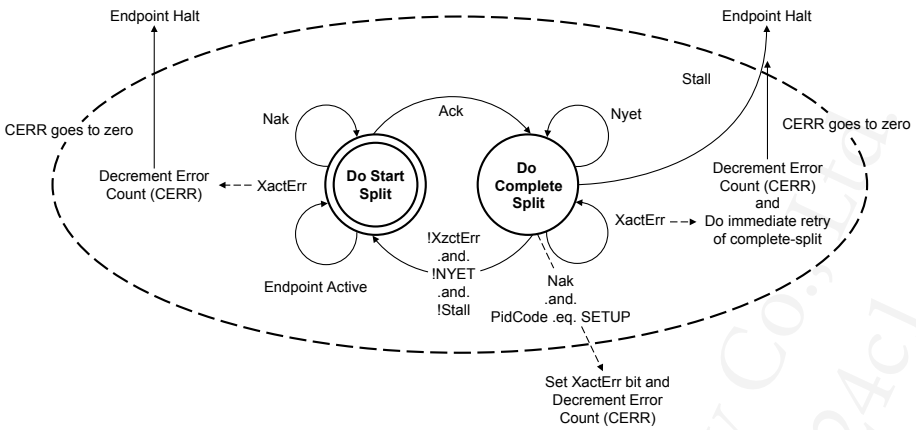

Figure 464. Host controller asynchronous schedule split-transaction state machine

55.10.4.1.1 Asynchronous—do start split

This is the state in which you must initialize a FS or LS asynchronous QH. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For QHs in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and PidCode indicates an IN or OUT transaction, then the host controller reloads the error counter (CErr). If it is a successful bus transaction and the PidCode indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the QH remains in this state, and the host controller proceeds to the next QH in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements Cerr and proceeds to the next QH in the asynchronous schedule.

55.10.4.1.2 Asynchronous—do complete split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For QHs in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the QH remains in this state, the error counter is reset and the host controller proceeds to the next QH in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the QH's PidCode indicates an IN or OUT, the host controller reloads the error counter (CErr). When a Nyet handshake is received for a complete-split bus transaction where the QH's PidCode indicates a SETUP, the host controller must not adjust the value of CErr.

Independent of PIDCode, the following responses have these effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (Cerr) is decremented by 1 and the complete split transaction is immediately retried (if possible). If there is not enough time in the microframe to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the asynchronous schedule, it must begin executing from this QH. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next microframe, the first transaction from the schedule is the retry for this endpoint.

If Cerr went to 0, the host controller must halt the queue.

- NAK. The target endpoint generates a NAK response for the FS or LS transaction. The state of the transfer is not advanced and the state is exited. If the PidCode is a SETUP, then the Nak response is a protocol error. The XactErr status field is set to 1 and the CErr field is decremented.

- STALL. The target endpoint responded with a STALL handshake. The host controller sets the Halt field in the status byte and retires the qTD, but does not attempt to advance the queue.

If the PidCode indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected Data Toggle and checks CRC. If the packet is good, the host controller advances the state of the transfer; for example, it moves the data pointer by the number of bytes received, decrements the BytesToTransfer field by the number of bytes received, and toggles the DT field. The host controller then exits this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected result, the data is ignored, the transfer state is not advanced, and this state is exited. If the PidCode indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The Current Offset field is incremented by Maximum Packet Length or Bytes to Transfer, whichever is less. The field Bytes To Transfer is decremented by the same amount and the Data Toggle field (DT) is toggled. The host controller then exits this state.
- Advancing the transfer state may cause other processing events, such as retirement of the qTD and advancement of the queue (see Managing control/bulk/interrupt transfers through QHs).

55.10.4.2 Split transaction interrupt

Split-transaction interrupt-IN/OUT endpoints are managed through the same data structures used for HS interrupt endpoints; they coexist in the periodic schedule.

QHs/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a HS endpoint, the host controller visits a QH, executes a HS transaction (if the criteria are met) and advances the transfer state (or not) depending on the results of the entire transaction. For LS and FS endpoints, the details of the execution phase are different (it takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing control/bulk/interrupt transfers through QHs, but only occurs upon the completion of a split transaction.

55.10.4.2.1 Split transaction scheduling mechanisms for interrupt

FS and LS interrupt QHs have an EPS field indicating FS or LS and have a non-zero S-mask field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. LS and FS interrupt QHs require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. You must not set these fields to indicate the QH is an interrupt unless the QH is used in the periodic schedule.

System software manages the per-transaction translator periodic pipeline by budgeting and scheduling exactly during which microframes the start-splits and complete-splits for each endpoint occur. The characteristics of the transaction translator are such that the HS transaction protocol must execute during explicit microframes, or else the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and QH data structure. The S and C_X labels indicate microframes in which you can schedule start-splits and complete splits, respectively.

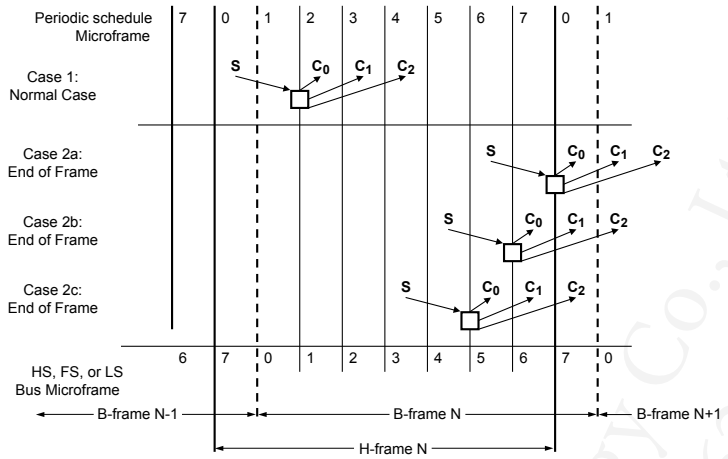

Figure 465. Split transaction, interrupt scheduling boundary conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (H-Frame, in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, determining when and how many complete-splits must be scheduled to account for earliest to latest execution on the FS/LS link. The complete-splits may span the H-Frame boundary when the start-split is in microframe four or later. When this occurs, the H-Frame to B-Frame alignment requires that the QH be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

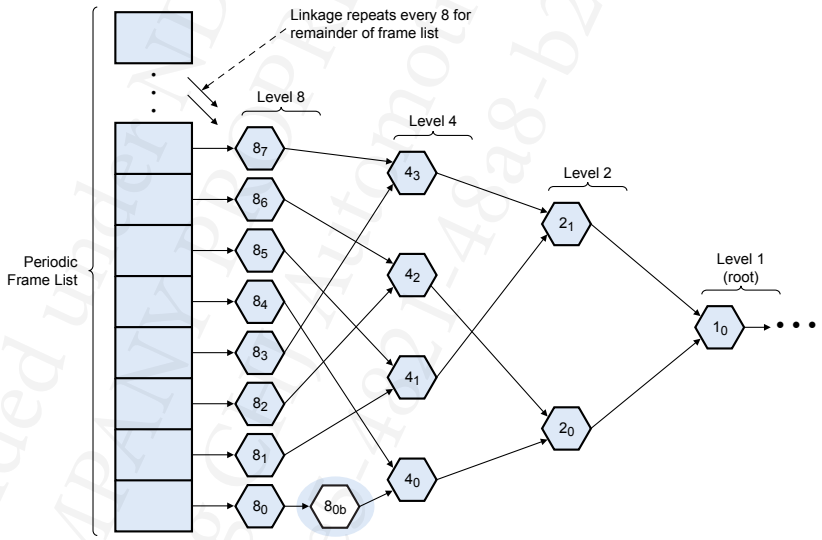

Figure 466. General structure of EHCI periodic schedule using interrupt spreading

The periodic frame list is effectively the leaf level of a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. You can efficiently manage periodic bandwidth on the USB by spreading interrupt QHs that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate and eight QHs and account for them once in the HS bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the QH for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} were such an endpoint. Without additional support on the

interface, for 8_{0b} to be reachable at the correct time, you would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host controller operational model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following QH fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- SplitXState. This is a single bit that resides in the Status field of a QH (see Table 419). This bit is used to track the current state of the split transaction.
- Frame S-mask. The system software sets a bit within this field corresponding to the microframe (within an H-Frame) for which the host controller should execute a start-split transaction. This is always qualified by the value of the SplitXState bit in the Status field of the QH. For example, referring to case one in Figure 465, the S-mask would have a value of 0000_0001b; this indicates that if the QH is traversed by the host controller, and the SplitXState indicates Do_Start, and the current microframe indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- Frame C-mask. The system software sets one or more bits within this field corresponding to the microframes (within an H-Frame) for which the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the SplitXState bit in the Status field of the QH. For example, referring to case one in Figure 465, the C-mask would have a value of 0001_1100b; this indicates that if the QH is traversed by the host controller, and the SplitXState indicates Do_Complete, and the current microframe indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. You are responsible for ensuring that the translation between H-Frames and B-Frames is correctly performed when setting bits in S-mask and C-mask.

55.10.4.2.2 Host controller operational model for FSTNs

The FSTN data structure is used to manage LS/FS interrupt QHs that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a back pointer, similar in intent to the back pointer field in the siTD data structure (see siTD back link pointer).

This feature provides you with a simple primitive to save a schedule position, redirect the host controller to traverse the necessary QHs in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs are:

- FSTN data structure.
- A Save Place indicator. This is always an FSTN with its Back Path Link Pointer.T-bit set to 0.
- A Restore indicator. This is always an FSTN with its Back Path Link Pointer.T-bit set to 1.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during microframes 2 through 7 it simply follows the node's Normal Path Link Pointer to access the next schedule data structure.

NOTE

The FSTN's Normal Path Link Pointer.T-bit may set to 1, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a Save-Place FSTN in microframes 0 or 1, it saves the value of the Normal Path Link Pointer and sets an internal flag indicating that it is executing in Recovery Path mode. Recovery Path mode modifies the host controller's rules for how it traverses the schedule and limits which data structures are considered for execution of bus transactions. The host controller continues executing in Recovery Path mode until it encounters a Restore FSTN or it determines that it has reached the end of the microframe (see details in the list below).

The rules for schedule traversal and limited execution when in Recovery Path mode are:

- Always follow the Normal Path Link Pointer when it encounters an FSTN that is a Save-Place indicator. The host controller must not recursively follow Save-Place FSTNs. Therefore, when executing in Recovery Path mode, it must never follow an FSTN's Back Path Link Pointer.
- Do not process an siTD or iTD data structure. Simply follow its Next Link Pointer.
- Do not process a QH whose EPS field indicates a HS device. Simply follow its Horizontal Link Pointer.
- When a QH's EPS field indicates a FS/LS device, the host controller only considers it for execution if its SplitXState is DoComplete (note: this applies whether the PID Code indicates an IN or an OUT). See Execute transaction and Tracking split transaction progress for interrupt transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction when executing in Recovery Path mode. See Periodic isochronous - do complete split for special handling when in Recovery Path mode.
- Stop traversing the recovery path when it encounters an FSTN that is a Restore indicator. The host controller unconditionally uses the saved value of the Save-Place FSTN's Normal Path Link Pointer when returning to the normal path traversal. The host controller must clear the context of executing a Recovery Path when it restores schedule traversal to the Save-Place FSTN's Normal Path Link Pointer.
- If the host controller determines that there is not enough time remaining in the microframe to complete processing of the periodic schedule, it abandons traversal of the recovery path and clears the context of executing a recovery path. The result is that at the start of the next consecutive microframe, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

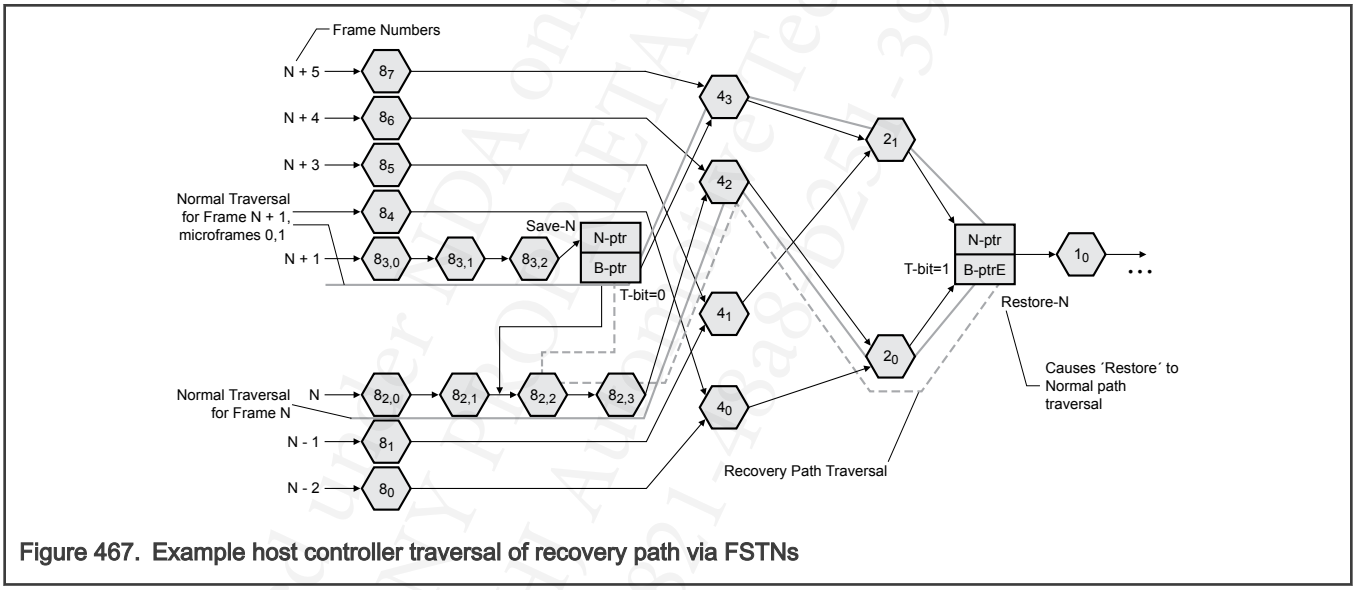

Figure 467. Example host controller traversal of recovery path via FSTNs

In frame N+1 (microframes 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that the Save-N.Back Path Link Pointer.T-bit is 0 (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in Recovery Path mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to 1 (definition of a Restore indicator), so the host controller exits Recovery Path mode by clearing the internal Recovery Path mode flag and commences (restores) schedule traversal using the saved value of the Save-Place FSTN's Normal Path Link Pointer (for example Save-N.Normal Path Link Pointer). The nodes traversed during these microframes include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 ...}. The nodes on the recovery-path are in bold. In frame N (microframes 0-7), for this example, the host controller traverses all of the schedule data structures using the Normal Path Link Pointers in any FSTNs it encounters. This is because the host controller has not yet encountered a Save-Place FSTN so it is not executing in Recovery Path mode. When it encounters the Restore FSTN, (Restore-N), during microframes 0 and 1, it uses Restore-N.Normal Path Link Pointer

to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's Normal Path Link Pointer when not executing in a Recovery Path mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 ...}.

In frame N+1 (microframes 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these microframes include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 ...}.

55.10.4.2.3 Software operational model for FSTNs

You must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, the system software must adhere to the following rules:

- Each Save-Place indicator requires a matching Restore indicator.
  - The Save-Place indicator is an FSTN with a valid Back Path Link Pointer and T-bit equal to 0.
    - Back Path Link Pointer.Typ field must be set to indicate the referenced data structure is a QH. The Restore indicator is an FSTN with its Back Path Link Pointer.T-bit set to 1.
  - A Restore FSTN may be matched to one or more Save-Place FSTNs. For example, if the schedule includes a poll-rate one level, then system software only needs to place a Restore FSTN at the beginning of this list in order to match all possible Save-Place FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more Save-Place FSTNs are used, then System software must ensure the Restore FSTN's Normal Path Link Pointer's T-bit is set to 1, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a Restore FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that Recovery Path mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A Save-Place FSTN's Back Path Link Pointer must reference a QH data structure. The referenced QH must be reachable from the previous frame list location. In other words, if the Save-Place FSTN is reachable from frame list offset N, then the FSTN's Back Path Link Pointer must reference a QH that is reachable from frame list offset N-1.

You should make the schedule as efficient as possible. What this means in this context is that you must have no more than one Save-Place FSTN reachable in any single frame. Note there are times when two (or more, depending on the implementation) could exist as FS/LS footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the Save-Place FSTN from one poll rate level to another. During the transition, you must preserve the integrity of the previous schedule until the new schedule is in place.

55.10.4.2.4 Tracking split transaction progress for interrupt transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to obtain it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted, and successfully executed by the USB 2.0 Hub, but the complete-splits generate unrecoverable errors on the HS link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the correct time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot obtain timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition and instead affects only the progress of the transfer. The QH has the following fields to track the progress of each split transaction. These fields are used to record an incremental state about which (and when) portions have been executed.

- C-prog-mask. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur

due to system hold-offs where the host controller cannot access the memory-based schedule. C-prog-mask is a simple bit-vector in which the host controller sets one of the C-prog-mask bits for each complete-split executed. The bit position is determined by the microframe number in which the complete-split was executed. The host controller always checks C-prog-mask before executing a complete-split transaction. If the previous complete-splits have not been executed, then one (or more) have been skipped and data has potentially been lost.

- FrameTag. This field is used by the host controller during the complete-split portion of the split transaction to tag the QH with the frame number (H-Frame number) when the next complete split must be executed.
- S-bytes. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The S-bytes field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

55.10.4.2.5 Split transaction execution state machine for interrupt

In this section, all references to microframe are in the context of a microframe within an H-Frame.

As with asynchronous FS and LS endpoints, a split-transaction state machine is used to manage the split transaction sequence.

In addition to the fields defined in the QH for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- cMicroFrameBit. This is a single-bit encoding of the current microframe number. It is an eight-bit value calculated by the host controller at the beginning of every microframe. It is calculated from the three least significant bits of USB Frame Index (FRINDEX) (that is, cMicroFrameBit = (1 shifted-left(FRINDEX[2:0])). The cMicroFrameBit has at most one bit asserted, which always corresponds to the current microframe number. For example, if the current microframe is 0, then cMicroFrameBit will equal 00000001b. The variable cMicroFrameBit is used to compare against the S-mask and C-mask fields to determine whether the QH is marked for a start- or complete-split transaction for the current microframe.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the SplitXState is at Do_Start and the single bit in cMicroFrameBit has a corresponding bit active in QH.S-mask. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to 1 in the QH.C-mask field.

The host controller keeps the QH in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the three-strikes-rule (for example, after the host tries the same transaction three times, and each encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

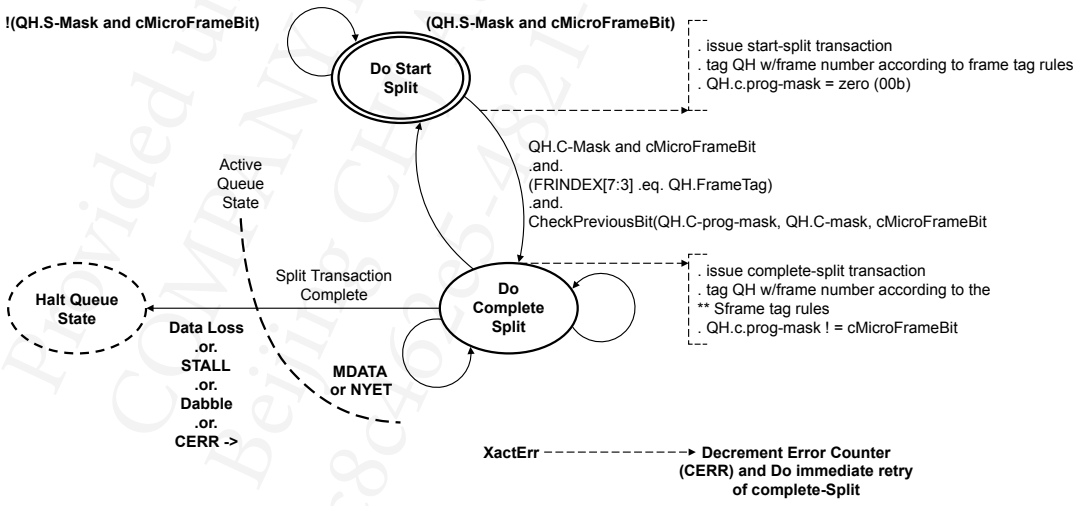

Figure 468. Split transaction state machine for interrupt

See the previous sections for the frame tag management rules.

55.10.4.2.5.1 Periodic interrupt—do start split

This is the state in which you must initialize a FS or LS interrupt QH StartXState bit. The state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur. The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the FS or LS endpoint's NAK response.
- ACK. An ACK response is a propagation of the FS or LS endpoint's ACK response. It only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the LS/FS link below the transaction translator had a failure (for example, timeout, bad CRC, and so on.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the FS or LS endpoint. See Section Periodic isochronous - do complete split for the definition of "Last".

Each time the host controller visits a QH in this state (when within the Execute Transaction state), it performs the following test to determine whether to execute a start-split:

- QH.S-mask is bit-wise anded with cMicroFrameBit.

If the result is non-zero, then the host controller will issue a start-split transaction. If the PIDCode field indicates an IN transaction, the host controller must zero-out the QH.S-bytes field. After the split-transaction has been executed, the host controller sets up state in the QH to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into the QH.FrameTag field, sets the C-prog-mask to 0 (00h), and exits this state. Note that the host controller must not adjust the value of CErr as a result of completion of a start-split transaction.

55.10.4.2.5.2 Periodic interrupt—do complete split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a QH in this state (when within the Execute Transaction state), it checks to determine whether a complete-split transaction must be executed at that time.

There are four tests to determine whether a complete-split transaction must be executed.

- Test A. cMicroFrameBit is bit-wise anded with QH.C-mask field. A non-zero result indicates that you scheduled a complete-split for this endpoint, during this microframe.
- Test B. QH.FrameTag is compared with the current contents of FRINDEX[7:3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous microframe. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
```

```
                                If not(previousBit bitAND QH.C-prog-mask) then
                        rvalue = FALSE;
              End if
End If
-- If the C-prog-mask already has a 1 in this bit position,
-- then an aliasing
-- error has occurred. It will probably be caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- must not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this microframe. Note this is the same test performed in the Do Start Split state (see Section Periodic isochronous - do start split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a Recovery Path mode, it means a start-split should occur in this microframe. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If logically (A .and. B .and. C .and. not(D)) is true, then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates QH.C-prog-mask by performing a bit-OR with cMicroFrameBit. On completion of the complete-split transaction, the host controller records the result of the transaction in the QH and sets QH.FrameTag to the expected H-Frame number. The effect to the state of the QH and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the given effects (note that any responses that result in decrementing of CErr will result in the QH being halted by the host controller if the result of the decrement is 0):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition in which all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the QH is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR QH.C-mask with QH.C-prog-mask. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the XactErr status bit is set to a 1 and the CErr field is decremented.
- NYET (and not Last). See the above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for C-prog-mask and FrameTag) and stay in this state. The host controller must not adjust CErr on this response.
- Transaction Error (XactErr). Timeout, data CRC failure, and so on. The CErr field is decremented and the XactErr bit in the Status field is set to a 1. The complete split transaction is immediately retried (if Cerr is non-zero). If there is not enough time in the microframe to complete the retry and the endpoint is an IN, or CErr is decremented to a 0 from a 1, the queue is halted. If there is not enough time in the microframe to complete the retry and the endpoint is an OUT and CErr is not 0, then this state is exited (that is, returned to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. See the Hubs (specifically, the "FS and LS interrupts") section in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint responded with ACK for the data, and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The Current Offset field is incremented by Maximum Packet Length or Bytes to Transfer, whichever is less. The field Bytes To Transfer is decremented by the same amount. And the data toggle bit (DT) is toggled. The host controller will then exit this state for this QH. The host controller must reload CErr with the maximum value on this

response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Managing control/bulk/interrupt transfers through QHs).

- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in QH.S-bytes. The host controller must not adjust CErr on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in QH.S-bytes. The state of the transfer is advanced by the result and the host controller will exit this state for this QH.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing control/bulk/interrupt transfers through QHs).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced, and this state is exited.
- NAK. The target endpoint generated a NAK response for the FS or LS transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload CErr with the maximum value on this response.
- ERR. There was an error during the FS or LS transaction. The ERR status bit is set to a 1, Cerr is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The Active status field is set to 0, the Halted status field is set to a 1, and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that the data or the response was lost. The table below lists the possible combinations and the appropriate actions.

Table 447. Interrupt IN/OUT do complete split state execution criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current microframe. The host controller should continue walking the schedule.
A not(C)	If PIDCode = IN then halt QHD If PIDCode = OUT then retry start-split	Progress bit check failed. This means a complete-split has been missed. There is the possibility of lost data. If PIDCode is an IN, then the QH must be halted. If PIDCode is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect CERR. In either case, set the Missed Microframe bit in the status field to a 1.
A not(B) C	If PIDCode = IN then halt QHD If PIDCode = OUT then retry start-split	QH.FrameTag test failed. This means that exactly one or more H-Frames have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If PIDCode is an IN, then the QH must be halted. If PIDCode is an OUT, then the transfer state is not advanced and the state is exited (for example, start-split is retried). This is a host-induced error and does not effect CERR. In either case, set the Missed Microframe bit in the status field to a 1.
A B	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.

Table continues on the next page...

Table 447. Interrupt IN/OUT do complete split state execution criteria (continued)

Condition	Action	Description
C not(D)		
D	If PIDCode = IN then halt QHD If PIDCode = OUT then retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to result in detection. If PIDCode is an IN, then the QH must be halted. If PIDCode is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not affect CERR. In either case, you must set the Missed Microframe bit in the status field to a 1. Note: When executing in the context of a Recovery Path mode, the host controller is allowed to process the QH and take the actions indicated above, or it may wait until the QH is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a Recovery Path mode.

55.10.4.2.5.3 Managing the QH.FrameTag field

The QH.FrameTag field in a QH is completely managed by the host controller. The rules for setting QH.FrameTag are these (see USB Frame Index (FRINDEX)):

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of FRINDEX[2:0] is 6, then QH.FrameTag is set to FRINDEX[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different H-Frames (case 2a, see Figure 465).
- Rule 2: If the current value of FRINDEX[2:0] is 7, then QH.FrameTag is set to FRINDEX[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (see Figure 465).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of FRINDEX[2:0] is not 6, or currently in Do Complete Split and the current value of (FRINDEX[2:0]) is not 7, FrameTag is set to FRINDEX[7:3]. This accommodates all other cases (see Figure 465).

55.10.4.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic QH's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more QHs are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that the system software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the Inactivate-on-next-Transaction (I) field to a 1 to signal the host controller that it intends to update the S-mask and C-mask on this QH. System software will then wait for the host controller to observe the I-bit is a 1 and transition the Active field to a 0. Following are the rules for how and when the host controller sets the Active field to 0:

- If the Active field is a 0, no action is taken. The host controller does not attempt to advance the queue when the I-bit is a 1.
- If the Active field is a 1 and the SplitXState is DoStart (regardless of the value of S-mask), the host controller will simply set the Active field to a 0. The host controller is not required to write the transfer state back to the current qTD. Note that if the S-mask indicates that a start-split is scheduled for the current microframe, the host controller must not issue the start-split bus transaction. It must set the Active field to 0.

The system software must save the transfer state before setting the I-bit to a 1. This is required so that it can correctly determine what transfer progress (if any) occurred after the I-bit was set to a 1 and the host controller executed its final bus transaction and set Active to 0.

After system software has updated the S-mask and C-mask, it must then reactivate the QH. Because the Active field and the I-bit cannot be updated with the same write, the system software needs to use the following algorithm to coherently reactivate a QH that has been stopped via the I-bit.

1. Set the Halted field to 1.
2. Set the I-bit to 0.
3. Set the Active field to 1 and the Halted field to 0 in the same write.

Setting the Halted field to 1 inhibits the host controller from attempting to advance the queue between the time the I-bit goes to 0 and the Active field goes to 1.

55.10.4.3 Split transaction isochronous

FS isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller uses the siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (see iTD; also see Managing isochronous transfers using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This arrangement allows a single isochronous scheduling model with the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

55.10.4.3.1 Split transaction scheduling mechanisms for isochronous

FS isochronous transactions are managed through a transaction translator's periodic pipeline. As with FS and LS interrupts, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which microframes the start-splits and complete-splits for each FS isochronous endpoint occur.

The requirements described in Split transaction scheduling mechanisms for interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The S_X and C_X labels indicate microframes where you can schedule start- and complete-splits (respectively). The H-Frame boundaries are marked with a large, solid, bold vertical line. The B-Frame boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the H-Frame.

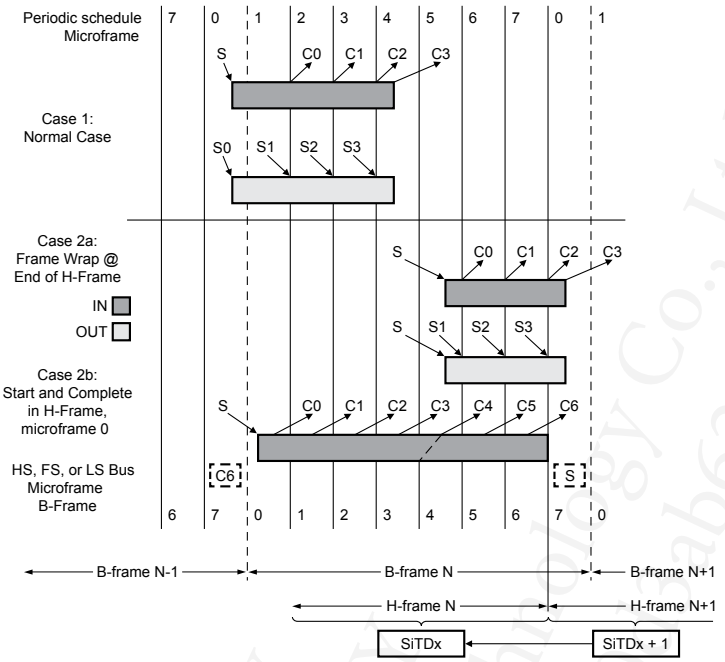

Figure 469. Split transaction, isochronous scheduling boundary conditions

When the endpoint is an isochronous OUT, there are only start-splits and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to N complete-splits. The scheduling boundary cases are:

- Case 1: The entire split transaction is completely bounded by an H-Frame. For example, the start-splits and complete-splits are all scheduled to occur in the same H-Frame.
- Case 2a: In this boundary case, one or possibly two complete-splits of a split transaction IN are scheduled across an H-Frame boundary. This can only occur when the split transaction has the possibility of moving data in B-Frame, microframes 6 or 7 (H-Frame microframe 7 or 0). When an H-Frame boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (for example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each FS IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- You must never schedule FS isochronous OUTs across an H-Frame boundary.
- Case 2b: This case can only occur for a very large isochronous IN, and is the only allowed scenario in which a start-split and complete-split for the same endpoint can occur in the same microframe. You must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579-byte maximum packet size.

A subset of the same mechanisms employed by full- and LS interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by the system software to instruct the host controller when to execute portions of the split transaction protocol.

- SplitXState. This is a single bit residing in the Status field of an siTD (see Figure 470). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Split transaction execution state machine for interrupt.
- Frame S-mask. This is a field in which the system software sets a bit corresponding to the microframe (within an H-Frame) for which the host controller should execute a start-split transaction. This is always qualified by the value of the SplitXState bit. For example, referring to the IN example in Figure 469, Case one, the S-mask would have a value of 00000001b, indicating that if the siTD is traversed by the host controller, and the SplitXState indicates Do Start Split, and the current microframe as indicated by USB_*n*_FRINDEX[2:0] is 0, then execute a start-split transaction.

- Frame C-mask. This is a field in which system software sets one or more bits corresponding to the microframes (within an H-Frame) for which the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the SplitXState bit. For example, referring to the IN example in Figure 469, Case one, the C-mask would have a value of 00111100b, indicating that if the siTD is traversed by the host controller, and the SplitXState indicates Do Complete Split, and the current microframe as indicated by USB_*n*_FRINDEX[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.
- Back Pointer. This field in an siTD is used to complete an IN split-transaction using the previous H-Frame's siTD. This is only used when the scheduling of the complete-splits span an H-Frame boundary.

There exists a one-to-one relationship between a HS isochronous split transaction (including all start- and complete-splits) and one FS isochronous transaction. An siTD contains (among other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one FS isochronous data payload. This means that for any FS transaction payload, a single siTD's data buffer must be used. This rule applies to both IN and OUT transactions. An siTD's scheduling information usually also maps to one HS isochronous split transaction. The exception to this rule is the H-Frame boundary wrap cases mentioned above.

The siTD data structure describes, at most, one frame's worth of HS transactions, and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the FS transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the B-Frames (HS, FS, or LS Bus) and the H-Frames. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each H-Frame corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

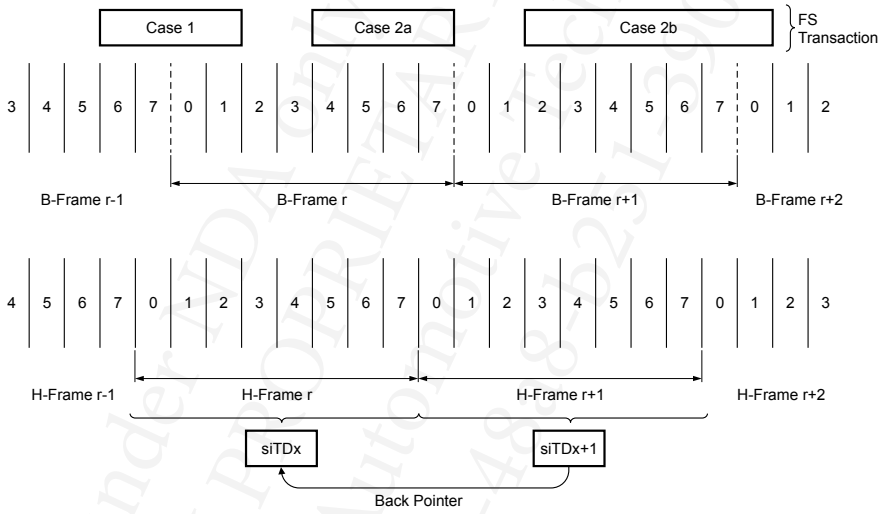

Figure 470. siTD scheduling boundary examples

Each case is described below:

- Case 1: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single H-Frame.
- Case 2a, 2b: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete. The scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The FS transaction (for these cases) can deliver data on the FS bus segment during microframe 7 of $H\text{-}Frame_{Y+1}$, or microframe 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits used to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$ is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described in Periodic isochronous - do complete split .

You must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- You must ensure that an isochronous split-transaction is started so that it will complete before the end of the B-Frame.
- You must ensure that, for a single FS isochronous endpoint, there is never a start-split and complete-split in H-Frame, microframe 1. This is mandated as a rule so that Case 2a and Case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split is in microframe 1 of H-Frame N and the last complete-split would need to occur in microframe 1 of H-Frame N+1. However, it is impossible to discriminate between Case 2a and Case 2b, which has a significant impact on the complexity of the host controller.

55.10.4.3.2 Tracking split transaction progress for isochronous transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device-to-host data is lost. Isochronous endpoints do not employ the concept of "halt on error"; however, the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped microframes), timeouts, and corrupted data received.

As is the case for interrupt split-transactions, the portions of the split transaction protocol must execute in the microframes they are scheduled. The QH data structure used to manage FS and LS interrupts has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs for their transfers, and the data structures are only reachable via the schedule in the exact microframe in which they are required (therefore, all of the mechanisms employed for tracking in QHs are not required for siTDs). You have the option of reusing an siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller returns to the siTD (in a future microframe).

Split-transaction isochronous OUTs use a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields TP and T-Count. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and managed by the transaction translator. See Periodic isochronous - do start split for a description of how these fields are used during a sequence of start-split transactions.

The fields siTD.T-Count and siTD.TP are used by the host controller to drive and sequence the TP annotations. It is the responsibility of the system software to properly initialize these fields in each siTD. After the budget for a split-transaction isochronous endpoint is established, S-mask, T-Count, and TP initialization values for all the siTD associated with the endpoint are constant, and they remain constant until you recalculate the budget for the endpoint and the periodic schedule is adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with a split transaction interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- C-prog-mask. This is an eight-bit bit-vector in which the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs for which the host controller cannot access the memory-based schedule. C-prog-mask is a simple bit-vector for which the host controller sets a field for each complete-split executed. The bit position is determined by the microframe (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks the C-prog-mask before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means that one (or more) have been skipped and data has potentially been lost. The system software must initialize this field to 0 before setting the Active field of an siTD to a 1.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. See Asynchronous—do complete split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field Total Bytes to Transfer to decrement to 0. This response can occur before all of the scheduled complete-splits have been executed. In other interface data structures (for example, HS data streams through QHs), the transition of Total Bytes to Transfer to 0 signals the end of the transfer and results in setting of the Active field to 0. However, in this case, the result has

not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary, the periodic pipeline rules require that, on a microframe boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the FS bus pipe stage and give the remaining bytes to the HS pipeline stage. At the microframe boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next microframe, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the FS pipeline stage). This could cause the siTD to decrement its Total Bytes to Transfer field to 0, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the FS transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the C-prog-mask is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then the system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

55.10.4.3.3 Split transaction execution state machine for isochronous

In the following presentation, all references to microframe are in the context of a microframe within an H-Frame.

If the Active field in the Status byte is a 0, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise, the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Tracking split transaction progress for interrupt transfers, plus the variable cMicroFrameBit defined in Section Split transaction execution state machine for interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the Active field in the Status field of an siTD. The bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

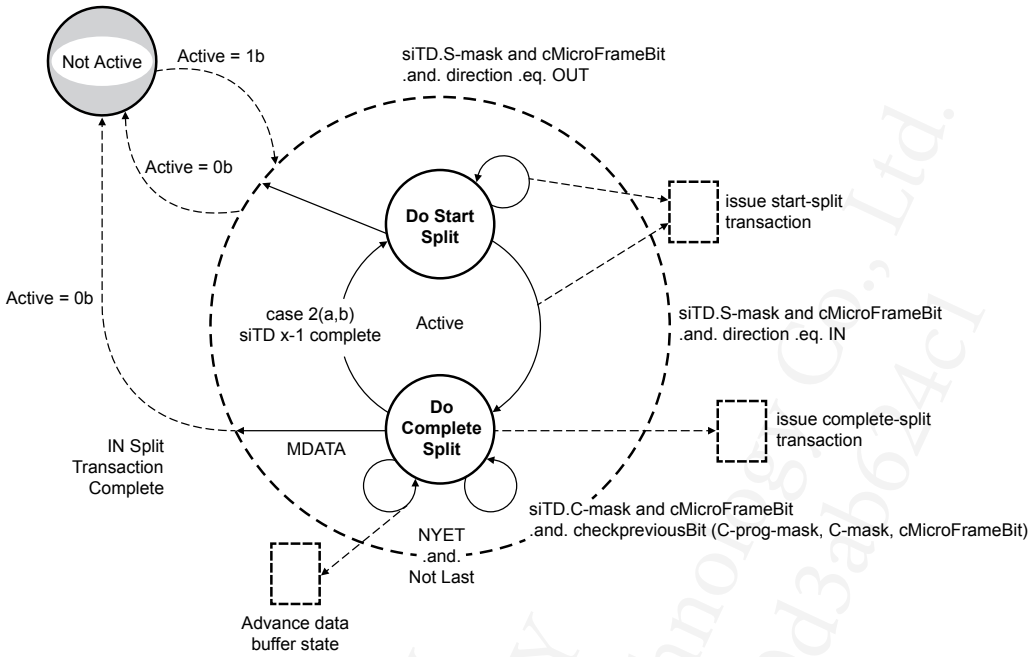

Figure 471. Split transaction state machine for isochronous

55.10.4.3.4 Periodic isochronous - do start split

Isochronous split OUT transactions use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the siTD.S-mask against cMicroFrameBit. If there is a 1 in the appropriate position, the siTD executes a start-split transaction. By definition, the host controller cannot reach an siTD at the wrong time. If the I/O field indicates an IN, then the start-split transaction includes only the extended token plus the FS token. You must initialize the siTD.Total Bytes To Transfer field to the number of bytes expected. This is usually the maximum packet size for the FS endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the I/O field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT, it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating siTD.Current Offset with the page pointer indicated by the page selector field (siTD.P). The value of 0 in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the siTD.P-bit from a 0 to a 1, and begin using the siTD.Page 1 with siTD.Current Offset as the memory address pointer. The field siTD.TP is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases, the host controller simply uses the value in siTD.TP to mark the start-split with the correct TP code.

T-Count is always initialized to the number of start-splits for the current frame. TP is always initialized to the first required TP identifier. The scheduling boundary case (see Split transaction scheduling mechanisms for isochronous) is used to determine the initial value of TP. The initial cases are summarized in the following table.

Table 448. Initial conditions for OUT siTD's TP and T-Count fields

Case	T-Count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes, more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates T-Count and TP appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the TP and T-Count transitions, which must be accomplished by the host controller.

Table 449. TP/T-Count transition table

TP	T-Count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when T-Count starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when T-Count starts at greater than 2.
MID	!=1	MID	TP stays at MID when T-Count is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the T-Count starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the T-Count starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state, the following operations take place:

- The siTD.Total Bytes to Transfer and the siTD.Current Offset fields are adjusted to reflect the number of bytes transferred.
- The siTD.P (page selector) field is updated appropriately.
- The siTD.TP and siTD.T-Count fields are updated appropriately as defined in Table 449.

These fields are then written back to the memory-based siTD. The S-mask is fixed for the life of the current budget. As mentioned above, TP and T-Count are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of S-mask, the actual number of start-split transactions depends on T-Count (or equivalently, Total Bytes to Transfer). The host controller must set the Active field to a 0 when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when T-Count decrements to 0 as a result of a start-split bus transaction. Equivalently, the host controller can detect when Total Bytes to Transfer decrements to 0. Either implementation must ensure that if the initial condition is Total Bytes to Transfer equal to 0 and T-Count is equal to a 1, then the host controller will issue a single start-split, with a zero-length data payload. You must ensure that TP, T-Count, and Total Bytes to Transfer are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the TP annotation will be incorrect as received by the transaction translator).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the siTD.C-prog-mask as it executes each scheduled start-split. The checkPreviousBit() algorithm defined in Periodic isochronous -

do complete split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed microframes. It can then set the siTD's Active field to 0 and stop execution of this siTD. This saves on both memory and HS bus bandwidth.

55.10.4.3.5 Periodic isochronous - do complete split

The state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence in which they are applied depends on which microframe the host controller is currently executing, meaning that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. cMicroFrameBit is bit-wise ANDed with the siTD.C-mask field. A non-zero result indicates that you scheduled a complete-split for this endpoint, during this microframe. This test is always applied to a newly-fetched siTD that is in this state.
- Test B. The siTD.C-prog-mask bit vector is checked to determine whether the previous complete splits have been executed. The sequence in which this test is applied depends on the current value of USB_*n*_FRINDEX[2:0]. If USB_*n*_FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used; otherwise, it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous microframe. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                              rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and the value of USB_n_FRINDEX[2:0] is 0 or 1, then this is a case 2a or 2b scheduling boundary (see Figure 469).

If Test A and Test B evaluate to true, then the host controller executes a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates QH.C-prog-mask by performing a bit-OR with the cMicroFrameBit. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from siTD.Total Bytes to Transfer,
- Adjust siTD.Current Offset by the number of bytes received,
- Adjust the siTD.P (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the siTD.Status field, depending on the results of the transaction.

Note that if the host controller encounters a condition where siTD.Total Bytes To Transfer is zero, and it receives more data, the host controller must not write the additional data to memory. The siTD.Status.Active bit must be set to 0 and the siTD.Status.Babble Detected bit must be set to a 1. The fields siTD.Total Bytes to Transfer, siTD.Current Offset, and siTD.P (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of siTD.Total Bytes To Transfer) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set siTD.Status Active to 0 and siTD.Status.Babble Detected to 1 when it receives an MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have these effects:

- ERR. FS transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the ERR bit in the siTD.Status field and sets the Active bit to 0.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, and so on. The siTD.Status field XactErr field is set to a 1 and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the microframe occurs, the Active bit is set to 0.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the Active bit is set to 0. If the Bytes To Transfer field has not decremented to 0 (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for, was actually received. This short packet event does not set USBSTS[UI] to 1. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the Active bit is set to 0. No bits are set in the Status field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. This result must be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.
- MDATA (and Last). See the above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the FS link, which delayed the completion of the FS transaction, or you set up the S-mask and/or C-masks incorrectly. The host controller must set the XactErr bit to 1 and the Active bit is set to 0.
- NYET (and not Last). See the above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for C-prog-mask), and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the FS transaction data payload spans from microframe X to X+1, and during microframe X the transaction translator will respond with an MDATA and the data accumulated up to the end of microframe X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the Missed Microframe status bit and sets the Active bit to 0.

55.10.4.3.6 Complete-split for scheduling boundary cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 469) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 450. Summary of siTD Split Transaction state

Buffer state	Status	Execution progress
Total Bytes to Transfer P (page select) Current Offset TP T-Count	All bits in the status field	C-prog-mask

NOTE

TP and T-Count are used only for Host to Device (OUT) endpoints.

If you have budgeted the schedule of this data stream with a frame wrap case, then it must initialize the siTD.Back Pointer field to reference a valid siTD and will have the siTD.Back Pointer.T-bit in the siTD.Back Pointer field cleared to 0. Otherwise, you

must set the siTD.Back Pointer.T-bit in the siTD.Back Pointer field to 1. The host controller's rules for interpreting when to use the siTD.Back Pointer field are listed below. These rules apply only when the value of siTD's Active field is 1 and the SplitXState is Do Complete Split:

- When the cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is 0
- If the cMicroFrameBit is a 2h and the value of siTDX.S-mask[0] is 0

When either of the above conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

To access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$.Back Pointer.

The host controller must save the entire state from $siTD_X$ when processing $siTD_{X-1}$. This is to accommodate for Case 2b processing. The host controller must not recursively walk the list of siTD.Back Pointers.

If $siTD_{X-1}$ is active (the Active field is 1 and SplitXStat is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 450) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s Active field is 1, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (the Active field is 1 and SplitXStat is Do Start Split), then the host controller must clear the Active field to 0, set the Missed Microframe status field to 1, and write the resultant status back to memory.

If $siTD_{X-1}$'sActive field is 0 (because it was 0 when the host controller first visited $siTD_{X-1}$ via $siTD_X$'s back pointer, it transitioned to 0 as a result of a detected error, or the results of $siTD_{X-1}$'s complete-split transaction transitioned it to 0), then the host controller returns to the context of $siTD_X$ and transitions its SplitXState to Do Start Split. The host controller then determines whether the Case 2b start split boundary condition exists (that is, if cMicroframeBit is a 1b and $siTD_X$.S-mask[0] is a 1b). If this criterion is met, the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.Next Pointer to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.Next Pointer to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its Active field cleared to 0 when the host controller returns to the context of $siTD_X$. Also, note that you must not initialize an siTD with C-mask bits 0 and 1 set to 1 and an S-mask with bit 0 set to 1. This scheduling combination is not supported and the resulting behavior of the host controller is undefined.

55.11 Deviations from the EHCI specifications

The Host mode operation of the USB host module is mostly EHCI-compatible, with a few minor differences. For the most part, the modules conform to the data structures and operations described in Section 3, "Data structures," and Section 4, "Operational model," in the EHCI specification. The particulars of the deviations occur in the following areas:

- Embedded transaction translator - Allows direct attachment of HS, FS and LS devices in Host mode without the need for a companion controller.
- Embedded design interface - The module does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.

55.11.1 Embedded transaction translator function

The USB Host mode supports directly-connected HS, FS, and LS devices without requiring a companion controller by including the capabilities of a USB 2.0 HS hub transaction translator. Although there is no separate transaction translator block in the system, the transaction translator function normally associated with a HS hub is implemented within the DMA and protocol engine blocks. The embedded transaction translator function is an extension to the EHCI interface, but makes use of the standard data structures and operational models in the EHCI specification to support FS and LS devices.

55.11.1.1 Capability registers

These additions to the capability registers support the embedded Transaction Translator function:

- N_TT added to HCSPARAMS - Host controller structural parameters
- N_PTT added to HCSPARAMS - Host controller structural parameters

See Host Controller Structural Parameters (HCSPARAMS) for usage information.

55.11.1.2 Operational registers

Operational registers are defined in the Universal Serial Bus Specification, Revision 2.0, in the section "Host Controller Operational Registers".

The following additions to the operational registers provide support for the embedded TT:

- Addition of a 2-bit port speed (PSPD) field to the PORTSC*n* register

55.11.1.3 Discovery

In a standard EHCI controller design, the EHCI host controller driver detects an FS or LS device by noting if the port enable field is set after the port reset operation. In a standard EHCI controller implementation, the port enable is set only after the port reset operation and when the host and device negotiate a HS connection (chirp completes successfully).

The module always sets the port enable field after the port reset operation regardless of the host device chirp result, and the resulting port speed is indicated by the PORTSC*n*[PSPD] field. Therefore, the standard EHCI host controller driver requires an alteration to manage directly-connected FS and LS devices or hubs. The change is a fundamental one that is summarized in the next table.

Table 451. Functional differences between EHCI and EHCI with embedded TT

Standard EHCI	EHCI with embedded transaction translator
After the port enable field is set following a connection and reset sequence, the device/hub is assumed to be HS.	After the port enable field is set following a connection and reset sequence, the device/hub speed is noted from PORTSCn.
FS and LS devices are assumed to be downstream from an HS hub. Therefore, all port-level control performs through the hub class to the nearest hub.	FS and LS devices can be downstream from an HS hub or directly attached. When the FS or LS device is downstream from an HS hub, port-level control acts using the hub class through the nearest hub. When an FS or LS device is directly attached, then port-level control is accomplished using PORTSCn.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr equal to X [where HubAddr > 0 and HubAddr is the address of the hub where the bus transitions from HS to FS or LS (split target hub)]	FS and LS devices can be downstream from an HS hub with HubAddr equal to X [HubAddr > 0] or directly attached [where HubAddr equals 0 and HubAddr is the address of the root hub where the bus transitions from HS to FS or LS (split target hub is the root hub)]

55.11.1.4 Data structures

The same data structures used for FS or LS transactions though a HS hub are also used for transactions through the root hub. It is demonstrated here how the hub address and endpoint speed fields must be set for directly-attached FS or LS devices and hubs:

- QH (for direct-attach FS or LS) - asynchronous (bulk/control endpoints) periodic (interrupt)
  - Hub address equals 0
  - Transactions to direct-attached device/hub.
    - QH.EPS equals port speed
  - Transactions to a device downstream from direct-attached FS hub.
    - QH.EPS equals downstream device speed

NOTE

When QH.EPS equals 01 (LS) and PORTSC*n*[PSPD] equals 00 (FS), a LS-pre-PID is sent before transmitting LS traffic.

Maximum packet size must equal 64 or less to prevent undefined behavior.

- siTD (for direct-attach FS) - Periodic (ISO endpoint)
  - All FS ISO transactions:
    - Hub address equals 0
    - siTD.EPS equals 00 (FS)

  Maximum packet size must equal 1023 or less to prevent undefined behavior.

55.11.1.5 Operational model

The operational models are well-defined for the behavior of the transaction translator (see the USB 2.0 specification) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded transaction translator exists within the USB host controller, no physical bus exists between the EHCI host controller driver and the USB FS or LS bus. These sections briefly discuss the operational model for how the EHCI and transaction translator operational models combine without the physical bus between them. The following sections assume that you are familiar with the EHCI and USB 2.0 transaction translator operational models.

55.11.1.5.1 Microframe pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B). The embedded transaction translator uses the same pipeline algorithms specified in the USB 2.0 specification for a hub-based transaction translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 are ready to execute on the bus in B-frame 0.

When programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream hub-based transaction translators.

After periodic transfers are exhausted, any stored asynchronous transfer is moved. Asynchronous transfers are opportunistic because they execute when possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer cannot babble through the SOF (start of B-frame 0.)

55.11.1.5.2 Split-state machines

The start and complete-split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete-split operation is a simple internal operation to the embedded transaction translator. The next table summarizes the conditions where handshakes are emulated from internal states instead of actual handshakes to HS-split bus traffic.

Table 452. Emulated handshakes

Condition	Emulated TT response
Start-Split: All asynchronous buffers are full	NAK
Start-Split: All periodic buffers are full	ERR

Table continues on the next page...

Table 452. Emulated handshakes (continued)

Condition	Emulated TT response
Start-Split: Success for start of asynchronous transaction	ACK
Start-Split: Start periodic transaction	No handshake (Okay)
Complete-Split: Failed to find transaction in queue	Bus time-out
Complete-Split: Transaction in queue is busy	NYET
Complete-Split: Transaction in queue is complete	Actual handshake from FS or LS device

55.11.1.5.3 Asynchronous transaction scheduling and buffer management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- USB 2.0 - 11.17.3
  - Sequencing is provided and a packet length estimator ensures no FS or LS packet babbles into SOF time.
- USB 2.0 - 11.17.4
  - Transaction tracking for two data pipes.
- USB 2.0 - 11.17.5
  - Clear_TT_Buffer capability

55.11.1.5.4 Periodic transaction scheduling and buffer management

The following USB 2.0 specification items are implemented in the embedded transaction translator:

- USB 2.0 - 11.18.6.[1-2]
  - Abort of pending start-splits
    - EOF (and not started in microframes 6)
    - Idle for more than four microframes
  - Abort of pending complete-splits
    - EOF
    - Idle for more than four microframes
- USB 2.0 - 11.18.[7-8]
  - Transaction tracking for up to four data pipes
    - No more than four periodic transactions (interrupt/isochronous) can be scheduled through the embedded TT per frame.
  - Complete-split transaction searching

NOTE

There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

processor NDA only

Beijing CHJ Automotive Technology Co., Ltd.
c8c62e54-821-48a8-b251-390a8a6242c1

55.11.1.5.5 Multiple transaction translators

The maximum number of embedded transaction translators currently supported is one, as indicated by HCSPARAMS[N_TT]. See Host Controller Structural Parameters (HCSPARAMS) for more information.

55.11.2 Non-zero fields in the register file

For the reserved fields and reserved addresses in the capability registers, you need to adhere to these steps:

- Write operations to all EHCI reserved fields in the operation registers must always write a value of 0.
- Read operations by the module must properly mask EHCI reserved fields.

55.11.3 SOF interrupt

The SOF interrupt is a free-running 125 µs or 1 ms interrupt for Host mode. EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. The free running interrupt is shared with the Device mode start-of-frame interrupt. See USB Status (USBSTS) and Interrupt Enable (USBINTR) for more information.

55.11.4 Embedded design

This is an embedded USB host controller as defined by the EHCI specification; therefore, it does not implement the PCI configuration registers.

55.11.4.1 Frame adjust register

Given that the optional PCI configuration registers are not included in this implementation, there are no corresponding bit-level timing adjustments like those provided by the frame adjust register in the PCI configuration registers. Starts of microframes are timed precisely to 125 µs using the transceiver clock as a reference clock or a 60 MHz transceiver clock for 8-bit physical interfaces and FS serial interfaces.

55.11.5 Miscellaneous variations from EHCI

55.11.5.1 Programmable physical interface behavior

The modules support multiple physical interfaces that can operate in different modes when the module is configured with the software-programmable physical interface modes. The control bits for selecting the PHY operating mode are added to PORTSCn, providing a capability not defined by the EHCI specification.

55.11.5.2 Discovery

55.11.5.2.1 Port reset

The port connect methods specified by EHCI require setting PORTSC*n*[PR] to 1 for a duration of 10 ms. Due to the complexity required for supporting the attachment of devices that are not HS, a counter is present in the design that can count the 10 ms reset pulse to alleviate the requirement for you to measure this duration. Therefore, the basic connection is summarized as:

- Port change interrupt - Port connect change occurs to notify the host controller driver that a device has attached.
- You write 1 to PORTSC*n*[PR] to reset the device.
- You write 0 to PORTSC*n*[PR] after 10 ms.
  - This step, necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a 0 to the reset field when a reset is in progress, the write is ignored and the reset continues until completion.
- Port change interrupt - Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed is determined.

55.11.5.2.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack must determine the port speed. Unlike the EHCI implementation, which reassigns the port owner for any device that does not connect at HS, this host controller supports direct-attach of non-HS devices. Therefore, the following differences are important regarding port speed detection:

- Port owner hand-off is not implemented. Therefore, PORTSC*n*[PO] is read-only and always reads 0.
- A 2-bit port speed indicator field has been added to PORTSCn to provide the current operating speed of the port to the host controller driver.
- A 1-bit HS indicator bit has been added to PORTSCn to signify that the port is in HS versus FS or LS.
  - This information is redundant with the 2-bit port speed indicator field above.

55.11.5.3 Port Test mode

Port Test Control mode behaves fully as described in EHCI since the release of revision 3.2.1. In earlier product revisions, the test packet mode was not EHCI compatible. An alternate host controller driver procedure is no longer necessary or supported.

Chapter 56
FlexRay Communication Controller (FlexRay)

56.1 Introduction

This module implements the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

To distinguish between the FlexRay protocol and the FlexRay module on this chip, this chapter also uses the term CC to refer to the module.

56.1.1 References

The FlexRay specifications have been developed for automotive applications. These specifications have not been developed or tested for non-automotive applications.

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*

  See this document for all of the FlexRay-related information including the configuration parameters and the allowed parameter ranges.

- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0*

56.1.2 Overview

CC has three main components:

- CHI
- PE
- CDC

The following figure represents a block diagram of CC and its surrounding modules.

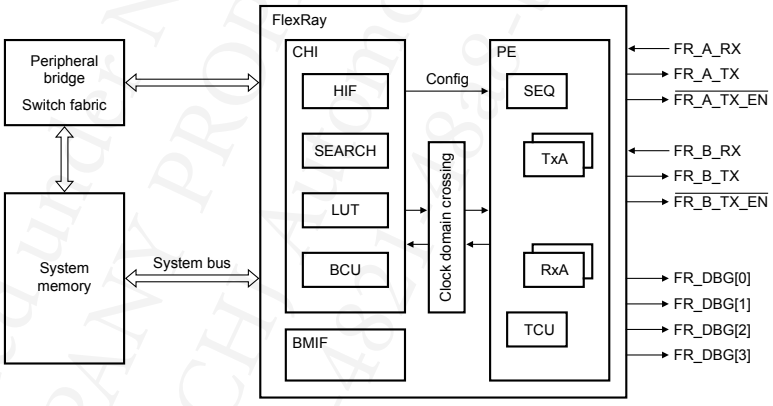

Figure 472. FlexRay block diagram

The protocol engine has two transmitter units, TxA and TxB, and two receiver units, RxA and RxB, for sending and receiving frames through the two FlexRay channels. TCU is responsible for maintaining global clock synchronization to the FlexRay network. SEQ controls the overall PE activity.

CHI provides host access to the module's configuration, control, and status registers, as well as to the MB configuration, control, and status registers.

CDC implements signal crossing between the CHI and PE clock domains, to allow for asynchronous PE and CHI clock domains.

CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames for CC to process. In addition

to the frame header and payload data, CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the MCU system memory. CC has access to the FlexRay memory area via its BMIF. The host provides the start address of the FlexRay memory area within the system memory by programming System Memory Base Address High (SYMBADHR) and System Memory Base Address Low (SYMBADLR). the System Memory Base Address Register (SYMBADHR and SYMBADLR). All offsets related to the FlexRay memory area are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values and the FlexRay memory base address.

CC does not provide a memory protection scheme for the FlexRay memory area.

56.1.3 Features

- Implements a protocol that complies with the protocol specification in References
- Implements a bus driver interface that complies with the physical layer specification in References
- Single-channel support, in which FlexRay port A can connect to physical FlexRay channel A or B
- Dual-channel support
- Supports FlexRay bus data rates of:
  - 10 Mbit/s
  - 8 Mbit/s
  - 5 Mbit/s
  - 2.5 Mbit/s
- Supports 256 configurable MBs with individual:
  - Frame ID filtering
  - Channel ID filtering
  - Cycle counter filtering
- MB header, status, and payload data stored in dedicated FlexRay memory area
  - Allows for flexible and efficient MB implementation
  - Ensures consistent data access via buffer locking scheme
  - Allows an application to lock multiple buffers simultaneously
- Size of MB payload data section configurable from 0 up to 254 bytes
- Two independent MB segments with configurable size of payload data section:
  - Each segment's payload data section has a configurable size
  - Each segment can contain MBs assigned to the static segment and MBs assigned to the dynamic segment simultaneously
- Zero padding for transmit MBs in the static segment, applied when the frame payload length exceeds the size of the MB data section
- Transmit MBs configurable with state/event semantics
- MBs that can be configured as receive and transmit MBs
- Supports individual MB reconfiguration, allowing you to:
  - Disable individual MBs safely
  - Reconfigure disabled MBs
- Two independent receive FIFOs

Provided under NDA
COMPANY PROPRIETARY
Beijing CIIC Automotive Technology Co., Ltd.
c8c20e3-43b1-48a8-b251-390d3ab624c1

  - One receive FIFO per channel
  - Up to 255 entries for each FIFO
  - Global frame ID filtering, based on both value/mask filters and range filters
  - Global channel ID filtering
  - Global message ID filtering for the dynamic segment
- Four configurable slot error counters
- Four dedicated slot status indicators, used to observe slots without using receive MBs
- Measured value indicators for the clock synchronization; the internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Supports fractional MTs for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- One absolute timer
- One timer that can be configured as absolute or relative
- Error correction and error detection (SECDED ECC) for PE data RAM
- Error detection (SECDED ECC) for CHI LRAM

56.1.4 Modes of operation

This section describes the basic CC operational power modes.

56.1.4.1 Disabled mode

CC enters Disabled mode during hard reset or when the host writes 0 to MCR[MEN]. The host can write 0 to this field only when the module is in the POC:default config mode. You can check whether CC is in Disabled mode by reading MCR[MEN].

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled Mode* can be accessed for writing as stated in Register descriptions.

You configure CC by accessing the configuration fields in Module Configuration (MCR) as described in Module Initialization.

56.1.4.1.1 Leave Disabled mode

CC leaves Disabled mode and enters Normal mode when you write 1 to MCR[MEN].

After you enable CC, you can disable it only during POC:default config.

56.1.4.2 Normal mode

In this mode, CC is fully functional. CC indicates that it is in Normal mode by writing 1 to MCR[MEN].

56.1.4.2.1 Enter Normal mode

CC enters this mode when you request CC to leave Disabled mode. If CC enters Normal mode by leaving Disabled mode, you must perform the protocol initialization described in Protocol Initialization to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB fields in Module Configuration (MCR), the corresponding FlexRay bus driver ports are enabled and driven.

56.2 External signal description

This section lists and describes the CC signals connected to external pins. These signals are summarized in the following table.

For the exact signal names on this chip, see the IOMUX file attached to this document. The off-chip signals FR_A_RX, FR_A_TX, and FR_A_TX_EN_b are available in each package option. The availability of the other off-chip signals depends on the package option and is specific to the chip.

Table 453. External signal properties

Name	Direction	Active	Reset	Function	Details
FR_A_RX	Input	—	—	Receive data channel A	Carries the receive data for channel A from the corresponding FlexRay bus driver
FR_A_TX	Output	—	1	Transmit data channel A	Carries the transmit data for channel A to the corresponding FlexRay bus driver
FR_A_TX_EN_b	Output	Low	1	Transmit enable channel A	Indicates to the FlexRay bus driver that CC is attempting to transmit data on channel A
FR_B_RX	Input	—	—	Receive data channel B	Carries the receive data for channel B from the corresponding FlexRay bus driver
FR_B_TX	Output	—	1	Transmit data channel B	Carries the transmit data for channel B to the corresponding FlexRay bus driver
FR_B_TX_EN_b	Output	Low	1	Transmit enable channel B	Indicates to the FlexRay bus driver that CC is attempting to transmit data on channel B
FR_DBG[0]	Output	—	0	Debug strobe 0	Provide the selected debug strobe signals For details of the debug strobe signal selection, see Strobe Signal Support.
FR_DBG[1]	Output	—	0	Debug strobe 1	
FR_DBG[2]	Output	—	0	Debug strobe 2	
FR_DBG[3]	Output	—	0	Debug strobe 3	

56.3 PE clocking

PE is clocked by an internal crystal oscillator, a crystal or CMOS compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version*2.1 Rev A.

56.4 Register descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

Table 454. Register access conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the field is not readable or not writeable.
R*	Reserved field; will not be changed. You must not write any value different from the reset value.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.

Table 455. Register field types

Convention	Description
rwm	A read/write field that hardware can modify in some fashion other than by a reset.
w1c	Write one to clear. A flag field that you can read and return to 0 by writing 1. Writing 0 has no effect.
Reset value	
0	Resets to zero.
1	Resets to one.
-	Not defined after reset and not affected by reset.

56.4.1 Register reset

After a system reset, all registers except the following reset to their reset value:

- MB Cycle Counter Filter (MBCCFR0 - MBCCFR255)
- MB Frame ID (MBFIDR0 - MBFIDR255)
- MB Index (MBIDXR0 - MBIDXR255)

The aforementioned registers are located in physical memory blocks and are therefore unaffected by reset.

For some register fields, additional reset conditions exist. The following table explains them.

Table 456. Additional register reset conditions

Condition	Description
Protocol RUN command	The field resets when you write 0101b (corresponding to the RUN command) to POCR[POCCMD].
MB disable	The field resets when you have disabled the MB. This happens when you write 1 to MBCCSR*n*[EDT] while the MB is enabled (MBCCSR*n*[EDS] = 1) and CC grants you the disabling by writing 0 to MBCCSR*n*[EDS].

56.4.2 Register write access

This section describes the write access restriction terms that apply to all registers.

56.4.2.1 Register write access restriction

The detailed register descriptions specify the write access conditions for each field. The table below describes the write access conditions. If none of the given write access conditions are fulfilled for a specific field, any write attempt to this field is ignored without any notification. The values of the fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 457. Register write access restrictions

Condition	Indication	Description
Any time	—	No write access restriction
Disabled mode	MCR[MEN] = 0	Write access only when CC is in Disabled mode
Normal mode	MCR[MEN] = 1	Write access only when CC is in Normal Mode
POC:config	PSR0[PROTSTATE] = 1b (representing POC:config)	Write access only when the protocol is in the POC:config state
MB_DIS	MBCCSR*n*[EDS] = 0	Write access only when related MB is disabled
MB_LCK	MBCCSR*n*[LCKS] = 1	Write access only when related MB is locked
IDL	EERICR[BSY] = 0	Write access only when ECC configuration is idle

56.4.2.2 Register write access requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in FlexRay register descriptions. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

56.4.2.3 Internal register access

The following memory mapped registers are used to access multiple internal registers.

- Strobe Signal Control (STBSCR)
- Slot Status Selection (SSSR)
- Slot Status Counter Condition (SSCCR)
- Receive Shadow Buffer Configuration Data

Each of these memory mapped registers provides a SEL and a WMD field. The SEL field is used to select the internal register. The WMD field controls the write mode. If you write 0 to WMD during the write access, all fields of the internal register are updated. If you write 1 to WMD, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

56.4.3 PCR*n* fields

Table 458. PCR*n* fields

Name	Description	Min	Max	Unit	PCR #
coldstart_attempts	gColdstartAttempts			number	3
action_point_offset	gdActionPointOffset - 1			MT	0
cas_rx_low_max	gdCASRxLowMax - 1			gdBit	4

Table 458. PCR*n* fields (continued)

Name	Description	Min	Max	Unit	PCR #
wakeup_pattern	pWakeupPattern			number	18
decoding_correction_a	pDecodingCorrection + pDelayCompensation[A] + 2			µT	19
decoding_correction_b	pDecodingCorrection + pDelayCompensation[B] + 2			µT	7
key_slot_header_crc	Header CRC for key slot	0h	7FFh	number	12
extern_offset_correction	pExternOffsetCorrection			µT	29
extern_rate_correction	pExternRateCorrection			µT	21

Table 459. Wakeup channel selection

wakeup_channel	Wakeup channel
0	A
1	B

56.5 FlexRay register descriptions

CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the chip memory map.

Do not access these address offsets:

- Ah

because corresponding features are unavailable.

You can write to the following registers only with 16-bit writes:

- Strobe Signal Control (STBSCR)
- PE DRAM Access (PEDRAR)
- PE DRAM Data (PEDRDR)
- Sync Frame ID Rejection Filter (SFIDRFR)
- Slot Status Selection (SSSR)
- Slot Status Counter Condition (SSCCR)
- Receive Shadow Buffer Index (RSBIR)
- Receive FIFO Range Filter Configuration (RFRFCFR)
- MB Cycle Counter Filter (MBCCFR0 - MBCCFR255)
- MB Frame ID (MBFIDR0 - MBFIDR255)
- MB Index (MBIDXR0 - MBIDXR255)
- MB Data Field Offset (MBDOR0 - MBDOR259)
- LRAM ECC Error Test Register (LEETR0 - LEETR5)

56.5.1 FlexRay memory map

FR_0 base address: 402F_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Version (MVR)	16	RO	A568h
2h	Module Configuration (MCR)	16	RW	0000h
4h	System Memory Base Address High (SYMBADHR)	16	RW	0000h
6h	System Memory Base Address Low (SYMBADLR)	16	RW	0000h
8h	Strobe Signal Control (STBSCR)	16	RW	0000h

Fields

Field	Function
15 MEN	Module Enable Indicates whether or not CC is in Disabled mode. You request CC to leave Disabled mode by writing 1 to this field. Before leaving Disabled Mode, you must configure the SCM, SBFF, CHB, CHA, TMODE, and BITRATE fields in this register. For details, see Modes of operation. If CC is enabled, it can only be disabled during mode: POC:default config. 0b - Write: only during POC:default config, CC disable Read: CC disabled 1b - Write: enable CC Read: CC enabled
14 SBFF	System Bus Failure Freeze Controls the CC behavior in case of a system bus failure. 0b - Continue normal operation 1b - Transition to freeze mode
13 SCM	Single Channel Device Mode Defines the CC channel device mode as described in Channel Device Modes. 0b - Dual channel 1b - Single channel
12 CHB	Channel B Enable Protocol related parameter: pChannels. The semantic of these control bits depends on the channel device mode controlled by the SCM bit and is given in the following table.

Table 460. FlexRay channel selection

SCM	CHB	CHA	Description
Dual Channel Device Modes

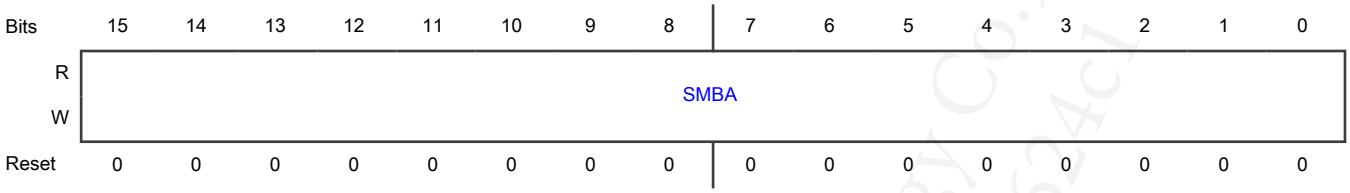
56.5.4 System Memory Base Address High (SYMBADHR)

Offset

Register	Offset
SYMBADHR	4h

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
c8c4625-4821-48a8-b251-390d3b624c1



Function

Contains the most significant bits of the base address.

This register and System Memory Base Address Low (SYMBADLR) define the base address of the FlexRay memory area within the system memory. BMIF uses the base address to calculate the physical memory address for system memory accesses.

You must set the system memory base address before enabling the CC.

Diagram

Fields

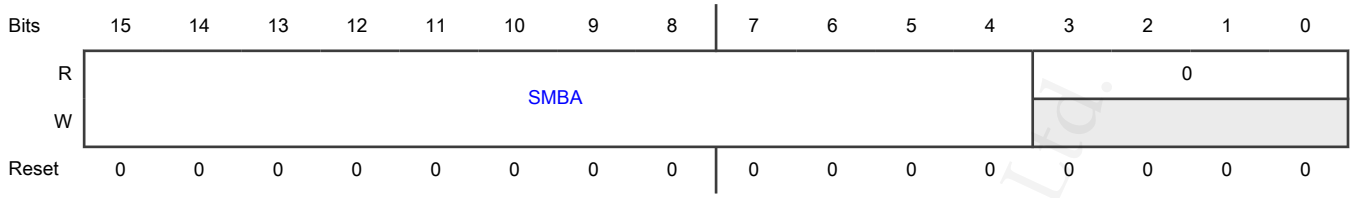
Field	Function
15-0 SMBA	System Memory Base Address High Contains the value of the system memory base address for the individual MBs and sync frame table. This is the value of the system memory base address for the receive FIFO if MCR[FAM] = 1. It is defined as a byte address.

56.5.5 System Memory Base Address Low (SYMBADLR)

Offset

Register	Offset
SYMBADLR	6h

Function



Contains the least significant bits of the base address.

This register and System Memory Base Address High (SYMBADHR) define the base address of the FlexRay memory area within the system memory. BMIF uses the base address to calculate the physical memory address for system memory accesses.

You must set the system memory base address before enabling the CC.

3-0 —	Reserved

56.5.6 Strobe Signal Control (STBSCR)

Offset

Register	Offset
STBSCR	8h

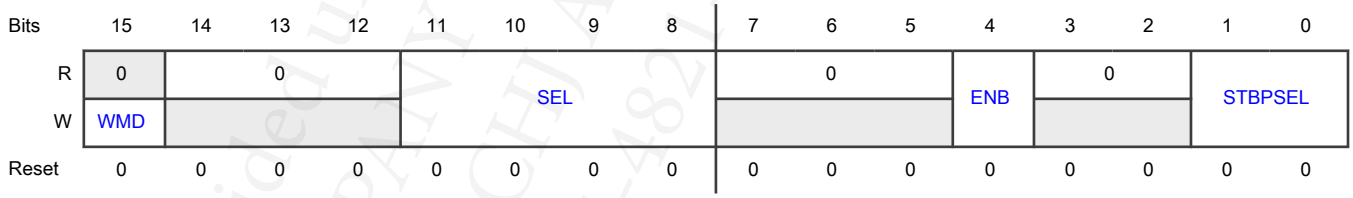
Function

Assigns the individual protocol timing related strobe signals given in Table 461 to the external strobe ports.

Each strobe signal can be assigned to at most one strobe port. Each write access to registers overwrites the previously written ENB and STBPSEL values for the signal indicated by SEL. If more than one strobe signal is assigned to a strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port. If no strobe signal is assigned to a strobe port, the strobe port carries logic 0. For more information, see Strobe Signal Support.

In single channel device mode, channel B related strobe signals are undefined and must not be assigned to the strobe ports.

Table 461. Strobe signal mapping



SEL		Description	Channel	Type	Offset (in PE clock cycles)	Reference
Dec	Hex					
0	0	Arm	-	Value	+1	MT start
1	1	MT	-	Value	+1	MT start
2	2	Cycle start	-	Pulse	0	MT start

Table continues on the next page...

Field	Function
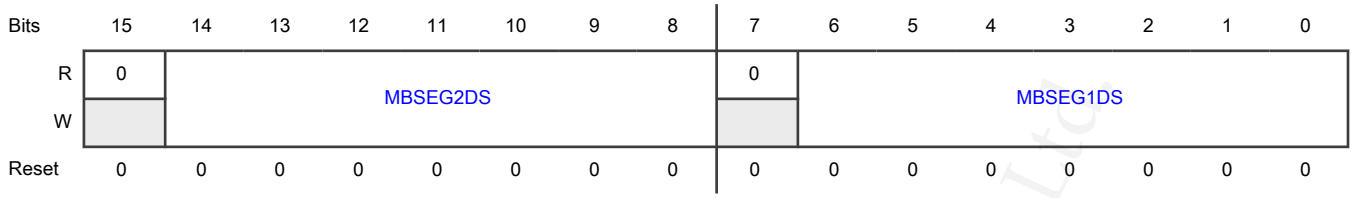
	0b - Write to all fields in this register on a write access 1b - Write only to the SEL field on write access
14-12 —	Reserved
11-8 SEL	Strobe Signal Select Selects one of the strobe signals given in Table 461 to be enabled or disabled and assigned to one of the four strobe ports given in that table. Write: Disabled Mode
7-5 —	Reserved
4 ENB	Strobe Signal Enable Enables and disables the strobe signal selected by STBSSEL. 0b - Disabled and not assigned to any strobe port 1b - Enabled and assigned to the strobe port selected by STBPSEL
3-2 —	Reserved
1-0 STBPSEL	Strobe Port Select Selects the strobe port that the strobe signal selected by SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00b - FR_DBG[0] 01b - FR_DBG[1] 10b - FR_DBG[2] 11b - FR_DBG[3]

56.5.7 MB Data Size (MBDSR)

Offset



Register	Offset
MBDSR	Ch

Function

Defines the size of the MB data section for the two MB segments in a number of two-byte entities.

CC provides two independent segments for the individual MBs. All individual MBs within a segment must have the same size for the MB data section. This size can be different for the two MB segments.

Diagram

Fields

Field	Function
15 —	Reserved
14-8 MBSEG2DS	MB Segment 2 Data Size Defines the size of the MB data section in two-byte entities for MBs within the second MB segment.
7 —	Reserved
6-0 MBSEG1DS	MB Segment 1 Data Size Defines the size of the MB data section in two-byte entities for MBs within the first MB segment.

56.5.8 MB Segment Size and Utilization (MBSSUTR)

Offset

Register	Offset
MBSSUTR	Eh

Function

Defines:

- The last individual MB that belongs to the first MB segment
- The number of the last used individual MB

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d2ab624c1

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LAST_MB_SEG1								LAST_MB_UTIL							
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
15-8 LAST_MB_SEG1	Last MB In Segment 1 Defines the MB number of the last individual MB that is assigned to the first MB segment. The individual MBs in the first segment correspond to the following MB control registers with n ≤ LAST_MB_SEG1: • MB Configuration Control Status (MBCCSR0 - MBCCSR255) • MB Cycle Counter Filter (MBCCFR0 - MBCCFR255) • MB Frame ID (MBFIDR0 - MBFIDR255) • MB Index (MBIDXR0 - MBIDXR255) The first MB segment contains: • At least one individual MB • LAST_MB_SEG1+1 individual MBs The individual MBs in the second MB segment correspond to the following MB control registers with LAST_MB_SEG1 < n < 256: • MB Configuration Control Status (MBCCSR0 - MBCCSR255) • MB Cycle Counter Filter (MBCCFR0 - MBCCFR255) • MB Frame ID (MBFIDR0 - MBFIDR255) • MB Index (MBIDXR0 - MBIDXR255) If LAST_MB_SEG1 = 255, all individual MBs belong to the first MB segment and the second MB segment is empty.
7-0 LAST_MB_UTIL	Last MB Utilized Defines the MB number of the last utilized individual MB. The MB search engine examines all individual MBs with an MB number n ≤ LAST_MB_UTIL. If LAST_MB_UTIL = LAST_MB_SEG1, all individual MBs belong to the first MB segment and the second MB segment is empty.

Preliminary Information COMPANY CONFIDENTIAL Beijing CJJ Automotive Technology Co., Ltd. c8c462e5-821f-48a3-b251-390d3a1624d1

56.5.9 PE DRAM Access (PEDRAR)

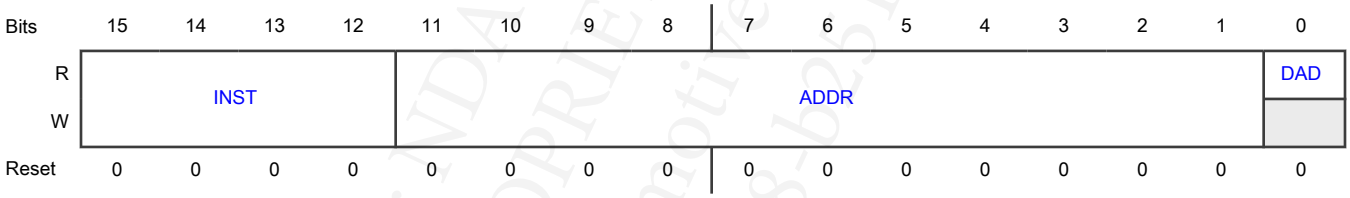
Offset

Register	Offset
PEDRAR	10h

Function

Triggers write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this register initiates a read or write operation on PE DRAM. CC writes 0 to PEDRAR[DAD] after the write access, and writes 1 to that field if the PE DRAM access is finished.



In case of a PE DRAM write access, the data provided in PEDRDR is:

- Written in PE DRAM
- Read back from PE DRAM
- Stored in PEDRDR

In case of an PE DRAM read access, the requested data is read from PE DRAM and stored in PEDRDR.

For a detailed description, see Memory Content Fault Detection.

Diagram

Fields

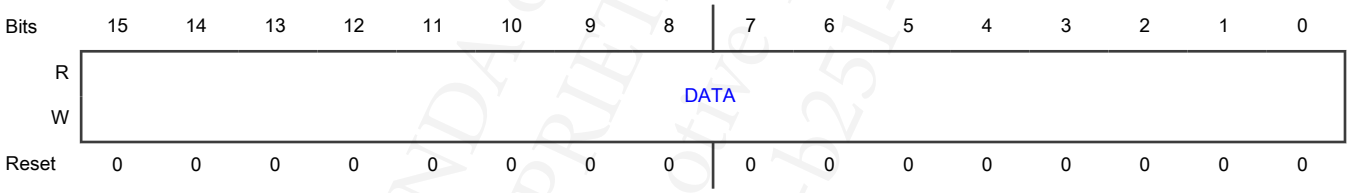
Field	Function
15-12 INST	PE DRAM Access Instruction Defines the operation to be executed on PE DRAM. other reserved 0011b - Write PEDRDR[DATA] to PE DRAM address ADDR (16 bit) 0101b - Read data from PE DRAM address ADDR (16 bit) into PEDRDR[DATA] All other values are reserved.
11-1 ADDR	PE DRAM Access Address Defines the address in PE DRAM to be written to or read from.
0 DAD	PE DRAM Access Done

Table continues on the next page...

Table continued from the previous page...

Field	Function
	CC writes 0 to this field when you have written to PERDR. CC writes 1 to this field when the PE DRAM access has finished. 0b - Access running 1b - Access done

56.5.10 PE DRAM Data (PEDRDR)



Offset

Register	Offset
PEDRDR	12h

Function

Provides the PE DRAM data that you want to write or read when you initiate a write access to PE DRAM Access (PEDRAR).

Diagram

Fields

Field	Function
15-0 DATA	Data To Or From PE DRAM Contains the PE DRAM that you want to write or read when you initiate a write access to PE DRAM Access (PEDRAR).

56.5.11 Protocol Operation Control Register (POCR)

Offset

Register	Offset
POCR	14h

Function

Issues commands for protocol control and external clock correction.

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see Protocol Control Command Execution.

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, see External Clock Synchronization.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0			EOC_AP		ERC_AP		BSY_WMC	0			POCCMD			
W	WME															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 WME	Write Mode External Correction Controls the write mode of the EOC_AP and ERC_AP fields. 0b - Write to EOC_AP and ERC_AP fields on register write. 1b - No write to EOC_AP and ERC_AP fields on register write.
14-12 —	Reserved
11-10 EOC_AP	External Offset Correction Application Triggers the application of the external offset correction value defined in Protocol Configuration 29 (PCR29). 00b - Do not apply external offset correction value 01b - Reserved 10b - Subtract external offset correction value 11b - Add external offset correction value
9-8 ERC_AP	External Rate Correction Application Triggers the application of the external rate correction value defined in Protocol Configuration 21 (PCR21). 00b - Do not apply external rate correction value 01b - Reserved 10b - Subtract external rate correction value 11b - Add external rate correction value
7 BSY_WMC	Protocol Control Command Busy Or Command Write Serves two functions depending on whether you are reading or writing this field. When you read this field, it indicates the acceptance of the protocol control command that you issued via the POCCMD field. CC writes 1 to BSY_WMC when you issue the command, and writes 0 to BSY_WMC when PE accepts the command. When you issue a protocol control command while BSY_WMC = 1, CC:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Ignores this command • Writes 1 to CHIERFR[PCMI_EF] ets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (CHIERFR) • Does not change the value of the POCCMD field When you write this field, it indicates the acceptance of the protocol control command that you issued via the POCCMD field. CC writes 1 to BSY_WMC when you issue the command, and writes 0 to BSY_WMC when PE accepts the command. When you issue a protocol control command while BSY_WMC = 1, CC: • Ignores this command • Writes 1 to CHIERFR[PCMI_EF] ets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (CHIERFR) • Does not change the value of the POCCMD field 0b - Read operation: Command write idle; command accepted and ready to receive new protocol command. Write operation: Write to POCCMD field on register write. 1b - Read operation: Command write busy; command not yet accepted; not ready to receive new protocol command. Write operation: Do not write to POCCMD field on register write.
6-4 —	Reserved
3-0 POCCMD	Protocol Control Command Write to this field to issue a protocol control command to the PE. CC sends the protocol command to the PE immediately. While the transfer is running, BSY_WMC is 1. 0000b - ALLOW_COLDSTART. Immediately activate capability of node to cold start cluster. 0001b - ALL_SLOTS. Delayed transition to the all slots transmission mode. (Delayed means on completion of current communication cycle.) 0010b - CONFIG. Immediately transition to the POC:config state. 0011b - FREEZE. Immediately transition to the POC:halt state. 0100b - READY, CONFIG_COMPLETE. Immediately transition to the POC:ready state. 0101b - RUN. Immediately transition to the POC:startup start state. 0110b - DEFAULT_CONFIG. Immediately transition to the POC:default config state. 0111b - HALT. Delayed transition to the POC:halt state 1000b - WAKEUP. Immediately initiate the wakeup procedure. All other values are reserved.

56.5.12 Global Interrupt Flag And Enable (GIFER)

Offset

Register	Offset
GIFER	16h

Function

Provides the means to control some of the interrupt request lines and provides the corresponding interrupt flags.

The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables. The generation scheme for these flags is depicted in Module Interrupt. For more details on interrupt generation, see Interrupt Support. These flags become 0 automatically when you write 0 to all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 MIF	Module Interrupt Flag CC writes 1 to this field if at least one of the other interrupt flags in this register and the related interrupt enable field are 1. 0b - No interrupt flag and related interrupt enable bit are set. 1b - At least one of the other interrupt flags in this register and the related interrupt field are 1.
14 PRIF	Protocol Interrupt Flag CC writes 1 to this field if at least one of the individual flags in Protocol Interrupt Flag 0 (PIFR0) and Protocol Interrupt Flag 1 (PIFR1), and the related interrupt enable field, are 1. 0b - No individual protocol interrupt flag and related interrupt enable field are 1. 1b - At least one of the individual protocol interrupt flags and the related interrupt enable field are 1.
13 CHIF	CHI Interrupt Flag CC writes 1 to this field if at least one of the error flags in CHI Error Flag (CHIERFR) and GIFER[CHIE] are 1. 0b - All CHI error flags are 0 or the CHI error interrupt is disabled. 1b - At least one CHI error flag and the CHI error interrupt enable are 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 WUPIF	Wakeup Interrupt Flag Indicates whether CC has received a wakeup symbol on the FlexRay bus. You can determine which channel received the wakeup symbol by reading the related WUB and WUA fields in Protocol Status 3 (PSR3). 0b - Not received 1b - Received
11 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag CC causes this field to become 1 when one of the following events occurs: • The current number of FIFO B entries is equal to or greater than the watermark defined by RFWMSR[WM] and CC writes a received message into FIFO A. • The current number of FIFO B entries is at least 1 and the periodic timer, as defined by Receive FIFO Periodic Timer (RFPTR), expires. 0b - No such event 1b - FIFO B almost-full event has occurred
10 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag CC causes this field to become 1 when one of the following events occurs: • The current number of FIFO A entries is equal to or greater than the watermark defined by RFWMSR[WM] and CC writes a received message into FIFO A. • The current number of FIFO B entries is at least 1 and the periodic timer, as defined by Receive FIFO Periodic Timer (RFPTR), expires. 0b - No such event 1b - FIFO A almost-full event has occurred
9 RBIF	Receive MB Interrupt Flag CC writes 1 to this field if for at least one of the individual MBs has the following field values in MB Configuration Control Status (MBCCSR0 - MBCCSR255): • MTD = 0 • MBIF = 1 • MBIE = 1 You cannot write 0 to this field directly. Instead, CC writes 0 to this field after either of the following occurs: • You write 0 to all of the individual MBIF fields of the individual transmit MBs. • You write 0 to the related MBIE field. 0b - None of the individual transmit MBs has MBIF = MBIE = 1. 1b - At least one individual transmit MB has MBIF = MBIE = 1.
8	Transmit MB Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TBIF	CC writes 1 to this field if for at least one of the individual MBs all of the following fields in MB Configuration Control Status (MBCCSR0 - MBCCSR255) are 1: • MTD • MBIF • MBIE You cannot write 0 to this field directly. Instead, CC writes 0 to this field after either of the following occurs: • You write 0 to all of the individual MBIF fields of the individual transmit MBs. • You write 0 to the related MBIE field. 0b - None of the individual transmit MBs has MBIF = MBIE = 1. 1b - At least one individual transmit MB has MBIF = MBIE = 1. In Functional Test Mode, writing 1 toggles the interrupt flags.
7 MIE	Module Interrupt Enable Enables or disables the Module Interrupt line when MIF = 1. 0b - Disable 1b - Enable
6 PRIE	Protocol Interrupt Enable Enables or disables the Protocol Interrupt line when PRIF = 1. 0b - Disable 1b - Enable
5 CHIE	CHI Interrupt Enable Enables or disables the CHI Interrupt line when CHIF = 1. 0b - Disable 1b - Enable
4 WUPIE	Wakeup Interrupt Enable Enables or disables the Wakeup Interrupt line when WUPIF = 1. 0b - Disable 1b - Enable
3 FAFBIE	Receive FIFO Channel B Almost Full Interrupt Enable Enables or disables the RX FIFO B Almost Full Interrupt line when FAFBIF = 1. 0b - Disable 1b - Enable
2	Receive FIFO Channel A Almost Full Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
FAFAIE	Enables or disables the RX FIFO A Almost Full Interrupt line when FAFAIF = 1. 0b - Disable 1b - Enable
1 RBIE	Receive MB Interrupt Enable Enables or disables the Receive MB Interrupt line when RBIF = 1. 0b - Disable 1b - Enable
0 TBIE	Transmit MB Interrupt Enable Enables or disables the Transmit MB Interrupt line when TBIF = 1. 0b - Disable 1b - Enable

56.5.13 Protocol Interrupt Flag 0 (PIFR0)

Offset

Register	Offset
PIFR0	18h

Function

Holds one set of the protocol-related individual interrupt flags.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FATL_IF	INTL_IF	ILCF_IF	CSA_IF	MRC_IF	MOC_IF	CCL_IF	MXS_IF	MTX_IF	LTXB_IF	LTXA_IF	TBVB_IF	TBVA_IF	TI2_IF	TI1_IF	CYS_IF

Fields

Field	Function
15 FATL_IF	Fatal Protocol Error Interrupt Flag Becomes 1 when PE has detected a fatal protocol error. In this case, PE enters the POC:halt state immediately. The fatal protocol errors are:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• pLatestTx violation, as described in the MAC process of the FlexRay protocol • Transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0b - No such event 1b - Fatal protocol error detected
14 INTL_IF	Internal Protocol Error Interrupt Flag Becomes 1 when PE engine has detected an internal protocol error. In this case, PE enters the POC:halt state immediately. An internal protocol error occurs when PE has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0b - No such event 1b - Internal protocol error detected
13 ILCF_IF	Illegal Protocol Configuration Interrupt Flag Becomes 1 when PE has detected an illegal protocol configuration parameter setting. In this case, PE enters the POC:halt state immediately. PE checks the listen_timeout field in Protocol Configuration 14 (PCR14) and Protocol Configuration 15 (PCR15) when the application sent the CONFIG_COMPLETE command via Protocol Operation Control Register (POCR). If listen_timeout = 0, the protocol configuration setting is considered illegal. 0b - No such event 1b - Illegal protocol configuration detected
12 CSA_IF	Cold Start Abort Interrupt Flag Becomes 1 when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by PCR3[coldstart_attempts]. 0b - No such event 1b - Cold start aborted and no more coldstart attempts allowed
11 MRC_IF	Missing Rate Correction Interrupt Flag Becomes 1 when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0b - No such event 1b - Insufficient number of measurements for rate correction detected
10 MOC_IF	Missing Offset Correction Interrupt Flag Becomes 1 when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0b - No such event 1b - Insufficient number of measurements for offset correction detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 CCL_IF	Clock Correction Limit Reached Interrupt Flag Becomes 1 when the internal calculated offset or rate calculation values have reached or exceeded configured thresholds as specified by PCR9[offset_correction_out] and PCR14[rate_correction_out]. 0b - No such event 1b - Offset or rate correction limit reached
8 MXS_IF	Max Sync Frames Detected Interrupt Flag Becomes 1 when the number of synchronization frames detected in the current communication cycle exceeds the value of PCR30[sync_node_max]. **NOTE** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account. 0b - No such event 1b - More than node_sync_max sync frames detected
7 MTX_IF	Media Access Test Symbol Received Interrupt Flag Becomes 1 when MTS was received on channel A or channel B. 0b - No such event 1b - MTS symbol received
6 LTXB_IF	pLatestTx Violation on Channel B Interrupt Flag Becomes 1 when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation, as described in the MAC process of the FlexRay protocol. 0b - No such event 1b - pLatestTx violation occurred on channel B
5 LTXA_IF	pLatestTx Violation on Channel A Interrupt Flag Becomes 1 when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation as described in the MAC process of the FlexRay protocol. 0b - No such event 1b - pLatestTx violation occurred on channel A
4 TBVB_IF	Transmission Across Boundary On Channel B Interrupt Flag Becomes 1 when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0b - No such event 1b - Transmission across boundary violation occurred on channel B

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 TBVA_IF	Transmission Across Boundary On Channel A Interrupt Flag Becomes 1 when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0b - No such event 1b - Transmission across boundary violation occurred on channel A
2 TI2_IF	Timer 2 Expired Interrupt Flag Becomes 1 whenever timer 2 expires. 0b - No such event 1b - Timer 2 has reached its time limit
1 TI1_IF	Timer 1 Expired Interrupt Flag Becomes 1 whenever timer 1 expires. 0b - No such event 1b - Timer 1 has reached its time limit
0 CYS_IF	Cycle Start Interrupt Flag Becomes 1 when a communication cycle starts. 0b - No such event 1b - Communication cycle started

56.5.14 Protocol Interrupt Flag 1 (PIFR1)

Offset

Register	Offset
PIFR1	1Ah

Function

Holds one set of the protocol-related individual interrupt flags.

Provided under NDA only

Fields

Field	Function
15 EMC_IF	Error Mode Changed Interrupt Flag Becomes 1 when CC changes the value of PSR0[ERRMODE]. 0b - No such event 1b - ERRMODE field changed
14 IPC_IF	Illegal Protocol Control Command Interrupt Flag Becomes 1 when PE tries to execute a protocol control command that POCR[POCCMD] issued and that PE detected that this protocol control command is not allowed in the current protocol state. In this case the command is not executed. For more details, see Protocol Control Command Execution. 0b - No such event 1b - Illegal protocol control command detected
13 PECF_IF	PE Communication Failure Interrupt Flag Becomes 1 if CC detects a communication failure between PE and CHI. 0b - No such event 1b - Failure detected
12 PSC_IF	Protocol State Changed Interrupt Flag Becomes 1 when the protocol state in PSR0[PROTSTATE] has changed. 0b - No such event 1b - Protocol state changed
11-8 SSIn_IF	Slot Status Counter Incremented Interrupt Flag n Becomes 1 when the SLOTSTATUSCNT field in the corresponding Slot Status Counter (SSCR0 - SSCR3) increments. 0b - No such event 1b - The corresponding slot status counter has incremented
7-6 —	Reserved
5	Even Cycle Table Written Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
EVT_IF	Becomes 1 if CC wrote the sync frame measurement or ID tables into the FlexRay memory area for the even cycle. 0b - No such event 1b - Sync frame measurement table written
4 ODT_IF	Odd Cycle Table Written Interrupt Flag Becomes 1 if CC wrote the sync frame measurement or ID tables into the FlexRay memory area for the odd cycle. 0b - No such event 1b - Sync frame measurement table written
3-0 —	Reserved

56.5.15 Protocol Interrupt Enable 0 (PIER0)

Offset

Register	Offset
PIER0	1Ch

Function

Defines whether the individual interrupt flags defined in Protocol Interrupt Flag 0 (PIFR0) can generate a protocol interrupt request.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 FRLB_EF	Frame Lost Channel B Error Flag Becomes 1 if a complete frame is received on channel B but could not be stored in the selected individual MB because the application has currently locked this MB. In this case, the frame and the related slot status information are lost. 0b - No such event 1b - Frame lost on channel B detected
14 FRLA_EF	Frame Lost Channel A Error Flag Becomes 1 if a complete frame is received on channel A but could not be stored in the selected individual MB because the application has currently locked this MB. In this case, the frame and the related slot status information are lost. 0b - No such error 1b - Frame lost on channel A detected
13 PCMI_EF	Protocol Command Ignored Error Flag Becomes 1 if the application has issued a POC command by writing to POCR[POCCMD] while the BSY flag is equal to 1. In this case CC ignores and discards the command. 0b - No such error 1b - POC command is ignored
12 FOVB_EF	Receive FIFO Overrun Channel B Error Flag Becomes 1 when an overrun of the FIFO for channel B occurrs. The error occurs if a semantically valid frame is received on channel B and matches the all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0b - No such error 1b - FIFO overrun on channel B is detected
11 FOVA_EF	Receive FIFO Overrun Channel A Error Flag Becomes 1 when an overrun of the FIFO for channel A occurs. The error occurs if a semantically valid frame is received on channel A and matches all the criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0b - No such error 1b - FIFO overrun on channel B is detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 MBS_EF	MB Search Error Flag Becomes 1 if at least one of the following events occurs: • The MB search engine is still running while the next search must be started because of the FlexRay protocol timing • A MB index greater than 259 is detected in the MBIDX field of MB Index (MBIDXR0 - MBIDXR255) of a found MB or in RSBIR[RSBIDX]. See MB search error for details. 0b - No such event 1b - Search engine is active while search start appears or illegal MB index is detected
9 MBU_EF	MB Usage Error Flag Becomes 1 if the application writes to a MB control field that is beyond the number of used MBs programmed in MB Segment Size and Utilization (MBSSUTR). If the application writes to MB Configuration Control Status (MBCCSR0 - MBCCSR255) with n > LAST_MB_UTIL, CC ignores the write attempt and causes MBU_EF to become 1. 0b - No such event 1b - Unused MB enabled
8 LCK_EF	Lock Error Flag Becomes 1 if the application tries to lock a MB that CC already locked because of internal operations. In that case, CC does not grant the lock to the application. The application must issue the lock request again. 0b - No such error 1b - Lock error detected
7 —	Reserved
6 SBCF_EF	System Bus Communication Failure Error Flag Becomes 1 if a system bus access is not finished within the required amount of time (see System Bus Access Timeout). 0b - No such event 1b - System bus access not finished in time
5 FID_EF	Frame ID Error Flag Becomes 1 if the frame ID stored in the MB header area differs from the frame ID stored in the MB control register. 0b - No such error occurred 1b - Frame ID error occurred
4	Dynamic Payload Length Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
DPL_EF	Becomes 1 if the payload length written into the MB header field of a transmit MB assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in PCR24[max_payload_length_dynamic]. 0b - No such error occurred 1b - Dynamic payload length error occurred
3 SPL_EF	Static Payload Length Error Flag Becomes 1 if the payload length written into the MB header field of a transmit MB assigned to the static segment is different from the payload length for the static segment as it is configured in PCR19[payload_length_static]. 0b - No such error occurred 1b - Static payload length error occurred
2 NML_EF	Network Management Length Error Flag Becomes 1 if the payload length written into the header structure of a receive MB assigned to the static segment is less than the configured NMV length as configured in Network Management Vector Length Register (NMVLR). In this case, the received NMV part is used to update NMV. 0b - No such error occurred 1b - Network management length error occurred
1 NMF_EF	Network Management Frame Error Flag Becomes 1 if a received message in the static segment with a Preamble Indicator flag PP asserted has its Null Frame indicator flag NF asserted as well. In this case, NMV n (NMVR0 - NMVR5) are not updated. 0b - No such error occurred 1b - Network management frame error occurred
0 ILSA_EF	Illegal System Bus Address Error Flag Becomes 1 if the external system bus subsystem has detected an access to an illegal system bus address from CC (see System Bus Illegal Address Access). 0b - No such event 1b - Illegal system bus address accessed

56.5.18 MB Interrupt Vector (MBIVEC)

Offset

Register	Offset
MBIVEC	22h

Function

Indicates the lowest numbered receive MB and the lowest numbered transmit MB that have their MBIF = MBIE = 1. This means that MBs with lower MB numbers have higher priority.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TBIVEC								RBIVEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-8 TBIVEC	Transmit Buffer Interrupt Vector Provides the MB number of the lowest numbered enabled transmit MB that has its MBIF = MBIE = 1. If no receive MB exists with MBIF = MBIE = 1, the value of this field is 0.
7-0 RBIVEC	Receive Buffer Interrupt Vector Provides the MB number of the lowest numbered receive MB that has its MBIF = MBIE = 1. If no receive MB exists with MBIF = MBIE = 1, the value of this field is 0.

56.5.19 Channel A Status Error Counter Register (CASERCR)

Offset

Register	Offset
CASERCR	24h

Function

Provides the channel status error counter for channel A.

PE generates a slot status vector for:

- Each static slot
- Each dynamic slot
- The symbol window
- NIT

The slot status vector contains the four protocol-related error indicator bits:

- vSS!SyntaxError
- vSS!ContentError
- vSS!BViolation
- vSS!TxConflict

Provided under NDA
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-3903ab624c1

CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is 1. The counter wraps around after it reaches the maximum value. For more information on slot status monitoring, see Slot Status Monitoring.

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-0 CHAERSCNT	Channel A Status Error Counter Provides the current channel status error count. The counter value is updated within the first MT of the following slot or segment.

56.5.20 Channel B Status Error Counter (CBSERCR)

Offset

Register	Offset
CBSERCR	26h

Function

Provides the channel status error counter for channel B.

PE generates a slot status vector for:

- Each static slot
- Each dynamic slot
- The symbol window
- NIT

The slot status vector contains the four protocol-related error indicator bits:

- vSS!SyntaxError
- vSS!ContentError
- vSS!BViolation
- vSS!TxConflict

CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is 1. The counter wraps around after it reaches the maximum value. For more information on slot status monitoring, see Slot Status Monitoring.

Fields

Field	Function
15	Cold Start Attempt Aborted Flag

Table continues on the next page...

Provided under NDA only
COMPANY PROPRIETARY
Beijing ESWIN Automotive Technology Co., Ltd.
8c4625-4821-48a8-b251-390d3ab624c1

Table continued from the previous page...

Field	Function
CSAA	Becomes 1 when CC aborts a cold start attempt. Protocol related event: set coldstart abort indicator in CHI 0b - No such event 1b - Cold start attempt aborted
14 CSP	Leading Cold Start Path Becomes 1 when CC reaches the POC:normal active state via the leading cold start path. This indicates that this node has started the network. 0b - No such event 1b - POC:normal active reached from POC:startup state via the leading cold start path
13 —	Reserved
12-8 REMCSAT	Remaining Coldstart Attempts Provides the number of remaining cold start attempts that CC will execute. Protocol related variable: vRemainingColdstartAttempts
7 CPN	Leading Cold Start Path Noise Becomes 1 if CC reaches the POC:normal active state via the leading cold start path under noise conditions. This indicates some activity occurred on the FlexRay bus while CC was starting up the cluster. Protocol related variable: vPOC!ColdstartNoise 0b - No such event 1b - POC:normal active state was reached from POC:startup state via noisy leading cold start path
6 HHR	Host Halt Request Pending Becomes 1 when CC receives the HALT command from the application via Protocol Operation Control Register (POCR). CC returns this field to 0 after a hard reset condition or when the protocol is in the POC:default config state. Protocol related variable: vPOC!CHIHaltRequest 0b - No such event 1b - HALT command received
5 FRZ	Freeze Occurred Becomes 1 when CC reaches the POC:halt state because of the host FREEZE command or an internal error condition requiring immediate halt. CC returns this field to 0 after a hard reset condition or when the protocol is in the POC:default config state. Protocol related variable: vPOC!Freeze

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No such event 1b - Immediate halt because of FREEZE or internal error condition
4-0 APTAC	Allow Passive To Active Counter Provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the POC:normal passive state because of an application configured delay to enter the POC:normal active state. This delay is defined by PCR12[allow_passive_to_active]. Protocol related variable: vPOC!vAllowPassivetoActive

56.5.23 Protocol Status Register 2 (PSR2)

Offset

Register	Offset
PSR2	2Ch

Function

Provides a snapshot of status information about:

- NIT
- The symbol window
- Clock synchronization

CC updates the NIT-related status fields—NBVB, NSEB, NBVA, and NSEA—after the end of the NIT and before the end of the first slot of the next communication cycle.

CC updates the fields related to the symbol window—STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA—after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the status fields related to the symbol window remain in their reset state.

CC updates the clock-synchronization-related CLKCORRFAILCNT after the end of the static segment and before the end of the current communication cycle.

Provided under NDA only

Fields

Field	Function
15 NBVB	NIT Boundary Violation On Channel B Becomes 1 when some media activity occurs on the FlexRay bus channel B at the end of NIT. Protocol related variable: vSS!BViolation for NIT on channel B 0b - No such event 1b - Media activity detected at boundaries
14 NSEB	NIT Syntax Error On Channel B Becomes 1 when a syntax error is detected during NIT on channel B. Protocol related variable: vSS!SyntaxError for NIT on channel B 0b - No such event 1b - Syntax error detected
13 STCB	Symbol Window Transmit Conflict On Channel B Becomes 1 if a transmission conflict occurs during the symbol window on channel B. Protocol related variable: vSS!TxConflict for symbol window on channel B 0b - No such event 1b - Transmission conflict detected
12 SBVB	Symbol Window Boundary Violation On Channel B Becomes 1 if some media activity occurs on the FlexRay bus channel B at the start or at the end of the symbol window. Protocol related variable: vSS!BViolation for symbol window on channel B 0b - No such event 1b - Media activity detected at boundaries
11 SSEB	Symbol Window Syntax Error On Channel B Becomes 1 when a syntax error is detected during the symbol window on channel B. Protocol related variable: vSS!SyntaxError for symbol window on channel B 0b - No such event 1b - Syntax error detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 MTB	MTS Received On Channel B Becomes 1 if MTS is received in the symbol window on channel B. Protocol related variable: vSS!ValidMTS for Symbol Window on channel B 0b - No such event 1b - MTS received
9 NBVA	NIT Boundary Violation On Channel A Becomes 1 when some media activity occurs on the FlexRay bus channel A at the end of NIT. Protocol related variable: vSS!BViolation for NIT on channel A. 0b - No such event 1b - Media activity detected at boundaries
8 NSEA	NIT Syntax Error On Channel A Becomes 1 when a syntax error is detected during NIT on channel A. Protocol related variable: vSS!SyntaxError for NIT on channel A 0b - No such event 1b - Syntax error detected
7 STCA	Symbol Window Transmit Conflict On Channel A Becomes 1 if transmission conflicts occur during the symbol window on channel A. Protocol related variable: vSS!TxConflict for symbol window on channel A 0b - No such event 1b - Transmission conflict detected
6 SBVA	Symbol Window Boundary Violation On Channel A Becomes 1 if some media activity occurs on the FlexRay bus channel A at the start or at the end of the symbol window. Protocol related variable: vSS!BViolation for symbol window on channel A 0b - No such event 1b - Media activity detected at boundaries
5 SSEA	Symbol Window Syntax Error On Channel A Becomes 1 when a syntax error is detected during the symbol window on channel A. Protocol related variable: vSS!SyntaxError for symbol window on channel A 0b - No such event 1b - Syntax error detected
4	MTS Received On Channel A

Table continues on the next page...

Table continued from the previous page...

Field	Function
MTA	Becomes 1 if MTS is received in the symbol window on channel A. Protocol related variable: vSS!ValidMTS for symbol window on channel A 0b - No such event 1b - MTS received
3-0 CKCORFCNT	Clock Correction Failed Counter Provides the number of consecutive even/odd communication cycle pairs that have passed without clock synchronization having performed an offset or a rate correction because of lack of synchronization frames. This field does not increment when it reaches the value in either the max_without_clock_correction_fatal or max_without_clock_correction_passive fields in Protocol Configuration 8 (PCR8). CC resets this field: • After a hard reset condition • When the protocol enters the POC:normal active state • When both the rate and offset correction terms have been calculated successfully Protocol related variable: vClockCorrectionFailed

56.5.24 Protocol Status 3 (PSR3)

Offset

Register	Offset
PSR3	2Eh

Function

Provides:

- Aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception
- Accrued information for:
  - The symbol window
  - NIT
  - The wakeup status

Provided under NDA of 1.1

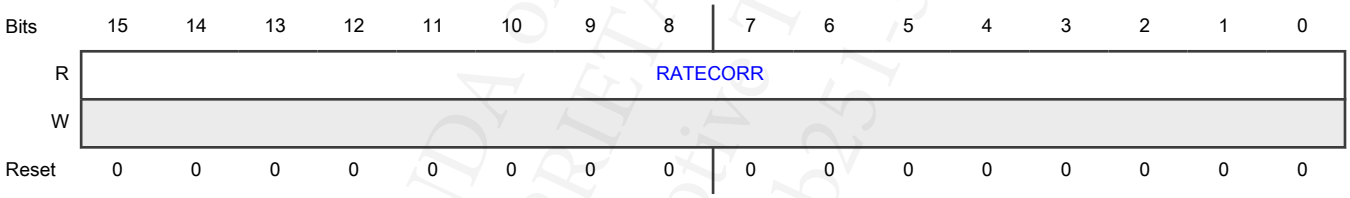
56.5.29 Rate Correction Value (RTCORVR)

Offset



Register	Offset
RTCORVR	38h

Function

Provides the sign-extended rate correction value in µTs as the clock synchronization algorithm calculates it.

CC updates this register during NIT of each odd-numbered communication cycle.

Diagram

Fields

Field	Function
15-0 RATECORR	Rate Correction Value Provides the sign-extended rate correction value in µTs as the clock synchronization algorithm calculates it. The value is represented in twos-complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by PCR14[rate_correction_out], CC changes PIFR0[CCL_IF] to 1. Protocol related variable: vRateCorrection (before value limitation and external rate correction). **NOTE** If CC cannot calculate a new rate correction term because of a lack of synchronization frames, the RATECORR value is not updated.

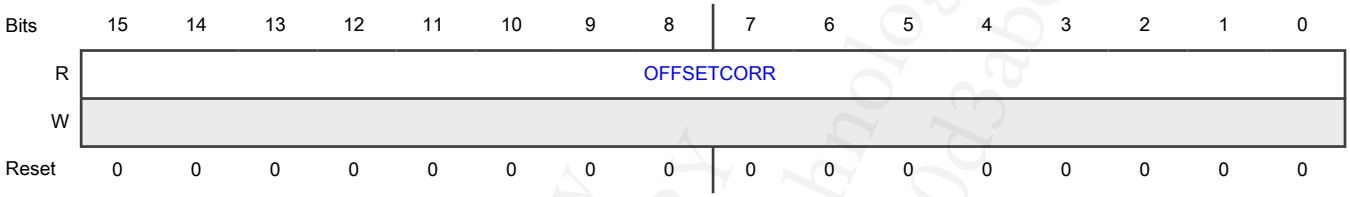
56.5.30 Offset Correction Value (OFCORVR)

Offset



Register	Offset
OFCORVR	3Ah

Function

Provides the sign-extended offset correction value in µTs as the clock synchronization algorithm calculates it.

CC updates this register during NIT.

Diagram

Fields

Field	Function
15-0 OFFSETCORR	Offset Correction Value Provides the sign-extended offset correction value in µTs as the the clock synchronization algorithm calculates it. The value is represented in twos-complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally-calculated rate correction value exceeds the limit set by PCR29[extern_offset_correction], CC changes PIFR0[CCL_IF] to 1. Protocol related variable: vOffsetCorrection (before value limitation and external offset correction) **NOTE** If CC cannot calculate a new offset correction term because of a lack of synchronization frames, the OFFSETCORR value is not updated.

56.5.31 Combined Interrupt Flag (CIFR)

Offset

Register	Offset
CIFR	3Ch

Function

Provides five combined interrupt flags and a copy of three individual interrupt flags.

The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable fields. The generation scheme for the combined interrupt flags is described in Module Interrupt.

The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in Global Interrupt Flag And Enable (GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, you must use Global Interrupt Flag And Enable (GIFER).

NOTE

The meanings of the combined status fields MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in Global Interrupt Flag And Enable (GIFER).

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-8 —	Reserved
7 MIF	Module Interrupt Flag Becomes 1 if at least one interrupt source has its interrupt flag equal to 1. 0b - No interrupt source has its interrupt flag equal to 1. 1b - At least one interrupt source has its interrupt flag equal to 1.
6 PRIF	Protocol Interrupt Flag Becomes 1 if at least one of the individual protocol interrupt flags in Protocol Interrupt Flag 0 (PIFR0) or Protocol Interrupt Flag 1 (PIFR1) is 1. 0b - All individual protocol interrupt flags are 0. 1b - At least one of the individual protocol interrupt flags is 1.
5 CHIF	CHI Interrupt Flag Becomes 1 if at least one of the individual CHI error flags in CHI Error Flag (CHIERFR) is 1. 0b - All CHI error flags are 0. 1b - At least one CHI error flag is 1.
4 WUPIF	Wakeup Interrupt Flag Provides the same value as GIFER[WUPIF].
3 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag Provides the same value as GIFER[FAFBIF].
2	Receive FIFO Channel A Almost Full Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FAFAIF	Provides the same value as GIFER[FAFAIF].
1 RBIF	Receive MB Interrupt Flag Becomes 1 if for at least one of the individual receive MBs (MBCCSR*n*[MTD] = 0), the corresponding MBCCSR*n*[MBIF] = 1. 0b - None of the individual receive MBs have have MBIF = 1. 1b - At least one individual receive MB has MBIF = 1.
0 TBIF	Transmit MB Interrupt Flag Becomes 1 if for at least one of the individual transmit MBs (MBCCSR*n*[MTD] = 1), the corresponding MBCCSR*n*[MBIF] = 1. 0b - None of the individual transmit MBs have MBIF = 1. 1b - At least one individual transmit MB has MBIF = 1.

56.5.32 System Memory Access Timeout (SYMATOR)

Offset

Register	Offset
SYMATOR	3Eh

Function

Controls when a system bus access timeout is detected.

For a detailed description, see Configure System Memory Access Time-Out Register (SYMATOR) and System Bus Access Timeout.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 TIMEOUT	System Memory Access Timeout Defines when a system bus access timeout is detected.

56.5.33 Sync Frame Counter (SFCNTR)

Offset

Register	Offset
SFCNTR	40h

Function

Provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle.

This register is updated after the start of NIT and before 10 MT after offset correction start.

If you have locked the even synchronization table at the end of the static segment of an even communication cycle, CC does not update the SFEVB and SFEVA fields.

Similarly, if you have locked the odd synchronization table at the end of the static segment of an odd communication cycle, CC does not update the SFODB and SFODA fields.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SFEVB				SFEVA				SFODB				SFODA			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

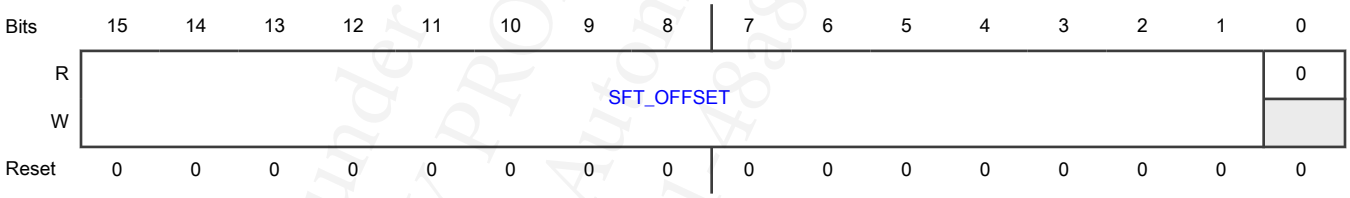
Field	Function
15-12 SFEVB	Sync Frames Channel B, Even Cycle Provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization. Protocol related variable: size of (vsSyncIdListB for even cycle)
11-8 SFEVA	Sync Frames Channel A, Even Cycle Provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization. Protocol related variable: size of (vsSyncIdListA for even cycle)

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 SFODB	Sync Frames Channel B, Odd cycle Provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization. Protocol related variable: size of (vsSyncIdListB for odd cycle)
3-0 SFODA	Sync Frames Channel A, Odd Cycle Provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization. Protocol related variable: size of (vsSyncIdListA for odd cycle)

56.5.34 Sync Frame Table Offset (SFTOR)



Offset

Register	Offset
SFTOR	42h

Function

Defines the FlexRay memory area related offset for sync frame tables. For more details, see Sync Frame ID and Sync Frame Deviation Tables.

Diagram

Fields

Field	Function
15-1 SFT_OFFSET	Sync Frame Table Offset Configures the offset of the sync frame tables in the FlexRay memory area. This offset must be 16-bit aligned. Thus, SFT_OFFSET[0] is always 0.
0 —	Reserved

Printed under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c46e25-4821-4848-b251-390d3ab624c1

56.5.35 Sync Frame Table Configuration Control Status (SFTCCSR)

Offset

Register	Offset
SFTCCSR	44h

Function

Provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see Sync Frame ID and Sync Frame Deviation Tables.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	CYCNUM						ELKS	OLKS	EVAL	OVAL	0	0	SDVEN	SIDEN
W	ELKT	OLKT												OPT		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 ELKT	Even Cycle Tables Lock/Unlock Trigger Locks and unlocks the even cycle tables. 0b - No effect 1b - Trigger lock and unlock
14 OLKT	Odd Cycle Tables Lock And Unlock Trigger Locks and unlocks the odd cycle tables. 0b - No effect 1b - Trigger lock and unlock
13-8 CYCNUM	Cycle Number Provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
7 ELKS	Even Cycle Tables Lock Status Indicates whether the application has locked the even cycle tables. 0b - Not locked 1b - Locked
6 OLKS	Odd Cycle Tables Lock Status Indicates whether the application has locked the odd cycle tables.

Table continues on the next page...

Table continued from the previous page...

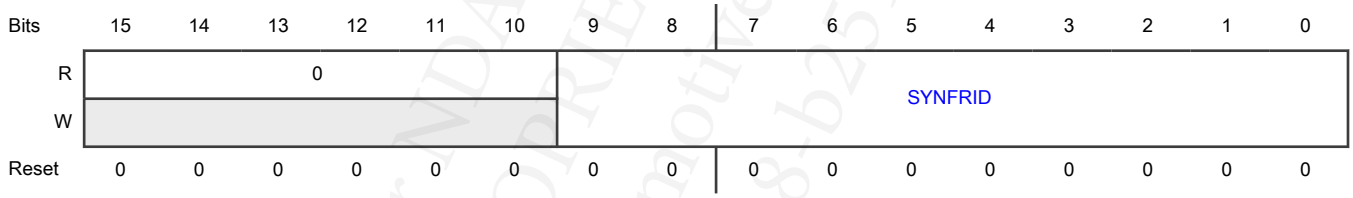
Field	Function
	0b - Not locked 1b - Locked
5 EVAL	Even Cycle Tables Valid Indicates whether the sync frame ID and sync frame deviation tables for the even cycle are valid. CC writes 0 to this field when CC starts updating the tables, and keeps its value at 0 while the update occurs. CC then writes 1 to this field when CC has finished the table update and the tables are consistent. 0b - Invalid 1b - Valid
4 OVAL	Odd Cycle Tables Valid Indicates whether the sync frame ID and sync frame deviation tables for the odd cycle are valid. CC writes 0 to this field when CC starts updating the tables, and keeps its value at 0 while the update occurs. CC then writes 1 to this field when CC has finished the table update and the tables are consistent. 0b - Invalid 1b - Valid
3 —	Reserved
2 OPT	One Pair Trigger Controls how CC writes pairs of sync frame tables into the FlexRay memory area. If OPT = 1 while SDVEN or SIDEN is 1, CC writes only one pair of the enabled sync frame tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, CC immediately changes SDVEN or SIDEN to 0. If OPT = 0 while SDVEN or SIDEN is 1, CC continuously writes the enabled sync frame tables into the FlexRay memory area. 0b - Write continuously 1b - Write only one pair
1 SDVEN	Sync Frame Deviation Table Enable Controls the generation of the sync frame deviation tables. You must write 1 to this field to request CC to write the sync frame deviation tables into the FlexRay memory area. **NOTE** If SDVEN = 1, then you must also write 1 to SIDEN. 0b - Do not write sync frame deviation tables 1b - Write sync frame deviation tables
0	Sync Frame ID Table Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
SIDEN	Controls the generation of the sync frame ID tables. You must write 1 to this field to request CC to write the sync frame ID tables into the FlexRay memory area. 0b - Do not write sync frame ID tables 1b - Write sync frame ID tables

56.5.36 Sync Frame ID Rejection Filter (SFIDRFR)



Offset

Register	Offset
SFIDRFR	46h

Function

Defines the sync frame rejection filter ID. You must update this register outside of the static segment. If you update this register in the static segment, it can appear that CC accepts the sync frame in the current cycle.

Diagram

Fields

Field	Function
15-10 —	Reserved
9-0 SYNFRID	Sync Frame Rejection ID Defines the frame ID of a frame that must not be used for clock synchronization. For details, see Sync Frame Rejection Filtering.

56.5.37 Sync Frame ID Acceptance Filter Value (SFIDAFVR)

Offset

Register	Offset
SFIDAFVR	48h

Function

Defines the sync frame acceptance filter value. For details on filtering, see Sync Frame Filtering.

56.5.39 NMV n (NMVR0 - NMVR5)

Offset

Register	Offset
NMVR0	4Ch
NMVR1	4Eh
NMVR2	50h
NMVR3	52h
NMVR4	54h
NMVR5	56h

Function

Each of these registers holds one NMV part. Network Management Vector Length Register (NMVLR) configures the NMV length. If Network Management Vector Length Register (NMVLR) is programmed with a value that is less than 12 bytes, the remaining bytes of the NMVR*n* registers, which are not used for the network management vector accumulating, remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Function
NMVL	Protocol related variable: gNetworkManagementVectorLength. This field defines the length of the Network Management Vector in bytes. Legal values are between 0 and 12.

56.5.41 Timer Configuration And Control (TICCR)

Offset

Register	Offset
TICCR	5Ah

Function

Configures and controls the two timers T1 and T2. For timer details, see Timer Support.

T1 is an absolute timer. T2 can be configured as an absolute or relative timer.

Both timers are deactivated immediately when the protocol enters a state different from POC:normal active or POC:normal passive.

56.5.42 Timer 1 Cycle Set Register (TI1CYSR)

Offset

Register	Offset
TI1CYSR	5Ch

Function

Defines the cycle filter value and the cycle filter mask for timer T1. For a detailed description of timer T1, see Absolute Timer T1.

NOTE

If you modify the value in this register while the timer is running, the change becomes effective immediately and timer T1 expires according to the changed value.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Function
10-0 SLOTNUMBER	Slot Number Specifies the number of the slot whose status is saved in the corresponding slot status registers. **NOTE** If SLOTNUMBER = 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the NIT status after the cycle start.

56.5.49 Slot Status Counter Condition (SSCCR)

Offset

Register	Offset
SSCCR	66h

Function

Allows you to access and program the four internal non-memory mapped Slot Status Counter Condition (SSCCR0–SSCCR3) registers. Each of these registers define the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter (SSCR0-SSCR3) registers. Table 464 shows the mapping. For a detailed description of slot status counters, see Slot Status Counter Registers.

Table 464. Mapping between internal SSCCR*n* and SSCR*n*

8 MCY	Multi Cycle Selection Defines whether the slot status counter accumulates over multiple communication cycles or provides information only for the previous communication cycle. 0b - Only for the previous communication cycle 1b - Over multiple communication cycles

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 VFR	Valid Frame Restriction This bit is used to restrict the counter only to valid received frames. 0b - Not restricted 1b - Restricted
6 SYF	Sync Frame Restriction Restricts the counter to received frames that have the sync frame indicator bit set to 1. 0b - Not restricted 1b - Restricted
5 NUF	Null Frame Restriction Restrict the counter to received frames that have the null frame indicator bit set to 0. 0b - Not restricted 1b - Restricted
4 SUF	Startup Frame Restriction Restricts the counter to received frames that have the startup frame indicator bit set to 1. 0b - Not restricted 1b - Restricted
3-0 STATUSMASK	Slot Status Mask Enable the counter with respect to the four slot status error indicator bits.

Bit position in STATUSMASK	Function
0	Enables the counting for slots with the transmission conflict indicator bit set to 1.
1	Enables the counting for slots with the boundary violation indicator bit set to 1.
2	Enables the counting for slots with the content error indicator bit set to 1.
3	Enables the counting for slots with the syntax error indicator bit set to 1.

56.5.50 Slot Status (SSR0 - SSR7)

Offset

For n = 0 to 7:

Register	Offset
SSRn	68h + (n × 2h)

Function

Holds the status vector of the slot specified in the corresponding internal slot status selection register, which can be programmed using Slot Status Selection (SSSR). Each register is updated after the end of the corresponding slot as shown in Slot Status Monitoring. The register fields directly relate to the protocol variables and described in more detail in Slot Status Monitoring.

56.5.51 Slot Status Counter (SSCR0 - SSCR3)

Offset

Register	Offset
SSCR0	78h
SSCR1	7Ah
SSCR2	7Ch
SSCR3	7Eh

Function

Provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control fields in the related internal slot status counter condition registers SSCCR*n*, which you can program by using Slot Status Counter Condition (SSCCR). For more details, see Slot Status Counter Registers.

NOTE

If the counter has reached its maximum value FFFFh and is in Multicycle mode—that is, SSCCR*n*[MCY] = 1—the counter is not reset to 0h.You can reset the counter by writing 0 to SSCCR*n*[MCY] and waiting for the next cycle start, when CC clears the counter. Subsequently, the counter can be set into Multicycle mode again.

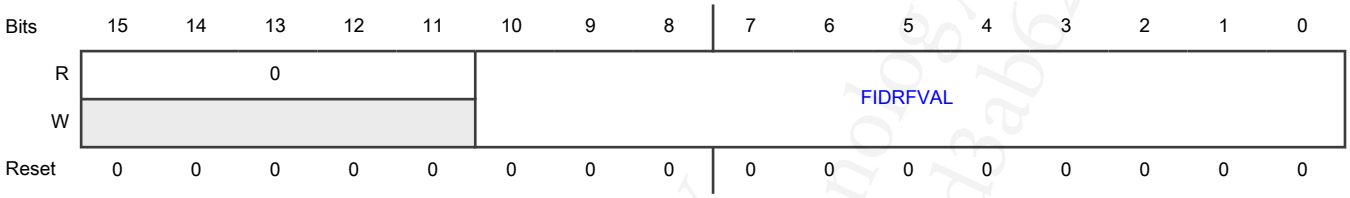
56.5.62 Receive FIFO Frame ID Rejection Filter Value (RFFIDRFVR)



Offset

Register	Offset
RFFIDRFVR	94h

Function

Defines the filter value for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering, see FIFO Filtering.

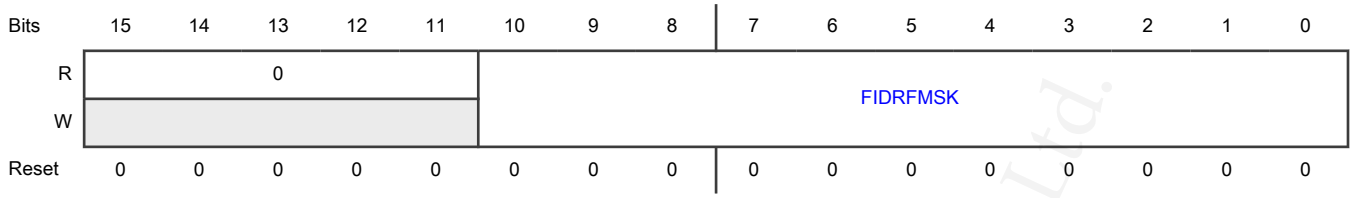
Diagram

Fields

Field	Function
15-11 —	Reserved
10-0 FIDRFVAL	FIDRFVALA Or FIDRFVALB Frame ID Rejection Filter Value Contains the value for the frame ID rejection filter.

56.5.63 Receive FIFO Frame ID Rejection Filter Mask (RFFIDRFMR)

Offset



Register	Offset
RFFIDRFMR	96h

Function

Defines the filter mask for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering, see FIFO Filtering.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

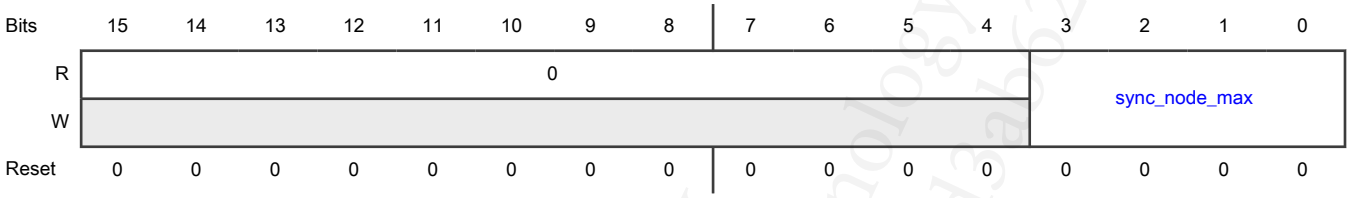
12-0 minislots_max	minislots_max gNumberOfMinislots - 1

56.5.98 Protocol Configuration 30 (PCR30)



Offset

Register	Offset
PCR30	DCh

Function

Provides the necessary configuration information to PE. The individual values are described in Table 458.

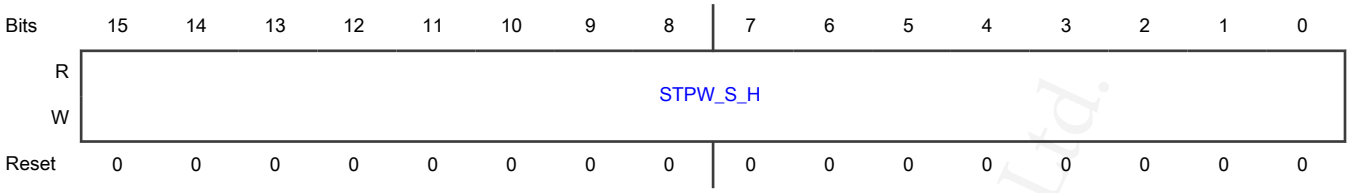
Diagram

Fields

Field	Function
15-4 —	Reserved
3-0 sync_node_max	sync_node_max gSyncNodeMax

56.5.99 Stopwatch Count High (STPWHR)

Offset



Register	Offset
STPWHR	DEh

Function

Works with Stopwatch Count Low (STPWLR) to form a stopwatch counter that runs on the system clock. This counter starts on cycle start even and stops on an external event “OS_tick”. When all 32 bits of the stopwatch counter are read, the counter automatically clears. For details, see StopWatch function.

Provided under NDA only

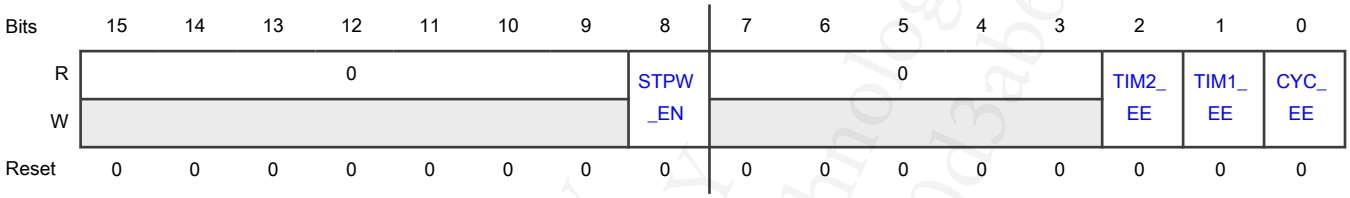
56.5.101 Protocol Event Output Enable And Stopwatch Control (PEOER)



Offset

Register	Offset
PEOER	E2h

Function

Defines whether or not the event output ports are enabled based on the events such as Cycle start and Timer1 and Timer2 expiration (see Timer Support for details).

Diagram

Fields

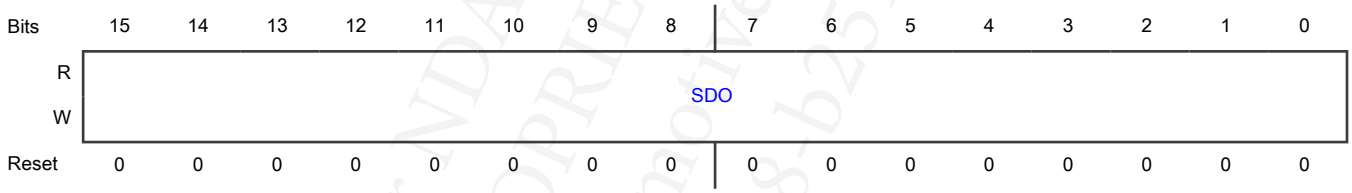
Field	Function
15-9 —	Reserved
8 STPW_EN	Stopwatch Count Enable Enables and disables the stopwatch counter. 0b - Disabled 1b - Enabled
7-3 —	Reserved
2 TIM2_EE	Timer 2 Expired Event Output Enable Enables and disables the event on the "fr_evt_tim2" port. 0b - Disabled 1b - Enabled
1 TIM1_EE	Timer 1 Expired Event Output Enable Enables and disables the event on the "fr_evt_tim1" port. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 CYC_EE	Cycle Start Event Output Enable Enables and disables the event on the "fr_evt_cyc" port. 0b - Disabled 1b - Enabled

56.5.102 Receive FIFO Start Data Offset (RFSDOR)



Offset

Register	Offset
RFSDOR	E6h

Function

Because all data fields of the FIFO are of equal length and are located at subsequent system memory addresses, the content of this register corresponds to the start address of payload area of the selected FIFO.

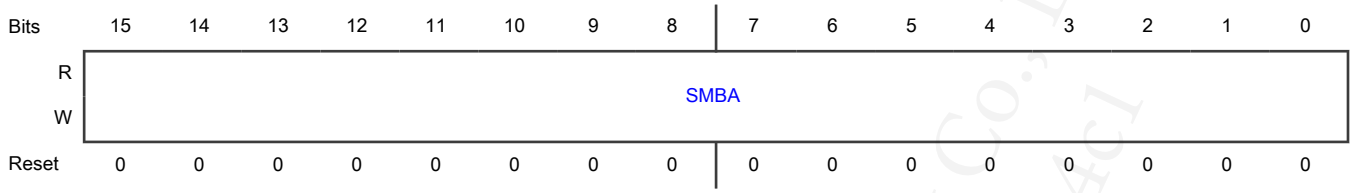
Diagram

Fields

Field	Function
15-0 SDO	SDOA And SDOB Start Data Field Offset Defines the data field offset of the header field of the first MB of the selected FIFO. CC uses the SDO value to determine the physical location of the receiver FIFO's first MB header field. For configuration constraints, see Configure Data Field Offsets.

56.5.103 Receive FIFO System Memory Base Address High (RFSYMBADHR)

Offset



Register	Offset
RFSYMBADHR	E8h

Provided under NDA only
CONFIDENTIAL PROPRIETARY
Beijing C.T Automotive Technology Co., Ltd.
c8c46285-4214-48a8-b251-3900a3ab624c1

Function

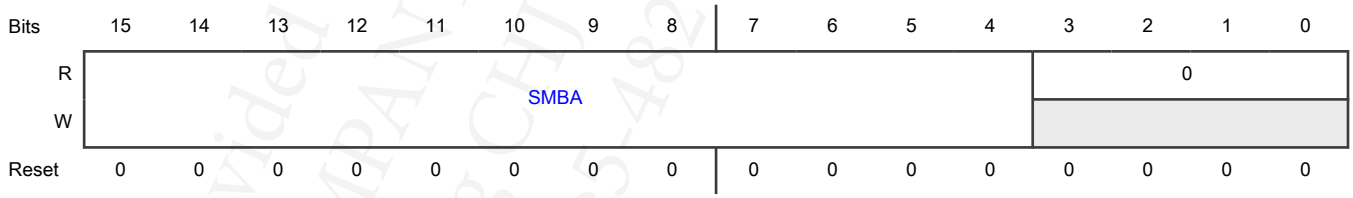
Works with Receive FIFO System Memory Base Address Low (RFSYMBADLR) to define the system memory base address for the receive FIFO if MCR[FAM] = 1. BMIF uses the system memory base address to calculate the physical memory address for system memory accesses for the FIFOs.

Diagram

Fields

Field	Function
15-0 SMBA	System Memory Base Address Contains the value of the system memory base address, defined as a byte address.

56.5.104 Receive FIFO System Memory Base Address Low (RFSYMBADLR)



Offset

Register	Offset
RFSYMBADLR	EAh

Function

Works with Receive FIFO System Memory Base Address High (RFSYMBADHR) to define the system memory base address for the receive FIFO if MCR[FAM] = 1. BMIF uses the system memory base address to calculate the physical memory address for system memory accesses for the FIFOs.

Diagram

Fields

Field	Function
15-4 SMBA	System Memory Base Address Contains the value of the system memory base address, defined as a byte address.

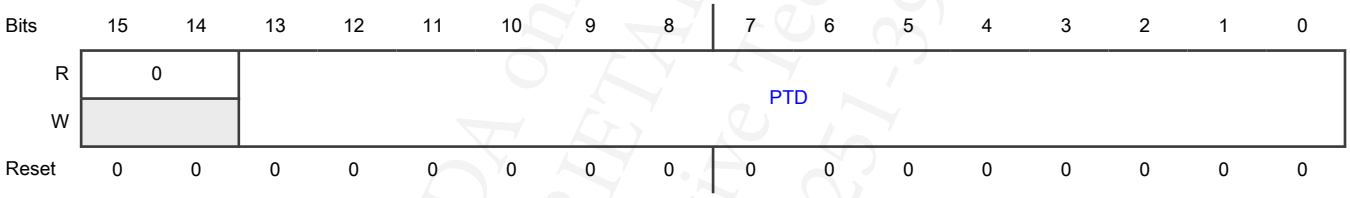
Table continued from the previous page...

Field	Function
3-0 —	Reserved

56.5.105 Receive FIFO Periodic Timer (RFPTR)



Offset

Register	Offset
RFPTR	ECh

Function

Holds the duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (see FIFO Periodic Timer).

Diagram

Fields

Field	Function
15-14 —	Reserved
13-0 PTD	Periodic Timer Duration Defines the periodic timer duration, in terms of µTs, as follows: 0h - Timer remains expired 1–3FFEh - Timer expires after PTD µTs and restarts at each cycle start 3FFFh - Timer never expires

56.5.106 Receive FIFO Fill Level and Pop Count (RFFLPCR)

Offset

Register	Offset
RFFLPCR	EEh

Function

Provides the current fill level of the two receiver FIFOs and allows you to pop a number of entries from the FIFOs.

If the pop count value (PCA or PCB) is greater than the current FIFO fill level (FLB or FLA), then the FIFO is empty after the update. You do not receive any notification that the required number of entries was not removed.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FLB_or_PCB								FLA_or_PCA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-8 FLB_or_PCB	FLB Or PCB Displays the fill level value FLB or configures the pop count value PCB. **NOTE** This field behaves differently for read and write operations. When reading 00000000-11111111b - Fill Level FIFO B (FLB): Provides the current number of entries in FIFO B When writing 00000000-11111111b - Pop Count FIFO B (PCB): Defines the number of entries to be removed from FIFO B
7-0 FLA_or_PCA	FLA Or PCA Displays the fill level value FLA or configures the pop count value PCA. **NOTE** This field behaves differently for read and write operations. When reading 00000000-11111111b - Fill Level FIFO A (FLA): Provides the current number of entries in FIFO A When writing 00000000-11111111b - Pop Count FIFO A (PCA): Defines the number of entries to be removed from FIFO A

56.5.107 ECC Error Interrupt Flag And Enable (EEIFER)

Offset

Register	Offset
EEIFER	F0h

Function

Controls the ECC-related interrupt request lines and provides the corresponding interrupt flags.

You can return the interrupt flags to 0 by writing 1 to them. This resets the corresponding report registers. For a detailed description, see Memory Error Reporting.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 BSY	Register Update Busy Indicates the current state of the ECC configuration update and controls the register write access condition IDL specified in Register write access. 0b - Idle

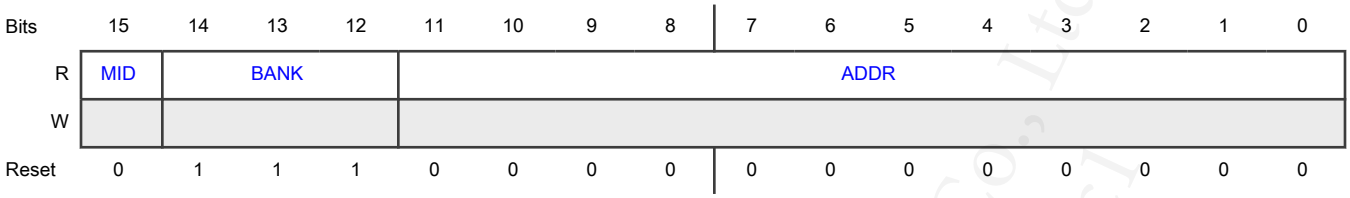
Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Running
14-10 —	Reserved
9-8 ERS	Error Report Select Selects the content of the ECC error reporting registers. 00b - Show PE DRAM noncorrected error information. 01b - Show PE DRAM corrected error information. 10b - Show CHI LRAM noncorrected error information. 11b - Show CHI LRAM corrected error information.
7-5 —	Reserved
4 ERM	Error Report Mode Configures the type of data written into the internal error report registers on the detection of a memory error. 0b - Store data and code as delivered by ECC decoding logic. 1b - Store data and code as read from the memory.
3-2 —	Reserved
1 EIM	Error Injection Mode Configures the ECC error injection mode. 0b - Use EEIDR[DATA] and EEICR[CODE] as XOR distortion pattern for error injection. 1b - Use EEIDR[DATA] and EEICR[CODE] as write value for error injection.
0 EIE	Error Injection Enable Enables and disables the ECC error injection on the memories. 0b - Disabled 1b - Enabled

56.5.109 ECC Error Report Address (EERAR)

Offset



Register	Offset
EERAR	F4h

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c46225-4821-48a8-b251-390d3ab624c1

Function

Provides the memory identifier, bank, and address for which the memory error is reported.

Diagram

Fields

Field	Function
15 MID	Memory Identifier Provides the memory instance for which the memory error is reported. 0b - PE DRAM 1b - CHI LRAM
14-12 BANK	Memory Bank Provides the BANK for which the memory error is reported. BANK = 111b indicates that no error was found after reset. When MID = 0, BANK values indicate the following: 000b - PE DRAM [7:0] 001b - PE DRAM [15:8] 010b–111b - Not used When MID = 1, see the following table for the assignment of the LRAM banks.

BANK	Register		
000	MBCCFR(2n)	MBDOR(6n)	LEETR0

Field	Function
15	Memory Identifier

Table continues on the next page...

Table continued from the previous page...

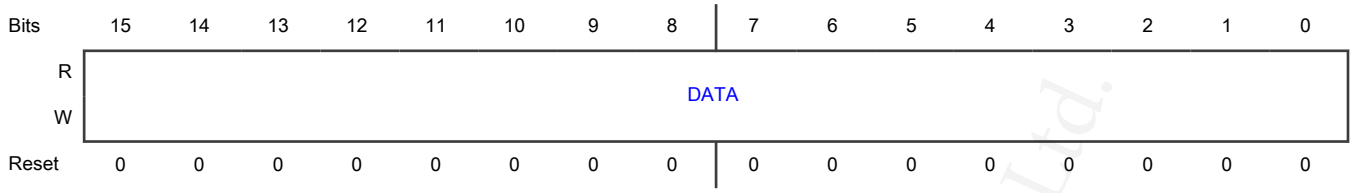
Field	Function
MID	Defines the memory instance for ECC error injection. 0b - PE DRAM 1b - CHI LRAM
14-12 BANK	Memory Bank This field defines the memory bank for ECC error injection. When MID = 0, BANK values indicate the following: 000b - PE DRAM [7:0] 001b - PE DRAM [15:8] 010b–111b - Reserved When MID = 1, see ECC Error Report Address (EERAR) for the assignment of the LRAM banks.
11-0 ADDR	Memory Address Defines the memory address for ECC error injection.

56.5.113 ECC Error Injection Data (EEIDR)

Offset

Register	Offset
EEIDR	FCh

Function



Defines the data distortion pattern for the error injection write. The number of valid bits depends on the selected memory and memory bank as shown in ECC Error Report Data (EERDR).

NOTE

The effect of the error injected depends from the LRAM content at the address accessed and from the module internal usage of the data. See Memory Error Response for details.

Provided under NDA only

56.5.115 MB Configuration Control Status (MBCCSR0 - MBCCSR255)

Offset

For n = 0 to 255:

Register	Offset
MBCCSRn	800h + (n × 8h)

Function

Contains:

- MB configuration data
- MB control data
- MB status information
- MB interrupt flags

A detailed description of all flags can be found in Individual MB functional description.

If you write 1 to EDT, no write access to the other register fields is performed.

If you write 0 to EDT and 1 to LCKT, no write access to the other fields is performed.

Diagram

12 MTD	MB Transfer Direction Configures the MB transfer direction.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receive MB 1b - Transmit MB
11 CMT	Commit To Transmission Indicates whether the transmit MB data is ready for transmission. **NOTE** This field is read/write but may be modified by hardware other than by a reset. 0b - Not ready 1b - Ready
10 EDT	Enable And Disable Trigger If you write 1 to this field, a MB enable or disable is triggered, depending on the current value of EDS. 0b - No effect 1b - MB enable or disable is triggered
9 LCKT	Lock And Unlock Trigger If you write 1 to this field and write 0 to EDT bit, a MB lock or unlock is triggered, depending on the current LCKS value. 0b - No effect 1b - MB lock or unlock is triggered
8 MBIE	MB Interrupt Enable Defines whether the MB generates an interrupt request when the MB's MBIF field is 1. 0b - Disabled 1b - Enabled
7-5 —	Reserved
4 DUP	Data Updated Indicates whether the frame header in the MB header field and the data in the MB data field are updated after a frame reception. 0b - Not updated 1b - Updated
3 DVAL	Data Valid For receive MBs, indicates whether the MB data field contains valid frame data. For transmit MBs, indicates if a message is transferred again because of the state transmission mode of the MB.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receive MB contains no valid frame data, or message is transmitted for the first time 1b - Receive MB contains valid frame data, or message will be transferred again
2 EDS	Enable And Disable Status Indicates whether the MB is enabled or disabled. 0b - Disabled 1b - Enabled
1 LCKS	Lock Status Indicates the current lock status of the MB. 0b - You have not locked the MB 1b - You have locked the MB
0 MBIF	MB Interrupt Flag Becomes 1 when the MB slot status field is updated after frame transmission or reception, or when you just enabled a transmit MB. 0b - No such event 1b - Slot status field updated or transmit MB just enabled

56.5.116 MB Cycle Counter Filter (MBCCFR0 - MBCCFR255)

Offset

For n = 0 to 255:

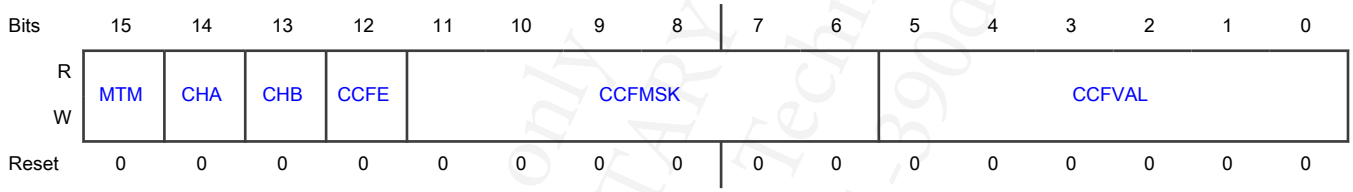
Register	Offset
MBCCFRn	802h + (n × 8h)

Function

Contains MB configuration data for the:

- Transmission mode
- Channel assignment
- Cycle counter filtering

For detailed information on cycle counter filtering, see MB cycle counter filtering.



NOTE

- If at least one MB assigned to a certain slot is assigned to both channels, then all MBs assigned to that slot must be assigned to both channels. Otherwise, the MB configuration is illegal and the result of the MB search is not defined.
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves Disabled mode. For details, see CHI LRAM Initialization.

Table 467. Channel assignment description

CHA	CHB	Transmit MB		Receive MB	
		Static segment	Dynamic segment	Static segment	Dynamic segment
1	1	Transmit on both channel A and channel B	Transmit on channel A only	Store first valid frame received on either channel A or channel B	Store first valid frame received on channel A; ignore channel B
0	1	Transmit on channel B	Transmit on channel B	Store first valid frame received on channel B	Store first valid frame received on channel B
1	0	Transmit on channel A	Transmit on channel A	Store first valid frame received on channel A	Store first valid frame received on channel A
0	0	No frame transmission	No frame transmission	No frame stored	No frame stored

Diagram

Fields

Field	Function
15 MTM	MB Transmission Mode Applies only to transmit MBs and defines the transmission mode. 0b - Event 1b - State
14 CHA	Channel Assignment A In conjunction with the CHB field, defines the channel assignment and controls the receive and transmit behavior of the MB according to MB Cycle Counter Filter Register.
13 CHB	Channel Assignment B In conjunction with the CHB field, defines the channel assignment and controls the receive and transmit behavior of the MB according to MB Cycle Counter Filter Register.
12 CCFE	Cycle Counter Filtering Enable Enables and disables the cycle counter filtering. 0b - Disabled 1b - Enabled

Table continues on the next page...

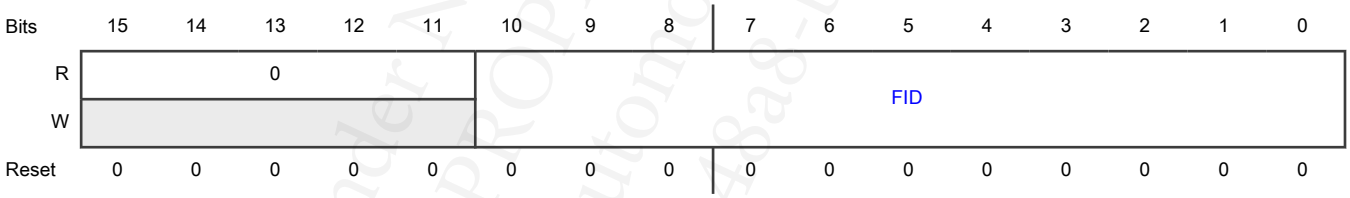
Table continued from the previous page...

Field	Function
11-6 CCFMSK	Cycle Counter Filtering Mask Defines the filter mask for the cycle counter filtering.
5-0 CCFVAL	Cycle Counter Filtering Value Defines the filter value for the cycle counter filtering.

56.5.117 MB Frame ID (MBFIDR0 - MBFIDR255)

Offset

For n = 0 to 255:



Register	Offset
MBFIDRn	804h + (n × 8h)

Function

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves Disabled mode. For details, see CHI LRAM Initialization.

Diagram

Fields

Field	Function
15-11 —	Reserved
10-0 FID	Frame ID The meaning of this field depends on the MB transfer type. • For a receive MB, this field is used as a filter value to determine if the MB is used for reception of a message received in a slot with the slot ID equal to FID. • For a transmit MB, this field is used to determine the slot in which the message in this MB must be transmitted.

56.6 Functional description

This section provides a detailed description of the implemented CC functionality.

56.6.1 MB concept

The CC uses MBs—data structures that store frame data, configuration, control, and status data. Each MB consists of two parts—the MB control data and the physical MB. The MB control data is located in dedicated registers. The structure of the MB control data depends on the MB type and is described in MB types. The physical MB is located in the FlexRay memory area and is described in the next section.

56.6.2 Physical MB

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called physical MBs. The physical MBs are located in the FlexRay memory area. The following figure shows the structure of a physical MB.

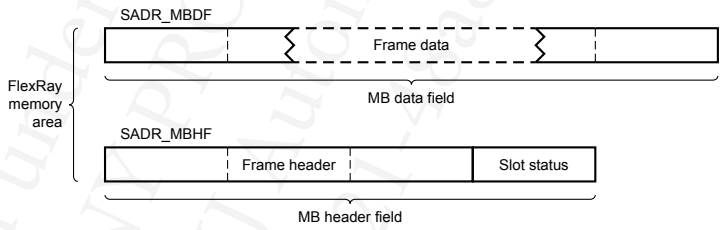

Figure 473. Physical MB structure

A physical MB consists of two fields—the MB header field and the MB data field. The MB header field contains the frame header and the slot status. The MB data field contains the frame data.

The connection between the two fields is established by the data field offset.

56.6.2.1 MB header field

The MB header field is a contiguous region in the FlexRay memory area and occupies eight bytes. It contains the frame header and the slot status. Its structure is shown in Figure 473.

The physical start address SADR_MBHF of the MB header field must be 16-bit aligned.

56.6.2.1.1 Frame header

The frame header occupies the first six bytes in the MB header field. It contains all information related to the FlexRay frame header, according to FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

A detailed description of the usage and the content of the frame header is provided in Frame header description.

56.6.2.1.2 Slot status

The slot status occupies the last two bytes of the MB header field. It provides the slot and frame status related information according to FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

A detailed description of the content and usage of the slot status is provided in Slot status description.

56.6.2.2 MB data field

The MB data field is a contiguous area of 2-byte entities. This field contains all or part of the frame payload data of the frame to be transmitted or received on the FlexRay bus. The minimum length of this field depends on the specific MB configuration and is specified in the MB descriptions given in the following section.

56.6.3 MB types

CC provides three different MB types:

- Individual MBs
- Receive shadow buffers
- Receive FIFO buffers

For each MB type, the structure of the physical MB is identical. The MB types differ only in the structure and content of MB control data, which control the related physical MB. The MB control data is described in the following sections.

56.6.3.1 Individual MBs

The individual MBs are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each MB. CC supports three types of individual MBs, which are described in Individual MB functional description.

Each individual MB consists of two parts:

- The physical MB, located in the FlexRay memory area
- The MB control data, located in dedicated registers

This figure shows the structure of an individual MB.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-8253-390d3ab624c1

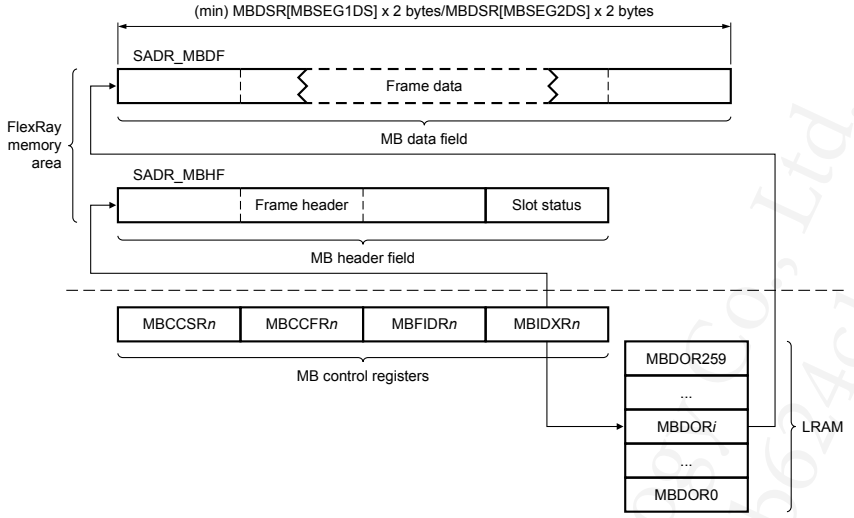

Figure 474. Individual MB structure

Each MB has an MB number *n* assigned. This number determines the set of MB control registers associated with this individual MB. The following registers control the individual MB with number *n*:

- MB Configuration Control Status (MBCCSR0 - MBCCSR255)
- MB Cycle Counter Filter (MBCCFR0 - MBCCFR255)
- MB Frame ID (MBFIDR0 - MBFIDR255)
- MB Index (MBIDXR0 - MBIDXR255)

The MBIDX field in MB Index (MBIDXR0 - MBIDXR255) establishes the connection between the MB control registers and the physical MB. The start address SADR_MBHF of the related MB header field in the FlexRay memory area is determined according to Equation 1.

$$SADR\_MBHF = (MBIDXRn[MBIDX] \times 8) + SMBA$$

Equation 1. Equation for SADR_MBHF

The data field belonging to a particular physical MB is characterized by the data field offset. For each physical MB with MBIDX *i*, MBDOR*i* contains the offset of the corresponding MB data field with respect to the CC FlexRay memory area base address as provided by the SMBA field in the System Memory Base Address Register (SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding MB data field in the FlexRay memory area according to Equation 2.

$$SADR\_MBDF = [DataFieldOffset] + SMBA$$

Equation 2. Equation for SADR_MBDF

MBDOR*n* are stored in the module internal memory LRAM. See CHI LRAM Initialization for the setup of the data field offset values.

56.6.3.1.1 Individual MB segments

The set of individual MBs can be split in two MB segments using MB Segment Size and Utilization (MBSSUTR). All individual MBs with a MB number n ≤ MBSSUTR[LAST_MB_SEG1] belong to the first MB segment. All individual MBs with a MB number n > MBSSUTR[LAST_MB_SEG1] belong to the second MB segment. The following rules apply to the length of the MB data field:

- All physical MBs associated with individual MBs that belong to the same MB segment must have MB data fields of the same length.
- The minimum length of the MB data field for individual MBs in the first MB segment is 2 × MBDSR[MBSEG1DS] bytes.

- The minimum length of the MB data field for individual MBs in the second segment is 2 × MBDSR[MBSEG2DS] bytes.

56.6.3.2 Receive shadow buffers

The receive shadow buffers are required for the frame reception process for individual MBs. CC provides four receive shadow buffers, one receive shadow buffer per channel and per MB segment.

Each receive shadow buffer consists of two parts—the physical MB located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in the figure below. The four internal shadow buffer control registers can be accessed by Receive Shadow Buffer Index (RSBIR).

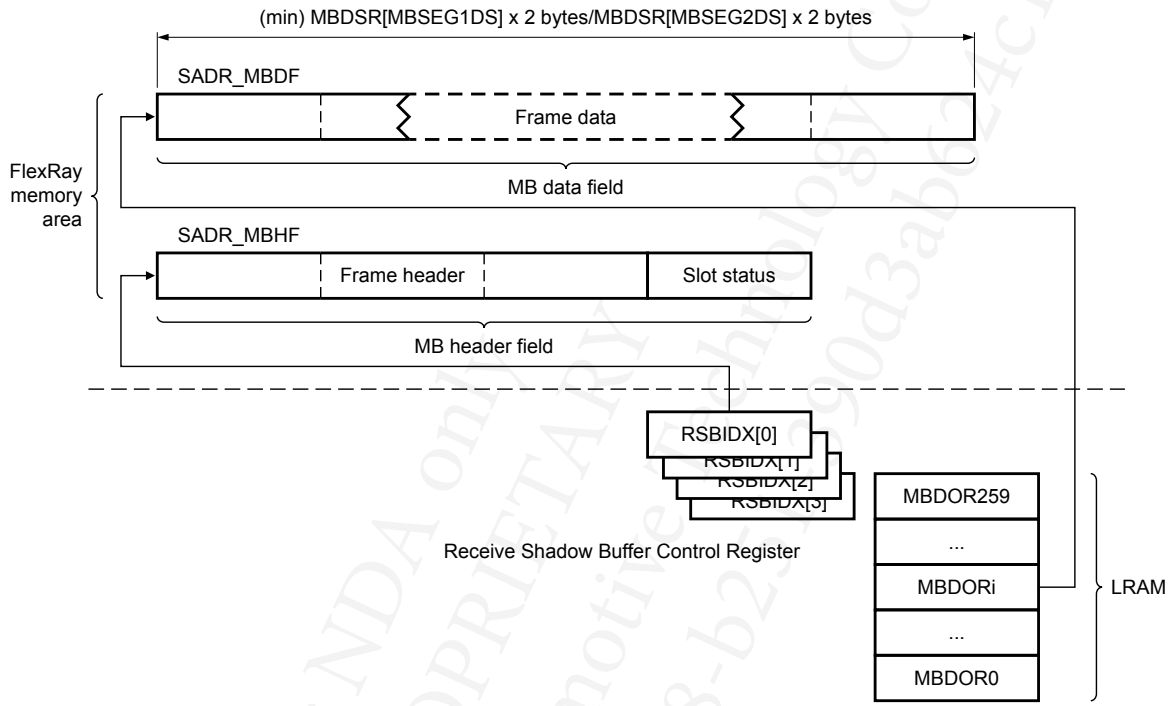

Figure 475. Receive shadow buffer structure

RSBIR[RSBIDX] establishes the connection between the receive shadow buffer control register and the physical MB for the selected receive shadow buffer. The start address SADR_MBHF of the related MB header field in the FlexRay memory area is determined according to this equation:

$$SADR\_MBHF = (RSBIR[RSBIDX] \times 8) + SMBA$$

Equation 3. Equation for SADR_MBHF

The length required for the MB data field depends on the MB segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first MB segment, the length must be the same as for the individual MBs assigned to the first MB segment. For the receive shadow buffers assigned to the second MB segment, the length must be the same as for the individual MBs assigned to the second MB segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index (RSBIR).

56.6.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical MBs in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The following figure shows the structure of a receive FIFO.

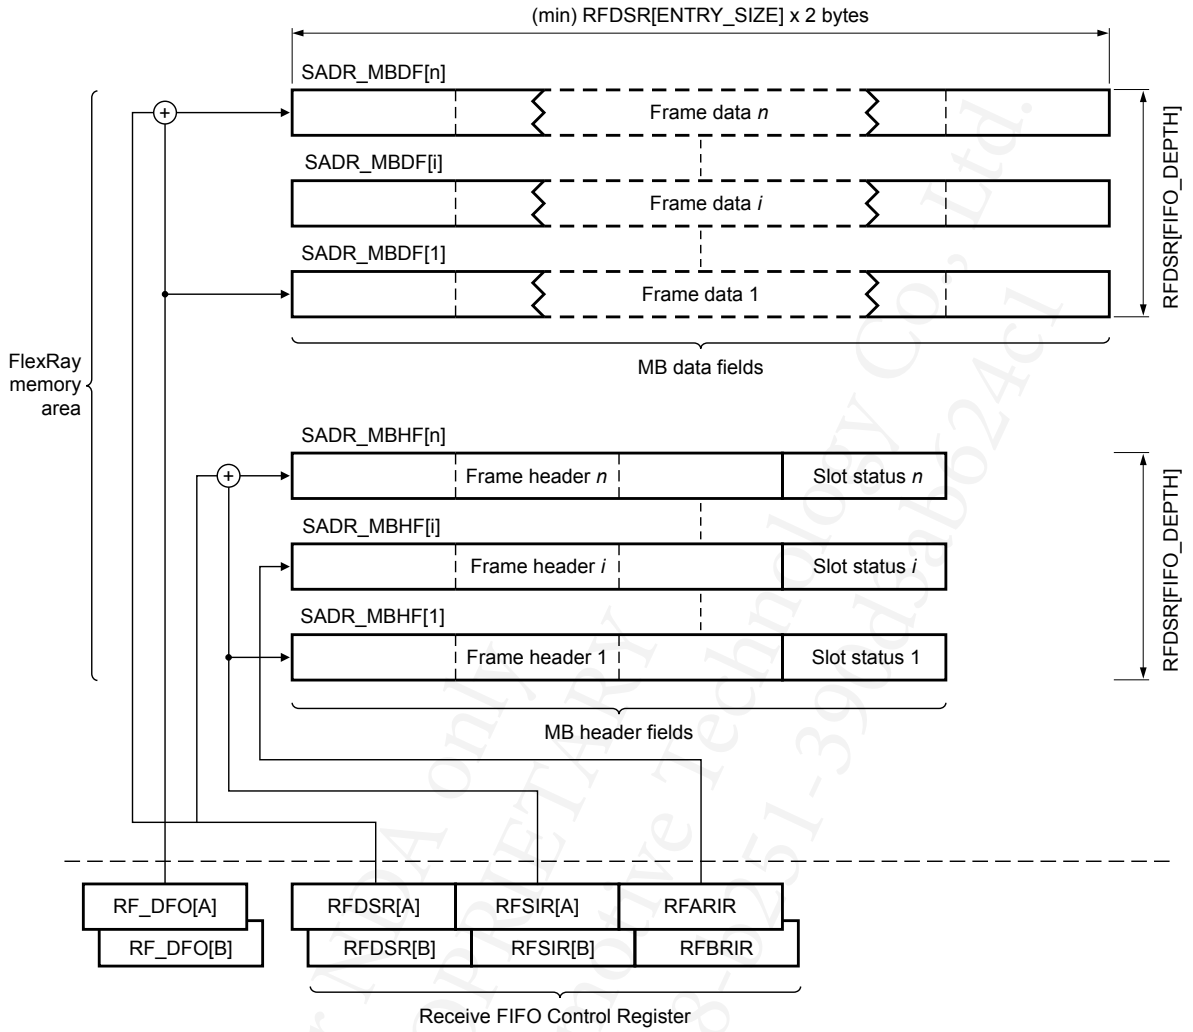

Figure 476. Receive FIFO structure

The following registers establish the connection between the receive FIFO control registers and the set of physical MBs:

- Receive FIFO Start Index (RFSIR)
- Receive FIFO Depth And Size (RFDSR)
- Receive FIFO A Read Index (RFARIR)
- Receive FIFO B Read Index (RFBRIR)

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register that MCR[FAM] selects.

Equation 4 determines the start byte address SADR_MBHF[1] of the first MB header field that belongs to the receive FIFO.

$$SADR\_MBHF[1] = (8 \times RFSIR[SIDX]) + SMBA$$

Equation 4. Equation for SADR_MBHF[1]

Equation 5 determines the start byte address SADR_MBHF[n] of the last MB header field that belongs to the receive FIFO in the FlexRay memory area.

$$SADR\_MBHF[n] = (8 \times (RFSIR[SIDX] + RFDSR[FIFO\_DEPTH])) + SMBA$$

Equation 5. Equation for SADR_MBHF[n]

Receive FIFO A Read Index (RFARIR) and Receive FIFO B Read Index (RFBRIR) provide:

- The required information to access the current entry of the FIFO
- The index of the physical MB belonging to the current entry

You must calculate the data field offset belonging to the current FIFO entry RF_DFO[X] using the current read index *i* according to Equation 6.

$$RF\_DFO[X] = FR\_RFSDOR[X] + (FR\_RFDSR[X][ENTRY\_SIZE] \times 2) \times i - FR\_RFSIR[X][SID])$$

Equation 6. Calculating data field offset

The current read index loops up starting at the number given in the RD[A/B]RDIDX register for the required number of entries.

See FIFO Update for details about updating the FIFO read pointer.

All MB header fields assigned to a receive FIFO are within a contiguous region defined by RFSIR[SIDX] and RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by RFDSR[FIFO_SIZE].

You must calculate the actual values of the data field offsets RF_DFO[A/B] according to Equation 6. They are not stored in a register.

56.6.3.4 MB configuration and control data

This section describes the configuration and control data for each MB type.

56.6.3.4.1 Individual MB configuration data

Before an individual MB can be used for transmission or reception, you must configure it. There is a set of common configuration parameters that applies to all individual MBs and a set of configuration parameters that applies to each MB individually.

56.6.3.4.1.1 Common configuration data

The set of common configuration data for individual MB is located in the following registers:

- MB Data Size (MBDSR): The MBSEG2DS and MBSEG1DS fields define the minimum length of the MB data field with respect to the MB segment.
- MB Segment Size and Utilization (MBSSUTR): The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual MBs and the number of individual MBs that are used. For more details, see Individual MB segments.

56.6.3.4.1.2 Specific configuration data

The set of MB-specific configuration data for individual MBs is located in the following registers:

- MB Configuration Control Status (MBCCSR0 - MBCCSR255): The MTD field configures the MB type.
- MB Cycle Counter Filter (MBCCFR0 - MBCCFR255):
  - The MTM, CHA, and CHB fields configure the transmission mode and the channel assignment.
  - The CCFE, CCFMSK, and CCFVAL fields configure the cycle counter filter.
- MB Frame ID (MBFIDR0 - MBFIDR255): For a transmit MB, the FID field determines the slot in which the message in this MB is transmitted.
- MB Index (MBIDXR0 - MBIDXR255): The MBIDX field provides the index of the MB header field of the physical MB that is currently associated with this MB.

56.6.3.5 Individual MB control data

During normal operation, each individual MB can be controlled by the control and trigger fields CMT, LCKT, EDT, and MBIE in MB Configuration Control Status (MBCCSR0 - MBCCSR255).

56.6.3.6 Receive shadow buffer configuration data

Before frame reception into the individual MB can be performed, you must configure the receive shadow buffers. Receive Shadow Buffer Index (RSBIR) provides the configuration data. For each receive shadow buffer, the application provides the MB header index. When the protocol is in the "POC:normal active" or "POC:normal passive" state, the receive shadow buffers are under full CC control.

56.6.3.7 Receive FIFO control and configuration data

This section describes the configuration and control data for the two receive FIFOs.

56.6.3.7.1 Receive FIFO configuration data

CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data in Receive FIFO Periodic Timer (RFPTR). Each FIFO has its own set of configuration data that is located in the following registers:

- Receive FIFO Watermark And Selection (RFWMSR)
- Receive FIFO Start Index (RFSIR)
- Receive FIFO Start Data Offset (RFSDOR)
- Receive FIFO Depth And Size (RFDSR)
- Receive FIFO Message ID Acceptance Filter Value (RFMIDAFVR)
- Receive FIFO Message ID Acceptance Filter Mask (RFMIDAFMR)
- Receive FIFO Frame ID Rejection Filter Value (RFFIDRFVR)
- Receive FIFO Frame ID Rejection Filter Mask (RFFIDRFMR)
- Receive FIFO Range Filter Configuration (RFRFCFR)

56.6.3.7.2 Receive FIFO control data

You can access the FIFOs at any time using the control fields in the following registers:

- Global Interrupt Flag And Enable (GIFER)
- Receive FIFO Fill Level and Pop Count (RFFLPCR)

56.6.3.7.3 Receive FIFO status data

The current status of the receive FIFO is provided in the following registers:

- Global Interrupt Flag And Enable (GIFER)
- Receive FIFO A Read Index (RFARIR)
- Receive FIFO B Read Index (RFBRIR)
- Receive FIFO Fill Level and Pop Count (RFFLPCR)

56.6.4 FlexRay memory area layout

CC supports a wide range of possible layouts for the FlexRay memory area. You can select two basic layout modes using MCR[FAM].

Preliminary under NDA only
COMPANY CONFIDENTIAL
Beijing CJJ Automotive Technology Co., Ltd.
ca2462e5-4821-4da8-b251-390d3b624c1

56.6.4.1 FlexRay memory area layout when MCR[FAM] = 0

The figure provided below shows an example layout for the FIFO address mode associated with MCR[FAM] = 0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- It is one contiguous region.
- Its size is a maximum of 64 KB.
- It starts at a 16-byte boundary.

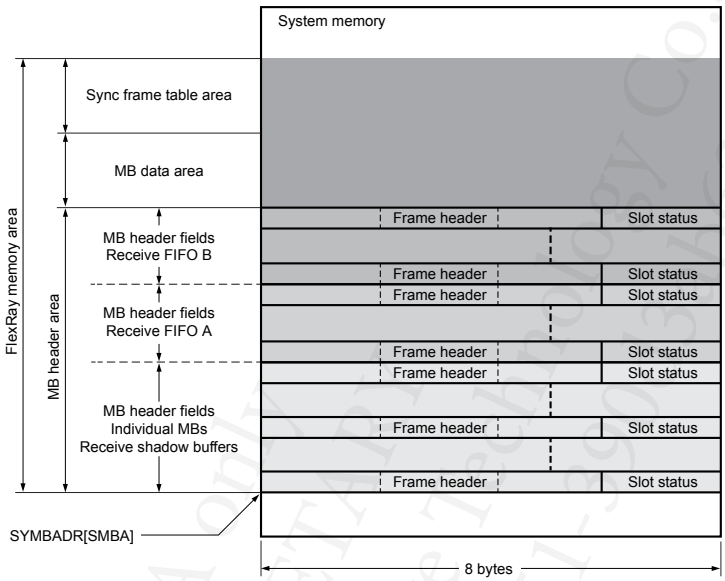

Figure 477. Example of FlexRay memory area layout when MCR[FAM] = 0

The FlexRay memory area contains three areas:

- MB header area
- MB data area
- Sync frame table area

56.6.4.2 FlexRay memory area layout when MCR[FAM] = 1

The following figure shows an example layout for the FIFO address mode associated with MCR[FAM] = 1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is a maximum of 64 KB.
- Each region starts on a 16-byte boundary.

Provided under NDA only
COMMERCIAL PROPRIETARY
Beijing CHY Automotive Technology Co., Ltd.
c8c462e5-4621-48a8-b251-9903b624c1

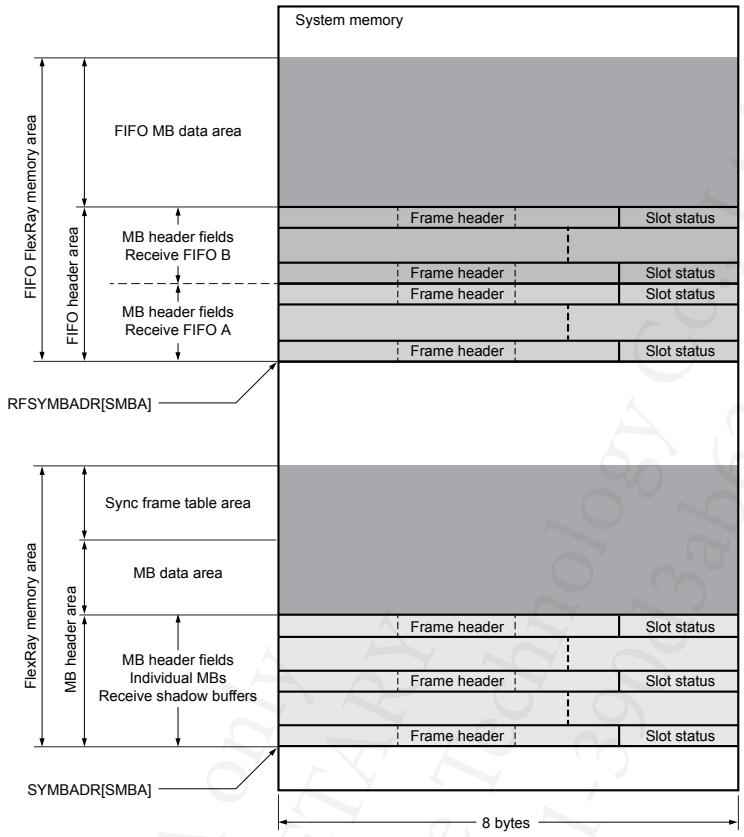

Figure 478. Example of FlexRay memory area layout when MCR[FAM] = 1

56.6.4.3 MB header area when MCR[FAM] = 0

The MB header area contains all MB header fields of the physical MBs for all MB types. The following rules apply to the MB header fields for the three type of MBs.

- The start byte address SADR_MBHF of each MB header field for individual MBs and receive shadow buffers must fulfill Equation 7:

$$SADR\_MBHF = (i \times 8) + SYMBADR[SMBA]\ ;\ (0 \le i \le 259)$$

Equation 7. Equation for SADR_MBHF of individual MBs and receive shadow buffers

- The start byte address SADR_MBHF of each MB header field for the FIFO must fulfill Equation 8:

$$SADR\_MBHF = (i \times 8) + SYMBADR[SMBA]\ ;\ (0 \le i \le 1023)$$

Equation 8. Equation for SADR_MBHF of the FIFO

- The MB header fields for each FIFO must be a contiguous area.

56.6.4.4 MB header area with MCR[FAM] = 1

The MB header area contains all MB header fields of the physical MBs for the individual MBs and receiver shadow buffers.

For the two type of MBs, the start address SADR_MBHF of each MB header field for individual MBs and receive shadow buffers must fulfill Equation 9:

$$SADR\_MBHF = (i \times 8) + SYMBADR[SMBA]\ ;\ (0 \le i \le 259)$$

Equation 9. Equation for SADR_MBHF

56.6.4.5 FIFO MB header area with MCR[FAM] = 1

The FIFO MB header area contains all MB header fields of the physical MBs for the FIFO. The following rules apply to the FIFO MB header fields:

- The start byte address SADR_MBHF of each MB header field for the FIFO must fulfill the following equation:

$$SADR\_MBHF = (i\gamma 8) + RFSYMBADR[SMBA];(0 \le i \le 1023)$$

Equation 10. Equation for SADR_MBHF

- The MB header fields for each FIFO must be a contiguous area.

56.6.4.6 MB data area

The MB data area contains all the MB data fields of the physical MBs. Each MB data field must start at a 16-bit boundary.

56.6.4.7 Sync frame table area

The sync frame table area provides a copy of the internal sync frame tables for application access. See Sync Frame ID and Sync Frame Deviation Tables for the description of the sync frame table area.

56.6.5 Physical MB description

This section provides a detailed description of the usage and the content of the two parts of a physical MB—the MB header field and the MB data field.

56.6.5.1 MB protection and data consistency

The physical MBs are located in the FlexRay memory area. CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical MBs, you must follow the write access scheme that is given in the description of each of the physical MB fields.

56.6.5.2 MB header field description

This section provides a detailed description of the usage and content of the MB header field. A description of the structure of the MB header fields is provided in MB header field. Each MB header field consists of two sections—frame header and slot status.

56.6.5.2.1 Frame header description

56.6.5.2.1.1 Frame header content

The semantic and content of the frame header section depends on the MB type.

For individual receive MBs and receive FIFOs, the frame header receives the frame header data of the first valid frame received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit MBs, you write the frame header of the to-be-transmitted frame to this location. The frame header is read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the MB header field for receive MBs and the receive FIFO is given in Table 468. A detailed description is given in Table 472.

Table 468. Frame header structure (receive MB and receive FIFO)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0h	R	PPI	NUF	SYF	SUF	FID										
2h	0	0	CYCCNT						0	PLDLEN						
4h	0	0	0	0	0	HDCRC										

The structure of the frame header in the MB header field for transmit MBs is given in Table 469. A detailed description is given in Table 473. The checks to be performed are described in Frame header checks.

Table 469. Frame header structure (transmit MB)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0h	R	PPI	NUF	SYF	SUF	FID (checked)										
2h			CYCCNT							PLDLEN (checked if not static)						
4h						HDCRC										

= Not used

The structure of the frame header in the MB header field for transmit MBs assigned to key slot is provided in Table 470.

Table 470. Frame header structure (transmit MB for key slot)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0h	R	PPI	NUF	SYF	SUF	FID										
2h			CYCCNT							PLDLEN						
4h						HDCRC										

= Not used

56.6.5.2.1.2 Frame header access

The frame header is located in the FlexRay memory area. To ensure data consistency, you must follow the write access scheme described below.

For receive MBs, receive shadow buffers, and receive FIFOs, you must not write to the frame header field.

For transmit MBs, you must follow the write access restrictions given in the following table. This table shows the condition under which you can write to the frame header entries without corrupting the FlexRay message transmission.

Table 471. Frame header write access constraints (transmit MB)

Field	Static segment	Dynamic segment
FID	POC:config or MB_DIS	

Table continues on the next page...

Table 471. Frame header write access constraints (transmit MB) (continued)

Field	Static segment	Dynamic segment
PPI, PLDLEN, HDCRC	POC:config or MB_DIS	
		MB_LCK

56.6.5.2.1.3 Frame header checks

As shown in Table 469 and Table 470, not all fields in the MB frame header are used for transmission. Some fields in the MB frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that are performed are described below.

For MBs assigned to the key slot, no checks are performed.

The value of the FID field must be equal to the value of the corresponding MB Frame ID (MBFIDR0 - MBFIDR255). If CC detects a mismatch while transmitting the frame header, it causes CHIERFR[FID_EF] to become 1. The value of the FID field is ignored and replaced by the value provided in MB Frame ID (MBFIDR0 - MBFIDR255).

For transmit MBs assigned to the static segment, the PLDLEN value must be equal to PCR19[payload_length_static]. If this is not fulfilled, CHIERFR[SPL_EF] becomes 1 when the MB is under transmission. A syntactically and semantically correct frame is generated with PCR19[payload_length_static] payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit MBs assigned to the dynamic segment, the PLDLEN value must be less than or equal to PCR24[max_payload_length_dynamic]. If this is not fulfilled, CHIERFR[DPL_EF] becomes 1 when the MB is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 472. Frame header field descriptions (receive MB and receive FIFO)

Field	Description
R	Reserved field—This is the value of the reserved field of the received frame stored in the MB.
PPI	Payload preamble indicator—This is the value of the payload preamble indicator of the received frame stored in the MB.
NUF	Null frame indicator—This is the value of the null frame indicator of the received frame stored in the MB.
SYF	Sync frame indicator—This is the value of the sync frame indicator of the received frame stored in the MB.
SUF	Startup frame indicator—This is the value of the startup frame indicator of the received frame stored in the MB.
FID	Frame ID—This is the value of the frame ID field of the received frame stored in the MB.
CYCCNT	Cycle count—This is the number of the communication cycle in which the frame stored in the MB was received.
PLDLEN	Payload length—This is the value of the payload length field of the received frame stored in the MB.
HDCRC	Header CRC—This is the value of the header CRC field of the received frame stored in the MB.

Table 473. Frame header field descriptions (transmit MB)

Field	Description
R	Reserved field—Not used; the value of the reserved field is generated internally according to *FlexRay Communications System Protocol Specification, Version* 2.1 Rev A.
PPI	Payload preamble indicator—This field provides the value of the payload preamble indicator for the frame transmitted from the MB.
NUF	Null frame indicator—Not used; the value of the null frame indicator is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SYF	Sync frame indicator—Not used; the value of the sync frame indicator is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SUF	Startup frame indicator—Not used; the value of the startup frame indicator is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
FID	Frame ID—This field is checked as described in Frame Header Checks.
CYCCNT	Cycle count—Not used; the value of the transmitted cycle count field is taken from the internal communication cycle counter.
PLDLEN	Payload length—This field is checked and used as described in Frame Header Checks.
HDCRC	Header CRC—This field provides the value of the header CRC field for the frame transmitted from the MB.

56.6.5.2.2 Slot status description

The slot status is a read-only structure for you and a write-only structure for CC. The meaning and content of the slot status in the MB header field depends on the MB type.

56.6.5.2.2.1 Slot status description for the receive MBs and receive FIFOs

The content of the slot status structure for receive MBs depends on the MB type and on the channel assignment for individual receive MBs as given in Table 474.

Table 474. Receive MB slot status content

Receive MB type	MBCCFR*n*[CHA]	MBCCFR*n*[CHB]	Slot status content
Individual receive MB assigned to both channels	1	1	See Table 475.
Individual receive MB assigned to channel A	1	0	See Table 476.
Individual receive MB assigned to channel B	0	1	See Table 477.
Receive FIFO channel A MB	—	—	See Table 476.
Receive FIFO channel B MB	—	—	See Table 477.

Table 478 provides the meaning of the fields in the slot status structure.

Table 475. Receive MB slot status structure (ChAB)

56.6.5.2.2.2 Slot status description for transmit MBs

Only the TCA and TCB status fields are directly related to the transmission process. All other status fields in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit MBs depends on the channel assignment as given in Table 479.

Table 479. Transmit MB slot status content

Transmit MB type	MBCCFR*n*[CHA]	MBCCFR*n*[CHB]	Slot status content
Individual transmit MB assigned to both channels	1	1	See Table 480.
Individual transmit MB assigned to channel A	1	0	See Table 481.
Individual transmit MB assigned to channel B MBCCFRn[CHA]=0 and MBCCFRn[CHB]=1	0	1	See Table 482.

Table 483 provides the meaning of the fields in the slot status structure.

56.6.5.3 MB data field description

The MB data field is used to store the payload data—or a part of that data—of the frame that you want to transmit or receive on the FlexRay bus. The minimum required length of this field depends on the MB type that the physical MB is assigned to and is given in Table 484. Table 485 shows the structure of the MB data field.

Table 484. MB data field minimum length

Physical MB assigned to	Minimum length defined by
Individual MB in segment 1	MBDSR[MBSEG1DS]
Receive shadow buffer in segment 1	
Individual MB in segment 2	MBDSR[MBSEG2DS]
Receive shadow buffer in segment 2	
Receive FIFO for channel A	RFDSR[ENTRY_SIZE] (RFWMSR[SEL] = 0)
Receive FIFO for channel B	RFDSR[ENTRY_SIZE] (RFWMSR[SEL] = 1)

NOTE

CC does not access any locations outside the MB data field boundaries given in Table 484.

Table 485. MB data field structure

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0h	DATA0 / MID0 / NMV0								DATA1 / MID1 / NMV1							
2h	DATA2 / NMV2								DATA3 / NMV3							
…	…								…							

Table continues on the next page...

Table 485. MB data field structure (continued)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
(N-2)h	DATA N-2								DATA N-1							

The MB data field is located in the FlexRay memory area; thus, CC has no means to control your write access to the field. To ensure data consistency, you must follow a write and read access scheme.

56.6.5.3.1 MB data field read access

For transmit MBs, CC does not modify the content of the MB data field. Thus you can read back the data at any time without any impact on data consistency.

For receive MBs, you must lock the related receive MB and retrieve the MB header index from MB Index (MBIDXR0 - MBIDXR255). While the MB is locked, CC does not update the MB data field.

For receive FIFOs, you can read the MB indicated by Receive FIFO A Read Index (RFARIR) or Receive FIFO B Read Index (RFBRIR) when the related fill levels in Receive FIFO Fill Level and Pop Count (RFFLPCR) indicate a non-empty FIFO.

56.6.5.3.2 MB data field write access

For receive MBs, receive shadow buffers, and receive FIFOs, you must not write to the MB data field.

For transmit MBs, you must follow the write access restrictions provided in Table 486.

Table 486. Frame data write access constraints

Field	CC/MB state
DATA, MID, NMV	POC:config or MB_DIS or MB_LCK

Table 487. Frame data field descriptions

Field	Description
DATA 0–DATA N-1	Message Data Provides the message data received or to be transmitted. For receive MBs and receive FIFOs, this field provides the message data received for this MB. For transmit MBs, the field provides the message data to be transmitted.
MID 0–1	Message Identifier If the MB frame header's PPI field is 1, MID *n* holds the message ID of a dynamic frame located in the MB. The receive FIFO filter uses the received message ID for message ID filtering.
NMV 0–11	NMV If the MB frame header's PPI field is 1, NMV *n* holds the NMV of a static frame located in the MB. **NOTE** The MID and NMV bytes replace the corresponding DATA bytes.

56.6.6 Individual MB functional description

CC provides these basic types of individual MBs:

- Transmit MBs

- Receive MBs

Before an individual MB can be used, you must configure it. After the initial configuration, the MB can be reconfigured later. Individual MB configuration data provides the set of configuration data for individual MBs.

56.6.6.1 Individual MB configuration

The individual MB configuration consists of two steps:

1. Allocation of the required amount of memory for the FlexRay memory area
2. Programming of the MB configuration registers (described in the following subsections)

56.6.6.1.1 Common configuration data

One part of the MB configuration data is common to all individual MBs and the receive shadow buffers. This data can only be set when the protocol is in the POC:config state.

Table 488. Common configuration data

To configure this:	Do this:
The number of used MBs	Write the MB number of the last-used MB to MBSSUTR[LAST_MB_UTIL].
The size of the two segments of individual MBs	Write the MB number of the last MB in the first segment to MBSSUTR[LAST_MB_SEG1].
The length of the MB data fields for both MB segments	Write to MBDSR[MBSEG1DS] and MBDSR[MBSEG2DS].
The receive shadow buffers (depending on the current CC receive functionality)	Write to Receive Shadow Buffer Index (RSBIR) for each segment and for each channel with at least one individual receive MB assigned.

56.6.6.1.2 Specific configuration data

The second part of the MB configuration data is specific for each MB.

This data can be changed only when either of the following is true:

- The protocol is in the POC:config state.
- The MB is disabled—that is, MBCCSR*n*[EDS] = 0.

The individual MB type is defined by MBCCSR*n*[MTD] as given in the following table.

Table 489. Individual MB types

MBCCSR*n*[MTD]	Individual MB description
0	Receive MB
1	Transmit MB

The MB-specific configuration data is:

- MBCCSR*n*[MTD]
- All fields in MB Cycle Counter Filter (MBCCFR0 - MBCCFR255)
- All fields in MB Frame ID (MBFIDR0 - MBFIDR255)
- All fields in MB Index (MBIDXR0 - MBIDXR255)

The meaning of the specific configuration data depends on the MB type, as described in Transmit MBs and Receive MBs.

56.6.6.2 Transmit MBs

The section provides a detailed description of the functionality of single-buffered transmit MBs.

You use a transmit MB to provide message data to CC that is transmitted over the FlexRay bus. CC uses the transmit MBs to provide information about the transmission process and status information about the slot in which the message was transmitted.

The individual MB with MB number n is configured to be a transmit MB by the following settings:

- MBCCSR*n*[MBT] = 0 (single-buffered MB)
- MBCCSR*n*[MDT] = 1 (transmit MB)

56.6.6.2.1 Access regions

Both you and CC have access to certain MB fields. To ensure data consistency, an MB locking scheme controls the access to the MB data, control, and status fields. The access regions for transmit MBs are depicted in the following figure. A description of the regions is given in Table 491. If a region is active as indicated in Table 492, the access scheme given for that region applies to the MB.

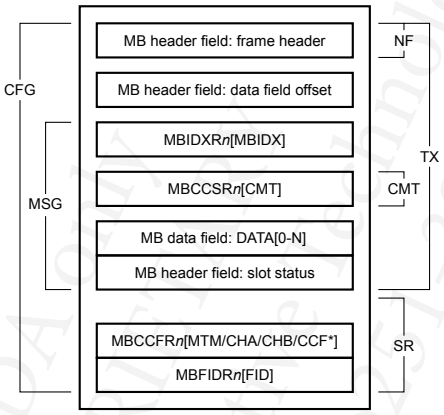

Figure 479. Transmit MB access regions

Table 490. Transmit MB access region description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	MB configuration
MSG	Read/write	—	Message data and slot status access
NF	—	Read-only	Message header access for null frame transmission
TX	—	Read/write	Message transmission and slot status update
CM	—	Read-only	MB validation
SR	—	Read-only	MB search

The EDT and LCKT trigger fields, and the MBIE interrupt-enable field, in MB Configuration Control Status (MBCCSR0 - MBCCSR255) are not under access control and can be accessed from the application at any time. The EDS and LCKS status fields are not under access control and can be accessed from CC at any time.

MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and CC at any time. CC clear access has higher priority.

CC restricts its access to the regions depending on the current state of the MB. You must comply with these restrictions to ensure data consistency. The transmit MB states are given in Figure 480. A description of the states is given in Table 491, which also provides the access scheme for the access regions.

The EDS and LCKS status fields in MB Configuration Control Status (MBCCSR0 - MBCCSR255) provide you with the required MB status information. The internal status information is not visible to you.

56.6.6.2.2 MB states

This section describes the transmit MB states and provides a state diagram.

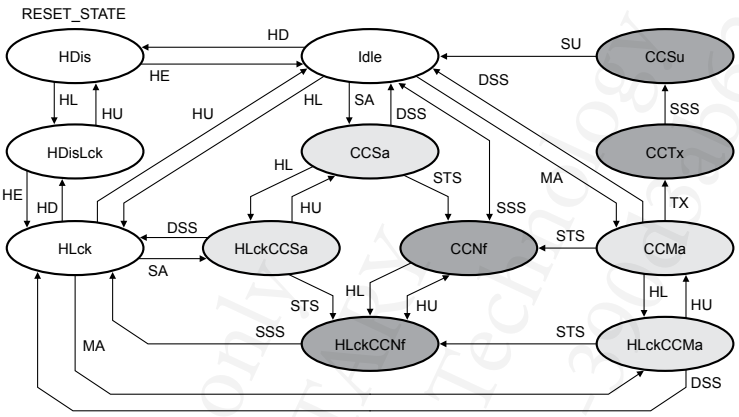

Figure 480. Transmit MB states

Table 491. Transmit MB state description

State	MBCCSRn		Access region		Description
	EDS	LCKS	Application	Module	
Idle	1	0	—	CM, SR	Idle MB is idle. Included in MB search.
HDis	0	0	CFG	—	Disabled MB under configuration. Excluded from MB search.
HDisLck	0	1	CFG	—	Disabled and locked MB under configuration. Excluded from MB search.
HLck	1	1	MSG	SR	Locked Applications access to data, control, and status. Included in MB search.
CCSa	1	0	—	—	Slot assigned MB assigned to next static slot. Ready for null frame transmission.
HLckCCSa	1	1	MSG	—	Locked and slot assigned

Table continues on the next page...

Table 491. Transmit MB state description (continued)

State	MBCCSRn		Access region		Description
	EDS	LCKS	Application	Module	
					Applications access to data, control, and status. MB assigned to next static slot.
CCNf	1	0	—	NF	Null frame transmission Header is used for null frame transmission.
HLckCCNf	1	1	MSG	NF	Locked and null frame transmission Applications access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	—	CM	Message available MB is assigned to next slot and cycle counter filter matches.
HLckCCMa	1	1	MSG	—	Locked and message available Applications access to data, control, and status. MB is assigned to next slot and cycle counter filter matches.
CCTx	1	0	—	TX	Message transmission MB data transmit. Payload data from buffer transmitted.
CCSu	1	0	—	TX	Status update MB status update. Update of status flags, the slot status field, and the header index.

56.6.6.2.3 MB transitions

This section discusses:

- Application transitions
- Module transitions
- Transition priorities

56.6.6.2.3.1 Application transitions

You can trigger the application transitions using the commands described in Table 492. You issue the commands by writing to MB Configuration Control Status (MBCCSR0 - MBCCSR255). Only one command can be issued with one write access. Each command executes immediately. If the command is ignored, you must issue it again.

56.6.6.2.3.1.1 MB enable and disable

You issue the enable and disable commands by writing 1 to MBCCSR*n*[EDT]. The transition that each of these commands triggers depends on the current value of MBCCSR*n*[EDS].

If the command triggers the disable transition HD and the MB is in one of the states:

- CCSa
- HLckCCSa

- CCMa
- HLckCCMa
- CCNf
- HLckCCNf
- CCTx

then the disable transition has no effect (the command is ignored) and the MB state does not change. You do not receive any notification.

NOTE

Do not disable an MB when FlexRay is in the STARTUP protocol state.

56.6.6.2.3.1.2 MB lock and unlock

You issue the lock and unlock commands by writing 1 to MBCCSR*n*[LCKT]. The transition that each of these commands triggers depends on the current value of MBCCSR*n*[LCKS]. If the command triggers the HL lock transition and the MB is in the CCTx state, the lock transition has no effect (command is ignored) and the MB state does not change. In this case, CHIERFR[LCK_EF] becomes 1.

Table 492. Transmit MB application transitions

Transition	Command	Condition	Description
HE	Write 1 to MBCCSR*n*[EDT]	MBCCSR*n*[EDS] = 0	Application triggers MB enable.
HD		MBCCSR*n*[EDS] = 1	Application triggers MB disable.
HL	Write 1 to MBCCSR*n*[LCKT]	MBCCSR*n*[LCKS] = 0	Application triggers MB lock.
HU		MBCCSR*n*[LCKS] = 1	Application triggers MB unlock.

56.6.6.2.3.2 Module transitions

The following table describes the module transitions that CC can trigger. Each transition is triggered for certain MBs when the related condition is fulfilled.

Table 493. Transmit MB module transitions

Transition	Condition	Description
SA	Slot match and static slot	Slot assigned MB is assigned to the next static slot.
MA	Slot match and cycle counter match	Message available MB is assigned to the next slot and cycle counter filter matches.
TX	Slot start and MBCCSR*n*[CMT] = 1	Transmission slot start Slot start and MBCCSR*n*[CMT] = 1. In case of a dynamic slot, pLatestTx is not exceeded.
SU	Status updated	Status updated Slot status field and MB status flags updated. Interrupt flag becomes 1.

Table continues on the next page...

Table 493. Transmit MB module transitions (continued)

Transition	Condition	Description
STS	Static slot start	Static slot start
DSS	Dynamic slot start, symbol window start, or NIT start	Dynamic slot or segment start
SSS	Slot start, symbol window start, or NIT start	Slot or segment start

56.6.6.2.3.3 Transition priorities

You can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of the following table, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and subsequently the module transition to the intermediately reached state. For example, if all of the following is true:

- The MB is in the HLck state
- Your application unlocks the MB by using the HU transition
- The module triggers the slot assigned transition SA

then the intermediate state is Idle and the resulting state is CCSa.

The second part of the following table gives the priorities among the module transitions.

Table 494. Transmit MB transition priorities

State	Priorities	Description
Module vs. application		
Idle, HLck	SA > HD	Slot assigned > MB disable
	MA > HD	Message available > MB disable
CCMa	TX > HL	Transmission start > MB lock
Module internal		
Idle, HLck	MA > SA	Message available > slot assigned
CCMa	TX > STS	Transmission slot start > static slot start
	TX > DSS	Transmission slot start > dynamic slot start

56.6.6.2.4 Transmit message setup

To transmit a message over the FlexRay bus, you:

- Write the message data into the MB data field
- Write 1 to MBCCSR*n*[CMT]

Individual MBs describes the physical access to the MB data field.

As indicated by Table 483, you must write to the MB data field and change MBCCSR*n*[CMT] only if the transmit MB is in one of these states:

- HDis

- HDisLck
- HLck
- HLckCCSa
- HLckCCMa
- HLckCCMa

You can change the MB state if you issue the appropriate commands shown in Table 483. The EDS and LCKS fields of MB Configuration Control Status (MBCCSR0 - MBCCSR255) indicate the state change.

If the transmit MB enters one of these states:

- HDis
- HDisLck
- HLck
- HLckCCSa
- HLckCCMa

then MBCCSR*n*[DVAL] becomes 0.

56.6.6.2.5 Message transmission

As a result of the MB search described in Individual MB search, CC triggers the message-available transition (MA) for up to two transmit MBs. This changes the MB state from Idle to CCMa and the MBs can be used for message transmission in the next slot.

CC transmits a message from an MB if both of the following conditions are fulfilled at the start of the transmission slot:

- The MB is in the message available state CCMa
- The message data is still valid—that is, MBCCSR*n*[CMT] = 1

In this case, CC triggers the TX transition and changes the MB state to CCTx.

Figure 481 shows transmit MB timing and state changes. In this example:

- The MB with MB number n is idle at the start of the search slot.
- The MB with MB number n matches the slot and cycle number of the next slot.
- MB data is valid—that is, MBCCSR*n*[CMT] = 1.

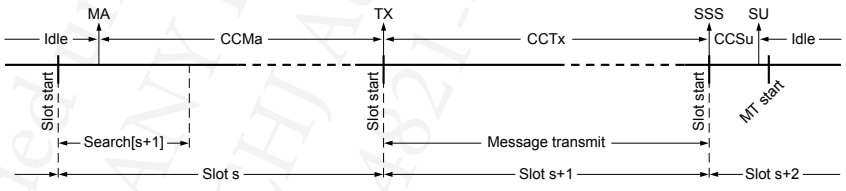

Figure 481. Message transmission timing

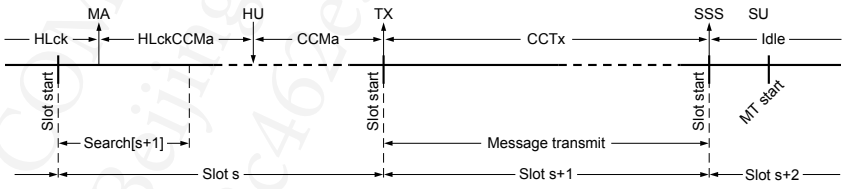

Figure 482. Message transmission from HLck state with unlock

The following items determine the amount of message data read from the FlexRay memory area and transferred to the FlexRay bus:

- The MB segment that the MB is assigned to, as defined by MB Segment Size and Utilization (MBSSUTR)
- The MB data field size, as defined by the related field of MB Data Size (MBDSR)
- The value of the PLDLEN field in the MB header field, as described in Frame header description

If an MB is assigned to MB segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes are read from the MB data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN ≤ MBSEG1DS, CC reads and transfers 2 × PLDLEN bytes. The same is true for segment 2 and MBSEG2DS.

56.6.6.2.6 Null frame transmission

A static slot with slot number S is assigned to CC for channel A if at least one transmit MB is configured with MBFIDR*n*[FID] = S and MBCCFR*n*[CHA] = 1. A null frame is transmitted in the static slot S on channel A if both of the following are true:

- This slot is assigned to CC for channel A.
- One of the following is true for all transmit MBs with MBFIDR*n*[FID] = S and MBCCFR*n*[CHA] = 1:
  - Not committed (that is, MBCCSR*n*[CMT] = 0)
  - You locked them (that is, MBCCSR*n*[LCKS] = 1)
  - The cycle counter filter is enabled and does not match

Additionally, you can write 0 to the commit field of an MB that is in the CCMa state, which is called "uncommit" or "transmit abort". This MB is used for null frame transmission.

As a result of the MB search described in Individual MB search, CC triggers the slot assigned transition SA for up to two transmit MBs if at least one of the conditions mentioned above is fulfilled for these MBs. The transition SA changes the MB states from either Idle to CCSa or from HLck to HLckCCSa. In each case, these MBs are used for null frame transmission in the next slot.

Figure 483 shows an MB timing and state-change diagram for null frame transmission from Idle state.

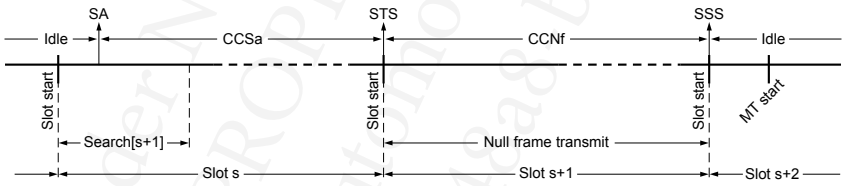

Figure 483. Null frame transmission from Idle state

Figure 484 shows an MB timing and state-change diagram for null frame transmission from HLck state.

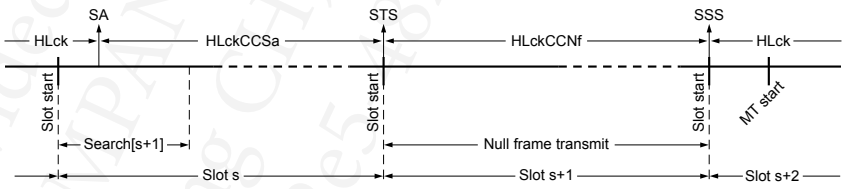

Figure 484. Null frame transmission from HLck state

If a transmit MB is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the MB is unlocked or committed before the transmission slot starts. Figure 485 shows a transmit MB timing and state-change diagram for null frame transmission for this case.

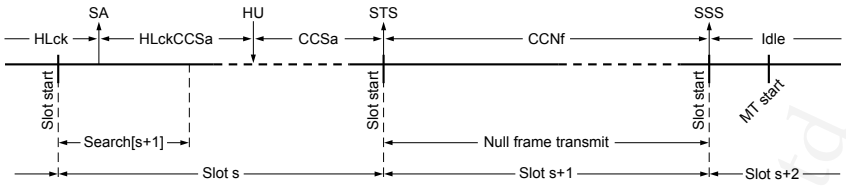

Figure 485. Null frame transmission from HLck state with unlock

Because the null frame transmission does not use the MB data, you can lock and unlock the MB during null frame transmission. Figure 486 shows a transmit MB timing and state-change diagram for null frame transmission for this case.

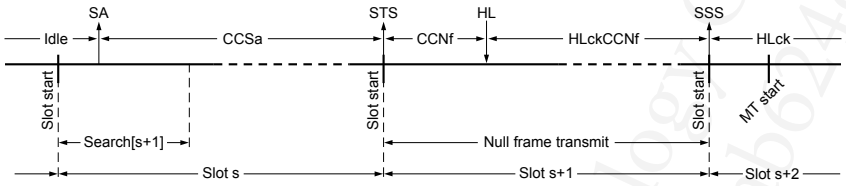

Figure 486. Null frame transmission from Idle state with locking

56.6.6.2.7 MB status update

After the end of each slot, PE generates the slot status vector. Depending on the status, the transmitted frame type, and the amount of transmitted data, the MB status is updated.

56.6.6.2.7.1 MB status update after complete message transmission

The term "complete message transmission" refers to the fact that all payload data stored in the MB were sent to the FlexRay bus. In this case, CC updates the MB slot status field and triggers the status-updated transition SU. With the SU transition, CC sets the MB interrupt flag (MBCCSR*n*[MBIF]) to indicate successful message transmission.

Depending on MBCCFR*n*[MTM], CC changes the commit flag (MBCCSR*n*[CMT]) and the valid flag (MBCCSR*n*[DVAL]). If MBCCFR*n*[MTM] = 0, the MB is in Event Transmission mode. In this case, each committed message is transmitted only one time. The commit flag is cleared with the SU transition. If MBCCFR*n*[MTM] = 1, the MB is in State Transmission mode. In this case, each committed message is transmitted as long as you provide new data or lock the MBs. CC does not clear the commit flag at the end of transmission and sets the valid flag to indicate that the message is transmitted again.

56.6.6.2.7.2 MB status update after incomplete message transmission

The term "incomplete message transmission" refers to the fact that not all payload data that must be transmitted was sent to the FlexRay bus. The following regular conditions in the dynamic segment may cause incomplete message transmission:

- The transmission slot starts in a minislot with a minislot number greater than pLatestTx.
- The transmission slot never existed in the dynamic segment.

If either of these conditions occur, the MB status does not change with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, CC sets the PIFR1[PECF_IF].

56.6.6.2.7.3 MB status update after null frame transmission

After the transmission of a null frame, the status of the MB that was used for the null frame transmission does not change. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

56.6.6.3 Receive MBs

This section provides a detailed description of the functionality of the receive MBs. If you use receive MBs, you must configure the related receive shadow buffer as described in Receive shadow buffers.

You use a receive MB to receive a message from the FlexRay Bus based on individual filter criteria. CC uses the receive MB to provide the following data to you:

- Message data received
- Information about the reception process
- Status information about the slot in which the message was received

An individual MB with number *n* is configured as a receive MB by the following configuration settings shown in Equation 11:

$$MBCCSRn[MTD] = 0(receivemessagebuffer)$$

Equation 11. Configuration equation

Both you and CC have access to certain MB fields, To ensure data consistency, CC implements an MB locking scheme that controls the access to the MB data, control, and status fields.

Figure 487 shows the access regions for receive MBs. Table 495 describes the regions. If a region is active as indicated in Table 496, the access scheme given for that region applies to the MB.

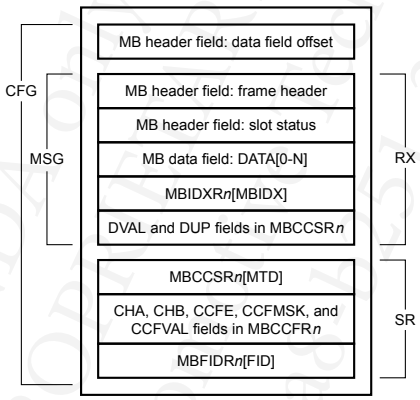

Figure 487. Receive MB access regions

Table 495. Receive MB access region description

Region	Access from		Region used for
	Application	CC	
CFG	Read and write	—	MB configuration, message data, and status access
MSG	Read and write	—	Message data, header, and status access
RX	—	Write-only	Message reception and status update
SR	—	Read-only	MB search data

In MB Configuration Control Status (MBCCSR0 - MBCCSR255):

- The EDT, LCKT, and MBIE fields in are not under access control and can be accessed from the application at any time.

- The EDS and LCKS fields are not under access control and can be accessed from CC at any time. They provide you with the required status information. The internal status information is not visible to you.
- The MBIF field is not under access control and can be accessed from the application and CC at any time. CC set access has higher priority.

CC restricts its access to the regions depending on the current MB state. You must comply with these restrictions to ensure data consistency.

Figure 488 shows the receive MB states. Table 491 describes the MB states and provides the access scheme for the access regions.

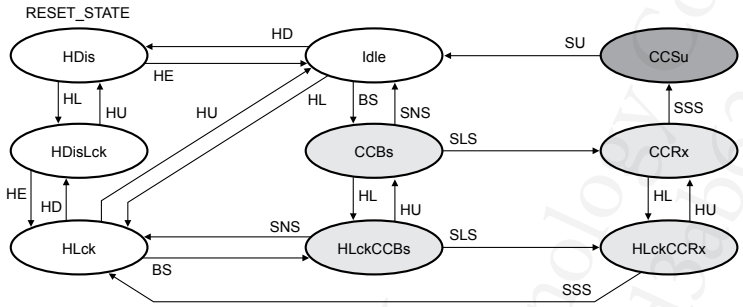

Figure 488. Receive MB states

Table 496. Receive MB states and access

State	MBCCSR*n*		Access from		Description
	EDS	LCKS	Application	Module	
Idle	1	0	—	SR	Idle MB is idle. Included in MB search.
HDis	0	0	CFG	—	Disabled MB under configuration. Excluded from MB search.
HDisLck	0	1	CFG	—	Disabled And Locked MB under configuration. Excluded from MB search.
HLck	1	1	MSG	—	Locked Application access to data, control, and status. Included in MB search.
CCBs	1	0	—	—	Buffer Subscribed MB subscribed to reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	—	Locked And Buffer Subscribed Application access to data, control, and status. MB subscribed to reception.
CCRx	1	0	—	—	Message Receive

Table continues on the next page...

Table 496. Receive MB states and access (continued)

State	MBCCSR*n*		Access from		Description
	EDS	LCKS	Application	Module	
					Message data received in the related shadow buffer.
HLckCCRx	1	1	MSG	—	Locked And Message Receive Application access to data, control, and status. Message data received in the related shadow buffer.
CCSu	1	0	—	RX	Status Update MB status update. Update of status flags, the slot status field, and the header index.

56.6.6.3.1 MB transitions

56.6.6.3.1.1 Application transitions

The application transitions that can be triggered by the application using the commands described in Table 492. You issue the commands by writing to MB Configuration Control Status (MBCCSR0 - MBCCSR255). One write access can issue only one command. Each command executes immediately. If the command is ignored, you must issue it again.

56.6.6.3.1.2 MB enable and disable

You issue the enable and disable commands by writing 1 to MBCCSR*n*[EDT]. The transition that each of these commands triggers depends on the current value of MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the MB is in the CCBs, HLckCCBs, or CCRx state, the disable transition has no effect (the command is ignored) and the MB state does not change. You do not receive any notification.

56.6.6.3.1.3 MB lock and unlock

You issue the lock and unlock commands by writing 1 to MBCCSR*n*[LCKT]. The transition that each of these commands triggers depends on the current value of the status bit MBCCSR*n*[LCKS]. If the command triggers the HL lock transition HL while the MB is in the CCRx state, the lock transition has no effect (the command is ignored) and the MB state does not change. In this case, CC sets the MB lock error flag (CHIERFR[LCK_EF]).

Table 497. Receive MB application transitions

Transition	Host command	Condition	Description
HE	Write 1 to MBCCSR*n*[EDT]	MBCCSR*n*[EDS] = 0	Application triggers MB enable.
HD		MBCCSR*n*[EDS] = 1	Application triggers MB disable.
HL	Write 1 to MBCCSR*n*[LCKT]	MBCCSR*n*[LCKS] = 0	Application triggers MB lock.
HU		MBCCSR*n*[LCKS] = 1	Application triggers MB unlock.

56.6.6.3.1.4 Module transitions

The following table describes the module transitions that CC can trigger. Each transition triggers for certain MBs when the related condition is fulfilled.

Table 498. Receive MB module transitions

Transition	Condition	Description
BS	Slot and CycleCounter match	Buffer Subscribed The MB filter matches the next slot and cycle.
SLS	Slot start	Slot Start Start of either a static or dynamic slot.
SNS	Start of symbol window or NIT	Symbol Window Or NIT Start Start of either the symbol window or NIT
SSS	Start of slot, symbol window, or NIT	Slot Or Segment Start Start of static slot, dynamic slot, symbol window, or NIT
SU	Status updated	Status Updated Slot Status field, MB status flags, and header index updated. Interrupt flag set.

56.6.6.3.1.5 Transition priorities

You can trigger only one transition at a time. You do not need to specify priorities among them.

As shown in the following table, the module transitions have a higher priority than the application transitions. For all states except CCRx, a module transition and the application lock/unlock transition HL/HU and can execute at the same time. You reach the resulting state by applying the module transition and the application transition, in that order, to the intermediately-reached state. For example, if the MB is in the Buffer Subscribed CCBs state and the module triggers the slot start transition SLS at the same time as the application locks the MB by the HL transition, the intermediate state is CCRx and the resulting state is locked Buffer Subscribed state HLckCCRx.

Table 499. Receive MB transition priorities

State	Priorities	Description
Module vs. application		
Idle	BS > HD	Buffer Subscribed > MB Disable
HLck	BS > HD	Buffer Subscribed > MB Disable
CCRx	SSS > HL	Slot or Segment Start > MB Lock

56.6.6.3.2 Message reception

As a result of the MB search, CC changes the state of up to two enabled receive MBs from Idle or HLck state to either CCBs or HLckCCBs state by triggering the BS transition.

If the receive MBs for the next slot are assigned to both channels, then CC changes at most one receive MB to a buffer-subscribed state.

If more than one matching MB is assigned to a certain channel, then only the MB with the lowest MB number is in one of the states mentioned above.

With the start of the next static or dynamic slot, the module triggers the SLS transition. This changes the state of the subscribed receive MBs from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data is written into the shadow buffers. For details on receive shadow buffers, see Receive shadow buffer concept. The data and status of the receive MBs that are in the CCRx or HLckCCRx states are not modified in the reception slot.

56.6.6.3.3 MB update

CC triggers the SSS transition at the start of any of these:

- Next static slot
- Next dynamic slot
- The symbol window
- NIT

This transition changes the state of the receiving receive MBs from either CCRx to CCSu or from HLckCCRx to HLck.

If an MB is in the HLckCCRx state, no update is performed. The received data is lost. CC indicates this by setting the FRLA_EF or FRLB_EF flags in CHI Error Flag (CHIERFR).

If an MB was in the CCRx state, it is now in the CCSu state. CC updates the MB after evaluating the PE-provided slot status. The MB update depends on the slot-status bits and the segment the MB is assigned to. This is described in Table 503.

Table 500. Receive MB update

vSS!ValidFrame	vRF!Header!NFIndicator	Update description
1	1	Valid non-null frame received • MB data field updated • Frame header field updated • Slot status field updated • DUP = 1 • DVAL = 1 • MBIF = 1
1	0	Valid null frame received • MB data field not updated • Frame header field not updated • Slot status field updated • DUP = 0 • DVAL not changed • MBIF = 1
0	0 or 1	No valid frame received

Table continues on the next page...

Table 500. Receive MB update (continued)

vSS!ValidFrame	vRF!Header! NFIndicator	Update description
		• MB data field not updated • Frame header field not updated • Slot status field updated • DUP = 0 • DVAL not changed. • MBIF = 1 if the slot was not an empty dynamic slot An empty dynamic slot occurs when all of the following are 0: • vSS!ValidFrame • vSS!SyntaxError • vSS!ContentError • vSS!BViolation

NOTE

If the number of the last slot in the current communication cycle on a given channel is *n*, then all receive MBs assigned to this channel with MBFIDR*n*[FID] > *n* are not updated.

When the receive MB update completes, CC triggers the SU transition. This changes the buffer state from CCSu to Idle. The next figure shows an example receive MB timing and state change diagram for a normal frame reception.

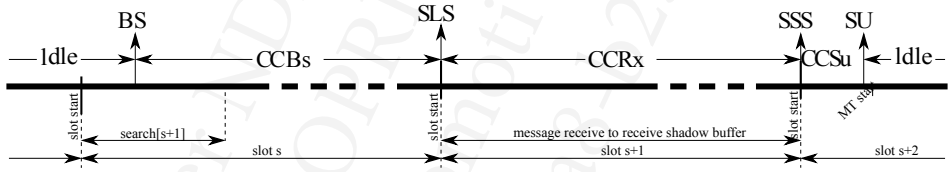

Figure 489. Message reception timing

The following considerations determine the amount of message data written into the MB data field of the receive shadow buffer:

- The MB segment that the MB is assigned to, as defined by MB Segment Size and Utilization (MBSSUTR)
- The MB data field size, as defined by the related field in MB Data Size (MBDSR)
- The number of bytes received over the FlexRay bus

If the MB is assigned to MB segment 1, and the number of received bytes is greater than 2 × MBDSR[MBSEG1DS], CC writes only 2 × MBDSR[MBSEG1DS] bytes into the MB data field of the receive shadow buffer. If the number of received bytes is less than 2 × MBDSR[MBSEG1DS], CC writes only the received number of bytes and does not change the trailing bytes in the MB data field of the receive shadow buffer. The same holds for the message buffer segment 2 with MBDSR[MBSEG2DS].

56.6.6.3.4 Received message access

To access the message data received over the FlexRay bus, you read the message data stored in the MB data field of the corresponding receive MB. Individual MBs describes the access to the MB data field.

You can read the MB data field if the receive MB is in one of these states:

- HDis
- HDisLck

- HLck

If the MB is in one of these states, CC does not change the MB content.

56.6.6.3.5 Receive shadow buffer concept

The receive shadow buffer concept applies only to individual receive MBs. The concept ensures that the receive MB presents only syntactically- and semantically-valid received non-null frames to you. Receive shadow buffers describes the basic structure of a receive shadow buffer.

The receive shadow buffers temporarily store the received frame header and message data. The slot-status information is generated after the slot boundary. If the slot-status information indicates the reception of the valid non-null frame (see Table 500), CC writes the slot status into the Slot Status field of the receive shadow buffer and exchanges the content of MB Index (MBIDXR0 - MBIDXR255) with the content of the corresponding internal shadow buffer index register. In all other cases, CC writes the slot status into the identified receive MB, depending on the slot status and the FlexRay segment the MB is assigned to.

The shadow buffer concept, with its index exchange, results in the FlexRay memory area located MB associated to an individual receive MB changes after successful reception of a valid frame. This means that the MB area in the FlexRay memory area that you access for reading the received message is different from the initial MB setting. Therefore, you must not rely on the index information written initially into MB Index (MBIDXR0 - MBIDXR255). Instead, you must fetch the index of the MB header field from MB Index (MBIDXR0 - MBIDXR255).

56.6.7 Individual MB search

This section provides a detailed description of the MB search algorithm.

For each channel, the MB search determines whether a slot *s* in a communication cycle *c* is assigned to frame or null-frame transmission or is subscribed to frame reception on that channel.

The MB search is a sequential algorithm that is invoked at the following protocol-related events:

- NIT start
- Slot start in the static segment
- Minislot start in the dynamic segment

The MB search within the NIT searches for MBs assigned or subscribed to slot 1. The MB search within slot *n* searches for MBs assigned or subscribed to slot *n+1*.

In general, the MB search for the next slot *n* considers only MBs that are both of the following:

- Enabled—that is, MBCCSR*n*[EDS] = 1
- Match the next slot *n*—that is, MBFIDRn[FID] = *n*

Table 501 introduces and defines matching MBs. For each enabled channel, the MB search may identify multiple matching MBs. CC considers all matching MBs and selects the MBs with highest priority according to Table 502 and Table 503.

Table 501. Matching MBs

For this segment:	An MB is a matching MB if it:
Static	Matches the condition of at least one row of Table 502
Dynamic	Matches the condition of at least one row of Table 503

Table 502. MB search priority (static segment)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
0 (highest)	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA

Table continues on the next page...

Table 502. MB search priority (static segment) (continued)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
1	1	—	0	1	Transmit buffer, matches cycle count, not committed	SA
	1	1	—	1	Transmit buffer, matches cycle count, locked	
2	1	—	—	—	Transmit buffer	
3	0	0	—	1	Receive buffer, matches cycle count, not locked	SB
4 (lowest)	0	1	—	1	Receive buffer, matches cycle count, locked	

1. Cycle counter filter match; see MB cycle counter filtering.

Table 503. MB search priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
0 (highest)	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	—	1	Receive buffer, matches cycle count, not locked	SB
2 (lowest)	0	1	—	1	Receive buffer, matches cycle count, locked	

1. Cycle Counter Filter Match, see MB cycle counter filtering.

If there are multiple MBs with highest priority, CC selects the MB with the lowest MB number. All MBs that have the highest priority must have a consistent channel assignment as specified in MB channel assignment consistency.

Depending on the MB channel assignment, the same MB can be found for both channel A and channel B. In this case, use this MB as described in Individual MBs.

56.6.7.1 MB cycle counter filtering

The MB cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in MB Cycle Counter Filter (MBCCFR0 - MBCCFR255). This filter determines a set of communication cycles in which the MB is considered for message reception or transmission. If the cycle counter filter is disabled (MBCCFR*n*[CCFE] = 0), this set of cycles consists of all communication cycles.

If the MB cycle counter filter does not match a certain communication cycle number, this MB is not considered for message transmission or reception in that communication cycle. In case of a transmit MB assigned to a slot in the static segment, though, this buffer is added to the matching MBs to indicate the slot assignment and to trigger the null-frame transmission.

The MB cycle counter filter matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

- MBCCFR*n*[CCFE] = 0
- CYCCNT & MBCCFR*n*[CCFMSK] = MBCCFR*n*[CCFVAL] & MBCCFR*n*[CCFMSK]

56.6.7.2 MB channel assignment consistency

The MB channel assignment given by the CHA and CHB fields in MB Cycle Counter Filter (MBCCFR0 - MBCCFR255) defines the channels on which the MB receives or transmits. The MB with number *n* transmits or receives:

- On channel A if MBCCFR*n*[CHA] = 1
- On channel B if MBCCFR*n*[CHB] = 1

To ensure correct MB operation, all MBs assigned to the same slot and with the same priority must have a consistent channel assignment. That means they must be either assigned to one channel only, or must be assigned to both channels. The behavior

of the MB search is undefined if both types of channel assignments occur for one slot and priority. The following figure illustrates an inconsistent channel assignment for MB 0 and MB 1.

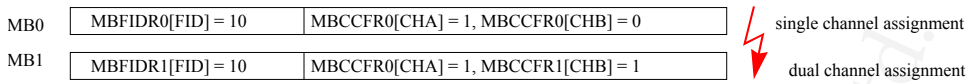

Figure 490. Inconsistent channel assignment

56.6.7.3 Node-related slot multiplexing

Node-related slot multiplexing applies only to the dynamic segment and refers to the functionality in which transmit as well as receive MBs are configured for the same slot.

According to Table 503, the transmit buffer is found only if the cycle counter filter matches and the buffer is not locked and committed. In all other cases, the receive buffer is found. Thus, if the block has no data to transmit in a dynamic slot, it can receive frames on that slot.

56.6.7.4 MB search error

This section describes the types of errors that may occur during the MB search.

FIFO reception is not affected by the search errors. Additionally, if no receive buffer has been found because of a search error, the received frame is considered for FIFO reception.

56.6.7.4.1 MB search start while running

If the MB search is running in slot *n-1* and the next MB search start event appears because of the start of slot *n*, the MB search engine stops and CC sets the Message Buffer Search Error flag (CHIERFR[MBS_EF]). As a result of this stop, no individual MB is identified for transmission or reception in slot *n*. Additionally, the search engine does not start in slot *n*, and consequently no individual MB is identified for transmission or reception in slot *n+1*.

An MB search error appears only if the CHI frequency is too slow to allow the search through all MBs to be completed within the NIT or a minislot.

For more details of the minimum required CHI frequency, see Number of Usable Message Buffers.

56.6.7.4.2 Illegal MB index found

If the MB search has finished the MB search in slot *n-1*, it retrieves the data offset values for the found MBs and the receive shadow buffers. If one of these MBs contains an illegal MB index, CC sets the Message Buffer Search Error flag (CHIERFR[MBS_EF]) and no individual MB is identified for transmission or reception in slot *n*. Receive Shadow Buffer Index (RSBIR) and MB Index (MBID XR0 - MBIDXR255) specify the legal MB index values for the individual and receive shadow buffers.

56.6.8 Individual MB reconfiguration

Individual MB reconfiguration is the ability to change the initial configuration of each individual MB even when the protocol is not in the POC:config state. The configuration bits and fields that can be changed are given in the section on specific configuration data. The common configuration data given in the section on specific configuration data cannot be reconfigured when the protocol is out of the POC:config state.

56.6.8.1 Reconfiguration Schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.

56.6.8.1.1 Basic Type Not Changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit MBCCSRn[MTD] are not changed. This type of reconfiguration is denoted by RC1 in Figure 491. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

56.6.8.1.2 Buffer Type Not Changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in the figure below. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

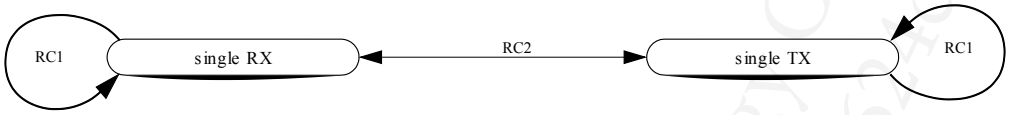

Figure 491. Message Buffer Reconfiguration Scheme

56.6.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

56.6.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. One FIFO is assigned to channel A, the other FIFO is assigned to channel B. Both FIFOs work completely independent from each other.

The message buffer structure of each FIFO is described in Receive FIFO. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- *The FIFO system memory base address*
- *The index of the first FIFO entry given by Receive FIFO Start Index Register (RFSIR)*
- *The data field offset of the data field belonging to the first FIFO entry given by Receive FIFO Start Data Offset Register (RFSDOR)*
- *The number of FIFO entries and the length of each FIFO entry as given by Receive FIFO Depth and Size Register (RFDSR)*

56.6.9.2 FIFO Configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO address mode bit FAM in the Module Configuration Register (MCR).

56.6.9.2.1 Single System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is System Memory Base Address Register (SYMBADR).

56.6.9.2.2 Dual System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is Receive FIFO System Memory Base Address Register (RFSYMBADR).

The FIFO control and configuration data are given in Receive FIFO control and configuration data. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details see FlexRay memory area layout.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

- Configure the FIFO update and address modes in Module Configuration Register (MCR)
- Configure the FIFO system memory base address
- Configure the Receive FIFO Start Index Register (RFSIR) with the first message buffer header index that belongs to the FIFO
- Configure the Receive FIFO Start Data Offset Register (RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO
- Configure the Receive FIFO Depth and Size Register (RFDSR) with FIFO entry size
- Configure the Receive FIFO Depth and Size Register (RFDSR) with FIFO depth
- Configure the FIFO Filters

56.6.9.3 FIFO Periodic Timer

The FIFO periodic timer is used to generate an FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached, but the FIFO is not empty. This can be used to prevent frames from get stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (RFPTR). If the periodic timer duration RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd*, greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

56.6.9.4 FIFO Reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO, if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case the FIFO filter path shown in Figure 492 is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (RFFLPCR) is incremented. If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

56.6.9.5 FIFO Almost-Full Interrupt Generation

If the fifo fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM, i.e. FLA>WM_A (FLB>WM_B), then the FIFO almost-full interrupt flag GIFER[FAFAIF] (GIFER[FAFBIF]) is asserted.

If the periodic timer expires, and FIFOA (FIFOB) is not empty, i.e. FLA>0 (FLB>0), then the FIFO almost-full interrupt flag GIFER[FAFAIF] (GIFER[FAFBIF]) is asserted.

56.6.9.6 FIFO Overflow Error Generation

If the FIFOA (FIFOB) is full, i.e. FLA=$FIFO\_DEPTH_A$ (FLB=$FIFO\_DEPTH_B$) and the conditions for a FIFO reception as described in FIFO Reception are fulfilled, then the fifo overflow error flag CHIERFR[FOVA_EF] (CHIERFR[FOVB_EF]) is asserted.

56.6.9.7 FIFO Message Access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (RFARIR) and the (Receive

FIFO B Read Index Register (RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to Equation 6.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (RFFLPCR) is 0, than the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (RFARIR) or (Receive FIFO B Read Index Register (RFBRIR) point to a message buffer with invalid content. In this case the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (RFARIR) (Receive FIFO B Read Index Register (RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to Equation 6. The application can access the message data as described in Receive FIFO. When the application has read the message buffer data and status information, it can update the FIFO as described in FIFO Update.

56.6.9.8 FIFO Update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (RFARIR) (Receive FIFO B Read Index Register (RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (RFSIR) automatically.

56.6.9.8.1 FIFO Interrupt Flag Update

The FIFO Interrupt Flag Update mode is configured, when the FIFO update mode flag MCR[FUM] is set to 0. In this mode FIFOA (FIFOB) will be updated by 1 entry, when the interrupt flag GIFER[FAFAIF] (GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the Receive FIFO A Read Index Register (RFARIR) (Receive FIFO B Read Index Register (RFBRIR)) is incremented by 1, if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

56.6.9.9 FIFO Filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides three sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in the figure below.

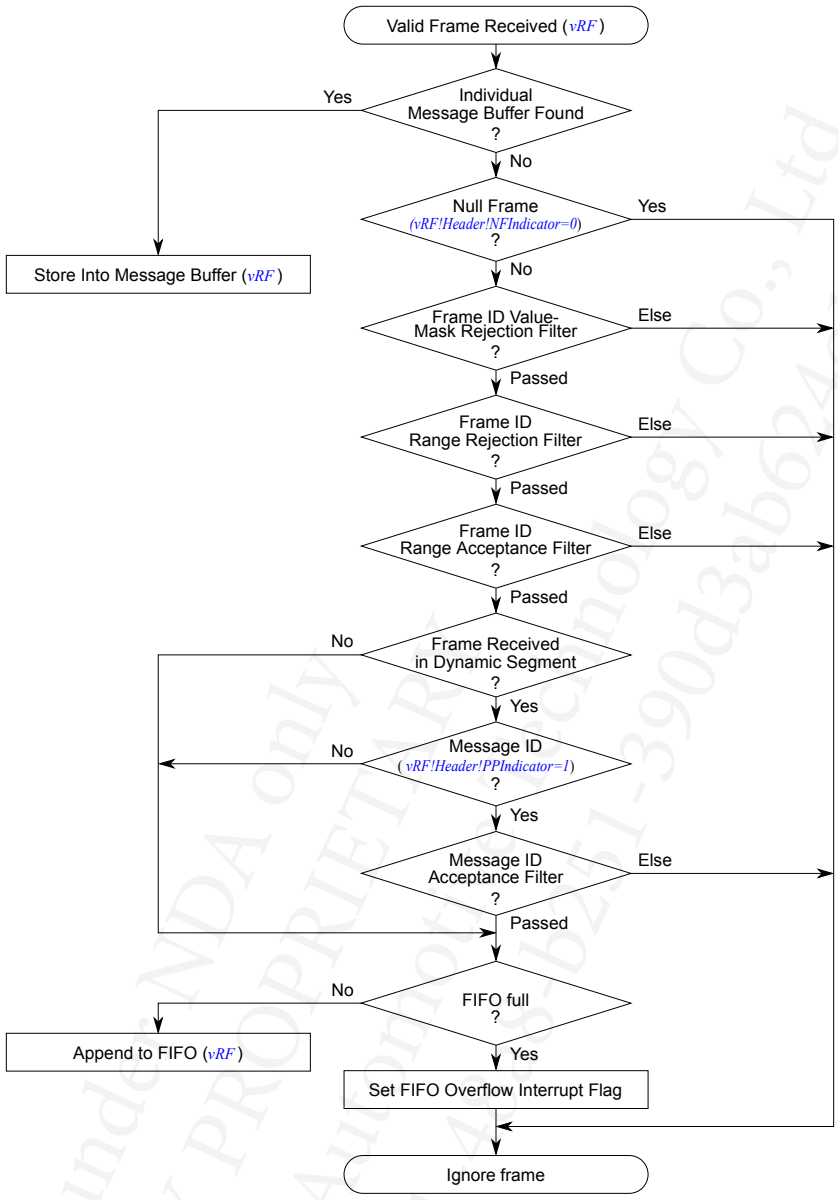

Figure 492. Received Frame FIFO Filter Path

A received frame passes the FIFO filtering if it has passed all three type of filter.

56.6.9.9.1 RX FIFO Frame ID Value-Mask Rejection Filter

The frame ID value-mask rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter, i.e. is not rejected.

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-Mask Rejection Filter if the following equation is fulfilled.

$$FID \,\&\, RFFIDRFMR[FIDRFMSK] \neq RFFIDRFVR[FIDRFVAL] \,\&\, RFFIDRFMR[FIDRFMSK]$$

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to pass all frames by the following settings.

$$RFFIDRFVR[FIDRFVAL] = 0x000 \text{ and } RFFIDRFMR[FIDRFMSK] = 0x7FF$$

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to reject all frames by the following settings.

$$RFFIDRFMR[FIDRFMSK] = 0x000$$

Using these settings, the first equation can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

56.6.9.9.2 RX FIFO Frame ID Range Rejection Filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range rejection filters if either no rejection filter is enabled, or, for all of the enabled RX FIFO Frame ID Range rejection filters, i.e. RFRFCTR[FiMD] = 1 and RFRFCTR[FiEN] = 1, fulfilling the following equation: .

$$FID < RFRFCFR_{SEL}[SID_{IBD=0}]) or (RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Consequently, all frames with a frame ID that fulfills the following equation for at least one of the enabled rejection filters will be rejected and thus not pass.

$$RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq RFRFCFR_{SEL}[SID_{IBD=1}]$$

56.6.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, for at least one of the enabled RX FIFO Frame ID Range acceptance filters, i.e. RFRFCTR[FiMD] = 0 and RFRFCTR[FiEN] = 1, the following equation is fulfilled.

$$RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq RFRFCFR_{SEL}[SID_{IBD=1}]$$

56.6.9.9.4 RX FIFO Message ID Acceptance Filter

The RX FIFO Message ID Acceptance Filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance Filter if the following equation is fulfilled.

$$MID \& RFMIDAFMR[MIDAFMSK] = RFMIDAFMR[MIDAFVAL] \& RFMIDAFMR[MIDAFMSK]$$

The RX FIFO Message ID Acceptance Filter can be configured to accept all frames by setting

$$RFMIDAFMR[MIDAFMSK]: = 0x000$$

Using these settings, the first equation is always fulfilled and all frames will pass.

56.6.10 Channel Device Modes

This section describes the two FlexRay channel device modes that are supported by the CC.

56.6.10.1 Dual Channel Device Mode

In the dual channel device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and FR_A_TX_EN_b is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and FR_B_TX_EN_b is connected to the physical bus channel B. The dual channel system is shown in the following figure.

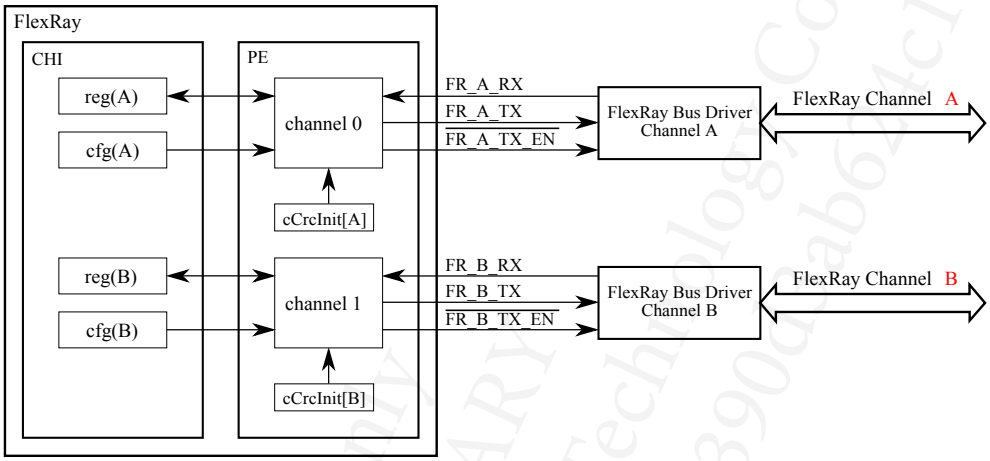

Figure 493. Dual Channel Device Mode

56.6.10.2 Single Channel Device Mode

The single channel device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and FR_A_TX_EN_b and can be connected to either the physical bus channel A (shown in the "Single Channel Device Mode (Channel A)" figure below) or the physical bus channel B (shown in the "Single Channel Device Mode (Channel B)" figure below).

If the device is configured as a single channel device by setting MCR[SCM] to 1, only the internal channel A and the FlexRay Port A is used. Depending on the setting of MCR[CHA] and MCR[CHB], the internal channel A behaves either as a FlexRay Channel A or FlexRay Channel B. The bit MCR[CHA] must be set, if the FlexRay Port A is connected to a FlexRay Channel A. The bit MCR[CHB] must be set if the FlexRay Port A is connected to a FlexRay Channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single channel device, the application can access and configure only the registers related to internal channel A.

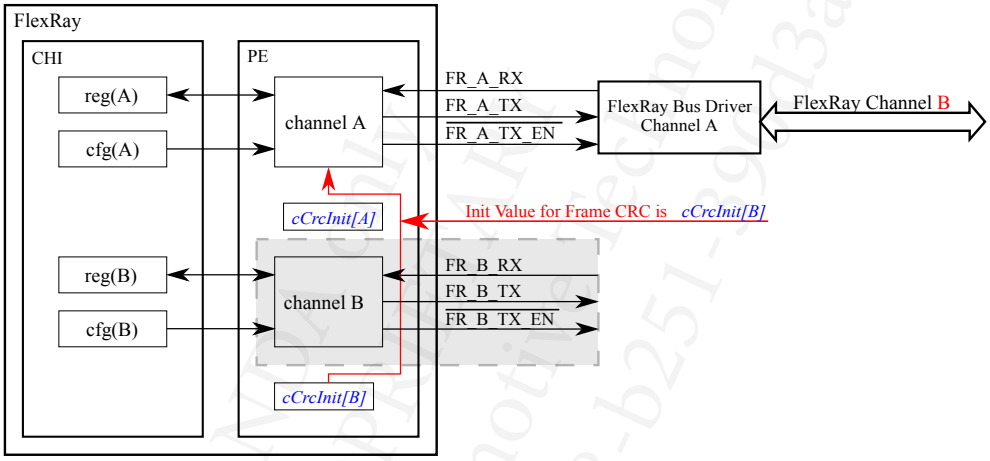

Figure 495. Single Channel Device Mode (Channel B)

56.6.11 External Clock Synchronization

The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in the "External Offset Correction Write and Application Timing" figure and the "External Rate Correction Write and Application Timing" figures below.

NOTE

The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n+1 shall be affect by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end of the static segment of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle 2n+1. If the value is not applied in cycle 2n+1, then the value will be applied in the cycle 2n+3. Refer to the following for timing details.

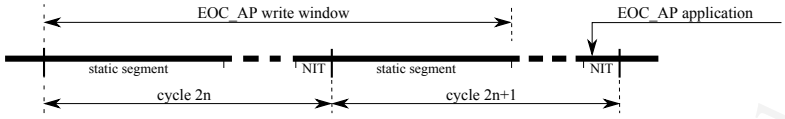

Figure 496. External Offset Correction Write and Application Timing

If the rate correction for the cycle pair [2n+2, 2n+3] shall be affect by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle pair [2n+2, 2n+3]. If the value is not applied for cycle pair [2n+2, 2n+3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to the following for details.

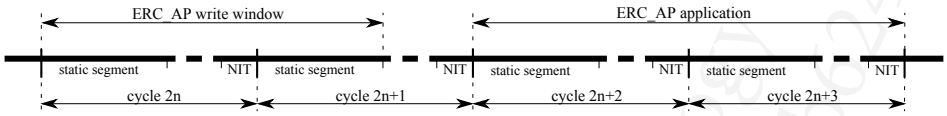

Figure 497. External Rate Correction Write and Application Timing

56.6.12 Sync Frame ID and Sync Frame Deviation Tables

The FlexRay protocol requires the provision of a snapshot of the Synchronization Frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

NOTE

Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.

56.6.12.1 Sync Frame ID Table Content

The Sync Frame ID Table is a snapshot of the protocol related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

56.6.12.2 Sync Frame Deviation Table Content

The Sync Frame Deviation Table is a snapshot of the protocol related variable zsDev(id)(oe)(ch)!Value. Each Sync Frame Deviation Table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the Sync Frame ID Table.

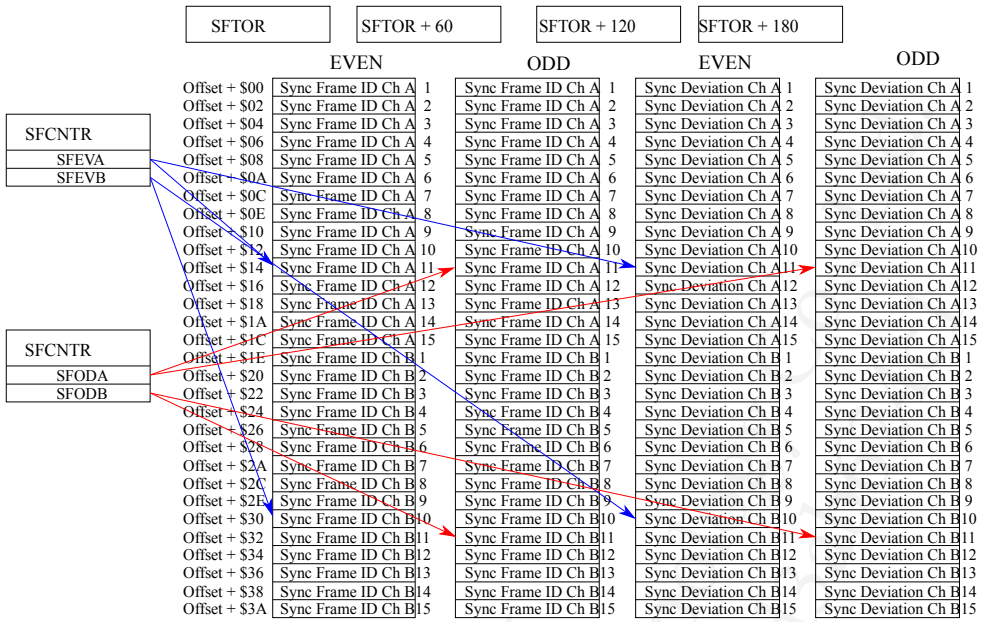

Figure 498. Sync Table Memory Layout

56.6.12.3 Sync Frame ID and Sync Frame Deviation Table Setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in Figure 498. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (SFTOR).

56.6.12.4 Sync Frame ID and Sync Frame Deviation Table Generation

The application controls the generation process of the Sync Frame ID and Sync Frame Deviation Tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (SFTCCSR). A summary of the copy modes is given in the table below.

Table 504. Sync Frame Table Generation Modes

SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No Sync Frame Table copy
0	0	1	Sync Frame ID Tables will be copied continuously
0	1	0	Reserved
0	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables will be copied continuously
1	0	0	No Sync Frame Table copy
1	0	1	Sync Frame ID Tables for next even-odd-cycle pair will be copied

Table continues on the next page...

Table 504. Sync Frame Table Generation Modes (continued)

SFTCCSR			Description
OPT	SDVEN	SIDEN	
1	1	0	Reserved
1	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables for next even-odd-cycle pair will be copied

The Sync Frame Table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting SFTCCSR[SIDEN] to 1, the CC starts the update of the even cycle related tables after the start of the NIT of the next even cycle. The CC checks if the application has locked the tables by reading the SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit SFTCCSR[EVAL]. Once all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.

To read the generated tables, the application must lock the tables to prevent the CC from updating these tables. The locking is initiated by writing a 1 to the even table lock trigger SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding status information fields SFRA, SFRB in the Sync Frame Counter Register (SFCNTR). The value in the SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the SFCNTR[SFEVA] and SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in Figure 498.

After reading all the data from the locked tables, the application must unlock the table by writing to the even table lock trigger SFTCCSR[ELKT] again. The even table lock status bit SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits SFTCCSR[EVAL] and SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (SFCNTR).

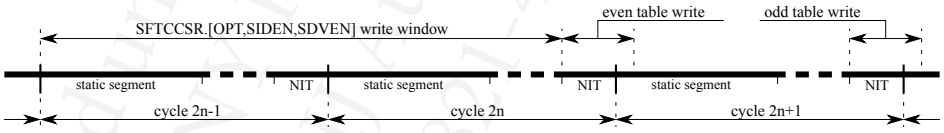

Figure 499. Sync Frame Table Trigger and Generation Timing

56.6.12.5 Sync Frame Table Access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in Figure 498. During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

56.6.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

56.6.13 MTS Generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol MTS in the symbol window on channel A or channel B.

The application can configure the set of communication cycles in which the MTS will be transmitted over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (MTSACFR) and MTS B Configuration Register (MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (MTSACFR) or MTS B Configuration Register (MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT, if the following equations are fulfilled.

PSR0[PROTSTATE] = POC: normalactive
MTSACRF[MTE] = 1
CYCCNT & MTSACFR[CYCCNTMSK] = MTSACFR[CYCCNTVAL] & MTSACFR[CYCCNTMSK]

The MTS is transmitted over channel B in the communication cycle with number CYCCNT, if the following equations are fulfilled.

MTSBCRF[MTE] = 1
CYCCNT & MTSBCFR[CYCCNTMSK] = MTSBCFR[CYCCNTVAL] & MTSBCFR[CYCCNTMSK]

56.6.14 Key Slot Transmission

Key slot assignment, transmission in POC:startup state, and transmission in POC:normal active state are discussed in this section.

56.6.14.1 Key Slot Assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (PCR18) is configured with a value greater than 0 and less or equal to number_of_static_slots in Protocol Configuration Register 2 (PCR2), otherwise no key slot is assigned.

56.6.14.2 Key Slot Transmission in POC:startup

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version *2.1 Rev A*.

56.6.14.3 Key Slot Transmission in POC:normal active

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in the following table is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see Message transmission). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see Null frame transmission).

Table 505. Key Slot Frame Type

PCR11[key_slot_used_for_sync]	PCR11[key_slot_used_for_startup]	key slot frame type
0	0	normal frame
0	1	normal frame1[1]
1	0	sync frame
1	1	startup frame

1. The frame transmitted has an semantically incorrect header and will be detected as an invalid frame at the receiver.

56.6.15 Sync Frame Filtering

Each received synchronization frame must pass the Sync Frame Acceptance Filter and the Sync Frame Rejection Filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled, i.e. the SFFE control bit in the Module Configuration Register (MCR) is cleared, all received synchronization frames are considered for clock synchronization. If a received synchronization frame did not pass at least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

56.6.15.1 Sync Frame Acceptance Filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if the following equations evaluates to true.

$MCR[SFFE] = 0$
$FID \,\&\, SFIDAFMR[FMSK] = SFIDAFVR[FVAL] \,\&\, SFIDAFMR[FMSK]$

NOTE

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

56.6.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if the following equations evaluates to true.

$MCR[SFFE] = 0$
$FID \neq SFIDRFR[SYNFRID]$

NOTE

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

56.6.16 Strobe Signal Support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in the Strobe Signal Mapping table, located in the Register Descriptions section.

56.6.16.1 Strobe Signal Assignment

Each of the strobe signals listed in the Strobe Signal Mapping table, located in the Register Descriptions section, can be assigned to one of the four strobe ports using the Strobe Signal Control Register (STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (STBSCR) with appropriate settings.

To read out the current settings for a strobe signal with number N, the application must execute the following sequence.

1. Write to STBSCR with WMD = 1 and SEL = N. (updates SEL field only)
2. Read STBCSR.

   The SEL field provides N and the ENB and STBPSEL fields provides the settings for signal N.

56.6.16.2 Strobe Signal Timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.

The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay Bus. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a negative clock offset. An example waveform is given in the following figure.

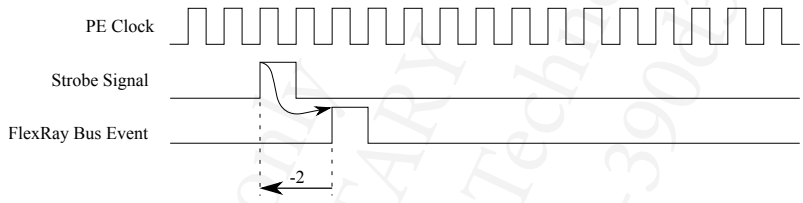

Figure 500. Strobe Signal Timing (type = pulse, clk_offset = -2)

Other signals refer to events that occurred on the FlexRay Bus some cycles before the strobe signal is changed. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a positive clock offset. An example waveform is given in the figure below.

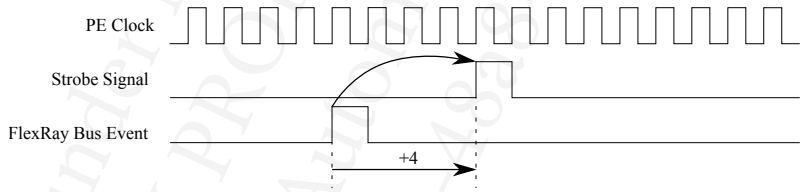

Figure 501. Strobe Signal Timing (type = pulse, clk_offset = +4)

56.6.17 Timer Support

The CC provides two timers, which run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In the non-repetitive mode, timer stops if it expires. In repetitive mode, timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

56.6.17.1 Absolute Timer T1

The absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (PIFR0) is set at the macrotick start event, if the following equations are fulfilled.

CYCTR[CTCCNT] & T1ICYSR[T1_CYC_MSK] = T1ICYSR[T1_CYC_VAL] & T1ICYSR[T1_CYC_MSK]
MTCTR[MTCT] = T1IMTOR[T1_MTOFFSET]

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding Interrupt condition (i.e., when the abovementioned equations are fulfilled) also leads to an event out indication on an output port (*fr_evt_tim1*) based on the [TIM1_EE] bit of the Protocol Event Output Enable Register (PEOER).

56.6.17.2 Absolute / Relative Timer T2

The timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

56.6.17.2.1 Absolute Timer T2

If timer T2 is configured as an absolute timer, it has the same functionality timer T1 but the configuration from Timer 2 Configuration Register 0 (TI2CR0) and Timer 2 Configuration Register 1 (TI2CR1) is used. On expiration of timer T2, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (PIER0) is asserted, an interrupt request is generated.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the [TIM2_EE] bit of the Protocol Event Output Enable Register (PEOER).

56.6.17.2.2 Relative Timer T2

If the timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (PIFR0) is set, when the programmed amount of macroticks MT[31:0], defined by Timer 2 Configuration Register 0 (TI2CR0) and Timer 2 Configuration Register 1 (TI2CR1), has expired since the trigger or restart of timer 2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the [TIM2_EE] bit of the Protocol Event Output Enable Register (PEOER).

56.6.18 Slot Status Monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per channel base. The content of the slot status vector is described in the "Slot Status Content" table below. The PE provides the slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in the below figure.

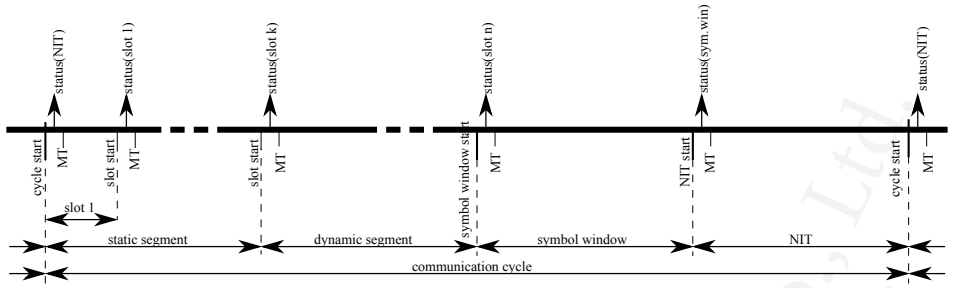

Figure 502. Slot Status Vector Update

NOTE

The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 506. Slot Status Content

	Status Content
static /dynamic Slot	**slot related status** *vSS!ValidFrame* - valid frame received *vSS!SyntaxError* - syntax error occurred while receiving *vSS!ContentError* - content error occurred while receiving *vSS!BViolation* - boundary violation while receiving *for slots in which the module transmits:* *vSS!TxConflict* - reception ongoing while transmission starts *for slots in which the module does not transmit:* *vSS!TxConflict* - reception ongoing while transmission starts first valid - channel that has received the first valid frame **received frame related status** *extracted from* *a)header of valid frame, if vSS!ValidFrame = 1* *b) last received header, if vSS!ValidFrame = 0* *c) set to 0, if nothing was received* *vRF!Header!NFIndicator* - Null Frame Indicator (0 for null frame) *vRF!Header!SuFIndicator* - Startup Frame Indicator *vRF!Header!SyFIndicator* - Sync Frame Indicator
Symbol Window	**window related status** *vSS!ValidFrame* - always 0 *vSS!ContentError* - content error occurred while receiving *vSS!SyntaxError* - syntax error occurred while receiving *vSS!BViolation* - boundary violation while receiving

Table continues on the next page...

Table 506. Slot Status Content (continued)

	Status Content
	vSS!TxConflict - reception ongoing while transmission starts **received symbol related status** *vSS!ValidMTS* - valid Media Test Access Symbol received **received frame related status** *see static/dynamic slot*
NIT	**NIT related status** *vSS!ValidFrame* - always 0 *vSS!ContentError* - content error occurred while receiving *vSS!SyntaxError* - syntax error occurred while receiving *vSS!BViolation* - boundary violation while receiving *vSS!TxConflict* - always 0 **received frame related status** *see static/dynamic slot*

56.6.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, Channel A Status Error Counter Register (CASERCR) and Channel B Status Error Counter Register (CBSERCR), incremented by one, if at least one of four slot status error bits, *vSS!SyntaxError, vSS!ContentError, vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap round after they have reached the maximum value.

56.6.18.2 Protocol Status Registers

The Protocol Status Register 2 (PSR2) provides slot status information about the Network Idle Time NIT and the Symbol Window. The Protocol Status Register 3 (PSR3) provides aggregated slot status information.

56.6.18.3 Slot Status Registers

The eight slot status registers, Slot Status Registers (SSR0–SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status related and received frame / symbol related status information, as given in Table 506, except of the *first valid* indicator for non-transmission slots.

56.6.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (SSCR0–SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in the figure below.

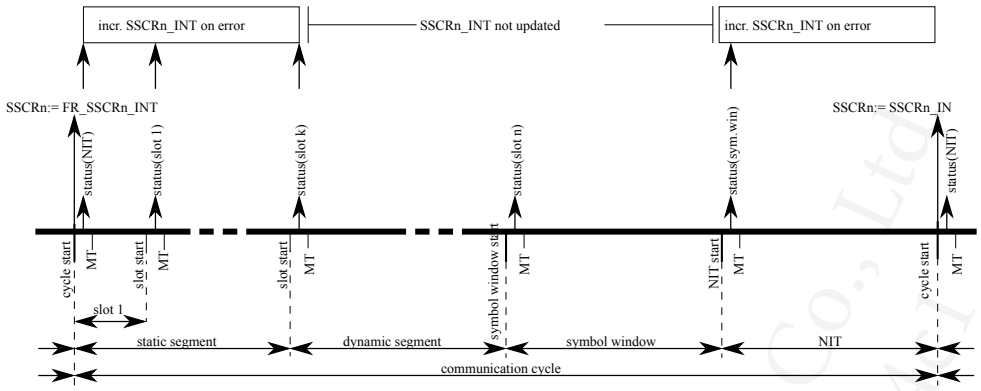

Figure 503. Slot Status Counting and SSCRn Update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the SSCRn register reflects, in cycle n, the status of the NIT of cycle n-2, and the status of all static slots and the symbol window of cycle n-1.

The increment condition for each slot status counter consists of two parts, the frame related condition part and the slot related condition part. The internal slot status counter SSCRn_INT is incremented if at least one of the conditions is fulfilled:

1. frame related condition:

   (SSCCRn[VFR] | SSCCRn[SYF] | SSCCRn[NUF] | SSCCRn[SUF]) // count on frame condition

   = 1;

   and

   ((~SSCCRn[VFR] | vSS!ValidFrame) & // valid frame restriction

   (~SSCCRn[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction

   (~SSCCRn[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction

   (~SSCCRn[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction

   = 1;

   NOTE

   The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus it is required to set the VFR always, whenever count on frame condition is used.

   slot related condition:

   ((SSCCRn[STATUSMASK[3]] & vSS!SyntaxError) | // increment on syntax error

   (SSCCRn[STATUSMASK[2]] & vSS!ContentError) | // increment on content error

   (SSCCRn[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation

   (SSCCRn[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict

   = 1;

If the slot status counter is in single cycle mode, i.e. SSCCRn[MCY] = 0, the internal slot status counter SSCRn_INT is reset at each cycle start. If the slot status counter is in the multicycle mode, i.e. SSCCRn[MCY] = 1, the counter is not reset and incremented, until the maximum value is reached.

56.6.18.5 Message Buffer Slot Status Field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in Table 506 for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update Sections in Individual MB configuration data.

56.6.19 System Bus Access

This section provides a description of the system bus accesses failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in System Bus Access Failure Types.

The behavior of the CC after the occurrence of a system bus access failure is described in System Bus Access Failure Response.

56.6.19.1 System Bus Access Failure Types

This section describes the two types of system bus access failures.

56.6.19.1.1 System Bus Illegal Address Access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions which are treated as a system bus illegal address access:

- The system bus subsystem detects an CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see CHI LRAM Error Response after CC Read).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (CHIERFR).

56.6.19.1.2 System Bus Access Timeout

A system bus access timout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see Configure System Memory Access Time-Out Register (SYMATOR)).

If a system bus access timout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (CHIERFR).

56.6.19.2 System Bus Access Failure Response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (MCR).

56.6.19.2.1 Continue after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (MCR) is 0, the CC will continue its operation after the occurrence of the system bus access failure, but will not generate any system bus accesses until the start of the next communication cycle.Since no data are read from or written to the FlexRay memory area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated with the remaining header and frame data are replaced by all zeros. Depending on the point in time this can affect the PPI bit, the Header CRC, the Payload Length in case of an dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted and received, except for the key slot, where a sync or startup null-frame is transmitted, if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

56.6.19.2.2 Freeze after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (MCR) is set to 1, the CC will go into the freeze mode immediately after the occurrence of one of the system bus access failures.

56.6.20 Interrupt Support

The CC provides 300 individual interrupt sources and five combined interrupt sources.

56.6.20.1 Individual Interrupt Sources

Message buffer interrupts are discussed in this section.

56.6.20.1.1 Message Buffer Interrupts

The CC provides 256 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag MBCCSRn[MBIF] and an interrupt enable bit MBCCSRn[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

56.6.20.1.2 FIFO Interrupts

The CC provides 2 FIFO interrupt sources.

Each of the 2 FIFO provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (GIFER[FAFBIF], GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (GIFER) if the corresponding Receive FIFO fill level exceeds the defined watermark.

56.6.20.1.3 Wakeup Interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit GIFER[WUPIE] is asserted.

56.6.20.1.4 Protocol Interrupts

The CC provides 25 interrupt sources for protocol related events. For details, see Protocol Interrupt Flag Register 0 (PIFR0) and Protocol Interrupt Flag Register 1 (PIFR1). Each interrupt source has its own interrupt enable bit.

56.6.20.1.5 CHI Interrupts

The CC provides 16 interrupt sources for CHI related error events. For details, see CHI Error Flag Register (CHIERFR). There is one common interrupt enable bit GIFER[CHIE] for all CHI error interrupt sources.

56.6.20.2 Combined Interrupt Sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

56.6.20.2.1 Receive Message Buffer Interrupt

The Receive Message Buffer Interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit GIFER[RBIE] is set.

56.6.20.2.2 Transmit Message Buffer Interrupt

The Transmit Message Buffer Interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit GIFER[TBIE] is asserted.

56.6.20.2.3 Protocol Interrupt

The Protocol Interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit GIFER[PRIE] is set.

56.6.20.2.4 CHI Interrupt

The CHI Interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit GIFER[CHIE] is set.

56.6.20.2.5 Module Interrupt

The Module Interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit GIFER[MIE] is set.

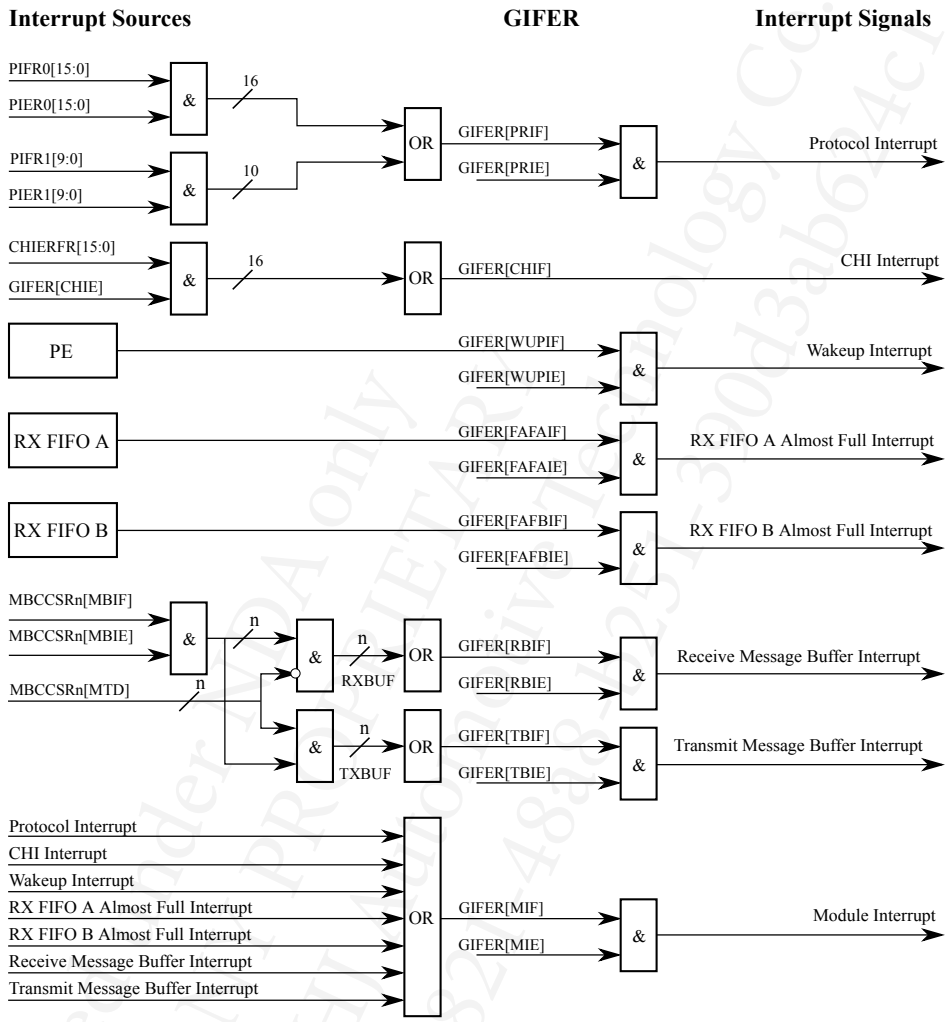

Figure 504. Scheme of GIFER interrupt signal generation

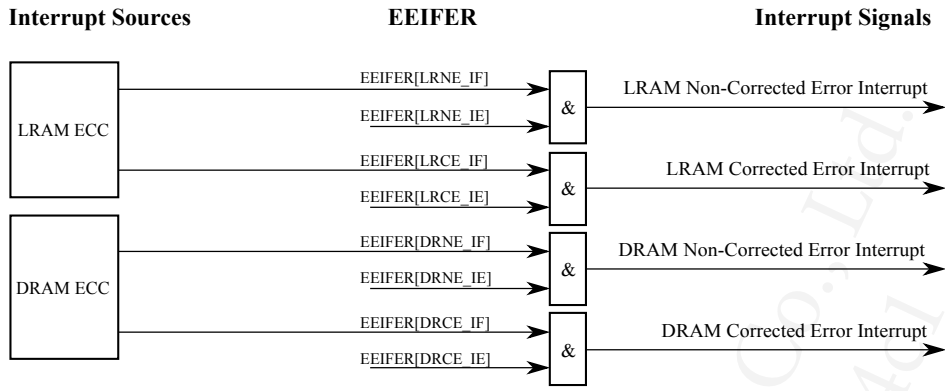

Figure 505. Scheme of EEIFER interrupt signal generation

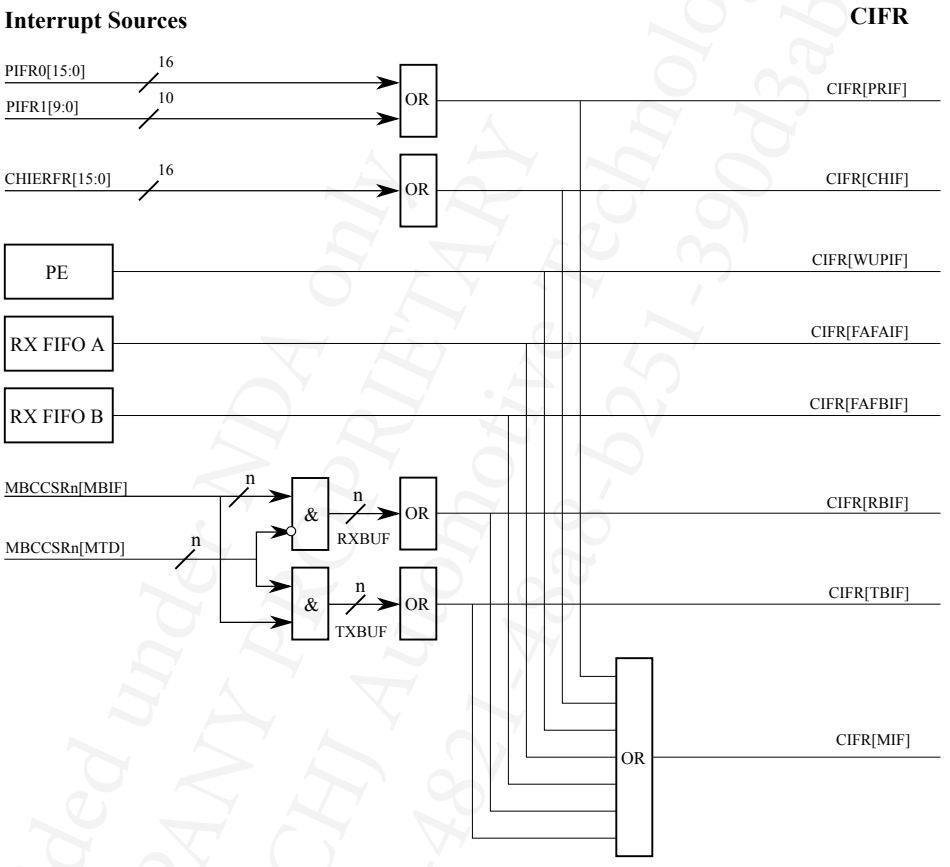

Figure 506. Scheme of CIFR flags generation

56.6.21 Lower Bit Rate Support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset*. The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings and related protocol parameter values are shown in the "FlexRay Channel Bit Rate Control" table below.

Table 507. FlexRay Channel Bit Rate Control

FlexRay Channel Bit Rate [Mbit/s]	MCR[BITRATE]	*pdMicrotick [ns]*	*gdSampleClockPeriod [ns]*	*pSamplesPerMicrotick*	*cSamplesPerBit*	*cStrobeOffset*
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

NOTE

The bit rate of 8 Mbit/s is not defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

56.6.22 PE Data Memory (PE DRAM)

The PE Data Memory (PE DRAM) is 128 word, 16-bit wide memory with byte access, which contains the program data of the PE internal CPU. The PE DRAM is divided into two banks, 8-bit each. The memory data [7:0] are assigned to BANK0, the memory data [15:8] are assigned to BANK1.

Table 508. PE DRAM Layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
	…	
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via PE DRAM Access Register (PEDRAR) and PE DRAM Access Register (PEDRAR). This functionality is used to check the memory error detection.

56.6.22.1 PE DRAM Read Access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. PEDRAR:= 0x50E0;

   // INST=0x5; ADDR=070

2. wait until PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = PEDRDR[DATA];

   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25us).

56.6.22.2 PE DRAM Write Access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. PEDRDR:= DATA;

   // write value to be written into data register

2. PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

3. wait until PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

4. val = PEDRDR[DATA];

   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may causes an response delay with a maximum of 1000 PE clock cycle (25us).

If the conditions given in PE DRAM Write Access Limitations are fulfilled, the data provided in PE DRAM Access Regsiter (PEDRAR) are written into the PE DRAM, read back in the next clock cycle and stored into the PE DRAM Access Register (PEDRAR). Otherwise, data are not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (PEDRAR).

56.6.22.3 PE DRAM Write Access Limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not *in POC:default config* state, only PE DRAM address 0x70 is writable.

56.6.23 CHI Lookup-Table Memory (CHI LRAM)

The CHI Lookup-Table Memory (CHI LRAM) is an CHI internal memory which contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or 6 data field offsets are contained in one memory row. The CHI LRAM is divided into 6 memory BANKs.

Table 509. CHI LRAM Layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	MBIDXR1	MBFIDR1	MBCCFR1	MBIDXR0	MBFIDR0	MBCCFR0
0x01	MBIDXR3	MBFIDR3	MBCCFR3	MBIDXR2	MBFIDR2	MBCCFR2
…						

Table continues on the next page...

Table 509. CHI LRAM Layout (continued)

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x7F	MBIDXR255	MBFIDR255	MBCCFR255	MBIDXR254	MBFIDR254	MBCCFR254
0x80	MBDOR5	MBDOR4	MBDOR3	MBDOR2	MBDOR1	MBDOR0
…						
0xAB	-	-	-	-	MBDOR259	MBDOR258
0xAC	LEETR5	LEETR4	LEETR3	LEETR2	LEETR1	LEETR0

56.6.23.1 CHI LRAM Read and Write Access

The CHI LRAM is accessed by the application via regular register read and write accesses.

56.6.24 Memory Content Fault Detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses an standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED) .The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

56.6.24.1 Memory Error Types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as an special case. The FlexRay module detects and indicates the memory errors as shown in the "Detected Memory Error Types" table below. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row, and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error free bank has been read.

Table 510. Detected Memory Error Types

Memory	Priority	Memory Data	Indication
CHI LRAM	0 (highest)	All Zero's	Non-Corrected Error
PE DRAM			Non-Corrected Error
CHI LRAM		All One's	Non-Corrected Error
PE DRAM			
CHI LRAM	1 (lowest)	One Bit Flipped	Non-Corrected Error

Table continues on the next page...

Table 510. Detected Memory Error Types (continued)

Memory	Priority	Memory Data	Indication
PE DRAM			Corrected Error
CHI LRAM		Two Bits Flipped	Non-Corrected Error
PE DRAM			
CHI LRAM		Three or more Bits Flipped	one out of {No error, Non-Corrected Error}, defined by coding given in CHI LRAM checkbits and CHI LRAM Syndrome
PE DRAM			one out of {No error, Corrected Error, Non-Corrected Error}, defined by coding given in PE DRAM Checkbits and PE DRAM Syndrome

56.6.24.2 Memory Error Reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (MCR) is set.

For each of the two memories exists two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (EEIFER) is set.

- *If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.*
- *If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.*

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to above the Error indications (corrected / non corrected) along with the failing address is sent out from the module for external error logging and corrective actions by the Software.

56.6.24.2.1 PE DRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (EERCR) for PE DRAM memory errors is shown in Table 510. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 511. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4[1]	X	X	X	X	X	X	X	X	X	X	X	X
3[2]	-	-	-	-	X	X	X	X	-	-	-	-

Table continues on the next page...

Table 511. PE DRAM checkbits coding (continued)

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
2	-	-	-	-	X	-	-	-	X	X	X	-
1	-	-	-	-	-	X	X	-	X	X	-	X
0	-	-	-	-	-	X	-	X	X	-	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is a even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is a odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words and written into the memory.

56.6.24.2.2 PE DRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (EERCR) for PE DRAM memory errors is shown in the following table.

Table 512. EERCR[CODE] PE DRAM Syndrome Coding

EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (Never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected Error (Parity Bit 0)
0x0	0x2	Corrected Error (Parity Bit 1)
0x0	0x3	Corrected Error (Data Bit 0)
0x0	0x4	Corrected Error (Parity Bit 2)
0x0	0x5	Corrected Error (Data Bit 1)
0x0	0x6	Corrected Error (Data Bit 2)
0x0	0x7	Corrected Error (Data Bit 3)
0x0	0x8	Corrected Error (Parity Bit 3)
0x0	0x9	Corrected Error (Data Bit 4)
0x0	0xA	Corrected Error (Data Bit 5)
0x0	0xB	Corrected Error (Data Bit 6)

Table continues on the next page...

Table 512. EERCR[CODE] PE DRAM Syndrome Coding (continued)

EERCR[CODE]		Description
[4]	[3:0]	
0x0	0xC	Corrected Error (Data Bit 7)
0x0	0xD-0xF	Non-Corrected Error
0x1	0x1-0xF	Non-Corrected Error

56.6.24.2.3 CHI LRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (EERCR) for CHI LRAM memory errors is shown in the table below. This table shows the implemented Hamming code. If the error injection is applied to distort the checkbits, then the distorted checkbits are reported.

Table 513. CHI LRAM checkbits coding

CODE[1]	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	-	-	-	-	-	-	-	-	-	-	-
3	-	-	-	-	-	X	X	X	X	X	X	X	-	-	-	-
2	X	X	-	-	-	X	X	X	X	-	-	-	X	X	X	-
1	-	-	X	X	-	X	X	-	-	X	X	-	X	X	-	X
0	X	-	X	-	X	X	-	X	-	X	-	X	X	-	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is a odd number of 1's in all columns with X.

56.6.24.2.4 CHI LRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (EERCR) for CHI LRAM memory errors is shown in the next table.

Table 514. EERCR[CODE] CHI LRAM Syndrome Coding

EERCR[CODE]	Description
0x00	No Error (Never appears in error report registers)
0x01-0x1F	Non Corrected Error

56.6.24.3 Memory Error Response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (MCR) is set.

In case of the detection of a *corrected* memory error, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

56.6.24.3.1 CHI LRAM Error Response after CC Read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access the error response of the module depends from LRAM location where the error occurred.

- *If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.*

  If the affected message buffer is a tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is a rx message buffer, no frame will be received to this message buffer in the next slot.
- *If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx the first access to the system memory caused by payload read or write yields to the assertion of the CHIERFR[ILSA_EF]. No memory access occurs w.r.t. payload access is performed for the complete frame.*

56.6.24.3.2 CHI LRAM Error Response after Application Read

The application can read the content of the CHI LRAM via reading the MBCCFRn, MBFIDRn, MBIDXRn, MBDORn, and LEETRn registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read and continues its normal operation.

56.6.24.3.3 PE DRAM Error Response after CC Read

If the CC detects an non-corrected memory error during internal read of program data which is contained in PE DRAM, this is considered as an fatal protocol error and the module enters the protocol freeze state immediately.

56.6.24.3.4 PE DRAM Error Response after Application Read in *POC:default config* state

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered as an fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

56.6.24.3.5 PE DRAM Error Response after Application Read out of *POC:default config*

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address, and the protocol is not in the *POC:default config* state, this error is not considered as an fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

56.6.25 Memory Fault Injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (EERICR) are set.

The error injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (EERICR).

When the error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

56.6.25.1 CHI LRAM Error Injection

The following sequence describes an memory error injection sequence for the CHI LRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content. The content of the CHI LRAM is described in Table 509.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see Memory Fault Injection out of POC:default config.

Injector Setup:

1. MCR[ECCE]:= 1;

   // enable ECC functionality
2. EERICR[EIE]:=I_MODE;

   // configure error injection mode
3. EEIAR[MID]:= 1;

   // select CHI LRAM for error injection
4. EEIAR[BANK]:= I_BANK;

   // select bank for error injection; I_BANK = {0,1,2,3,4,5}
5. EEIAR[ADDR]:= I_ADDR;

   // select address for error injection; I_ADDR <= 0xAC
6. EEIDR[DATA]:= D_DIST;

   // define data distortion pattern
7. EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern
8. EERICR[EIE]:=1;

   // enable error injection

Application Write Access:

If (I_BANK==0) -> MBCCFR(2n) / MBDOR(6k) / LEETR0 := DATA;

If (I_BANK==1) -> MBFIDR(2n) / MBDOR(6k+1) / LEETR1 := DATA;

If (I_BANK==2) -> MBIDXR(2n) / MBDOR(6k+2) / LEETR2 := DATA;

If (I_BANK==3) -> MBCCFR(2n+1) / MBDOR(6k+3) / LEETR3 := DATA;

If (I_BANK==4) -> MBFIDR(2n+1) / MBDOR(6k+4) / LEETR4 := DATA;

If (I_BANK==5) -> MBIDXR(2n+1) / MBDOR(6k+5) / LEETR5 := DATA;

// write DATA to the defined injection bank and injection address (see Table 509).

56.6.25.2 PE DRAM Error Injection

The following sequence describes an memory error injection sequence for the PE DRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see PE DRAM Error Injection out of POC:default config.

Injector Setup:

1. MCR[ECCE]:= 1;

   // enable ECC functionality
2. EERICR[EIE]:=I_MODE;

   // configure error injection mode
3. EEIAR[MID]:= 0;

// select PE DRAM for error injection

4. EEIAR[BANK]:= I_BANK;

   // define bank for error injection; I_BANK = {0,1}

5. EEIAR[ADDR]:= I_ADDR;

   // define address for error injection; I_ADDR <= 0x7F

6. EEIDR[DATA]:= D_DIST;

   // define data distortion pattern

7. EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern

8. EERICR[EIE]:=1;

   // enable error injection

Application Write Access (e.g. I_ADDR=0x70):

1. PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

2. wait until PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = PEDRDR[DATA]; |

   // get read back PE DRAM data

NOTE

The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

56.6.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick and are fulfilled.

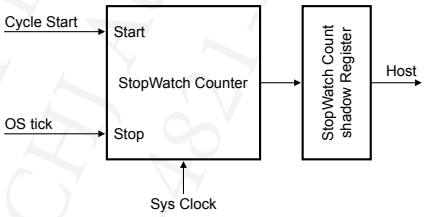

Figure 507. StopWatch counter logic

As shown below, there is a 32 bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (Stop Watch Count Register (STPWR)) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared. The StopWatch logic is controlled through a control bit STPW_EN in the PEOER (Protocol Event Output Enable and StopWatch Control Register (PEOER). The counter runs only when this bit is set. The following figure shows the actual timing of the stopwatch counter logic operation.

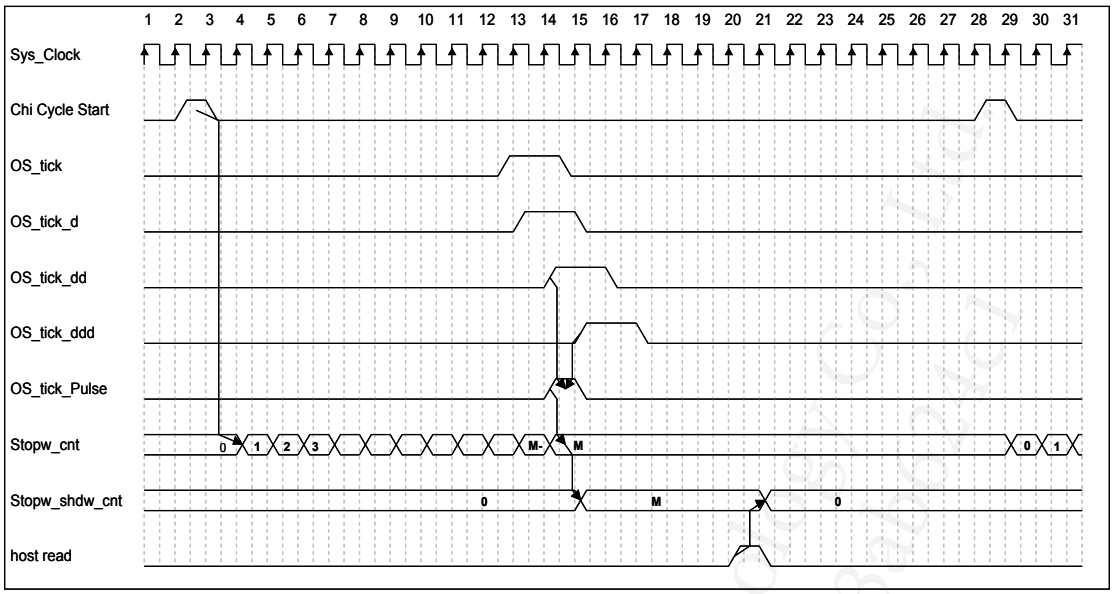

Figure 508. StopWatch function timing diagram

NOTE

'Host read' implies that all 32 bits have been read out completely. Any partial read (i.e for 8/16 bits access) will not clear the StopWatch count register.

NOTE

If cycle start and OS tick occurs simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and cycle_start has a single stage synchronizer into chi clock domain. So simultaneously here means OS_tick_pulse and chi_cycle_start occurring at the same cycle.

56.7 Application Information

Module operation is discussed in this section.

56.7.1 Module Configuration

This section describes essential parts of the module configuration.

56.7.1.1 Configure System Memory Access Time-Out Register (SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in System Memory Access Time-Out Register (SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill this equation[1]:

$$0 \le \mathrm{SYMATOR}[\mathrm{TIMEOUT}] \le \lfloor 0.45 \cdot f_{\mathrm{CHI}} - 8 \rfloor$$

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in the table below.

[1] See for all constraints of minimum CHI clock frequency.

Table 515. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
18 MHz	0	100 MHz	<= 37
23 MHz	<= 2	120 MHz	<= 46
27 MHz	<= 4	140 MHz	<= 55
32 MHz	<= 6	160 MHz	<= 64
60 MHz	<= 19	180 MHz	<= 73
80 MHz	<= 28	200 MHz	<= 82

56.7.1.1.1 System Bus Wait State Constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single channel configurations and if the sync frame table generation functionality is *not* used (SFTCCSR[SDVEN,SIDEN] = 0) no timeout will be detected if less than 2 × SYMATOR[TIMEOUT]+1 wait states will be seen on the system bus for each system bus access.

For dual channel configurations, or if the sync frame table generation functionality is used, no timeout will be detected if less than SYMATOR[TIMEOUT]-1 wait states will be seen on the system bus for each system bus access.

56.7.1.2 Configure Data Field Offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (MBDORn) and Receive FIFO Start Data Offset Register (RFSDOR). The application has to configure the data field offset values for all message buffers which are used.

When the module is enabled, the initilization value of the MBDORn[MBDO] and RFSDOR[SDO] is 0. This value is considered to be illegal (see System Bus Illegal Address Access).

56.7.2 Initialization Sequence

This section describes the required steps to initialize the CC. The first subsection describes the steps required after a module reset, the second section describes the steps required after preceding shutdown of the CC.

56.7.2.1 Module Initialization

This section describes the module related initialization steps after a system reset.

1. Configure CC.
    a. configure the control bits in the Module Configuration Register (MCR)
    b. configure the system memory base address in System Memory Base Address Register (SYMBADR)
2. Enable the CC.
    a. write 1 to the module enable bit MEN in the Module Configuration Register (MCR)

The CC now enters the Normal Mode. The application can commence with the protocol initialization described in Protocol Initialization.

56.7.2.2 Protocol Initialization

This section describes the protocol related initialization steps.

1. Configure the Protocol Engine.

a. issue CONFIG command via Protocol Operation Control Register (POCR)

b. wait for *POC:config* in Protocol Status Register 0 (PSR0)

c. configure the PCR0,…, PCR30 registers to set all protocol parameters

2. Configure the Message Buffers and FIFOs.

a. set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (MBSSUTR)

b. define the message buffer data size in the Message Buffer Data Size Register (MBDSR)

c. configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (MBCCSRn), Message Buffer Cycle Counter Filter Registers (MBCCFRn), Message Buffer Frame ID Registers (MBFIDRn), Message Buffer Index Registers (MBIDXRn)

d. configure the FIFOs

e. issue CONFIG_COMPLETE command via Protocol Operation Control Register (POCR)

f. wait for *POC:ready* in Protocol Status Register 0 (PSR0)

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

56.7.2.3 CHI LRAM Initialization

The initialization of the CHI LRAM is performed by the CC when it leaves the Disabled Mode. The unitization runs for 173 CHI clock cycles. All fields in the MBCCSRn, MBCCFRn, MBFIDRn, MBDORn, and LEETRn registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

56.7.2.4 PE DRAM Initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs, and will delay the state transition from *POC:default config* into *POC:config*.

56.7.3 Memory Fault Injection out of POC:default config

This section provides information for application driven memory fault injection out if *POC:default config*. The CC provides means to inject memory faults from the application without any impacts to the internal protocol operation of the CC.

56.7.3.1 CHI LRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in CHI LRAM Error Injection.

56.7.3.2 PE DRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only one PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM location to inject memory errors into the PE DRAM. The injection sequence is described in PE DRAM Error Injection.

56.7.4 Shut Down Sequence

This section describes a secure shut down sequence to stop the CC gracefully. The main targets of this sequence are

- *finish all ongoing reception and transmission*
- *do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication*

For a graceful shutdown the application shall perform the following tasks:

1. Disable all enabled message buffers.
    a. repeatedly write 1 to MBCCSRn[EDT] until MBCCSRn[EDS] == 0.
2. Stop Protocol Engine.
    a. issue HALT command via Protocol Operation Control Register (POCR)
    b. wait for *POC:halt* in Protocol Status Register 0 (PSR0)

56.7.5 Number of Usable Message Buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[1].

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of slot and must be finished before the start of the next slot.

The shortest FlexRay slot is a corrected empty dynamic slot. An corrected empty dynamic slot is a mini-slot and consists of gdMinislot corrected macroticks with a duration of *gdMacrotick*. The minimum duration of an corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of an correct slot

$$\Delta_{slotmin} = 39 \bullet pdMicrotick \bullet gdMinislot$$

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

$$\Delta_{search} = \frac{1}{f_{chi}} \bullet (MBSSUTR[LAST\_MB\_UTIL] + 27)$$

The message buffer search must be finished within one slot which requires fulfillment of this equation:

$$\Delta_{search} \leq \Delta_{slotmin}$$

This results in the formula given below which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

$$f_{chi} \geq \frac{(MBSSUTR[LAST\_MB\_UTIL] + 27)}{39 \bullet pdMicrotick \bullet gdMinislot}$$

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (MBSSUTR) set to 255 is given in the following table.

Table 516. Minimum fchi [MHz] examples (256 message buffers used)

pdMicrotick [ns]	*gdMinislot*					
	2	3	4	5	6	7
25.0	145.2	96.8	72.6	58.1	48.4	41.5
50.0	72.6	48.4	36.3	29.1	24.2	20.8

[1] See for all constraints of minimum CHI clock frequency.

NOTE

If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to the CHI Error Flag Register (CHIERFR) for details.

56.7.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of the POCR Field Descriptions table, located in the Register Descriptions section, by writing the command to the POCCMD field of the Protocol Operation Control Register (POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in the next table. If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by the table below. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 517. Protocol Control Command Priorities

Protocol Command	Priority	Interrupted By	Cleared and Terminated By
FREEZE	(highest) 1	none	
READY	2		
CONFIG_COMPLETE	3		
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLETE, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE, fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(lowest) 10		FREEZE, READY, CONFIG_COMPLETE, fatal protocol error

56.7.7 Message Buffer Search On Simple Message Buffer Configuration

This sections describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

56.7.7.1 Simple Message Buffer Configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *S*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has following configuration

Table 518. Transmit Buffer Configuration

Register	Field	Value	Description
MBCCSR*t*	MTD	1	transmit buffer
MBCCFR*t*	MTM	0	event transition mode
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000011	cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
MBFIDR*t*	FID	*S*	assigned to slot S

The availability of data in the transmit buffer is indicated by the commit bit MBCCSRt[CMT] and the lock bit MBCCSRt[LCKS].

The receive message buffer has the message buffer number r and has following configuration.

Table 519. Receive Buffer Configuration

Register	Field	Value	Description
MBCCSR*r*	MTD	0	receive buffer
MBCCFR*r*	MTM	-	n/a
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000001	cycle set = {2n} = {0,2,4,6,…}
	CCFVAL	000000	
MBFIDR*r*	FID	*S*	subscribed slot

Furthermore the assumption is that both message buffers are enabled (MBCCSRt[EDS] = 1 and MBCCSRr[EDS] = 1)

NOTE

The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

56.7.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *S* in the *static* segment.

The configuration of a transmit buffer for a static slot *S* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *S*. In any case, the result of the message buffer search will be the transmit message buffer *t*. The receive message buffer *r* will not be found, no reception is possible.

56.7.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *S* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

56.7.7.3.1 Transmit Data Not Available

If transmit data are *not available*, i.e. the transmit buffer is not committed MBCCSR*t*[CMT]=0 and/or locked MBCCSR*t*[LCKS]=1,

1. for the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in the following figure.

Figure 509. Transmit Data Not Available

56.7.7.3.2 Transmit Data Available

If transmit data are *available*, i.e. the transmit buffer is committed MBCCSR*t*[CMT]=1 and not locked MBCCSR*t*[LCKS]=0,

1. for the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in the following figure.

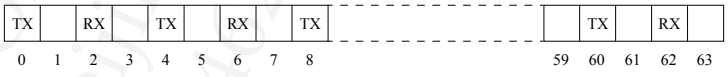

Figure 510. Transmit Data Available

56.8 Glossary

BCU	Buffer control unit—handles MB access
BMIF	Bus master interface—provides master access to the FlexRay memory area
CC	Communication controller
CDC	Clock domain crossing unit
CHI	Controller host interface
EBI	External bus interface
FlexRay memory area	Memory area to store the physical MB payload data, frame header, frame and slot status, and synchronization frame related tables
FSS	Frame start sequence
HIF	Host interface—provides host access to controller
Host	The FlexRay CC host MCU
Key slot	Transmits the startup frame, sync frame, or designated single slot frame
LUT	Lookup table—stores MB header index values
LRAM	LUT RAM—the module internal memory to store message buffer configuration data and data field offsets for individual message buffers and receive shadow buffers
MB	Message buffer
Mini-slot	An interval of time within the dynamic segment of the communication cycle that is of constant duration (in terms of macroticks) and that is used by the synchronized FTDMA media access scheme to manage media arbitration
MBIDX	MB index—the position of a header field entry within the header area; if the header area is accessed as an array, this is the same as the array index of the entry
MCU	Microcontroller unit
µT	Microtick
MT	Macrotick
MTS	Media access test symbol
Message frame	Frame for which the null frame indicator is 1
NMV	Network management vector
Normal frame	Null frame or message frame for which both the sync frame indicator and the startup frame indicator are 0
Null frame	Frame for which the null frame indicator is 0
NIT	Network idle time
PE	Protocol engine
POC	Protocol operation control; each state of the POC is denoted by POC:state
Rx	Reception
Slot	An interval of time during which access to a communication channel is granted exclusively to a specific node for the transmission of a frame with a frame ID corresponding to the slot
SEQ	Sequencer engine
SU	Status update

Chapter 57
Cross-Triggering Unit (CTU)

57.1 Chip-specific CTU information

57.1.1 CTU connections

The following table shows the CTU input triggers, ADC interconnections, and TGSISR assignments in this chip.

Table 520. CTU connections

Input module	Input signal	TGSISR I/P	Source	Driver signal
CTU	PWM_REL	0	FTM_0	CH0
CTU	PWM_ODD_0	1	FTM_0	CH1
CTU	PWM_ODD_1	2	FTM_0	CH2
CTU	PWM_ODD_2	3	FTM_1	CH0
CTU	PWM_ODD_3	4	FTM_1	CH1
CTU	PWM_EVEN_0	5	FTM_1	CH2
CTU	PWM_EVEN_1	6	PIT_0	TRIGGER[6]
CTU	—	7–14 (Reserved)		
CTU	EXT_IN	15	External pin	External pin
ADC_0[1]	TRIGGER	—	CTU	TRIGGER_0
ADC_0[1]	CMD	—	CTU	CMD_0
ADC_1[2]	TRIGGER	—	CTU	TRIGGER_1
ADC_1[2]	CMD	—	CTU	CMD_1

1. Throughout the CTU chapter, ADC_0 is referred to as ADC A (ADC_A).
2. Throughout the CTU chapter, ADC_1 is referred to as ADC B (ADC_B).

57.2 Introduction

In PWM driven systems, it is important to schedule the acquisition of the state variables with respect to the PWM cycle. State variables are obtained through the following peripherals: ADC, position counter (for example, quadrature decoder, resolver, and sine-cos sensor), and PWM duty cycle decoder.

The Cross-Triggering Unit (CTU) is intended to completely avoid CPU involvement in the acquisition of state variables during a control cycle defined by the PWM cycle, the half PWM cycle, or a multiple number of PWM cycles. Several CTU registers are double-buffered, thus allowing coherent update during the transition from one control cycle to the next. Thus, double-buffered registers updated at control cycle N are updated during the transition from control cycle N to control cycle N+1.

The CTU provides four FIFO memory blocks to temporarily store ADC results for CPU access.

57.3 Block diagram

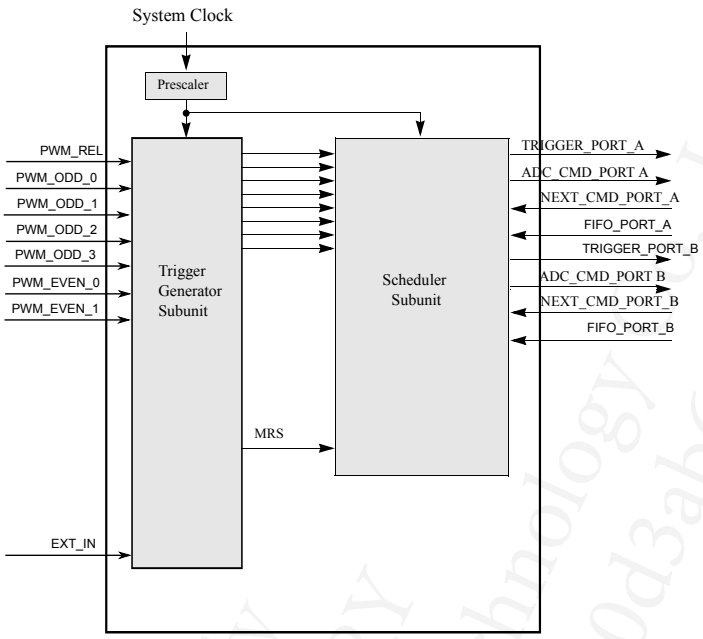

Figure 511. CTU block diagram

57.4 CTU overview

The CTU receives several signals from different sources such as FTM , timers, position decoder These signals are then processed to generate up to eight trigger events. An input event can be a rising edge, a falling edge, or both edges of the incoming signal. The output can be a pulse, an ADC command, or a stream of consecutive ADC commands for oversampling support. The outputs are targeted to one or more ADCs.

The CTU provides the following features:

- Cross triggering between ADC, FTM timers, on-chip general purpose timers
- Double-buffered trigger unit that generates up to eight triggers
- Trigger generation unit configurable in sequential or triggered modes
- Trigger delay functionality to compensate for the delay of external low-pass filters
- Double-buffered ADC command list pointers
- Double-buffered ADC conversion command list
- Each trigger has the capability to generate consecutive conversion commands
- ADC conversion commands allow two ADCs to be controlled synchronously with queue selection to store conversion results
- DMA support

In a typical application, the CTU interfaces with the following peripherals:

- FTM generators for motor control
- Timers

The inputs are 16 digital signals. The CTU detects the rising and/or falling edges for each one of them.

Figure 511 shows a high-level CTU block diagram. The CTU hardware architecture consists of two subunits:

- Trigger generator

- Scheduler

The Trigger generator subunit receives CTU input signals and selects the active edges to generate the Master Reload signal. The signal is used to load several CTU double buffered registers. See sections TGS in triggered mode and TGS in sequential mode for more details about the Master Reload signal. The Trigger generator subunit also generates up to eight trigger event signals are used by the Scheduler subunit.

This subunit generates the trigger event output according to the trigger event signals from the Trigger generator subunit. The trigger event output starts an ADC conversion or generates output signals to trigger events for IPs in the SoC. See section Scheduler subunit (SU) for more detail about the Scheduler subunit.

57.4.1 Modes of operation

The CTU has two main modes of operation:

- Triggered mode: This input event from the CTU interface is used to generate a sequence of up to eight triggers to several outputs such as the ADCs, timers, and external triggers. Internal sequencer logic is used to schedule the triggers based upon the input event occurrence.
- Sequential mode: Each input event generates only one trigger for the selected output, such as ADCs, timers, and external triggers.

57.5 Signal description

The following table shows the chip-level signals for the CTU module.

Table 521. Signal properties

Name	Function
EXT_IN	Input pin for external triggers

57.6 CTU register descriptions

CTU registers are implemented in two sizes:

- 32-bit registers: byte access for write operations and 32-bit access for read operations
- 16-bit registers: byte access for write operations and 32-bit access for read operations

If a 32-bit write operation is performed over a 16-bit register, the write operation is performed on the 4 aligned bytes. Read operation should be performed only at 32-bit boundary.

NOTE

Reserved bit registers, when available for write operations, should be written always with logic 0. Read access does not return meaningful data from reserved bit registers. This module does not issue transfer errors when trying to access its reserved locations.

The following tables describe the CTU memory mapped registers.

57.6.1 CTU memory map

CTU base address: 401F_C000h

Offset	Register	Width (In bits)	Access	Reset value

57.6.2 Trigger Generator Subunit Input Selection Register (TGSISR)

Offset

Register	Offset
TGSISR	0h

Function

The TGSISR register is double buffered. The load from the corresponding buffer to the register is controlled by the TGSISR_RE bit in the CTU_CR register. The TGSISR_RE bit is self negated. Once set, this bit remains set until the TGSISR register is updated from the corresponding buffer register. Reads to the TGSISR register actually return the content of the buffer and not the content of the register. Thus, a read will return the most recent data written to the register address even though the buffer data is not synchronized with the register data.

This device has of triggers available, bits corresponding to unavailable triggers, if any, have no effect.

NOTE

For the particular input connection assigned to each field in this register, see the CTU's chip-specific configuration details.

57.6.9 Trigger Handler Control Register 1 (THCR1)

Offset

Register	Offset
THCR1	24h

Function

The THCR1 register is double buffered. The update from the corresponding buffer register is controlled by the MRS signal. The THCR1 and THCR2 registers are together organized into 8 groups of enable bits. Each group is associated with one trigger from the Trigger subunit. Each group of enable bits enables corresponding to a master trigger enable, External Trigger outputs, and the ADC command list enable, respectively. If the master trigger enable Tn_E is cleared, the trigger is disabled and the other trigger enable bits in the group have no effect.

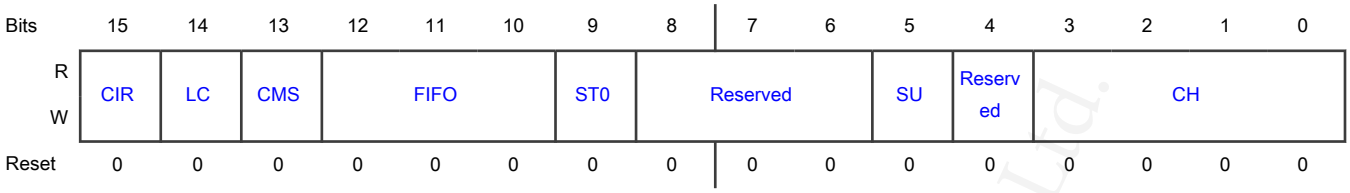
57.6.11 Commands List Register A for ADC single-conversion mode commands (CLR_A_1 - CLR_A_24)

Offset

For n = 1 to 24:

Register	Offset
CLR_A_n	2Ah + (n × 2h)

Function



The Command List Register (CLR_x_n), where n = 1,.....,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its CMS and ST0 bits. If CMS=0 and ST0=0, the single conversion mode is selected and the CLR register assumes the CLR_A_n format described in the following figure.

NOTE

Reserved fields of this register are read/write as they share same physical register and address. The value of reserved fields must be zero.

Provided under NDA only

4 —	Reserved The value of this field must be zero.
3-0 CH_A	ADC Port A Channel Number

57.6.13 Command List Register C for self-test commands (CLR_C_1 - CLR_C_24)

Offset

For n = 1 to 24:

Register	Offset
CLR_C_n	2Ah + (n × 2h)

Function

The Command List Register (CLR_x_n), where n = 1,.....,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its ST0 bit. You must first set ST0 to 1 to set the CLR register in the self-test mode register format. In this case, the CLR register assumes the CLR_C_n format described in the following figure.

NOTE

Reserved fields of this register are read/write as they share same physical register and address. The value of reserved fields must be zero.

57.6.14 FIFO DMA Control Register (FDCR)

Offset

Register	Offset
FDCR	6Ch

Function

The FDCR register enables the DMA requests issued by the CTU FIFOs. The DMA request occurs when it is enabled and the corresponding FIFO had reached a threshold defined in register FTH.

NOTE

Interrupt and DMA are controlled independently, thus FIFO DMA operation and interrupts can be enabled at the same time.

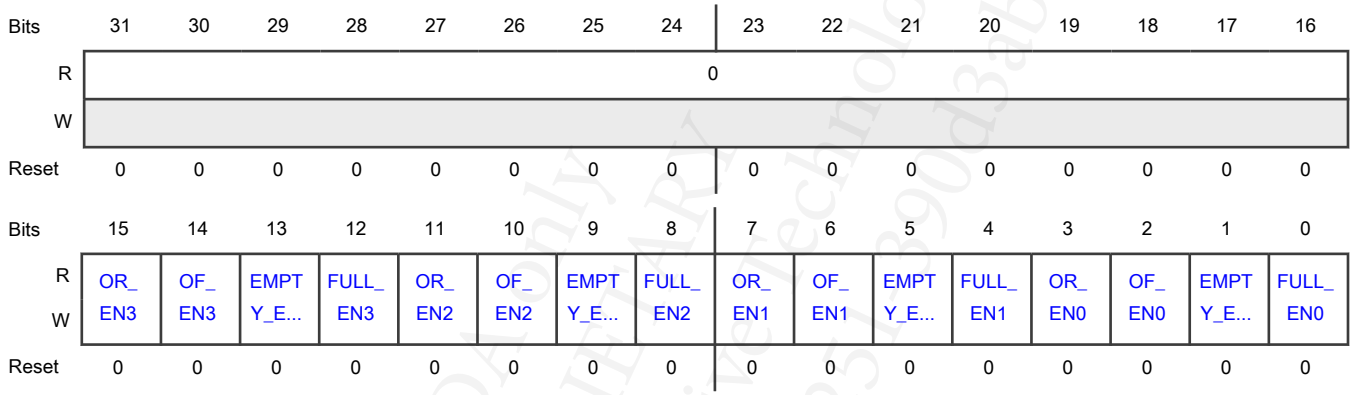
57.6.15 FIFO Control Register (FCR)



Offset

Register	Offset
FCR	70h

Function

This register implements interrupt enable bits to signal FIFO behavior. FIFO overrun, overflow, empty, and full indication from one of the FIFOs are OR-ed together to indicate through one interrupt line that one or more flags are active. After receiving an interrupt the FST register should be checked to evaluate what caused that interrupt. There is one interrupt line per FIFO module.

Diagram

57.6.16 FIFO Threshold Register (FTH)

Offset

Register	Offset
FTH	74h

Function

This register defines the threshold value for four FIFO modules. The threshold is used for comparison against the FIFO pointer and to evaluate if an overflow condition occurred for that FIFO. The overflow flag indicates that a certain amount of data, defined by the threshold value, is available in the FIFO for read. The overflow condition is set if the number of elements in the FIFO is greater than the threshold value. Thus, out of reset this register is set to detect one element in the respective FIFO since the initial value is zero.

NOTE

The threshold value should not exceed the FIFO size

57.6.17 FIFO Status Register (FST)

Offset

Register	Offset
FST	7Ch

Function

This register has the flags that indicate the status of the FIFO modules. Up to four FIFOs are supported. FIFO overrun, overflow, empty, and full flags are available. If enabled by the FCR register bits, these flags can generate an interrupt to the CPU. There is one interrupt signal per FIFO which combines overrun, overflow, empty, and full flags.

NOTE

The only actual error indication corresponds to the overrun flags which stay asserted once the overrun condition occurs. They are cleared by writing 1 to the respective flag. The overflow, empty, and full flags correspond to the current state of the FIFOs.

NOTE

Bits OR3, OR2, OR1, and OR0 can be read and cleared by software

57.6.19 FIFO Signed Left Aligned Data Register (FL0 - FL3)

Offset

Register	Offset
FL0	A0h
FL1	A4h
FL2	A8h
FL3	ACh

Function

NOTE

A read of this register consumes the data from the respective FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-20 —	Reserved
19 ADC	This bit indicates from which ADC Port the value in the DATA field corresponds to. 0b - Data coming from ADC Port B 1b - Data coming from ADC Port A
18-16 N_CH	Number of the channel that DATA field corresponds to.
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
14-3 LA_DATA	LA_DATA Data of stored channel.
2-0 —	Reserved

57.6.20 Error Flag Register (EFR)

Offset

Register	Offset
EFR	C0h

Function

The EFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

NOTE

The ERRCMP field reads 0 at reset. When reset is released, this field remains cleared until the CTU timer clock is enabled. After the CTU timer clock is enabled, ERRCMP reads 1. This field must be cleared before enabling the interrupt requests.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 —	Reserved
13 LIST_BE	List Busy Error. Indicates that a list of commands is trying to send commands to a busy ADC or to the same ADC at the same time. It also indicates a conflict in the self-test algorithm execution by the ADCs, see Self-Test Execution Errors section. Cleared if 1 is written to this bit location. 0b - No error 1b - Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 CS	Self test Counter Status. This bit indicates if a self-test algorithm is in progress. If 1 is written to this bit, a reset to the self test counter will occur, thus terminating the self-test algorithm execution. As a status bit it indicates: 0b - All the counters are at reset value, thus none of the self-test algorithm are executing 1b - One of the counters used in self test mode is not in the reset state, thus self-test is in progress.
11 —	Reserved
10 ERRCMP	Error Compare. When a match occurs, the TGS Counter has reached the TGSCCR value. Cleared if 1 is written to this bit location. 0b - No match 1b - Match
9 —	Reserved
8 —	Reserved
7 —	Reserved
6 —	Reserved
5 ADC_OE	ADC command generation Overrun Error. This bit is set if an ADC command is issued when there is a command already being processed. Cleared if 1 is written to this bit location. 0b - No Error 1b - Error
4 TGS_OSM	The TGS Overrun in Sequential Mode. This bit is set when a new event occurs before the trigger event selected by the previous event had occurred. The error is generated only if the trigger from the TGS is linked to a SU output. Cleared if 1 is written to this bit location. 0b - No overrun 1b - Overrun
3 MRS_O	Master Reload Signal Overrun. If the time window defined by two consecutive MRS is not enough for the number of programmed events in the THCR registers, an error occurs and MRS_O flag is set. Cleared if 1 is written to this bit location. 0b - No overrun

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Overrun
2 ICE	Invalid Command Error. An error that occurs when the shared channel is accessed by two ADCs at the same time, or when an ADC is already using the channel. This situation can occur with a dual conversion command or with two single conversions in parallel mode. 0b - No error 1b - Error
1 SM_TO	Trigger Overrun (more than 8 ES) in TGS Sequential Mode. If the number of positive edges of ES is higher than 8, an error occurs and SM_TO flag is set. Cleared if 1 is written to this bit location. 0b - No overrun 1b - Overrun
0 MRS_RE	Master Reload Signal Reload Error. If an MRS occurs while the user is updating a double-buffered register, the MRS_RE is set indicating an error condition. Cleared if 1 is written to this bit location. 0b - No error 1b - Error

57.6.21 Interrupt Flag Register (IFR)

Offset

Register	Offset
IFR	C2h

Function

The IFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

NOTE

The Tn_I fields read 0 at reset. When reset is released, these fields remain cleared until the CTU timer clock is enabled. After the CTU timer clock is enabled, the Tn_I fields read 1. These flags must be cleared before enabling the interrupt requests.

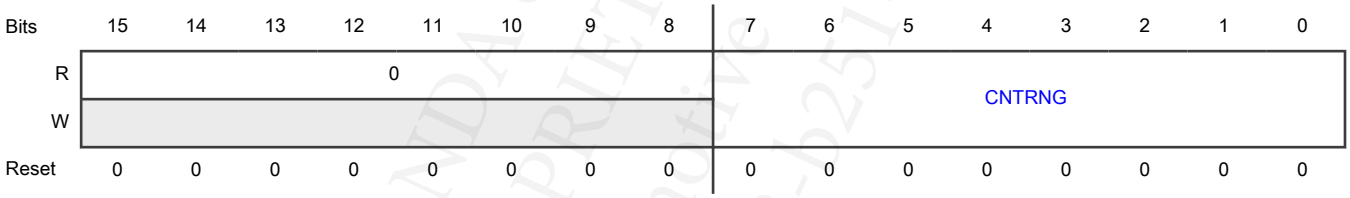
57.6.28 Counter Range Register (CNTRNGR)

Offset

Register	Offset
CNTRNGR	D0h

Function

The CNTRNGR register provides a way to mask out the less significant bits in the EXP_A and EXP_B fields of EXPAR and EXPBR registers, respectively. If set, bits in CNTRNG mask out related bits in EXP_A and EXP_B fields, thus providing a range in which a conversion should occur. The expression used for the conversion range check is: set SERR_A bit if (conversion counter & ~CNTRNG > EXP_A & ~CNTRNG) or (conversion counter & ~CNTRNG < EXPP_A & ~CNTRNG), where the conversion counter increments at system clock rate (slave bus clock rate). This equation also applies to SERR_B and EXP_B.



NOTE

The 1s in the CNTRNG must be set from the right to the left (less significant bits) without gap with 0.

NOTE

The safety counter allowed range is obtained by taking the EXPA/B value and exchanging to "X" the corresponding positions where the CNTRNG bit is 1.

Diagram

Fields

Field	Function
15-8 —	Reserved
7-0 CNTRNG	CNTRNG If set, the bits in this field mask out the equivalent bits of the expected values EXP_A and EXP_B. In this way, a range of system clock (slave bus clock) cycles is defined for a conversion to occur. This means the bit positions with 1s in the CNTRNG change the corresponding bits on EXPA/EXPB and safety counters A/B to "X". For example, with EXPA = 1b0010_1101 and CNTRNG = 0b0111, the safety counter can end with values of the format 0b0010_1XXX to avoid SERR_A error flag.

Field	Function
0 PAR_LIST	Parallel mode List. This bit selects the parallel mode for the list execution. 0b - List is executed in streaming mode 1b - List is executed in parallel mode

57.7 Functional description

The CTU is consists of two subunits: the Trigger Generator subunit, or TGS, and the Scheduler subunit, or SU. The TGS is responsible for generating triggers based on the module input signals connected to timer modules. The trigger signal from TGS is then connected to the scheduler subunit, which is responsible for the generation of ADC commands or triggers to on-chip logic such as timers. The following sections describe the TGS and SU in more detail.

57.7.1 Trigger Generator Subunit (TGS)

The Trigger Generator Subunit, TGS, generates up to eight trigger events. The main sub-blocks in the TGS are:

- Counter: generates sequential trigger events
- Trigger list: with 8 x 16-bit double-buffered registers for timing comparison

The TGS has two modes of operation:

- **Triggered mode**: each event source generates up to eight trigger event outputs.
- **Sequential mode**: each event source generates only one trigger event output.

NOTE

An *event* means a pulse generated from the selected CTU trigger inputs. It is represented in Figure 514 by the ES signal (event signal).

Trigger events can be initiated by hardware or by software. A software trigger is generated by writing to the CTU Control Register, CR. The CR register Tx_SG bits are automatically cleared by the CTU hardware when the respective trigger event is generated.

57.7.2 TGS in triggered mode

See Figure 512 that shows the TGS configuration in triggered mode.

Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a6-b251-390d1ab6...

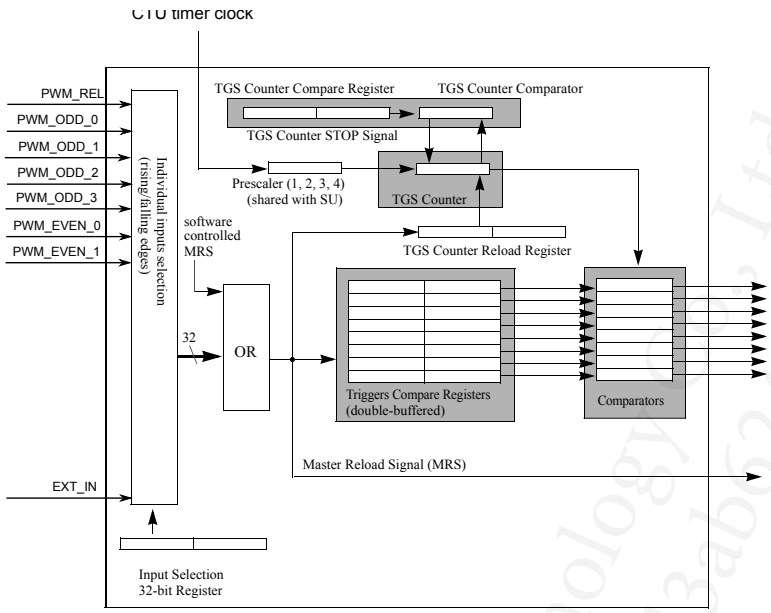

Figure 512. Trigger Generator subunit in the triggered mode

NOTE

The CTU timer clock should be connected to the same clock source used by the CTU inputs clock. See Figure 512 that shows these inputs are from the FTM generator, and EXT_IN.

The TGS has 16 input signals selected from the input selection register (TGSISR). The available selections are these:

- Inactive, no selection
- Rising edge
- Falling edge
- Both edges

Up to 2 x 16 input events corresponding to 16 input signals are selected through the TGSISR register and OR-ed in order to generate the Master Reload Signal (MRS), which defines a *control cycle*.

The MRS can also be generated by software. The software operation is done by writing to the MRS_SG bit in the CTU Control Register. The MRS_SG bit is self cleared; thus, it reads always as 0. The MRS is used to re-load the TGS Counter Register with the values from the double-buffered TGSCRR register. The MRS is also used to re-load all double-buffered registers, such as the trigger compare registers, TGSCR and TGSCRR, with the corresponding buffered values.

The triggers list registers consist of eight compare registers (T0CR through T7CR). Each register is associated with a comparator, where a match generates an output trigger. On the occurrence of a re-load triggered by MRS, the comparison for trigger events generation starts from the first cycle of counting. However, the comparison with the TGS Counter Compare Register (TGSCCR) is always disabled during one TGS clock cycle and then re-enabled. A match between the TGSCCR and TGS counter stops the TGS counter. Therefore, this one cycle disable allows the user to configure the TGSCCR and TGSCRR with the same value.

The prescaler for TGS and SU is defined by the PRES bits in the TGS Control Register and divides the CTU timer clock. The available selections for the prescaler values are 1, 2, 3, and 4.

Figure 513 shows a timing diagram for the TGS operation in the triggered mode. The MRS and the trigger event occurrences are indicated along with the delay relative to the MRS occurrence.

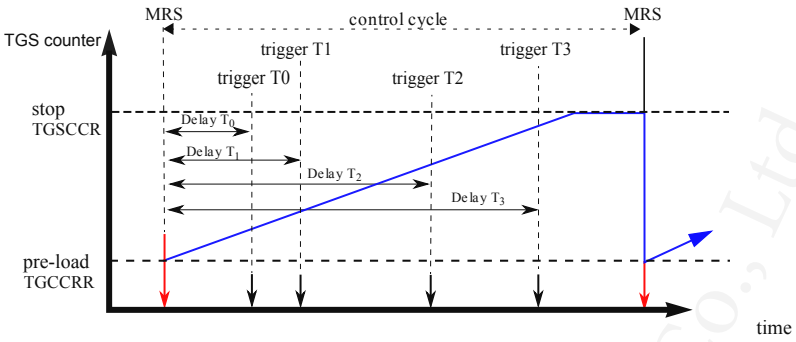

Figure 513. Example timing diagram for TGS in triggered mode

57.7.3 TGS in sequential mode

Figure 514 shows the blocks and signals related to TGS in sequential mode.

In sequential mode, only one of the 2 x 16 input signals is selected by the 5-bit MRS_SM (master reload selection). The selected signal re-loads the trigger list and resets the 3-bit ES counter which selects the trigger event. Sequences of up to eight trigger events are generated in one control cycle.

The 2 x 16 input events corresponding to 1'd0 input signals with 2 edges detection per signal are individually enabled through the register TGSISR and OR-ed in order to generate the event signal ES. This signal is used to re-load the TGS counter register and to increment the 3-bit ES counter.

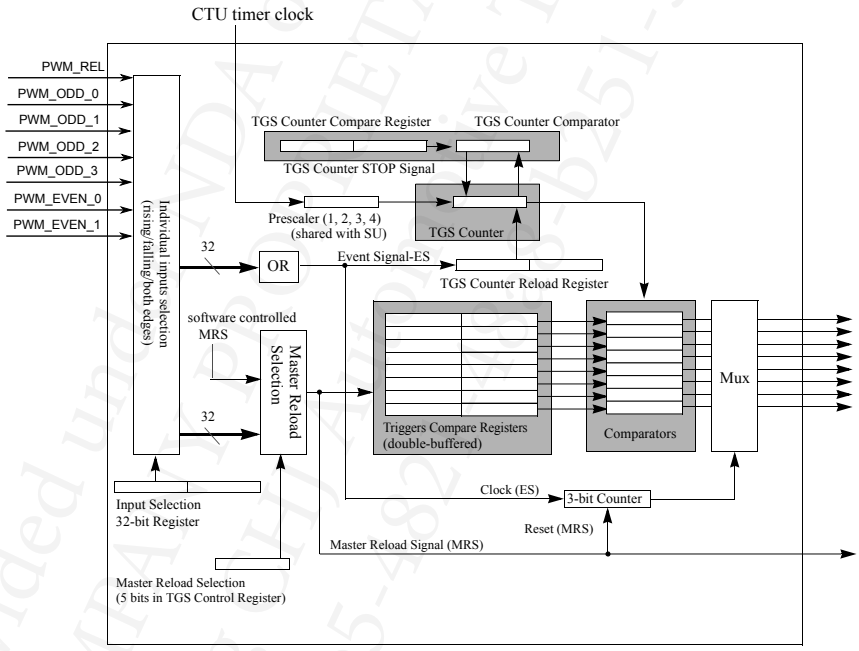

Figure 514. TGS in sequential mode

Figure 515 is a timing diagram for TGS in sequential mode showing the MRS and ES. The trigger events are indicated by a delay with respect to ES. Note that the ES and MRS are aligned in the beginning. The TGS counter is re-loaded on each ES and starts counting up until the next ES or until it matches the value in the TGSCCR register and stops.

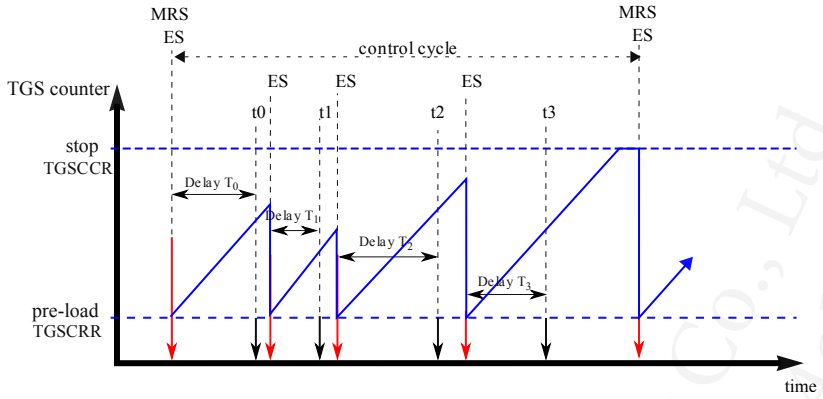

Figure 515. Example timing diagram for TGS in sequential mode

57.7.4 TGS counter

The TGS counter counts from negative to positive values as defined by the re-load and stop values defined in register TGSCRR and TGSCCR, respectively. The maximum counter value is 0x7FFF; after that, a counter wrap occurs and the counter value transitions from 0x7FFF to 0x8000. The following figure shows TGS counting examples.

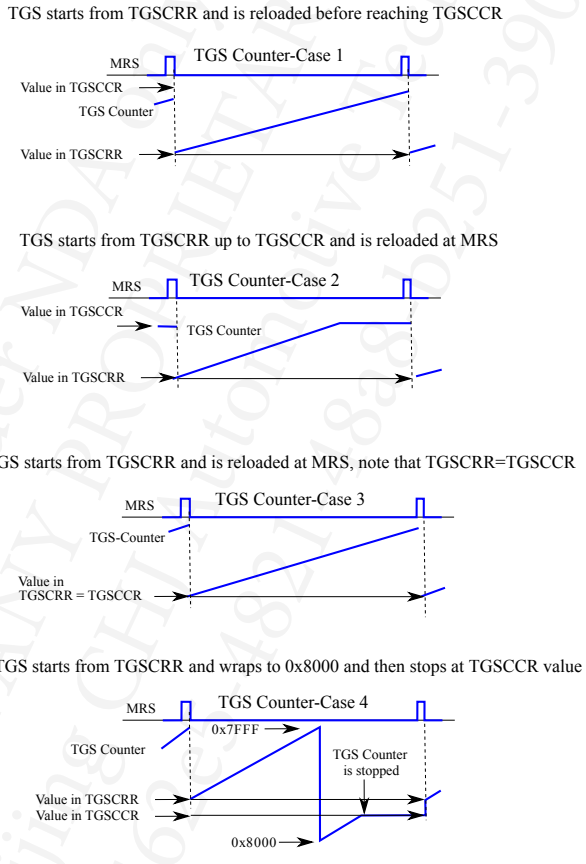

Figure 516. TGS counter behavior

NOTE

The TGS counter starts counting after an MRS and only stops if a counter wrap occurs and the TGSCCR value is reached before the next MRS occurs.

Loading the initial value of TGS counter in Triggered mode

TGSCRR is a double-buffered register. It has a CPU copy (TGSCRR) and a buffered copy (B_TGSCRR) for internal operation. The TGS counter and B_TGSCRR are loaded on the MRS pulse at the same clock cycle. So, the TGS counter is loaded with the existing value of B_TGSCRR before it is updated from TGSCRR. For this reason, the modified value of TGSCRR takes effect after one control cycle.

Following is a timing diagram of the TGSCRR and TGSCCR register updates. The CPU updates the TGSCRR and TGSCCR during the Nth control cycle (1), and then their buffer copies are updated with new values on the next MRS pulse (2). Because the TGS counter is loaded on the same MRS (3), it is reloaded with B_TGSCRR on the second MRS pulse (4) after the CPU writes the new values into the TGSCRR. So, the effect of TGSCRR takes place at N+2 control cycle (4) whereas the effect of TGSCCR takes place in N+1 control cycle (5).

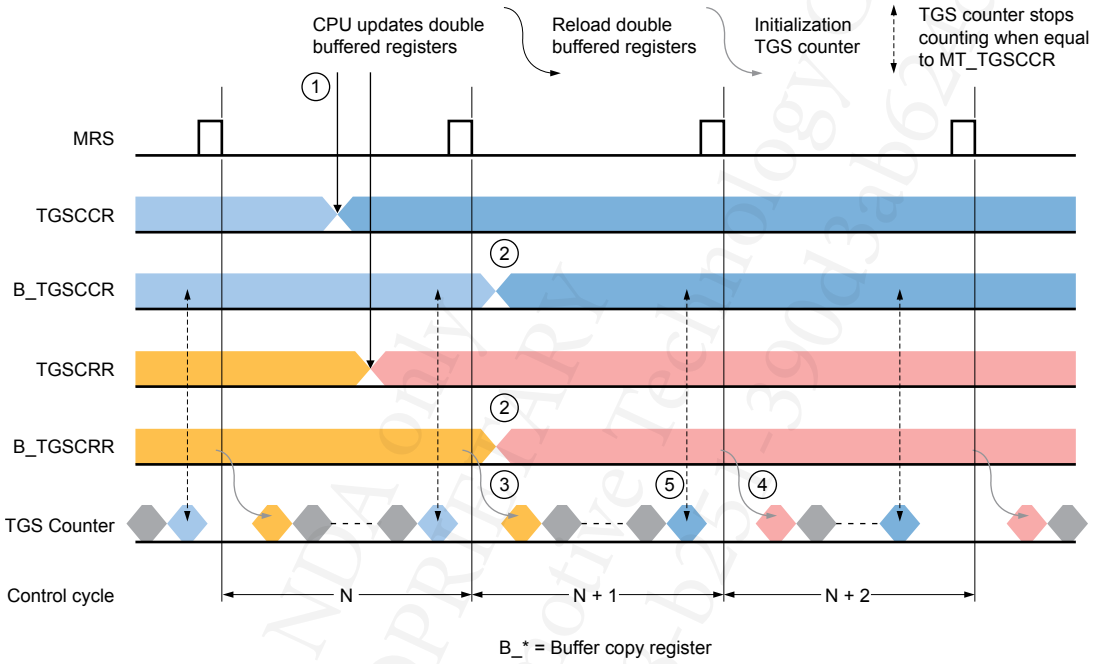

Figure 517. Update TGSCRR in the Triggered mode

NOTE

So, to conclude, the initial value of TGS counter, TGSCRR, must be set one control period earlier than the rest of the double-buffered registers.

Loading the initial value of TGS counter in Sequential mode:

In this mode, the TGS counter is loaded with B_ TGSCRR on every ES pulse, unlike in the Triggered mode. The MRS pulse always coincides with any one of the ES pulses, so they both occur on same clock cycle. For this reason, the TGS counter is loaded with the actual value of B_TGSCRR before it is updated from TGSCRR. So, the modified value of TGSCRR takes effect on the second ES pulse of the next control cycle with respect to the write to TGSCRR by CPU.

Following is the timing diagram of the TGSCRR and TGSCCR register updates. The CPU updates the TGSCRR and TGSCCR during the Nth control cycle (1), then their buffer copies are updated with new values on the next MRS pulse (2). Because the TGS counter is loaded on the same MRS (3), it is reloaded with updated B_TGSCRR on the second ES pulse (4) at N+1 cycle after the CPU writes the new values into the TGSCRR. So, the effect of TGSCRR takes place at N+1 control cycle (second ES pulse onwards (4)) whereas the effect of TGSCCR takes place in N+1 control cycle (first ES pulse onwards (5)).

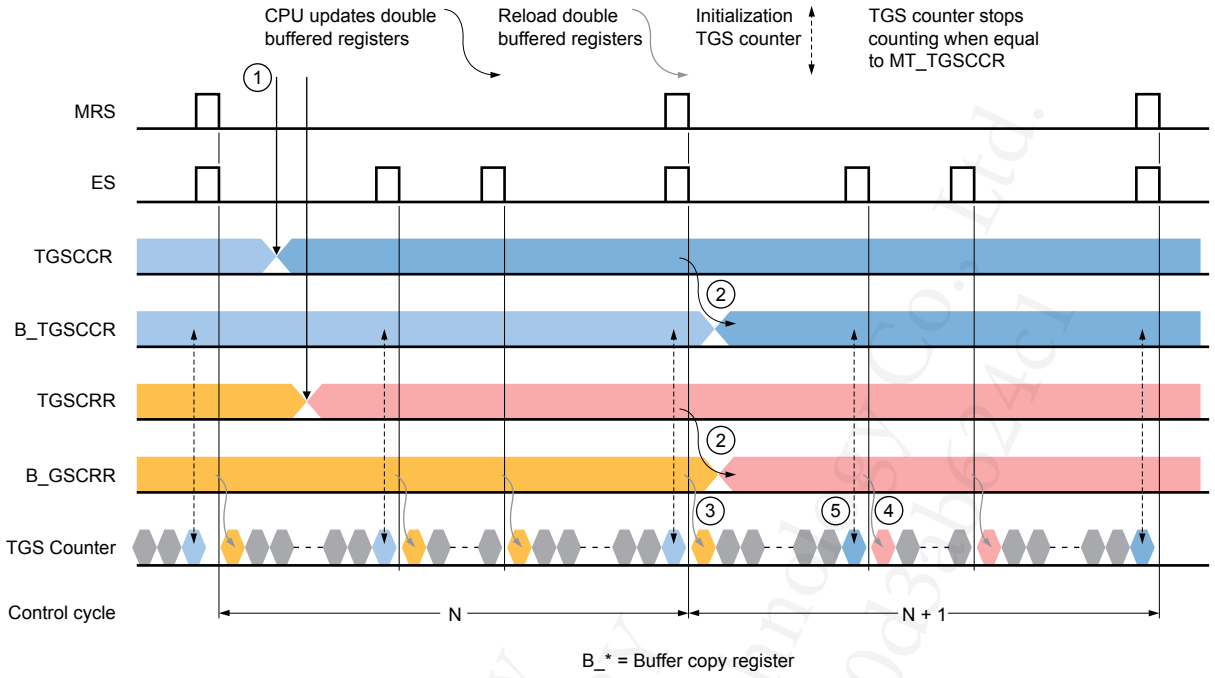

Figure 518. Update TGSCRR in the Sequential mode

57.7.5 Scheduler subunit (SU)

The following figure shows the block diagram of the Scheduler subunit. The SU trigger event outputs are these:

- ADC command or ADC stream of commands

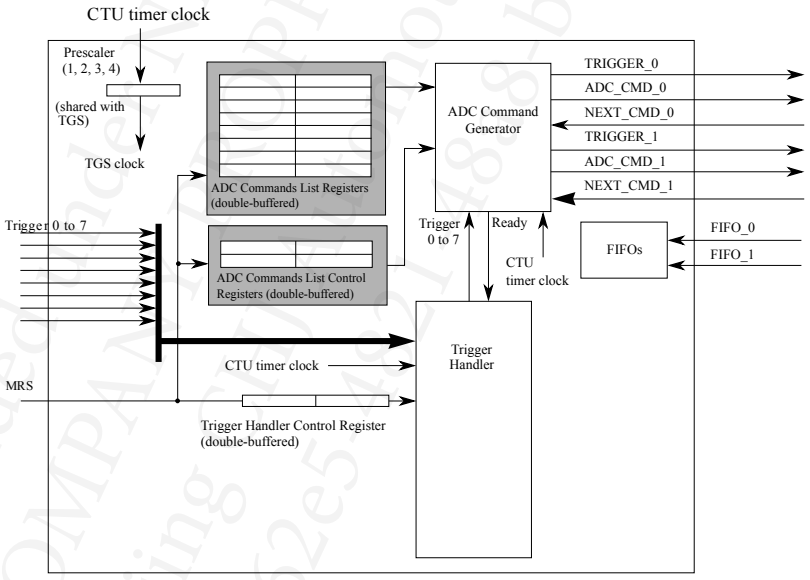

Figure 519. Scheduler subunit

The SU receives eight trigger signals from the Trigger Generator subunit(TGS) and starts a command list to the selected ADC or generates the trigger event outputs. This module has the same functionality in both TGS modes: triggered and sequential. Each of the 2 SU outputs can be linked to any of the eight trigger events from TGS. This is implemented by the Trigger Handler block. Each trigger event can be linked to one or more SU outputs.

If two events are linked at the same time to the same output (either ADC commands or output triggers), an error is generated and flagged in the EFR register's TnOE bits. In this case, only the trigger with the lowest index is used. For example, if trigger 0 and trigger 1 are linked to the same ADC output and they occur at the same time, an error is generated and the ADC command corresponding to trigger 0 is generated.

When a trigger is linked to an ADC, an associated ADC stream of commands is generated. The ADC Commands List Control Register CLCR1/2 defines the list entry point that is the first command to be executed. Subsequent list pointers are generated in an incremental way as the commands in the list are executed.

57.7.6 ADC commands list

The SU implements a command list that stores the ADC commands. The command list stores up to 24 x 16-bit commands (see ADC command list format) in a double-buffered implementation. The command list buffer registers may be updated at any time between two consecutive MRs, but the changes are transferred from the buffers to the actual registers only after an MRS occurs, so a correct reload procedure is performed (see Reload mechanism). The first command in a list is pointed by the 5-bit CLCRx register. After a command list is triggered, it executes until the last command is found. The last command (n) is defined by the LC bit of the next command (n+1) in the list. Note that the command with LC=1 does not belong to the list and thus it is not executed. Also note that the LC bit is ignored in the first command of a list. See the command list registers, CLR_A_n, CLR_B_n, or CLR_C_n, where n = 1,...,24. The figure below describes the state diagram for the Commands List execution. A sequence of commands on the list is executed until the last command is found. See ADC command list format for more details.

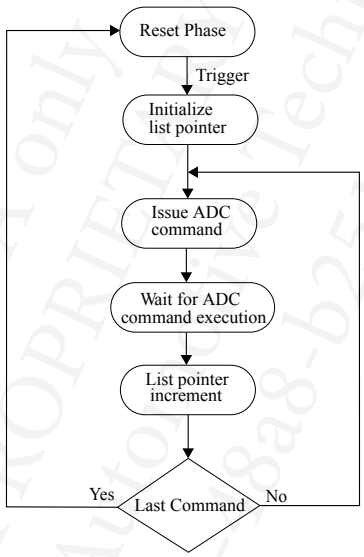

Figure 520. ADC command list scanning state diagram

NOTE

The CTU reads the next command line (the LC bit) to determine if the present command is the last one to be executed.

57.7.7 ADC command list format

The ADC command can be configured for single or dual conversion. In single conversion mode, the command targets one ADC only. In dual conversion mode, the conversion command is sent to both ADCs at the same time. Due to the clock domain crossing between CTU and ADCs, there could be a misalignment of up to one ADC clock cycle between the two commands.

The result of each conversion, in both modes, is stored in one of the four available FIFOs. In dual conversion mode, both ADCs store the result of their conversion in the same FIFO. If both ADCs access the FIFO in the same clock cycle, ADC unit A has higher priority, otherwise the first available conversion result is stored first.

The CTU supports up to 2 x 16 channels for both ADCs. The same physical channel cannot be assigned for both ADCs in a dual conversion mode. If there is an attempt to do so, an error is flagged in the EFR register's ICE bit, but the CTU sends the command to both ADCs.

In general, an ADC command consist of the following fields depending upon the conversion format used (see Commands List Register A for ADC single-conversion mode commands (CLR_A_1 - CLR_A_24)):

- Channel A: ADC A channel number (4 bits)
- Channel B: ADC B channel number (4 bits)
- Target ADC selection: ADC A or ADC B used in single conversion mode only (1 bit)
- FIFO selection bits for the selected ADC unit: up to four FIFOs (2 bits)
- Conversion mode selection: single or dual conversion mode (1 bit)
- Last command (LC): defines the last command in a list (1 bit)
- Interrupt request: enable interrupt request on command execution (1 bit)

The first command of a list is indicated by the CLCR1/2 registers' Tx_INDEX field. The last command is indicated by the last command bit(LC) of the following command in the command list. The first command is always executed, and the execution of the following commands is controlled by the LC bit.

The figure below describes several scenarios for the command sequencing. If the first command indicated by the CLCR1/2 register is one of the lines identified as "Last command," then the list is a single command list. Also note that the list pointer wraps back to the first command in the list after command 24 is executed and if it is not the last command. If no command is defined as the last command, then the list is executed continuously in a loop of 24 commands.

- Command List A: two command queues are available with elements 4 and 24 being last commands
- Command List B: sub-list 1 with one single command at address 1, and sub-list 2 with a queue of commands with last command at address 24
- Command List C: sub-list 2 with one single command at address 24, and sub-list 1 with a command queue with last command at address 23
- Command List D: two command queues with a wrap at address 24

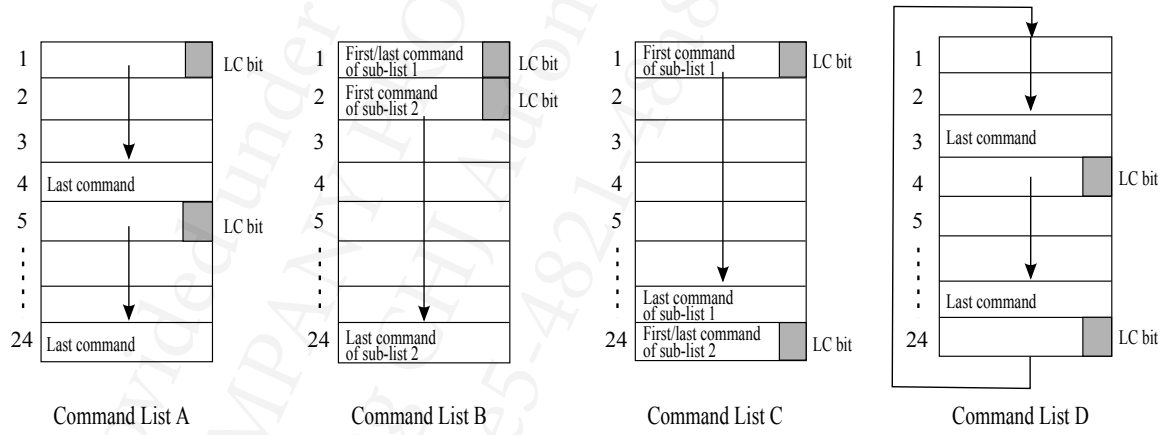

Figure 521. Command list sequencing

NOTE

The addresses shown in in the above figure do not represent addresses in the memory map. Please refer to the Memory Map section to check for the actual addresses.

57.7.8 ADC command list operation modes

There are two modes of operation in the ADC command list execution: streaming mode and parallel mode. In the streaming mode, the command lists should behave as a stream of commands, indicating that two or more lists cannot be executed at the same time, but only in a sequence. Thus, if list 1 is triggered, it should finish the execution of its last command before list 2 can be triggered. If there is an attempt to trigger more than one list at the same time, then an error occurs.

In the parallel mode, up to two lists can be executed at the same time. To avoid errors during the execution of two parallel lists, they should not have commands for both ADCs. Therefore, if list 1 has commands for ADC A, then list 2 should only have commands for ADC B. Also note that if a shared analog input is used by one of the lists, it should not be used by the other list to avoid a contention and therefore an error. ADC dual conversion commands should also not be used in the parallel mode.

Figure 522 shows the execution of two lists in streaming mode. While a list is being executed, any attempt to trigger the execution of another list while in this mode will cause an error. Note that both lists may have commands for ADC A or B with no restriction. Also, dual commands may be used.

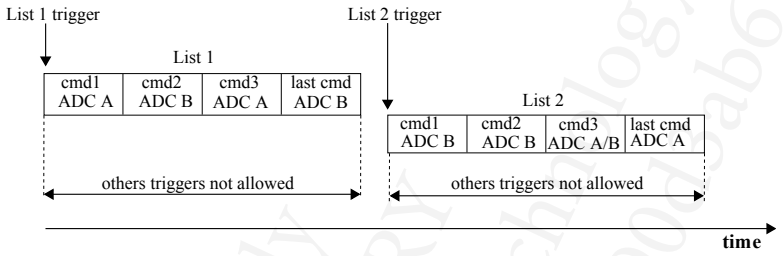

Figure 522. List execution in Streaming mode

Figure 523 shows the execution of two lists in the parallel mode. There are no restrictions for the triggers of both lists. After the two lists are triggered, no other triggers are allowed. If there is an attempt to trigger a third list while lists 1 and 2 are executing, then an error is issued by setting the ADC_OE bit in the EFR register. Note that list 1 only has commands for ADC A and list 2 only has commands for ADC B. Having ADC A and ADC B commands in the same list may cause an error because two commands for the same ADC cannot be executed from different lists at the same time.

NOTE

The mixing of commands for both ADCs in the same list in the parallel mode must not be used because the correct execution of commands in this case is not guaranteed by the CTU hardware.

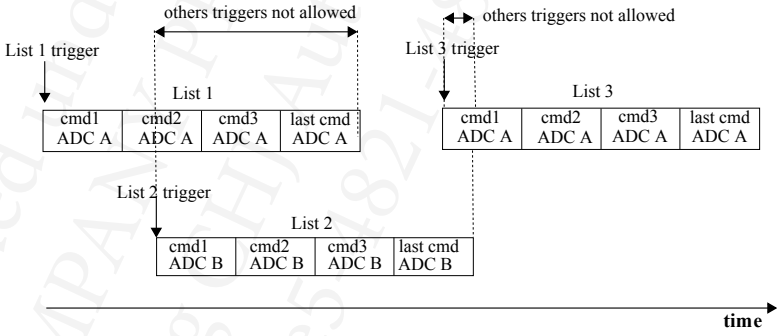

Figure 523. List execution in parallel mode

The list mode is controlled by the PAR_LIST bit in the LISTCSR register.

57.7.9 ADC results FIFOs

ADC results are stored in one of the four FIFOs. These FIFOs allow the storage of ADC results according to the type of data acquisition (phase currents, rotor position, ground-noise, and so on) so the software can distinguish data from several ADC channels. Each FIFO has its own interrupt line, DMA request signal, and a status register. The target FIFO for a conversion result

is specified in the ADC command. Each FIFO element is 32-bit wide. The following figure shows the FIFO selection for ADC A and ADC B results.

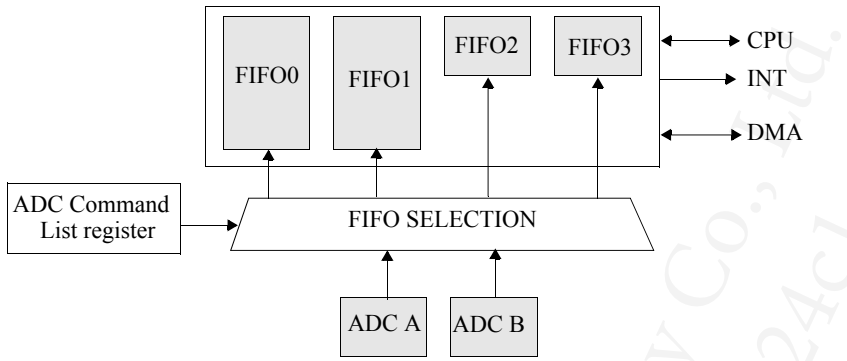

Figure 524. FIFO selection for ADC results storage

CTU has 4 FIFOs. The depth of each FIFO is fixed as given below:

- FIFO 0 : depth is 8.
- FIFO 1 : depth is 8.
- FIFO 2 : depth is 8.
- FIFO 3 : depth is 8.

FIFO access can be performed by 16-bit or 32-bit read transactions. If a 32-bit reads the conversion result, the target ADC and the channel number are accessed. An 8-bit access must not be used; otherwise, the FIFO pointer increments and the complete data is not retrieved. The FIFO result register can be read in a right- or left-aligned format using two different addresses:

- Unsigned right-justified, read from register FLx (for FIFO x)

  Conversion result is unsigned right-justified data, that is bits [11:0] are used for a 12-bit resolution and bits [15:12] always return zero

- Signed left-justified, read from register FLx (for FIFO x)

  Conversion result is signed left-justified data, i.e. bit [15] is reserved for sign and is always read as zero, bits [14:3] are used for 12-bit resolution and bits [2:0] always return zero

The FIFO access should be based on the status bits in the FCR register. Empty and full indications are provided. If data is read from an empty FIFO, then the read data should not be considered as valid data. Note that there is no indication of an underflow condition. If the FIFO is full and there is an attempt to write more data, then the new data is not written to the FIFO and an overrun flag is set.

57.7.10 Reload mechanism

To assure coherent programming, several CTU registers are double-buffered, thus allowing the programming of new data on the buffers while not affecting the data being used. All the registers are uploaded with buffer data at the same time. For the majority of the CTU registers, the re-load is controlled by the Master Reload Signal(MRS).

As the Master Reload Signal is generated by the hardware, it may occur while the software is still updating the buffer registers. In this case, non-coherent values are written to the registers because the CPU did not finish the programing of all registers. To avoid this situation, a General Reload Enable(GRE), control bit is provided. If GRE is cleared, then no reload occurs. If this bit is set, then the reload is performed when MRS occurs. The GRE bit is automatically cleared by MRS or is cleared by software using the CGRE bit in the same register. The CGRE bit is self-cleared and thus always read as zero.

The software should be able to program all registers buffers within a control cycle. To help the software to evaluate that a flawless register programing was executed, the MRS_RE flag is provided in the EFR register. If cleared, this flag indicates that all register buffers were programed before MRS occurred, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programing cycle has initiated.
- Set GRE to indicate that all updates to the buffer registers were performed.
- The reload of all registers is executed when the MRS occurs. Because GRE is set, MRS_RE is not be set.
- GRE and FGRE are cleared when MRS occurs.

See Figure 525 for more details.

An error is flagged by MRS_RE when MRS occurs, GRE is cleared, and FGRE is set. This scenario indicates that the software has initiated a register programming but has not finished it before the MRS, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programing cycle has initiated.
- MRS occurs and GRE is not set. In this case, MRS_RE is set and, if enabled, an interrupt is generated.
- FGRE is not cleared when MRS occurs and no register is updated, because GRE is cleared.

Note that the software does not need to update all double-buffered registers during a *control cycle*. To avoid the error indication, it is sufficient to set GRE before an MRS occurs.

A race condition occurs when GRE is being cleared by CGRE at the same time that an MRS occurs. In this case, GRE is considered to be cleared and no reload occurs. Another race condition may occur between CGRE and GRE being set. Because these two bits are in the same register, they could eventually be set at the same time. In this case, CGRE has precedence; thus, GRE is cleared.

NOTE

MRS has priority over the TGSISR_RE bit in the CR register, which is the re-synchronization bit of the TGSISR.

The following figure describes two scenarios for the register re-load. Scenario (a) is a normal re-load where the buffers of the double-buffered registers are programmed and the GRE bit is set before the next MRS occurs. The scenario presented in (b) describes an error condition where the software did not signal the hardware that all registers are ready for re-load before the next MRS. This is indicated by GRE being at zero when MRS occurs. In this case, the MRS_RE flag is set indicating the fault condition.

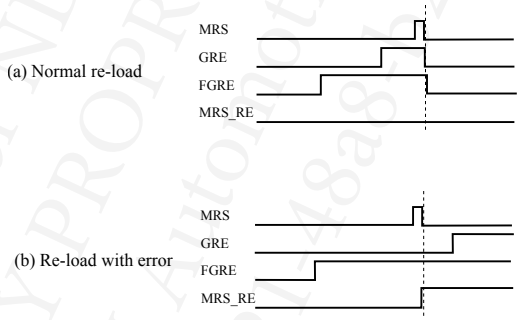

Figure 525. Reload scenarios

NOTE

If MRS is generated by software (by writing 1 b to CTU_CR [MRS_SG]) after GRE is set then due to longer processing path of GRE bit compared to MRS_SG bit, the effect of GRE may reach later occasionally in MT clock domain than MRS_SG (based on relative positioning of clock edges), consequently the original write sequence (GRE set -> MR pulse) may get reversed (MR pulse -> GRE set) in MT clock domain. This leads to loading error and MRS_RE is set with GRE and FGRE is not cleared. To avoid this situation user must maintain a minimum delay between the writes of GRE bit and MRS_SG bit as defined in the equation below.

The delay between writes of GRE and MRS_SG need to meet the below equation:

D min = 2 (system clock period + CTU timer clock period)

57.8 Interrupts and DMA requests

57.8.1 DMA support

The DMA interface can be used to configure the CTU registers. A DMA request is issued if MRS occurs and the GRE bit is set. In this case, the previously transferred data is loaded from the buffers into the registers and a new transfer cycle is initiated with the DMA request. The DMA done signal from the DMA controller is used to set the GRE bit that allows the reload to be performed. The following figure describes this operation.

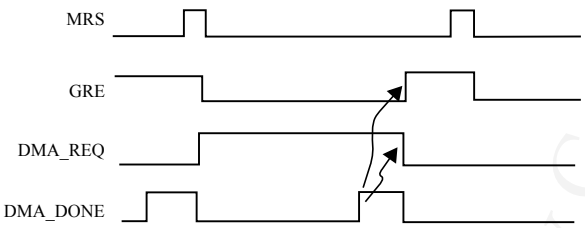

Figure 526. Register reload using DMA

DMA support can also be provided for reading FIFO stored data. Each FIFO can be configured to perform a DMA request when the number of stored words reaches a threshold value defined in the FTH register. See the FIFO Threshold(FTH), register for more information. After a DMA_DONE and the remaining data in the FIFO is below the watermark, the DMA request is removed. For an efficient operation, the DMA should be configured to execute a loop reading all the data in the FIFO, considering the amount of data the same as defined by the watermark.

57.8.2 CTU faults and errors

The CTU detects and signals the following error conditions:

- MRS reload error: MRS occurs while a user is updates the double-buffered registers.
- Sequential mode trigger overrun SM_TO: More than eight event signals occur before the next MRS in the TGS sequential mode.
- Trigger event overrun indicated by interrupt signals ADC_OE .
- The CTU allows the user to pre-set a trigger to eTimer1 in the middle of an ADC conversion. In parallel mode, even two ADC commands can be issued at the same time. The error only occurs if the second trigger is targeting the same ADC.
- Invalid (unrecognized) ADC command occurs and the ICE bit is set.
- Master reload signal overrun MRS_O: MRS occurs before all triggers selected by Tn_E and TnETE or TnTmE or Tn_ADCE bits in THCR1/2 registers have occurred.
- TGS_OSM TGS overrun in sequential mode: new event occurs before the trigger event selected by the previous event had occurred.

The faults/errors flags in the CTU error flag register and in the CTU interrupt flag register can be cleared by writing 1 to the respective bit. Writing 0 to these bits has no effect.

NOTE

The CTU does not support write-protection mechanism for any register, indicating that all registers are accessible at any time.

The CTU does not generate a transfer error when its reserved address space is accessed.

57.8.2.1 CTU parallel list errors

The command list operation in parallel mode may generate errors because two lists may be in execution at the same time. Following are some of the error conditions:

Commands for the same ADC are issued at the same time by two lists. In this case:

- One of the commands is disregarded and an error is issued.

- The LIST_BE bit in the EFR register is set.
- The address of the list commands is shown in the LISTCSR register.
- The address of the command that was not executed is indicated in the LISTCSR register.

A third list is triggered when two lists are already being executed. In this case:

- The third list is not executed and an error is indicated by the ADC_OE bit in the EFR register.

One list is being executed and a second list is triggered; the first command of the second list is for the same ADC being used by the first list. In this case:

- The command of the second list is not executed.
- The address of the second list command is shown in the LISTCSR register.
- The LIST_BE bit in the EFR register is set.

57.8.3 CTU interrupt/DMA requests

The CTU generates the following interrupt/DMA requests which are controlled by the IR register:

- Error interrupt request, see CTU faults and errors (1 interrupt line)
- ADC command interrupt request (1 interrupt line).
- MRS interrupt request (1 interrupt line)
- Trigger event interrupt request (1 interrupt line for each trigger event)
- FIFOs interrupt and/or DMA transfer request (1 interrupt line for each FIFO). See FIFO control register, FCR.
- DMA transfer request on the MRS occurrence if GRE bit is set

57.9 Self-test mode

The CTU is capable of issuing a self-test command to the ADC.

The CLRx register is used to set up a self-test command. Table 522 describes the ST0 and ST1 bits that control self-test functionality.

Table 522. Self-test command

ST_CMS bit	ST1 bit	ST0 bit	Command description
0	Not Used	0	no self test single conversion
1	Not Used	0	no self test dual conversion
Not Used	0	1	self test command
0	1	1	no self test command single conversion
1	1	1	no self test command dual conversion

Two algorithms are available in self-test mode, see Table 523.

Table 523. Self-test algorithm selection

ALG[1]	Number of steps	Executed Algorithm
00	3	Algorithm S
01[2]	-	Reserved

Table continues on the next page...

Table 523. Self-test algorithm selection (continued)

ALG[1]	Number of steps	Executed Algorithm
10	12	Algorithm C
11	15	Algorithm FULL (S + C)

1. ALG refers to the CLRx register field.
2. The 01 selection causes a command execution error and the LIST_BE flag is set in the Error Flag Register (EFR).

The self-test S algorithm is executed in an atomic burst of conversions independent of the BSIZE value in the CLRx register. The steps for this algorithm execution are these:

- Step 0: VREF test
- Step 1: VDD/VREF test
- Step 2: VREF/VREF test

When the FULL algorithm is selected, the CTU executes the S algorithm followed by the C algorithm.

The self-test execution follows the trigger scheme selected for the CTU, and either the triggered mode or sequential mode can be selected.

To completely execute one of the algorithms described in Table 523, a certain number of steps need to be performed. Each step corresponds to the time for one ADC conversion to complete. These steps may be executed at once, by just one command, or they can be interleaved with other ADC commands. To executed self-test commands interleaved with other conversion commands it is sufficient to set the BSIZE field in the CLRx register for a value lower than the number of steps defined for the selected algorithm. The following figure shows the execution of the C algorithm interleaved with regular ADC commands.

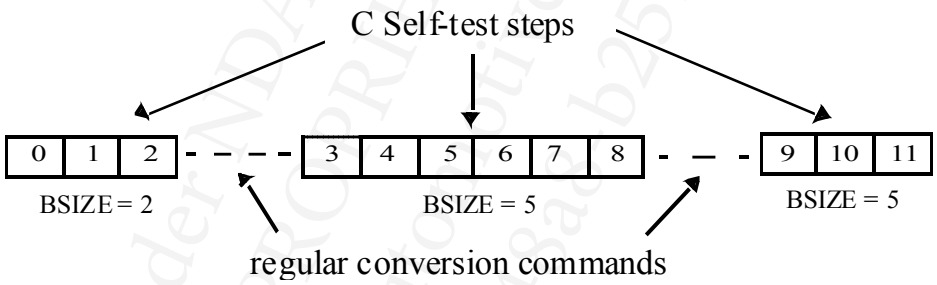

Figure 527. C Algorithm execution interleaved with others ADC commands

In the figure above, the last C self-test sequence intentionally shows BSIZE set to a larger value than the remaining steps needed to complete the C algorithm. In this case, the number of executed self-test steps do not follow BSIZE but instead follow the number of remaining steps for the selected self-test algorithm, which in this case is three steps.

NOTE

The S algorithm steps do not interleave with other ADC commands even if BSIZE is smaller than 3. Independent of the BSIZE value, all the three steps of the S algorithm are executed in a contiguous sequence.

The number of steps needed to completely execute the selected self-test algorithm are as follows:

- S algorithm requires three steps
- C algorithm requires 12 steps
- FULL runs all algorithms and requires 15 steps

In the figure below, the FULL algorithm is executed, interleaved with other ADC commands. The BSIZE = 3 in the first and second self-test commands produces different number of executed self-test steps.

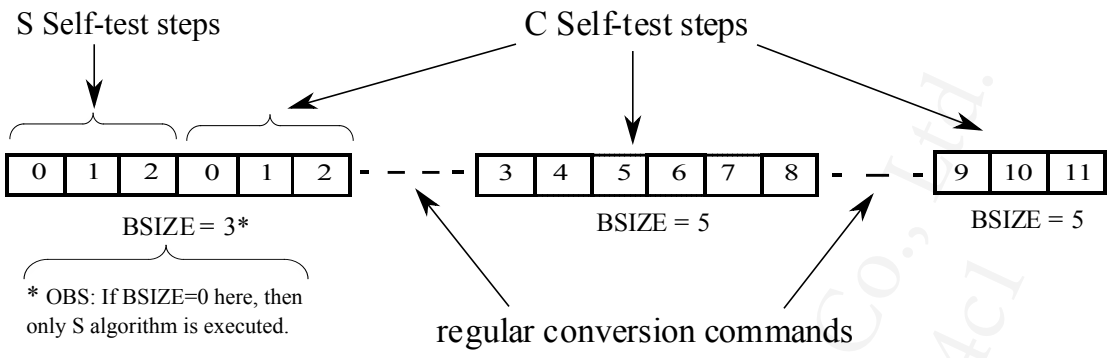

Figure 528. FULL algorithm execution interleaved with other ADC commands

57.9.1 Self-test execution errors

When a self-test algorithm is initiated for an ADC, it should complete before any other self-test algorithm is started in the same ADC. In other words, one self-test algorithm should not be interleaved with another self-test algorithm. Any attempt to do so causes the ongoing list execution to be halted and then cause the LIST_BE error flag to be set. See Error Flag Register (EFR)) for more information. To evaluate if a self-test algorithm is running, the CS bit can be checked. See Error Flag Register (EFR) for more information.. If set, this bit indicates a self-test has initiated in one of the ADCs. If a self-test algorithm conflict occurs, as described, the recovery procedure is to issue a software reset through the CTU_ADC_R bit in the CR register.

An error condition is also caused when the reserved value 01 is selected for the self-test algorithm see Error Flag Register (EFR).

Chapter 58
Analog-to-Digital Converter (SAR_ADC)

58.1 Chip-specific SAR_ADC information

58.1.1 SAR_ADC instances

The chip has two SAR_ADC instances, SAR_ADC_0 and SAR_ADC_1.

58.1.2 SAR_ADC resolution

Each SAR_ADC instance has 12-bit resolution.

58.1.3 Analog watchdogs

Each SAR_ADC instance has eight analog watchdogs.

58.1.4 Normal and injection trigger

Normal and injection triggers are supported through package pins and additional hardware triggers via CTU. CTU can trigger conversion only on external channels (mapped from pads). For details, see the IOMUX file attached to this document. This chip does not support CTU-initiated self-test on SAR_ADCs.

58.1.5 SAR_ADC channel assignments

This chip does not support any external analog muxes.

The following table identifies channel assignments for the SAR_ADC module.

Channel number	Group	Channel name	Channel type
SAR_ADC_0			
0	0	ADC_CH_00	Precision
1	0	ADC_CH_01	Precision
2	0	ADC_CH_02	Precision
3	0	ADC_CH_03	Precision
4	0	ADC_CH_04	Precision
5	0	ADC_CH_05	Precision
6	0	ADC_CH_06	Precision
7	0	ADC_CH_07	Precision
8–31	Reserved	Reserved	Reserved
32	32	Scaled Bandgap reference	Internal
33–34	Reserved	Reserved	Reserved
35	32	DVDD/2	Internal

Table continues on the next page...

Table continued from the previous page...

Channel number	Group	Channel name	Channel type
36	32	AVDD[1]	Internal
37	32	VREFL	Internal
38	32	VREFH	Internal
SAR_ADC_1			
0	0	ADC_CH_08	Precision
1	0	ADC_CH_09	Precision
2	0	ADC_CH_10	Precision
3	0	ADC_CH_11	Precision
4	0	ADC_CH_04	Precision
5	0	ADC_CH_05	Precision
6	0	ADC_CH_06	Precision
7	0	ADC_CH_07	Precision
8-31	Reserved	Reserved	Reserved
32	32	Scaled Bandgap reference	Internal
33-34	Reserved	Reserved	Reserved
35	32	DVDD/2	Internal
36	32	AVDD[1]	Internal
37	32	VREFL	Internal
38	32	VREFH	Internal
39	Reserved	Reserved	Reserved

1. AVDD corresponds to VDD_ADC.

58.2 Introduction

The ADC has 12-bit resolution and uses the Successive Approximation Register (SAR) method. It provides fast and accurate conversion, and is highly configurable for a wide range of applications.

58.3 Overview

The following figure shows the high-level interface diagram of the SAR_ADC.

Provided under NDA ONLY
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.
c8c462e5-4e21-48a8-b0f3-590d3ab624c1

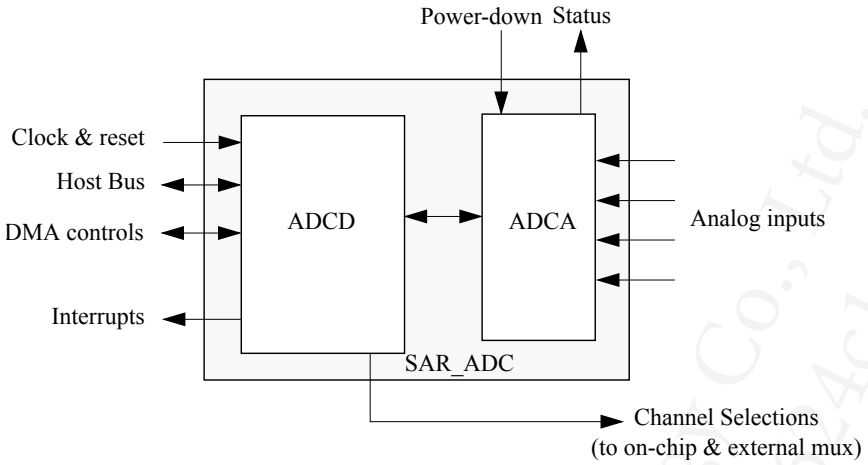

Figure 529. SAR_ADC high-level interface diagram

58.3.1 Interfaces

The SAR_ADC interfaces as shown in Figure 529 are as follows:

- Analog inputs to sample the channels to be converted.
- Channel selection controls are provided to use internal or external analog multiplexers.
- Host Bus allows access to configuration, control, and status registers which are used to start/stop conversions, monitor the conversion results, errors, violations, and so on.
- DMA interface transfers conversion results by the DMA controller.
- Interrupts can be generated for various events depending on configuration (data availability, threshold violation, error, and so on).
- Hardware triggers are used to start conversion from sources external to the SAR_ADC.
- Cross Triggering Unit (CTU) interface allows triggers from the CTU on the chip to start conversions.
- Power-down controls are used to place the analog block into a deactivated state.
- Fault indications from runtime self-test are generated for supply and analog faults.

58.3.2 Submodules

The SAR_ADC consists of two major functional parts:

- ADC Digital (ADCD)
- ADC Analog hard macro cell (ADCA)

The ADCD controls the ADCA. The ADCD holds the configuration, control, and status registers that are accessible through software using the host interface. The ADCD executes the SAR Control algorithm. The selection of channel multiplexers and analog gates are driven by the ADCD based on user configuration. Conversion results are stored in registers, and the results can be transferred to memory by DMA or read by host access.

The ADCA holds all analog circuitry which consists of a comparator, capacitor bank, bias generation, and so on. Only one channel is processed at a time. Multiple channels are processed sequentially by multiplexing the analog inputs. The duration time that each channel is sampled is configurable by the user. The hold value is used to calculate a channels digital code by successively comparing it with an analog voltage generated by a Digital to Analog Converter (DAC) inside the ADCA.

58.3.3 Clock and reset

The SAR_ADC has only one clock input (bus clock).

This clock is used for accessing registers through the Host Bus and operation of all interfaces.

The conversion clock (AD_CLK), is derived from the bus clock input. The AD_CLK can be equal to, or half of the bus clock frequency based on configuration (see register bit descriptions of MCR[ADCLKSE]).

If MCR[ADCLKSE] = 1, then the AD_CLK is equal to the bus clock. If MCR[ADCLKSE] = 0, then the AD_CLK is half of the bus clock frequency. However, depending on configuration and performance requirements, MCR[ADCLKSE] may always need to be 1.

The SAR_ADC has two resets, Functional (normal) and Calibration. Calibration reset is applied only when calibration is needed along, and is asserted with a functional reset. A functional reset can happen any time without a calibration reset.

Calibration reset is provided to hold internal calibration and status values if a functional reset occurs. The following register and field values are maintained after a functional reset:

- Main Status Register (MSR)
  - CALIBRTD
  - CALFAIL
- User OFFSET and Gain Register (USROFSGN) (Full register)
  - GAINUSER
  - OFFSUSER
- Calibration Status register (CALSTAT) (Full register)
  - TEST_RESULT
  - STAT[1:14]

58.3.4 Special channels

Reference voltages and supply voltages are available at predefined SAR_ADC channels.

58.4 Features

The general feature list of the SAR_ADC is shown below. Feature availability is chip-specific and is defined during module integration. See chip-specific SAR_ADC information for details.

- 4'd12-bit resolution
- Multiple modes of starting conversion (Normal, Injected, CTU)
  - Normal mode supports One-Shot and Scan (continuous) conversions
  - Injected mode supports One-Shot conversions only
  - CTU mode runs a single conversion per trigger
- Software-initiated conversions in Normal and Injected modes, or external hardware trigger
- Two different abort features for either a single or chain conversion in Normal and Injected modes
- Independent data registers for each channel contain information about mode of conversion, data validity, overwrite status, and conversion data
- Alternate analog watchdog thresholds (threshold selected through input ports)
- Programmable DMA enables for each channel
- Individual interrupt flags for the following conditions:
  - End of conversion of a single channel for Normal and Injected modes
  - End of chain conversion for both Normal and Injected modes
  - End of conversion in CTU mode

  - Watchdog threshold violations
- Programmable presampling for channels
- Auto-Clock-Off feature for improved power performance
- Power-Down mode to place the SAR_ADC in power-down state
- Programmable clock prescaler for SAR_ADC (bus clock, or bus clock divided by two or four)
- Software-initiated calibration
- Self-test feature

58.5 Functional description

The ADCD interfaces are shown in Figure 529. The available functionality in the ADCD is described in the following sections (see chip-specific SAR_ADC information for details).

58.5.1 Conversion

Conversions are software or hardware initiated.

The following list shows the methods of initiating conversions in order of priority (highest to lowest):

1. CTU trigger (hardware only)
2. Injection (see Injected Conversion mode)
3. Normal (see Normal Conversion mode)

Each type of conversion method has different processing features.

CTU trigger starts a single conversion for a single channel.

Injection can start a single chain of conversions one at a time, where a chain may have from one up to the maximum number of channels available (each channel appears once in the chain).

Normal conversion can start a continuous or single chain of conversion one at a time. In continuous mode, the chain of conversions is repeated unless you stop them.

When a normal conversion is in process, the starting injected conversions are done by software or hardware. Which allows a chain of channels that cannot wait to be converted (as selected by JCMR) to be handled immediately.

Conversions initiated by the CTU (one channel per trigger) are processed immediately by suspending normal conversions and discarding any ongoing injected conversion chain.

Analog watchdogs allow continuous hardware monitoring of input channel conversion results.

A built-in self-test function enables periodic checking of ADCA health. If a fault is detected, the FCCU can be signaled. The severity of the fault is programmable (critical/non-critical).

NOTE

ADC configurations must be changed only when ADC is in idle or power-down state (MSR[NSTART]=0 and MSR[ADCSTATUS] = idle/power-down).

58.5.2 Normal Conversion mode

The conversion method which is generally used to convert channels is Normal Conversion mode. To select channels for conversion, you program the Normal Conversion Mask Register (NCMR). Each channel can be individually enabled by setting the corresponding field in NCMR:

- NCMR0 selects channels in Group0.
- NCMR1 selects channels in Group32.

The mask registers must be programmed before starting the conversion and cannot be modified until all selected channel conversions have completed. A conversion always starts from the lowest channel number and continues sequentially to the highest channel number.

58.5.2.1 Starting conversions in Normal Conversion mode

After programming the required fields of the Main Configuration Register (MCR) and NCMR, conversion starts as follows:

- By software:
  - Conversion chain starts when one is written to MCR[NSTART].
- By hardware trigger:
  - If external trigger is enabled (MCR[TRGEN] = 1), and an external trigger enable is detected, the conversion will start. The enable is checked only during the start of conversion.
    - Detection of an active edge is defined by MCR[EDGE] (rising = 1, falling = 0). When an external trigger is recognized, MSR[NSTART] is set and normal conversion starts.

NOTE

A software-initiated conversion in Normal Conversion mode is ignored during any ongoing conversion chain.

NOTE

There must be a gap of three cycles between configuration of the NCMR and the start of conversion (setting of MCR[NSTART] or arrival of hardware start trigger) for proper SAR_ADC operation. The SAR_ADC calculates the total number of channels to be converted during this period.

58.5.2.2 Operation modes in Normal Conversion mode

Two operation modes are available for normal conversions:

- One-Shot Operation mode
- Scan Operation mode

The MCR[MODE] field determines the operating mode in normal conversion. The first phase of any conversion process involves sampling the analog channel. Which is followed by the conversion phase, when the sampled analog value is converted to digital as shown in Figure 530.

Figure 530. Normal conversion flow

In **One-Shot Operation mode** (MCR[MODE] = 0), a sequential conversion specified in the NCMR mask registers is performed once. At the end of each conversion, the digital result of the conversion is stored in the corresponding data register (CDR*n*; *n* = channel number).

For example: Channels A-B-C-D-E-F-G-H are available on the chip, where channels B-D-E are to be converted in One-Shot Operation mode. Conversion starts from channel B, followed by conversion of channels D-E. At the end of conversion of channel E the channel scanning stops.

MSR[NSTART] is automatically set when the normal conversion starts. At that time MCR[NSTART] is reset by hardware, allowing the software to program a new start of conversion in advance. In this case, the new requested conversion starts after completion of the currently running conversion. However, for correct device function, it is required to program MCR[NSTART] for the new conversion only after the current conversion is complete. Software can wait for the end of conversion (ISR[ECH] = 1) prior to setting MCR[NSTART] again.

If the conversion chain starts by external trigger (if MCR[TRGEN] = 1), the ADC cannot monitor the trigger input until the conversion chain finished. After the chain is finished, the next chain starts by subsequent hardware trigger edge.

In **Scan Operation mode** (MCR[MODE] = 1), a sequential conversion of *n* channels specified in the NCMR registers is continuously performed. At the end of each conversion the converted result is stored into the corresponding channel data register, as it is in One-Shot Operation mode.

MSR[NSTART] is automatically set when normal conversion starts. Unlike One-Shot Operation mode, MCR[NSTART] is not reset in Scan Operation mode. It can be reset by software when you need to stop the Scan Operation mode. In that case, the ADC will complete the current chain, and after the last conversion, it clears MSR[NSTART].

For example: Channels A-B-C-D-E-F-G-H are available on the chip, where channels B-D-E are to be converted in Scan Operation mode. Conversion starts from channel B followed by conversion of channels D-E. At the end of conversion of channel E the scanning of channel B starts again, followed by conversion of channels D-E. This sequence repeats itself until MCR[NSTART] is reset by software.

This scan chain can be stopped by writing zero to MCR[NSTART]. The conversion stops when the ongoing chain is finished.

If the conversion is started by an external trigger, MCR[NSTART] is not set. As a consequence, after it is started, the only way to stop a Scan Operation mode conversion started by external trigger is to write MCR[MODE] = 0.

End of conversion:

In both modes, at the end of each conversion an End of Conversion (EOC) interrupt is issued (if enabled by the corresponding mask bit in CIMR and IMR).

After conversion of all the selected channels in NCMR has completed, the conversion operation is considered finished. ISR[ECH] is then set and End of Chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]).

The corresponding channel bit of CEOCFR is updated to indicate data is available in data register CDR*n* of the corresponding channel.

If there is no channel selected in NCMR, and there is a start of conversion trigger, ISR[ECH] is set and an ECH interrupt is issued immediately, if enabled.

NOTE

In scan (continuous) mode, ADC conversions happen very regularly as per timing derived by sample time and resolution. The host reads the result registers after checking ECH flag. The reading time of the host after setting ECH could vary based on the load on it. So, it may occasionally get invalid data (valid bit 0b in data CDR register) in channels. To avoid such scenarios, check the ECH flag twice before reading the conversion results, to ensure that the host gets valid data always for all channels. The host needs to clear the ECH flag each time it finds it set. The sequence will be as below:

1. Host waits for ECH. On ECH, it clears it.
2. Host waits for second ECH. On ECH, it clears it.
3. Host reads data for all channels.
4. Repeat steps 1–3.

58.5.3 Injected Conversion mode

An injected conversion is a conversion of a programmed chain that can be injected anytime into an ongoing conversion chain processed in Normal Conversion mode. You require to configure Injected Mask Register(s) (JCMR*n*). In Normal Conversion mode each internal or external channel can be individually selected:

- JCMR0 for channels in Group0
- JCMR1 for channels in Group32

An injected conversion chain can only be run in One-Shot Operation mode and suspends the ongoing conversion chain processed in Normal Conversion mode. When an injected conversion chain is inserted into an ongoing chain processed in Normal Conversion mode, the ongoing chain is suspended and the injected conversion request is processed. After conversion completion of the last channel of the injected chain, conversion resumes from the channel at the chain which was suspended in Normal Conversion mode, as shown in Figure 531.

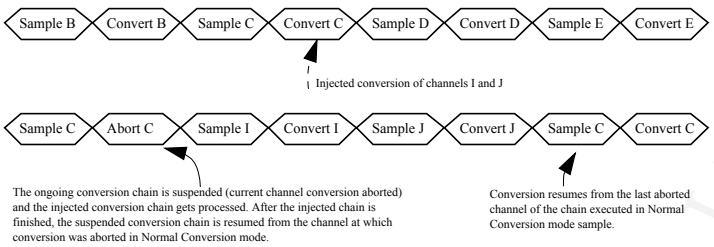

Figure 531. Injected sample/conversion sequence

58.5.3.1 Starting conversions in Injected Conversion mode

The injected conversion chain can be started by using one of the following methods:

- By software: When external triggering is disabled, MCR[JSTART] can be set. Setting MCR[JSTART] causes any Normal Conversion mode chain to be suspended and the injected chain to start processing.

MSR[JSTART] is automatically set when the injected conversion chain starts, and MCR[JSTART] is cleared. This allows the software to program a new start of conversion in advance. If a new injected conversion request occurs while an injected conversion chain is in progress (for example, setting MCR[JSTART] while MSR[JSTART] is set), then conversion will start after the current conversion has completed.

At the end of each conversion, an End Of Injected Conversion (JEOC) (ISR[JEOC] = 1) interrupt is issued (that is, IMR[MSKJEOC] = 1), and at the end of the chain an End of Injected Chain (JECH) (ISR[JECH] = 1) interrupt is issued (that is, IMR[MSKJECH] = 1).

The corresponding channel bit of CEOCFR*n* is set, indicating that data is available in the CDR of the respective channel.

After it is started, an injected chain conversion cannot be interrupted.

NOTE

If there is no channel selected in JCMR*n*, and an injected conversion is started, then ISR[JECH] is immediately set and the corresponding interrupt is asserted (if enabled). This behavior is independent of normal conversion status.

For correct operation of SAR_ADC, there must be a gap of at least three cycles between configuration of JCMR*n* and the start of a conversion (setting MCR[JSTART], or receiving a hardware start trigger (external/internal). The SAR_ADC calculates the total number of channels to be converted during this period.

58.5.4 Abort of conversion

Two different abort functions are provided:

- Abort of a single channel
- Abort of chain

You can abort the ongoing conversion by setting MCR[ABORT]. SAR_ADC then aborts the current conversion and immediately starts the conversion of the next channel of the chain. The abort action may take 1–4 cycles of bus clock to abort the current conversion, depending on the state of the conversion. At the start of any conversion and at the end of a particular conversion, when internal state counters are changing, then the abort get delay by a maximum of three cycles. This allows all states to be placed in stable condition before aborting.

So, you are advised not to change the abort field status for the next three cycles to achieve this effect.

Abort also not to be programmed along with and within three cycles of programming MCR[NSTART] or MCR[JSTART].

In the case of an abort operation, MSR[NSTART/JSTART] remains set if not in the last channel of the chain, and MCR[ABORT] is reset as soon as the channel is aborted. The EOC corresponding to the aborted channel is not generated. This behavior is true for Normal or Injected Conversion modes. If the last channel of a chain is aborted, the end of chain is reported, generating an ECH interrupt.

It is also possible to abort the current chain of conversions by setting MCR[ABORTCHAIN]. In that case, the behavior of the ADC depends on MCR[MODE] (One-Shot/Scan Operation modes). If Scan Operation mode is disabled, MSR[NSTART] is automatically reset together with MCR[ABORTCHAIN]. Otherwise, in Scan Operation mode, a new chain is started. The EOC of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

NOTE

For a single channel chain, ECH is not generated in the case of an abort or abort chain.

When an ABORTCHAIN is requested while an injected chain is running over a suspended normal chain, both injected and normal chains are aborted. Both ISR[ECH] and ISR[JECH] are set. MSR[JSTART] is reset to mark the end of the injected chain. MSR[NSTART] is reset if normal conversion is running in One-Shot mode. Otherwise, in Scan mode it remains set and a new chain is started.

58.5.5 CTU

The CTU interface enhances the injected conversion capability of the ADC. They contain multiple control inputs that can be used to select the channels to be converted from the appropriate event configuration register. Figure 532 shows the interface.

The CTU generates a trigger ctu_trigger and a channel number ctu_numchannel to be converted. A single channel is converted for each request. After performing the conversion, the ADC returns the result on the ctu_dataout bus together with two output signals named ctu_nextcmd and ctu_push. The assertion of signal ctu_nextcmd means that ADC is ready to accept the next trigger from CTU. The ctu_push signal is asserted at the end of conversion, meaning that conversion is finished and the conversion result available at output ctu_dataout is valid.

The conversion result is also saved in the corresponding channel's data register. It is compared with watchdog thresholds when requested.

The CTU and ADC are always connected to the same clock domain and therefore are synchronous (same frequency and domain).

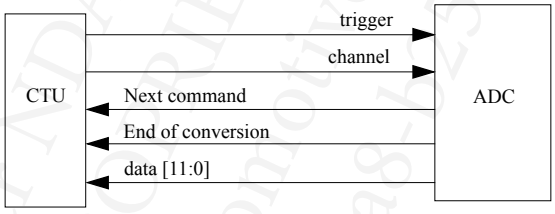

Figure 532. CTU interface

Program MCR[CTUEN] to enable the CTU interface. The operating mode (Trigger/Control) can be fixed or programmable. If available, in Power-Down mode MCR[CTU_MODE] program the CTU interface operating mode.

58.5.6 ADC clock prescaler and sample time settings

The AD_CLK frequency can be scaled by programming MCR[ADCLKSE]. If MCR[ADCLKSE] is set, then the AD_CLK frequency is the same as the bus clock. Otherwise, AD_CLK frequency is half of bus clock, MCR[ADCLKSE] bit can be written in power-down only when MCR[PWDN] = 1.

In order to support different sampling times for different type of channels the different conversion timing registers are used (CTR0, CTR1). CTR0 is associated to channels (0 to 31), CTR1 is associated to channels (32 to 63). See the register description for details.

58.5.7 Presampling

The presampling feature allows precharging or discharging the SAR_ADC internal sample capacitor node to a defined level before sampling of the selected analog input channel starts. This is useful for resetting information (history effect/offset) regarding the last converted data. During presampling, ADC samples the internally generated voltage, while in the sampling SAR_ADC samples analog input coming from pads.

Presampling can be enabled/disabled on a per-channel basis by setting the corresponding bits in the PSR0, PSR1 registers. PSR0 serves channels 0–31 , PSR1 serves channels 32–63 .

After enabling the presampling for a channel, the normal sequence of operation will be Presampling → Sampling → Evaluation for that channel. Sampling of all channels can be bypassed by setting PSCR[PRECONV]. When sampling of a channel is bypassed, the sampled and stored internal voltage applied during the presampling phase get converted (see Figure 533). See Conversion time for the timing equation for conversion.

Presampling does not apply to self-test channels.

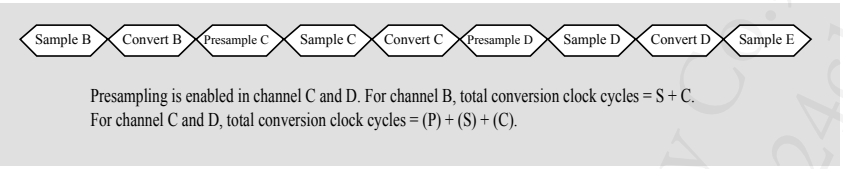

Figure 533. Presampling sequence

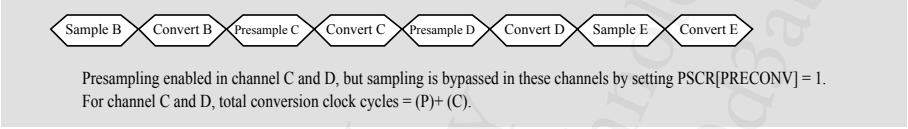

Figure 534. Presampling sequence with PRECONV=1

58.5.7.1 Presampling channel enable

The presampling channels are selected by programming the PSCR. It is possible to select between four internally generated voltages depending on the value of PSCR[PREVAL*n*], as shown in the following table.

Table 524. Presampling voltage selection

PSCR[PREVAL*n*]	Presampling voltage
00	Presample voltage - 1: (DVDD0P8/2)
01	Presample voltage - 2: (AVDD1p8/4)
10	Presample voltage - 3: VREFL_1p8
11	Presample voltage - 4: VREFH_1p8

NOTE

The voltage for presampling is (AVDD1p8/4) when PSCR[PREVAL]=01b. However, when this value is measured in sample bypass mode (PSCR[PRECONV]=1), the raw conversion result is shifted by two bits to the left (multiplied by 4) before error compensation. So the expected value of the final conversion result is AVDD1p8 (deviation may be in the range 0–3 LSB, due to left shift).

The PSCR[PREVAL*n*] fields are associated with SAR_ADC channels as follows:

- PREVAL0 for channels 0–31
- PREVAL1 for channels 32–63

58.5.8 Programmable analog watchdog

The analog watchdogs are used to monitor the conversion result to see if it is within defined limits (as shown in the figure below), specified by an upper and a lower threshold value named THRH and THRL, respectively.

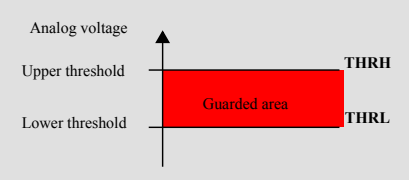

Figure 535. Guarded area

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value is outside the threshold values, then a corresponding threshold violation interrupt is generated.

The comparison result is stored as WDG*n*H and WDG*n*L fields in WTISR as explained in the following table. Depending on the values of WTIMR[MSKWDG*n*L] and WTIMR[MSKWDG*n*H] mask bits, an interrupt is generated on a threshold violation.

Table 525. Values of WDGxH and WDGxL fields

WDG*n*H	WDG*n*L	Converted data
1	0	Converted data > THRH
0	1	Converted data < THRL
0	0	THRH >= converted data >= THRL

Depending on the device settings, the number of analog watchdogs can vary for each instance of the SAR_ADC (see chip-specific SAR_ADC information for details).

Analog watchdog setting

For each watchdog there is one threshold value (low and high) register (THRHLR*n* [*n*=0..15]).

The analog watchdog for each channel can be enabled independently by programming the corresponding CWENR fields.

- CWENR0 for Group0 channels
- CWENR1 for Group32 channels

Watchdog selection of each channel is done by configuring CWSELR*n*[WSEL_CH*m*] (where *n* = CWSELR instance and *m* = channel number).

Each CWSELR*n* holds a selection for a maximum of eight consecutive channels (for example, CWSELR0 holds eight WSEL_CH fields for channels 0–7, CWSELR1 is for channels 8–15, and so on).

If the conversion result of a selected channel is outside the range specified by threshold values, then the corresponding bit is set in the Analog Watchdog Out of Range Register (AWORR) (for example, if channel number 12 is to be monitored with the threshold values in register THRHLR3, then WSEL_CH4 of CWSELR1 is to be programmed with 3). Enabling the watchdog is done by setting the corresponding bit for channel 12 in register CWENR0.

In this setting, a set of threshold values (THRHLR*n*) can be linked to several SAR_ADC channels. The threshold values to be selected for a channel must be programmed only once in CWSELR*n* register.

NOTE

If the higher threshold of the analog watchdog is programmed to be below the lower threshold and the conversion result is below the lower threshold, then the WTISR[WDG*n*L] interrupt for the low threshold violation is set. If the conversion result is greater than the lower threshold (consequently also greater than the higher threshold), then the interrupt WTISR[WDG*n*H] for high threshold violation is set. Thus, you should take care to avoid that situation as it could lead to misinterpretation of the watchdog interrupts.

58.5.9 DMA functionality

Conversion data of any channel can be transferred from a register to system memory through Direct Memory Access (DMA). The DMA transfers can be enabled by setting DMAE[DMAEN]. When enabled, the on-chip DMA controller can receive a DMA request after the conversion of every channel by setting the respective masking bit in the DMAR*n* registers. The DMA masking registers must be programmed before starting any conversion.

The DMA request to DMA controller can be cleared at different times in two modes:

MODE 1: Clearing of DMA request on acknowledgment from DMA controller (setting DMAE [DCLR] = 0).

MODE 2: Clearing of DMA request on read to data registers (DMAE[DCLR] = 1).

The figures below show the operation of DMA in two modes (cycle counts are for a typical case).

NOTE

The DMA should complete the read of the SAR_ADC data within the throughput rate of SAR_ADC. For example, SAR_ADC can support a maximum throughput rate of 1 MSPS. Thus, DMA should complete a data read within 1 µs after assertion of dma requests (ipd_req).

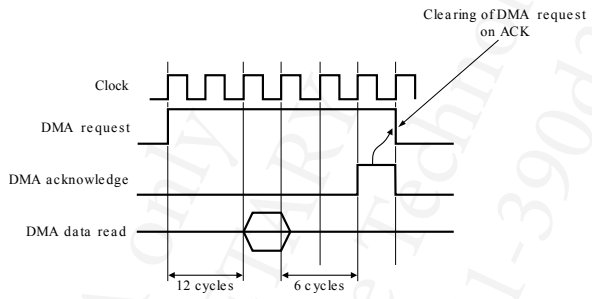

Figure 536. DMA operation MODE 1 (DMAE [DCLR] = 0)

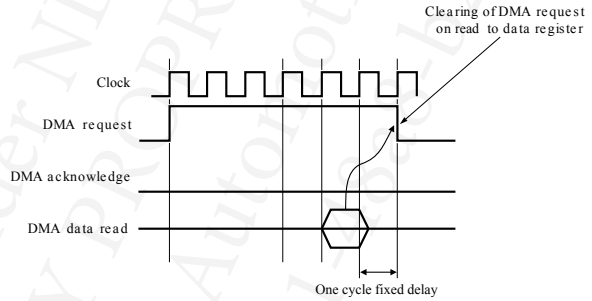

Figure 537. DMA operation MODE 2 (DMAE [DCLR] = 1)

58.5.10 Interrupts

SAR_ADC generates the following maskable interrupt signals:

- EOC (End of Conversion) interrupt request
- ECH (End of Chain) interrupt request
- JEOC (End of Injected Conversion mode) interrupt request
- JECH (End of injected Chain) interrupt request
- EOCTU (End of CTU conversion) interrupt request
- WDG*n*L and WDG*n*H (watchdog threshold) interrupt requests
- Self-testing Interrupts

Interrupts are generated during the conversion process to signal events such as EOC and so on, as explained in register description for ISR. Two registers named ISR (Interrupt Status Register) and IMR (Interrupt Mask Request Register) are provided in order to check and enable the interrupt request to external interrupt controller.

Interrupts can be individually enabled on a channel-by-channel basis by programming CIMR (Channel Interrupt Mask).

For pending EOC interrupts, registers with one bit per channel are provided to indicate completed conversions on a channel basis (CEOCFR*n*).

Interrupts generated due to the analog watchdogs are handled by two 32-bit registers named WTISR (Watchdog Threshold Interrupt Status Register) and WTIMR (Interrupt Mask for the Watchdog Threshold Register). These registers are used to check and enable an interrupt request . A watchdog interrupt causes two corresponding bits to be set for each channel monitored. One bit is set in the WTISR[WDG*n*H] register and the other bit in the WTISR[WDG*n*L] register.

Generated events are logged into status registers and used to generate an interrupt if enabled in corresponding mask registers.

In the below list, there are different interrupt outputs of ADC. The interrupt structure is shown in Figure 538.

Each interrupt is generated by combining a group of events.

- Interrupts for EOC, ECH, EOCTU, JEOC, JECH , and End of self-test algorithm (WDG_EOA_S and WDG_EOA_C) in STSR1 are combined (logic OR) into one interrupt output. .
- Interrupts of WDG*n*H and WDG*n*L are combined on the second interrupt output.
- Interrupts of all self-test errors (watchdog threshold, sequence, and timer, that is, WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, and ERR_C in STSR1) are combined on the third interrupt output.

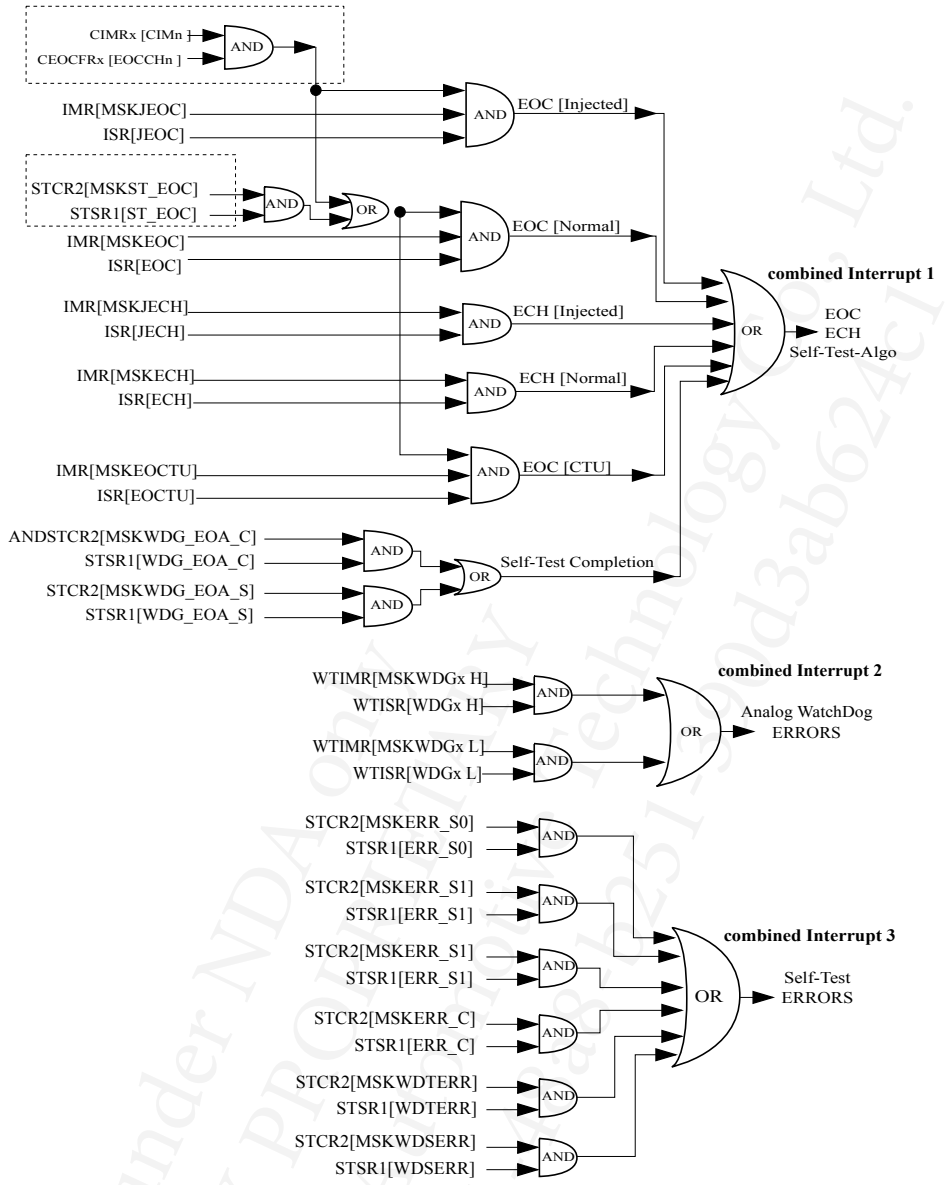

Figure 538. Interrupt structure of SAR_ADC

The ISR register contains the interrupt pending request status. If you want to clear a particular interrupt event status, then writing one to the corresponding status bit clears the pending interrupt flag (during this write operation all other bits of the ISR register must be maintained at zero).

The ISR must check the following for three different types of interrupts.

For interrupt 1:

- Read ISR to determine if the type of event falls in:
  - EOC
  - JEOC
  - ECH
  - JECH
  - EOCTU

- Read STSR1 to determine the end of self-test algorithm events (WDG_EOA_C / S) (if present).
- If the interrupt is EOC or JEOC:
  - Clear the channel pending bit of respective channel in CEOCFR*n* for EOC or JEOC in ISR.
  - Clear ISR[EOC] or ISR[JEOC].
- If the interrupt is ECH or JECH:
  - Clear ISR[ECH] or ISR[JECH].
- If the interrupt is EOCTU:
  - Clear ISR[EOCTU].
- If the interrupt is for self-test end of algorithm:
  - Clear STSR1[WDG_EOA_C/S] bit.

For interrupt 2:

- Read WTISR to determine which watchdog is giving the interrupt.
- Read AWORR*n* to determine which channel's data is creating the interrupt (if present).
- Clear the respective bit of WTISR [WDG*n*H / WDG*n*L] (*n* = watchdog number).
- Clear the respective bit of AWORR*n*[AWOR_CH*m*] (*n*=register, *m*=channel).

For Interrupt 3:

- Read STSR1 to determine the type of error that has occurred in self-test (ERR_S0/S1/S2/C/S, WDTERR, WDSERR, and so on) (if present).
- Clear the respective bit in STSR1.

The connectivity of interrupt lines at the chip level (external to SAR_ADC) determines whether software needs to read all the registers for all the interrupts or any one or a combination of any two.

58.5.11 Power-Down mode

The analog part along with SAR controller of the ADC can be put in Power-Down mode by setting MCR[PWDN] to shut down ADC hard macro and to stop the clock to SAR controller. After release of reset MCR[PWDN] remains one, so ADC analog module is kept in Power-Down mode by default. This state must be exited before starting any operation by resetting MCR[PWEN].

In Power-Down mode, no conversion can be started. If a CTU trigger pulse is received during power-down, it is discarded. You must ensure that CTU trigger is not initiated to ADC before resetting MCR[PWDN], as it may cause the CTU module to be stuck forever in a wait state.

MCR[PWDN] can be set anytime. If a conversion is ongoing, the ADC cannot move into Power-down mode immediately. The SAR_ADC enters Power-Down mode only after completion of the ongoing conversion. In Scan Operation mode the ongoing operation should be aborted manually by resetting MCR[NSTART] before or after setting MCR[PWDN].

The ADC Power-Down mode status is indicated by MSR[ADCSTATUS] when ADC enters into this mode.

If CTU is enabled, and MSR[CTUSTART] is one, then MCR[PWDN] cannot be set. When CTU Trigger mode is enabled, the application needs to wait for the end of conversion (MSR[CTUSTART] is automatically reset). When CTU Control mode is enabled, before entering Power-Down mode, the application needs to reset MCR[CTUEN] also.

If Power-Down mode is entered by setting MCR[PWDN], the process running before entry into the Power-Down mode must be restarted manually (by setting the appropriate START bit in MCR) after exiting Power-Down mode.

NOTE

Resetting MCR[PWDN] and setting MCR[NSTART] or MCR[JSTART] during the same cycle is forbidden.

58.5.12 Low-power mode support

For low-power operation, the SAR-ADC must be in an Idle state and then put into Power Down state to ensure proper signal condition at the analog boundary.

From any of the states listed below, follow the sequence of steps shown to put the SAR-ADC into a Power Down state.

1. Idle condition:
    a. Verify that the SAR_ADC is in an Idle state (MSR[ADCSTATUS[2:0]] = 000b).
    b. Set MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low-power mode.
    c. Verify that the ADC is in a Power-down state (MSR[ADCSTATUS[2:0]] = 001b).
2. During calibration:

    NOTE

    Setting MCR[PWDN] during calibration is prohibited. Once calibration is started, it should be allowed to finish normally. Alternatively, it can be terminated by starting a normal conversion before setting MCR[PWDN].

    a. Check the current SAR-ADC state through MSR[ADCSTATUS[2:0]] (000b = Idle, 011b = Calibration), or through MSR[CALBUSY] (1 = calibration is in progress).
    b. When the ADC is in an Idle state, set MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low-power mode.
    c. Verify that the ADC is in a Power-down state (MSR[ADCSTATUS[2:0]] = 001b).
3. During conversion (normal [one-shot]/Injected/CTU):
    a. Set MCR[PWDN].
    b. The SAR-ADC enters into Power-down mode after completing the current conversion chain (for normal and injected conversions) or the conversion for CTU-triggered conversion.
    c. Check the ADC state through MSR[ADCSTATUS[2:0]] (000b = Idle, 001b = power down).
4. During Scan mode operation of normal conversion:

    NOTE

    Setting MCR[PWDN] during Scan mode operation has no effect other than to prevent software from starting a new Normal or Injection conversion. It does not stop a conversion in progress and cannot put the ADC into a Power Down state.

    a. Software must write zero to MCR[NSTART] to stop the ongoing scan conversion before (or after) setting MCR[PWDN]. Which stops conversion at the current chain boundary.
    b. The ADC enters Power-down mode after coming to an Idle state after the MCR[PWDN] bit is set. Which shuts off the clock to the hard macro and puts analog inputs in the proper state required for Low-power mode.
    c. Verify that the ADC is in a Power-down state (MSR[ADCSTATUS[2:0]] = 001b).

58.5.13 External start feature

This feature allows synchronous conversion of two independent ADC instances operating in parallel. If the ADC is in Idle state (that is, no conversion phase ongoing and MCR[PWDN] and MCR[ACKO] are zero), and MCR[XSTRTEN] is set, an event on the external start signal causes the ADC to start a normal conversion operation. MSR[NSTART] is automatically set.

58.5.14 Auto-Clock-Off mode

To reduce the power consumption during Idle state (without going into Power-down mode), an 'Auto-Clock-Off' feature can be enabled by setting MCR[ACKO]. When enabled, the internal SAR operating clock (AD_CLK) is automatically switched off during idle periods (for example, you cannot programmed conversion).

58.5.15 Calibration

The accuracy of ADC depends on the manufacturing precision of the devices used to build the module (for instance, capacitor size matching, amplifier gain, and so on). Due to variations during manufacturing and various runtime environmental influences (like temperature), the conversion result contains errors.

To reduce or eliminate the various error contribution effects, the ADC provides self-test and calibration features.

In the calibration process, a known reference voltage is sampled and converted under controlled conditions to determine the correction values (calibration values) for offset, gain, and capacitor mismatch.

These calibration values (except gain calibration) are used in a result postprocessing step to reduce or eliminate the various error contribution effects. The gain calibration is used during sample phase to define the additional charge to be loaded in order to compensate for gain failure.

Calibration must be performed after every power-up reset (check chip-specific reset connectivity for appropriate reset applied) and whenever required in runtime operation. It is also recommended to run calibration if the operating conditions (particularly VrefH) change. Never apply functional reset during the calibration process. If applied, calibration must be rerun after exiting a reset condition; otherwise, the calibration generated values and conversion results may be unspecified.

Configuring and starting of calibration is done by programming the calibration attributes in MCR register. During calibration, the internal hardware averaging function should be enabled. Maximum averaging is recommended, with a minimum of 16.

Calibration time

Clock 40 MHz. (AD_Clk == (bus_clock / 2)) (MCR[ADCLKSE] = 0)

Average samples (MCR[NRSMPL])

- 16–327 µs
- 32–654 µs
- 128–2.612 ms
- 512–10.446 ms

The calibration status is captured by status flag (MSR[CALFAIL]) to indicate if any fault is detected during calibration execution, or if the calibration has aborted at a premature state (calibration is aborted if any normal conversion is initiated during the execution of calibration, which is called premature termination). MSR[CALFAIL] = 1 means a calibration fail and a determined calibration value is out of internal defined limits. It also means that the ADC health may not be good and may not meet specifications.

The results of individual steps are also updated in CALSTAT register (CALSTAT[STAT_*n*]). The result of the last failed step is dynamically updated in the same register.

To execute the calibration algorithm, perform the following steps:

1. Wait for deassertion of both calibration and functional reset.
2. Configure desired parameters for calibration in MCR:
   - MCR[TSAMP]
   - MCR[NRSMPL]
   - MCR[AVGEN]
   - MCR[ADCLKSE]
3. Set the ADC internal operating clock to 40 MHz (MCR[ADCLKSE] = 0). (This setting assumes that ADC input clock is set to 80 MHz.)
4. Exit power-down state (MCR[PWDN] = 0).
5. Start calibration (MCR[CALSTART] = 1). Calibration starts immediately.
6. Check the status of MSR[CALBUSY] periodically. Wait until it becomes zero (alternatively, MSR[ADCSTATUS] can be monitored until it indicates an idle condition).

7. Check the fail flag (MSR[CALFAIL]) to learn the final status. If it is set to one, then calibration failed.
8. Check the pass/fail status of each calibration step in the CALSTAT register to look for failures.
9. At the end, check the status of MSR[CALIBRTD]. If calibration is successful this bit sets to one.

58.5.16 Self-test

For safety applications, it is important to check at regular intervals whether the SAR_ADC is operating correctly. For this purpose, a self-test feature is provided. When self-test is enabled, SAR_ADC automatically checks its components and flags any errors it finds.

The test can be enabled to check the supply voltage (V_{DD}), reference voltage (V_{refH}), and calibrated values.

The following test algorithms have been implemented:

- Supply self-test (algorithm S): It includes the conversion of the band gap, supply, and VREF voltages. It includes a sequence of 'num_supply_steps' test conversions (steps). The supply test conversions must be an atomic operation (that is, all supply algorithm conversions must be performed one after another with no functional conversions in between).
- Capacitive self-test (algorithm C): It includes a sequence of test steps per definition of algorithm C (See Table 526) which executes the capacitive matrix of the CDAC used for sampling and conversion.

Individual steps can take up to 1 µs at 80 MHz SAR_ADC clock frequency.

Table 526. Self-test steps

STCR3[ALG]	STCR3 [Step] (per algorithm definition)	Description	Outcome	Comment
'00'(algorithm S)	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	Band gap is considered as a constant with very little variation across temperature and process.
	1	Supply self-test (analog supply)	Measures the analog supply for the SAR_ADC	
	2	Supply self-test (reference voltage high)	Measures the high reference voltage of the SAR_ADC	
'01' (Reserved)	Reserved			
'10'(algorithm C)	0–11	Capacitive self-test: One of the calibration steps is being run	The difference/error of individual offset value from the previously calibrated value is being returned as SAR_ADC result that is compared with programmed value in analog watch dog register(s) to detect any fault. The difference or error may be caused by any runtime fault, runtime accuracy shift, or by device noise.	The result value should be compared with analog watchdog values. See Self-test analog watchdog for more detail.

Table continues on the next page...

Table 526. Self-test steps (continued)

STCR3[ALG]	STCR3 [Step] (per algorithm definition)	Description	Outcome	Comment
'11'(algorithm S+C)	0–2 (S) 0–11 (C)	Supply for One-Shot and (Supply + Capacitive) for Scan mode only	Same as above	

In case some failure occurs in any step of the algorithm, ADC: Schedules self-testing algorithms using configuration registers Monitors the conversion result using analog watchdog registers Flags the error to a fault control unit (FCCU), if it exists.

Self-test steps can be activated from software (CPU) or CTU.

ADC mode	TEST algorithm (CPU)	TEST algorithm / step(CTU)
CPU mode (MCR.CTUEN = 0)	Yes • One-Shot mode • Scan mode	No
CTU mode	No	Yes

NOTE

ADC self-test should be run with MCR[ADCLKSE] bit set to 1. Self-test with ADCLKSE bit set to 0 can give erroneous results.

58.5.16.1 CPU mode

In this case, test conversion works similar to normal conversion. The self-test is enabled by setting STCR2[EN].

The self-test conversions are run with the functional conversions. The sequencing of steps of the selected algorithm depends on the operating mode of normal conversions as selected by MCR[MODE].

In **One-Shot mode**, if self-test is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in STCR3. So, in One-Shot mode the sequence is as follows:

1. Program NCMR*n* to select channels to be converted for normal conversion.
2. Program MCR[MODE] = 0 to select One-Shot mode.
3. Program sampling duration values in STCR1[INPSAMP*n*] field. (x = S,C).
4. Select the self-testing algorithm in STCR3[ALG] and step STCR3[MSTEP]. Default is Algorithm S step 0.
5. Enable self-testing by setting STCR2[EN].
6. Start the normal conversion by setting MCR[NSTART].
7. All normal conversions are executed as usual.
8. At the end of all the normal conversions in the chain, step number programmed in STCR3[MSTEP] field of self-testing algorithm selected by STCR3[ALG] is executed, similar to a normal functional channel.
9. On the receiving end of the conversion for test channel, the result is written in STDR1[TCDATA], and STDR1[VALID] is set. ISR[EOC], ISR[ECH] are set, and so is STSR1[ST_EOC].
10. ADC returns to Idle state.

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in One-Shot mode. At the end of conversion for channels B-D-E, self-test conversion is done and ISR[ECH] and ISR[EOC] are set. The sequence is B→D→E→self-test step.

MSR[NSTART] is automatically set when the normal conversion starts and is reset at the end of conversion for test channel.

In **Scan mode**, consecutive steps of the selected self-test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is one (except for Algorithm S, in which all the steps are performed at once without any functional conversion interleaved). So, in Scan mode the sequence is as follows.

1. Program NCMRx to select channels to be converted for normal conversion.
2. Program MCR[MODE] = 1 to select Scan mode.
3. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected that is, all algorithms will be executed step-by-step one after the other.
4. Enable self-testing by setting STCR2[EN].
5. Start the normal conversion by setting MCR[NSTART].
6. All normal conversions are executed as usual.
7. At the end of chain of the normal conversions (assuming default value of STCR3[ALG]) all steps of Algorithm S are performed (as Algorithm S is always atomic). MSR[SELF_TEST_S] is set.
8. On receiving end of conversion of test channel for last step of Algorithm S:
   - The result is written in STDR1[TCDATA] and STDR1[VALID] is set.
   - At the same time, MSR[SELF_TEST_S] is reset.
   - For Step 1, the integral part and fractional part are written in STDR2[IDATA] and STDR2[FDATA].
   - Also, EOC and ECH bits are set in ISR register and ST_EOC is set in STSR2.
9. The next chain of normal conversion then starts.
10. At end of the normal conversion chain, Step0 of algorithm C is executed.
11. On the receiving end of conversion of test channel for Step0 of algorithm C:
    - The result is stored in STDR1[TCDATA] and STDR1[VALID] is set (if MCR[OVERWR] is set).
    - Also, EOC and ECH bits are set in ISR register and ST_EOC is set in STSR2.
12. Then the next chain of normal conversion starts.
13. At end of the normal conversion chain, Step1 of algorithm C is executed.
14. This process continues for all the steps of all three algorithms.
15. ADC returns to Idle state when MCR[NSTART] is written to 0.

For example: channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in Scan mode. At the end of every conversion chain for channels B-D-E, one step of self-test conversion is done and ISR[ECH] and ISR[EOC] are set.

The sequence is:

1. B→D→E→ST-S0→ST-S1→ST-S2→B→D→E→ST-C0→B→D→E→ST-C1→B→D→E→ST-C2→ . . . B→D→E→ST-C11→B→D→E→ST-S0 . . .
2. ST-Sx - SelfTest Supply step x (x = 0,1,2)
3. ST-Cx - SelfTest Capacitive step x (x = 0 to 11)

MCR[NSTART] is automatically set when the normal conversion starts.

COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
ca4625c5-189c-4825-9251-390d3ab624c1

NOTE

In case of Injected Conversion modes, test channel conversion is not performed. It is performed only during normal conversions.

NOTE

If during a test channel conversion, injection conversion begins, then the test conversion is aborted (as with a normal functional channel) and Injected Conversion modes are completed. After Injected Conversion modes are completed, the test conversion resumes from the step at which it was aborted. In this case, MSR[SELF_TEST_S] remains high during Injected Conversion mode.

NOTE

For self-testing, the mode bit must be programmed at least one cycle before setting MCR[NSTART], and should not be changed thereafter until the conversion is finished or terminated.

58.5.16.2 CTU mode

The CTU mode is enabled by setting MCR[CTUEN]. The CTU operating mode selection if available, can be done through MCR[CTU_MODE]. *(Please check device configuration for availability.)*

The test conversion behaves in the same way for all CTU operating modes (Trigger and Control). In both cases, if MCR[CTUEN] is set, the test conversion can be started only by CTU interface–software cannot start it. Do not change MCR[CTUEN] during normal conversion. The interface between CTU and ADC (for Self-test) is shown in the following figure.

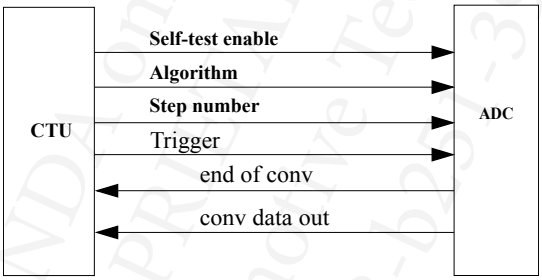

Figure 539. Self-test interface between ADC and CTU

For self-testing conversions in CTU mode, CTU asserts self-test enable along with trigger. The algorithm and the step number to be executed are put on Algorithm and Step number, respectively. The other command triggers, end of conversion and conversion data out has the same meaning as in normal CTU functional conversions.

As already mentioned for algorithm S, the three steps must be atomic. In CTU mode, CTU managed this itself, that is CTU has to send three triggers (one for each step) asserting self-test enable and updating test_step for each step.

58.5.16.3 Abort and abort chain for self-testing channel

Setting MCR[ABORT] during self-test channel conversion has no effect.

In One-Shot Operation mode, if MCR[ABORTCHAIN] is set when test channel conversion is ongoing, the test channel conversion is aborted and ISR[ECH] is set. In this case, ISR[EOC] for test channel is not generated.

In Scan Operation mode, if MCR[ABORTCHAIN] is set when test channel Step n is ongoing, the test channel Step n is aborted and next the chain conversion starts. At the end of this chain, Step n conversion is performed again. (In the case of Algorithm S, the full algorithm is executed again).

58.5.16.4 Self-test analog watchdog

The ADC digital interface also provides monitors for the conversion data for self-test algorithms. The analog watchdogs are used to determine whether the result of conversion for self-test algorithms is in the range of a particular guard area. For this purpose, separate self-test analog watchdog registers have been provided for each algorithm.

After the conversion of each step of an algorithm, a comparison is performed between the converted value and the threshold values if the analog watchdog feature is enabled by setting STAW*n*R[AWDE]. If the converted value does not lie between the upper and lower threshold values specified by Analog Watchdog Register of the particular algorithm, corresponding error bit STSR1[ERR_S*n*] is set and the step number in which the error occurred is updated in STSR1[STEP_C] (in case of algorithm C). Also, erroneous data is written in the STSR4[DATA*n*] field. The STSR1[ERR_S*n*] fields generate an interrupt if enabled by the corresponding mask bit in STCR2. The fault indication is also given to the fault control unit, if present, through critical and non-critical fault lines, so that necessary action can be taken at the chip level. Configuration in STCR2 register decides the choice between critical and noncritical type.

The analog watchdog feature works differently in algorithm S. As already mentioned, algorithm S is always an atomic operation. So, separate error bits are provided in STSR1 for each Step of algorithm S to avoid overwriting if error occurs in more than one Step. Hence, there are separate mask bits for each step in STCR1. For the same reason, separate fields exist in status registers (STSR2 and STSR3) to store erroneous data for each step.

In step0 of the supply algorithm, ADC measures the band gap voltage (+1.15 V), which is assumed to be stable. The conversion result of Step0 is measured with high (THRH) and low (THRL) thresholds defined in STAW0R if enabled (STAW0R[AWDE] = 1). STSR1[ERR_S0] is set to one if either threshold is violated. After set, it is cleared by writing a one to it.

For algorithm S Step1, a fixed-point division is performed, which takes about 26 cycles after EOC for Step1 to receive the divided value. It is used for analog watchdog checks. So, the value to be compared for Step1 contains the integer as well as fractional part—thus, two registers (STAW1AR and STAW1BR) are provided.

The comparison is done first for the integer part using the threshold values programmed in STAW1AR. If the integer part lies in the range, the fractional part comparison is skipped; otherwise it is compared to the values programmed in STAW1BR. The following table summarizes this feature for Step1.

Table 527. Algorithm S (Step1) threshold comparison

STDR2[IDATA] (integer part)	STDR2[FDATA] (fractional part)	STSR1[ERR_S1]
> STAW1AR[THRH]	Any value	Set
< STAW1AR[THRL]	Any value	Set
== STAW1AR[THRH]	> STAW1BR[THRH]	Set
== STAW1AR[THRL]	< STAW1BR[THRL]	Set

For algorithm S Step2, VREF/VREF is measured in order to check the integrity of the sampling signal. For this particular conversion, no higher threshold value is required, as the ideal value is FFFh. Only the lower threshold value is programmed in STAW2R.

For algorithm C, a separate register is provided for Step0. In Step0, an offset for other steps is measured. The converted data is compared with the threshold values provided by STAW5R if STAW4R[AWDE] is set. For other steps, this offset is subtracted from converted data before performing watchdog checks.

NOTE

The recommended analog watchdog threshold values are set according to the expected and tested results with a clean environment (noise introduction from external environment minimized) for ADC operation. In a noisier setup, running the self-test with these analog watchdog values may cause failures.

To overcome the failures, you can relax the threshold values if the needs of the application can tolerate the existing noise level. The more the threshold values are relaxed, the more the magnitude of true error that can pass. For example, looking at the values for the STAW4R and STAW5R registers, THRH of 010h (16d) and THRL of FF0h (–16d), means that the algorithm C fails for an error of magnitude greater than (16/8 = 2) 2LSB@12b. This is the recommended value for a clean environment.

Similarly, THRH of 020h (32d) and THRL of FE0h (–32d) means that the algorithm C fails for an error of a magnitude greater than 4LSB@12b. Thus to pass the self test in a noisy environment where the application can live with the noise level, the thresholds can be relaxed from ±40 to ±64 or as needed. However, it is preferable that the environment is cleaned up to match the expectation for better operation instead of relaxing the thresholds. Relaxing the thresholds too much (more than ±64) leads to a false pass, and is not recommended for safety applications.

Relaxation of the self-test thresholds due to noise does not directly relate to normal use conversions, and it is not possible to tell what the noise impact to those measurements is with respect to the threshold relaxation. The noise is application-specific and not under control/judgment of the chip. In this scenario, not passing with the default threshold values is caused by external noise and not by the constituent capacitors. Limits are relaxed knowing that there is noise in the system that rides on top of the actual capacitor error, and the magnitude of the noise component is so high that limits should be relaxed as a result. Thus in reality whenever tests are run environment noise will be there, and if there is any true shift of the capacitor error noise it will be added to this environment noise, and should result in a violation of the relaxed threshold limits. The self-test is designed to catch and flag runtime and catastrophic errors. It is not able to, and not meant to, test for specification limits.

58.5.16.5 S1 algorithm: calculated voltage comparison method

The software can implement a method of calculating S1 algorithm STDR2[IDATA], STDR2[FDATA], THRHLRn[THRH] and THRHLRn[THRL] voltage values, then perform a comparison to the calculated THRH and THRL voltages.

The steps involved in this method are as follows:

1. Calculate the high threshold voltage:

   (STAW1AR[THRH] + (STAW1BR[THRH] / 4096)) × $V_{BANDGAP}$

2. Calculate the low threshold voltage:

   (STAW1AR[THRL] + (STAW1BR[THRL] / 4096)) × $V_{BANDGAP}$

3. Calculate the converted results to voltage:

   (STDR2[IDATA] + (STDR2[FDATA] / 4096)) × $V_{BANDGAP}$

4. Compare result from step 3 to THRH and THRL. S1 algorithm passes if low threshold voltage ≤ converted voltage ≤ high threshold voltage.

58.5.16.6 Watchdog timer

The watchdog timer is an additional check which monitors the sequence of the self-testing algorithm implemented. It also verifies that the algorithm is completed within a safe time period. The watchdog timers can be enabled for CPU as well as CTU conversions.

Each algorithm has a different watchdog timer which runs independently of the other. The watchdog timer for a particular algorithm can be enabled by setting STAW*n*R[WDTE]. The safe time value can be programmed in STBRR[WDT] (default value is 10 ms assuming an 80 MHz clock).

The safe time is measured starting from Step0 of the algorithm (including all normal chain conversions in between) to the point where Step0 of the same algorithm starts again.

The programming sequence is as follows:

1. Program NCMR*n* to select the channels on which conversion needs to be performed for normal conversion in Scan Operation mode (MCR[MODE] = 1).
2. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected, that is, all algorithms will be executed step-by-step one after the other.
3. Enable self-testing channel by setting STCR2[EN].
4. Program safe period value in STBRR[WDT].
5. Enable watchdog timer by setting STAW*n*R[WDTE]. Assume setting of STAW*n*R[WDTE] to be 't0'. It is important to do all the programming first and then enable STAWnR[WDTE], as the safe time check is also performed between setting STAWnR[WDTE] and the start of Step0. This step checks that the algorithm has started within the safe time.
6. Start the normal conversion by setting MCR[NSTART].
7. At the end of the first conversion chain, three steps (Step 0/1/2) of algorithm S are executed in sequence. Let us assume the start of Step0 to be 't1'.
8. After completion of algorithm S, conversion of the next chain is performed.
9. At the end of the conversion chain, the first Step (Step0) of algorithm C is performed.
10. In this way, one Step of algorithm C is performed after completion of one conversion chain until all the steps have been completed. Steps are executed in sequence (Step 0, 1, 2, . . 11).
11. After the last step of algorithm C, another chain conversion is executed. At the end of this chain conversion, Step0 of algorithm S is started again, thus repeating the whole sequence. Let's assume this time (starting of Step0 of Supply algorithm) to be 't2'.
12. For S algorithm, if (t1–t0) > Safe Period or (t2–t1) > Safe Period, the watchdog timer flags an error and STSR1[WDTERR] is set. A fault is asserted on the specified module port as per criticality configuration (Critical or Non_critical), and an interrupt is also generated if enabled by STCR2[MSKWDTERR]. Otherwise, the watchdog timer counter is reset and starts again to monitor the same for the next sequence.
13. A similar sequence is followed for watchdog timers for algorithm C.

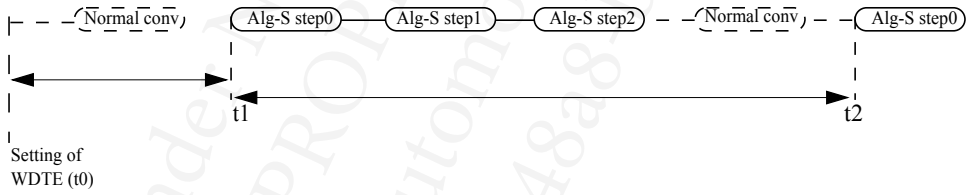

Figure 540. Watchdog timer monitor for Alg-S

NOTE

As CTU may not incorporate any safe period checking mechanism, the watchdog timers can be enabled for CTU conversions also.

NOTE

You must ensure that watchdog timers are disabled for self-test algorithms which are not executed.

58.5.16.6.1 Watchdog sequence checking

The watchdog timer also incorporates sequence checking features that check that the steps of a particular algorithm are in correct order. If steps are not in correct order, an error is flagged by setting STSR1[WDSERR]. A fault is indicated by an interrupt flag if enabled by STCR2[MSKWDSERR]. A fault is also asserted on the specified module port as per criticality configuration (Critical or Non_critical) and an interrupt generated if enabled by STCR2[MSKWDSERR].

A watchdog sequence error is flagged in the following cases:

- If steps of any algorithm are not executed in proper order.

- If abort chain occurs during test channel conversion. That step has to be repeated at the end of the next chain. This gives a sequence error when test channel conversion starts again.
  - Exception: If abort chain occurs during the last step of Algorithm S, then a sequence error is not flagged as the whole algorithm has to be repeated again.
- If, for CTU conversions, step numbers provided by CTU are not in order. Watchdog sequence checking is significant for CTU Burst mode only.

If injected conversion occurs during the test channel conversion, a watchdog sequence error is NOT flagged although the ongoing step number is aborted and is repeated again.

NOTE

Watchdog timer feature is applicable only for Scan Operation mode and not for One-Shot Operation mode.

58.5.16.7 Baud rate control for test channel

Baud rate control defines the scheduling of the test channel between the normal conversion chain. STBRR[BR] specify the scheduling rate.

By default, if a test channel is enabled, one step of the selected algorithm is executed after every chain of normal conversion. The bandwidth consumed by a test channel depends on the number of channels in a normal chain. For example, if we have 50 normal conversions in a chain, then a test channel consumes only 2% of total bandwidth. But if the number decreases to just 3 channels, then the bandwidth consumed by a test channel is 25%, which is significant (and may not be desirable as it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the test channel conversion to be performed not at the end of every chain, but at the end of BR+1 number of chains. For example, if BR = 5, a single step of the selected algorithm for a test channel is performed after six chain conversions, then the next step is performed at the end of the next six chain conversions, and so on. By default, the value of BR is zero.

NOTE

This feature is applicable only for Scan Operation mode of operation and not for One-Shot Operation mode. STBRR[BR] should be set to zero for One-Shot Operation mode.

To use the baud rate feature in Scan Operation mode, NCMR should have a non-zero value.

58.5.16.7.1 Abort chain when baud rate is non-zero

As already described, for a non-zero value of STBRR[BR], the test channel conversion is performed at the end of (BR+1) number of chains. If an abort chain occurs during the chain in which test conversion is scheduled to be converted, then test conversion is done after the next (BR+1) number of chains.

For example, if STBRR[BR] is programmed to two, the sequence will be two normal chains (without any test channel conversion) followed by a chain with test channel converted at the end. Now, if an abort chain occurs during the first two chains, it is treated as a normal chain abort and test channel is converted at the end of the third chain only (as is the case without any abort chain). But if an abort chain occurs during the third chain in which the test channel is scheduled to be converted, then the test channel is converted after the next three chains, that is at the end of sixth chain (counting from the beginning).

58.5.17 Conversion time

Total conversion time depends on the SAR_ADC clock (AD_CLK). This clock can be prescaled to half or one-fourth of bus clock. The SAR_ADC operating clock (AD_CLK) is always synchronous with the bus clock. The frequency of AD_CLK depends on MCR[ADCLKSE] settings.

- When MCR[ADCLKSE] = 1, AD_CLK = bus clock.
- When MCR[ADCLKSE] = 0, AD_CLK = (bus clock / 2).

Conversion timing detail is shown in the figure below. The description of each time segment follows the figure.

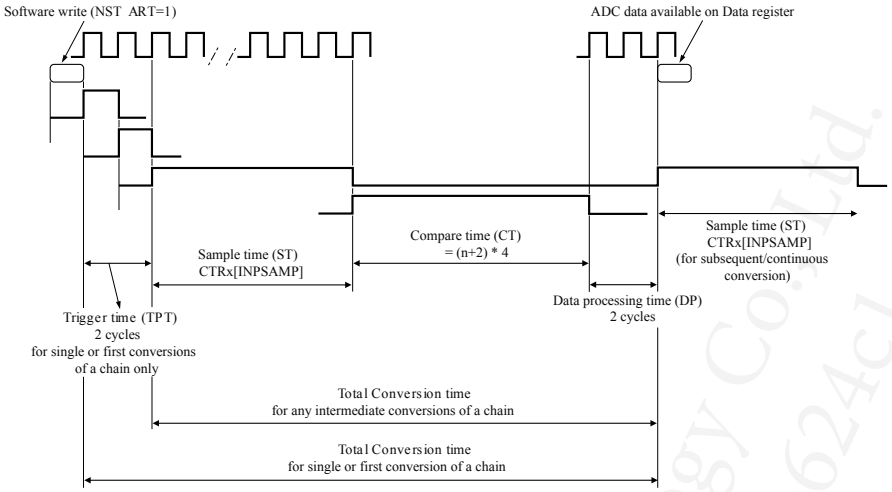

Figure 541. Conversion time

Trigger time (TPT):

To prepare a channel for conversion, two bus clock cycles are required by the SAR_ADC for the single conversion and for the first conversion in a chain. For continuous conversions and subsequent conversions in a chain, this time is not required because it is hidden in the pipeline operation.

Triggers from the synchronous CTU interface require two cycles of bus clock for the first conversion, but for back-to-back CTU conversions it takes only one cycle for trigger processing, because the other cycle is hidden in the pipeline operation.

Sample phase time (ST):

ST duration is controlled by the CTR*n*[INPSAMP[7:0]] configuration. The value in the register field represents units of AD_CLK cycles. The minimum value of sample time is eight AD_CLK cycles. If the value programmed in CTR*n*[INPSAMP[7:0]] is less than eight, it has no effect on sample time duration and will default to eight AD_CLK cycles.

Compare phase time (CT):

CT depends on the resolution of the SAR_ADC. The CT is ((x + 2) × 4) cycles of AD_CLK, where x is the resolution of SAR_ADC.

Data processing time (DP):

DP takes two AD_CLK cycles to post and load data into the data register.

Total conversion time:

The total time required for a single or first conversion is (TPT + ST + CT + DP) AD_CLK cycles. The time for subsequent conversions in a chain or continuous conversions is (ST + CT + DP) AD_CLK cycles.

Examples:

- CTR*n*[INPSAMP] = 20d (software triggered, MCR[NSTART]):
  - Single or first conversion: 2 + 20 + ((12 + 2) × 4) + 2 = 2 + 20 + 56 +2 = 80 AD_CLK cycles
  - Subsequent or continuous conversions: 20 + ((12 + 2)× 4) + 2 = 20 + 56 + 2 = 78 AD_CLK cycles
- CTR*n*[INPSAMP] = 20d (CTU triggered):
  - Single or first conversion: 2 + 20 + ((12 + 2)× 4) + 2 = 2 + 20 + 56 + 2 = 80 AD_CLK cycles
  - Subsequent back-to-back conversions: 1 + 20 +((12 + 2)× 4) + 2 = 1 + 20 + 56 + 2 = 79 AD_CLK cycles

Presample phase time (PST):

When presampling is enabled, the SAR_ADC presamples prior to starting the actual sampling, as described in Presampling. This phase takes the number of AD_CLK cycles defined in CTR*n*[INPSAMP]. Additionally, to switch from presample phase to actual channel sampling phase, it takes another two AD_CLK cycles. So, the total presampling AD_CLK cycle is CTR*n*[INPSAMP] + 2

additional cycles that are required for a conversion to complete. If presampling is implemented, all equations and examples above are valid only with the additional (CTRN*n*[INPSAMP] + 2) AD_CLK cycles.

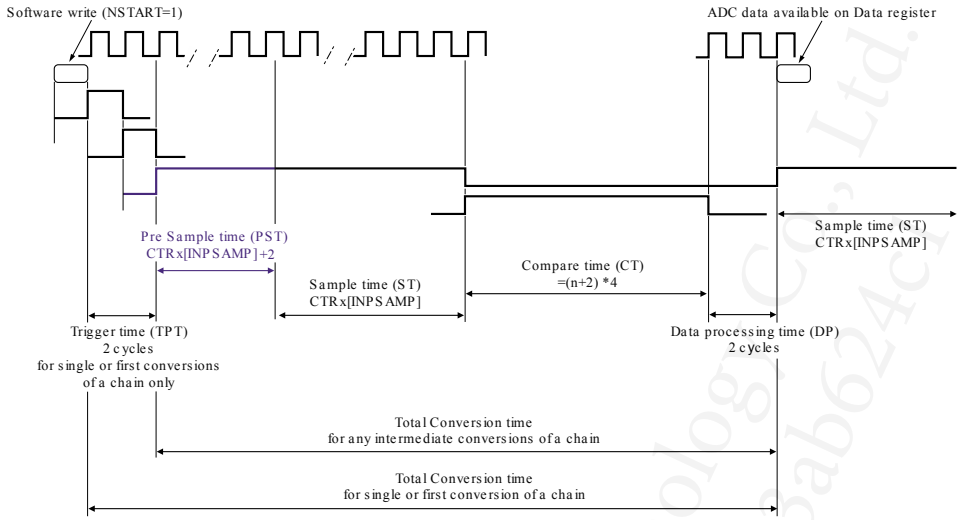

Figure 542. Conversion timing with presampling

Conversion time for calibration:

- Single conversion time = Sample time (MCR[TSAMP]) + CT (11 × 4) + DP (2)
- Interconversion gap = 1 cycle
- Total number of tests = 12
- Averaging = 32

One test duration = (single conversion time + interconversion gap) × averaging samples

Total test duration = (one test duration × total number of tests)

Example: Sample time = 22

Total test time = ((((22 + (11× 4) + 2) + 1) × 32) × 12) = 26496 cycles × 25 ns (40 MHz) = 662.4 µs

Conversion time for self-test conversion:

The time for a self-test conversion is one test period multiplied by the number of consecutive (atomic) steps. For supply self-tests, the atomic step is three and for other tests it is one.

One test period for self-test is:

- For supply tests: (ST + (14 × 4) + 2)
- For other algorithms: (ST + (11 × 4) + 2)

NOTE

Steps (conversions) of the supply algorithm always run in atomic operation, required for algorithmic procedure. So, in Scan Operation mode when all algorithms are selected, three steps (conversions) of supply algorithm run together after end of the chain. Steps (conversions) of algorithm C are not required to be run together, so after every chain one step (conversion) is executed serially. Conversion time in self-test also needs to be calculated accordingly.

Example:

- Channels in chain A→B→C
- Scan Operation mode

- All self-test algorithms selected

The resulting conversion order will be:

[A→B→C→AS_step0→AS_step1→AS_step2→A→B→C→AC_step0→A→B→C→AC_step1→A→B→C→AC_step2→ .....→A→B→C→AC_step11] →[same sequence repeats]

NOTE

AS = Algorithm S (supply self-test)

AC = Algorithm C (capacitive self-test)

58.5.18 Conversion data processing

The raw converted data of the SAR_ADC contains many types of errors like offset, gain, and so on. In order to reduce or eliminate errors, the raw conversion data is processed inside the SAR_ADC controller before sending to result register/output. The process of error correction happens in parallel during bit-by-bit evaluation, with the correction values generated during offset determination and calibration process.

The error correction value is subtracted from the raw conversion result whenever the comparator output for one of the calibrated capacitors evaluates high during the conversion period.

In order to reduce data processing time, the error correction is done in parallel during each bit evaluation of a conversion. All lower-weighted capacitors are not calibrated and no error correction is performed for these capacitors, but they are self-tested to guarantee error contribution is below specified accuracy limits.

The final result is checked for any overflow or underflow. If the processed data is above the maximum value that can be represented by ADC resolution, then the output data is forced to all ones (FFFh for 12-bit resolution). Similarly, if the processed data is negative, then output data is forced to all zeros (000h for 12-bit resolution).

58.5.19 User defined offset and gain values

Offset and gain errors in ADC are compensated by its calibration mechanism. However, there could be a source of errors outside the ADC module (for example, at system and/or board level). These errors can potentially contribute to ADC static errors and lower the overall TUE observed when an application runs. To compensate for these errors, there is a set of user-programmable offset and gain values in the User OFFSET and Gain Register (USROFSGN). By programming this register appropriately, the complete system's TUE can be enhanced (calibrated), when impacted by errors other than ADC itself.

These values (GAIN_USER and OFFSET_USER) must be stored in 2's complement format as described in the register section (see User OFFSET and Gain Register (USROFSGN)). The values stored here are being considered by the SAR_ADC engine and being computed/adjusted for every output. Using this register to compensate offset and gain is described below.

58.5.19.1 Writing for 12-bit ADC

58.5.19.1.1 User gain compensation (GAIN_USER)

The ADC can compensate a maximum of ±63 LSB @12b gain by programming GAIN_USER field in USROFSGN register. The field is in 2's complement format and stored with an 8x multiplication. Thus, if a value of ± Y is stored in this field, it leads to a final result adjusted with ±(Y/8) LSB from its unprogrammed version. It is required to keep the 3-LSBs zero to avoid any fractional subtraction/multiplication related errors.

ADC_OUTPUT_NEW = ADC_OUTPUT_OLD × (1 + (GAIN_USER / (8 × 4096))).

Example:

For GAIN_USER = 0, result is ADC_OUTPUT_NEW = ADC_OUTPUT_OLD = P

For GAIN _USER = +Y, result is ADC_OUTPUT_NEW = P × (1 + (Y / 32768))

For GAIN _USER = −Y, result is ADC_OUTPUT_NEW = P × (1 − (Y / 32768))

58.5.19.1.2 User offset compensation (OFFSET_USER)

The ADC can compensate a maximum of ±15LSB @12b offset by programming OFFSET_USER field in USROFSGN register. The field is in 2's complement format and stored with an 8x multiplication. Thus, if a value of ±X is stored in this field, it leads to a final result adjusted with ±(X/8) from its unprogrammed version. It is required to keep the 3-LSBs zero to avoid any fractional subtraction-related errors.

ADC_OUTPUT_NEW = ADC_OUTPUT_OLD − (OFFSET_USER/8)

Example:

For OFFSET_USER = 0, result is ADC_OUTPUT_NEW = ADC_OUTPUT_OLD = K

For OFFSET_USER = +X, result is ADC_OUTPUT_NEW = K − (X / 8)

For OFFSET_USER = −X, result is ADC_OUTPUT_NEW = K − (−X / 8) = K + (X / 8)

58.5.19.1.3 Using OFFSET_USER and GAIN_USER together

When both the fields are programmed together, gain is computed first and then offset is computed.

ADC_OUTPUT_NEW = (ADC_OUTPUT_OLD × (1 + (GAIN_USER / (8 × 4096)))) − ((OFFSET_USER / 8)).

Example:

For OFFSET_USER = 0 and GAIN_USER = 0, result is ADC_OUTPUT_NEW = ADC_OUTPUT_OLD = M

For OFFSET_USER = X and GAIN_USER = Y, result is ADC_OUTPUT_NEW = (M x (1 + (Y / 32768))) − (X / 8)

NOTE

Negative values are stored in 2's complement in these fields. Example:

GAIN_USER = 1F0h means +496d, and 210h means −496d

OFFSET _USER = 70h means +112d, and 90h means −112d

58.6 Programming sequences

ADC must be programmed properly to function correctly. This section describes the basic programming sequences for applications to use. Application software may use them in combination by sequencing them carefully.

58.6.1 Running calibration

Calibration is the first step that should be run after every power-on reset. ADC has two types of reset:

- Calibration
- Functional

Calibration reset is used for registers that store internal calibration settings and values. This reset is done to store them during functional reset. Functional reset may be applied many times during an application for various reasons and calibration may not required each time, so storing the settings and values in a higher level of reset avoids recalibration with every functional reset.

1. Wait for deassertion of functional reset.
2. Configure SAR controller operating clock (MCR[ADCLKSE] = 0).
3. Bring ADC out of Power-down state (MCR[PWDN] = 0).
4. Configure desired calibration settings (default values kept for highest accuracy maximum time).
   - MCR[TSAMP]: Sample time for calibration conversion
   - MCR[NRSMPL]: Number of samples in averaging
   - MCR[AVGEN]: Averaging function enable in calibration
5. Run calibration by writing a one to MCR[CALSTART].

6. Check calibration run status in MSR[CALBUSY]—wait until MSR[CALBUSY] = 0; alternatively, MSR[ADCSTAT] can be used to check status.
7. Check calibration pass/fail status in MSR[CALFAIL] field. If MSR[CALFAIL] = 1 then calibration failed. Detailed status can be checked in CALSTAT.

58.6.2 Running normal conversion

Normal conversion mode should usually be used to convert analog samples most of the time in an application, unless there is a special need. There are other modes available for special requirements as described in later sections of this document. Normal conversions can be initiated by software trigger. Calibration should be done before running any conversion to ensure an accurate result.

1. Configure channel mask registers NCMR*n*, for different channel groups.
2. Configure desired sample time in CTR*n*, for different channel groups.
3. Configure interrupt mask registers, IMR for global and CIMR*n*, for different channel groups.
4. Configure DMA registers, DMAE, and DMAR*n*, for different channel groups.
5. Configure pre-sampling registers, if needed, PSCR and PSR*n*, for different channel groups (if needed).
6. Configure watchdogs in WTIMR
7. Configure One-Shot or Scan mode in MCR[MODE] and other settings (MCR[WLSIDE], MCR[OWREN], and so on).
8. Start conversion by writing one to MCR[NSTART].
9. Check EOC status in ISR or wait for interrupt.
10. On interrupt read the data register, or DMA will read out data if configured.
11. Status of conversion for individual channel can be seen in CEOCFR*n*.
12. Clear the registers by writing one to the fields.
13. Steps 9 to 12 will continue in loop until conversion finishes or is terminated.

58.6.3 Running injected conversion

Injected conversion has a higher priority than normal conversion and it runs in One-Shot mode only. It can be started in idle condition or when normal conversion is in process. The configuration sequence is almost similar to normal conversion above, except for the registers discussed in the following steps.

1. Channel mask register JCMR*n*, is used for different channel groups.
2. Configure other channel attributes as done in normal conversion.
3. Start conversion by writing 1b to MCR[JSTART].
4. Check status of ISR[JEOC] or wait for interrupt.
5. Read out conversion data and clear interrupts as done in normal conversion.
6. Configure channel mask registers NCMR*n* for different channel groups.
7. Configure desired sample time in CTR*n* for different channel groups.
8. Configure interrupt mask registers, IMR for global and *n*, for different channel groups.
9. Configure DMA registers, DMAE and DMAR*n*, for different channel groups.
10. Configure presampling registers, if needed, PSCR and PSR*n*, for different channel groups (if needed).
11. Configure watchdogs in WTIMR.
12. Configure One-Shot or Scan mode in MCR[MODE] and other settings (MCR[WLSIDE], MCR[OWREN], and so on).
13. Start conversion by writing 1b to MCR[NSTART].

14. Check status of ISR[EOC] or wait for interrupt.
15. On interrupt, read the data register or DMA will read out data if configured.
16. Status of conversion for an individual channel can be seen in CEOCFR*n*.
17. Clear the registers by writing one to the bits.
18. Steps 9 to 12 will continue in loop until conversion finishes or is terminated.

58.6.4 Running CTU triggered conversion

CTU conversion has a higher priority than normal or injected conversion and runs only a single conversion. It can be started in the idle condition or when normal or injected conversion is in progress. Conversions initiated by the CTU (one channel per trigger) are processed immediately by suspending normal conversions and discarding any ongoing injected conversion chain. The configuration sequence is similar to normal conversion above except for the following steps:

1. Enable CTU conversion in MCR[CTUEN].
2. Start CTU trigger.
3. Check EOCTU status in ISR.

58.6.5 Running self-test

Self-test conversions run after a programmable number of normal conversion chains or by CTU trigger. To run normal conversions, additional configurations for self-test need to be implemented before starting normal conversion (as shown in Self-test). Also, you may need to configure the self-test watchdog, timer, and baud rate as described in Self-test analog watchdog.

58.7 SAR_ADC register descriptions

58.7.1 SAR_ADC memory map

Fields

Field	Function
31 OWREN	Overwrite enable Sets whether the latest conversion overwrites current value in data registers. 0b - Older valid conversion data is not overwritten by newer conversion data 1b - Newer conversion result is always overwritten, irrespective of the validity of older conversion data
30 WLSIDE	Selects whether conversion data is left or right aligned. 0b - Write right-aligned conversion data (from 11 to 0) 1b - Write left-aligned conversion data (from 15 to 4)
29 MODE	Normal scan mode select Selects between One-Shot or Scan Operation modes; MODE must be changed in ADC's Idle condition (check MSR [ADCSTATUS] field) 0b - One-Shot Operation mode: configuration for one chain conversion in Normal Conversion mode 1b - Scan Operation mode: configuration for continuous chain conversion in Normal Conversion mode. When the chain conversion is finished a new scan starts immediately.
28 —	Reserved
27 TRGEN	External trigger enable Enables external triggers to start conversions. 0b - External trigger is disabled 1b - Enables the external trigger to start a conversion
26 EDGE	Trigger edge select Selects which edge of the external trigger starts a conversion. This field is only valid if MCR[TRGEN] = 1b. 0b - Falling edge is trigger 1b - Rising edge is trigger
25 XSTRTEN	External start enable If this field is set, a normal conversion starts when an external start signal is detected. This can be used to synchronize the start conversion events of two ADCs.
24 NSTART	Normal conversion start Setting this field starts One-Shot or Scan Operation mode. In Scan Operation mode, this field remains high after setting. Clearing this field in Scan Operation mode causes the current chain conversion to finish, then stop the scan.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In One-shot Operation mode, this field is cleared immediately after the conversion starts. Setting this field during ongoing conversions keeps this field high until the requested conversion is started (or pending during Injected Operation mode).
23 —	Reserved
22 JTRGEN	Injection external trigger enable When set, enables the external trigger to start injected conversions. This field must be set if the external trigger feature is needed to start injected conversions. 0b - Injected conversion not started by external trigger 1b - Injected conversion started by external trigger
21 JEDGE	Injection trigger edge selection Selects which edge of the external trigger starts an injected conversion. This field is only valid if MCR[JTRGEN] = 1b. 0b - Falling edge is trigger 1b - Rising edge is trigger
20 JSTART	Start injection conversion Setting this field starts injected analog channels to be converted. Clearing this field has no effect since the injected chain conversion cannot be interrupted. If this field is set during on ongoing injected conversion, the field will remain set until the new conversion starts.
19-18 —	Reserved
17 CTUEN	Cross trigger unit enable This field enables conversions to starts by the CTU. **NOTE** This field must not be modified when CTU conversion is running (MSR[CTUSTART]= 1 b). 0b - The CTU is disabled and the triggered injected conversion cannot take place 1b - The CTU is enabled and the triggered injected conversion can take place
16 CTU_MODE	Cross trigger unit mode Sets the CTU operating mode of the SAR_ADC. This field can only be written in Power-Down mode. 0b - CTU control mode is selected 1b - CTU trigger mode is selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 STCL	Self-testing configuration lock 0b - Self-test registers are not locked 1b - The self-test configuration is locked (STCR1, STCR2, STCR3, STBRR, STAW0R, STAW1AR, STAW1BR, STAW2R, STAW3R, STAW4R, STAW5R are write-protected). It can be used only in CPU and Scan operation modes. It is cleared by reset only.
14 CALSTART	Calibration start Writing 1b to this field starts calibration. It is self-clearing, and is cleared by hardware when calibration completes or is terminated prematurely. 0b - No effect (default, return value) 1b - Start calibration
13 AVGEN	Average enable Allows averaging of calibration time. 0b - Disable 1b - Enable (default)
12-11 NRSMPL	Number of averaging samples Selects the number of averaging samples to be used during Calibration. 00b - 16 samples 01b - 32 samples 10b - 128 samples 11b - 512 samples
10-9 TSAMP	Sample period of calibration conversions 00b - 22 cycles of AD_CLK (default) 01b - 8 cycles of AD_CLK 10b - 16 cycle of AD_CLK 11b - 32 cycle of AD_CLK
8 ADCLKSE	Analog clock frequency select This field selects the clock frequency of the AD_CLK signal. It can be written in Power-Down mode only. 0b - AD_CLK frequency is half 1b - AD_CLK frequency is equal to bus clock frequency
7 ABORTCHAIN	Abort conversion chain If this field is set, the chain conversion in process is aborted. When the chain aborts, this field is reset by hardware.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Setting this field in idle state (for example, no normal/injected conversion is in process) has no effect. In this case, the field is reset immediately. During a CTU conversion, this field cannot be programmed. **NOTE** Abort and Abort Chain must not be applied simultaneously in SCAN mode operation. 0b - Chain conversion has been aborted, or chain conversion is not currently running. 1b - Abort current chain conversion.
6 ABORT	Abort conversion If this field is set during any ongoing conversion, it aborts that conversion and the next conversion starts. When the ongoing conversion aborts, this field is reset by hardware. This field is not written while the self-test channel conversion is in process. **NOTE** Abort and Abort Chain must not be applied simultaneously in SCAN mode operation.
5 ACKO	Auto-Clock-Off mode enable If this field is set, the Auto-Clock-Off feature is enabled. 0b - Auto-Clock-Off feature is disabled 1b - Auto-Clock-Off feature is enabled
4 —	Reserved
3-1 —	Reserved
0 PWDN	Power-down enable Request transitions to Power-Down or Idle modes. 0b - When ADC status is in Power-Down mode (MSR[ADCSTATUS] = 001b), start ADC transition to IDLE mode. 1b - Request to enter Power-Down mode.

Fields

Field	Function
31-8 —	Reserved
7-0 INPSAMP	Sampling phase duration This field configures the sample period duration in terms of the SAR Controller clock. The minimum acceptable value is 8. Configuring to a value lower than 8 sets the sample period to 8 cycles. NOTE

58.7.23 Conversion Timing Register 1 (CTR1)

Offset

Register	Offset
CTR1	98h

Function

This register is associated with channels 32 to 63. An exception exists for the temperature sensor channel, which always uses the CTR1 value.

Field	Function
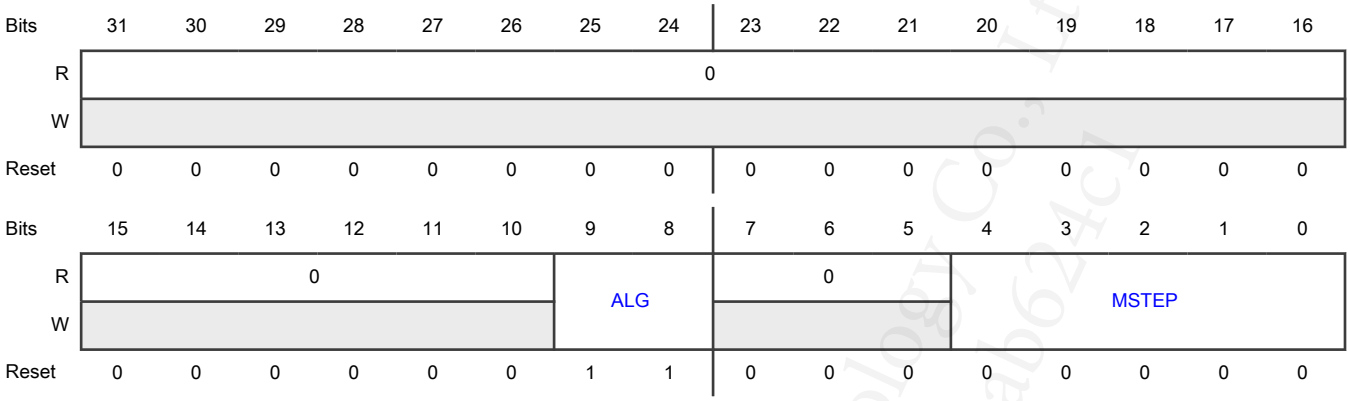
18 MSKWDG_EOA_C	End of algorithm C interrupt mask Enables the end of Algorithm C interrupt (STSR1[WDG_EOA_C] = 1). 0b - Interrupt disabled 1b - Interrupt enabled
17 —	Reserved
16 MSKWDG_EOA_S	End of algorithm S interrupt mask Enables the end of Algorithm S interrupt (STSR1[WDG_EOA_S] = 1). 0b - Interrupt disabled 1b - Interrupt enabled
15 MSKERR_C	Error on algorithm C channel interrupt mask Enables the error on Algorithm C channel interrupt (STSR1[ERR_C] = 1). 0b - Interrupt disabled 1b - Interrupt enabled
14 —	Reserved
13 MSKERR_S2	Error on algorithm S2 channel interrupt mask Enables the error on Algorithm S2 channel (SUPPLY, step 2) interrupt (STSR1[ERR_S2] = 1). 0b - Interrupt disabled 1b - Interrupt enabled
12 MSKERR_S1	Error on algorithm S1 channel interrupt mask Enables the error on Algorithm S1 channel (SUPPLY, step 1) interrupt (STSR1[ERR_S1] = 1). 0b - Interrupt disabled 1b - Interrupt enabled
11 MSKERR_S0	Error on algorithm S0 channel interrupt mask Enables the error on Algorithm S1 channel (SUPPLY, step0) interrupt (STSR1[ERR_S0] = 1). 0b - Interrupt disabled 1b - Interrupt enabled
10-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 EN	Self-testing channel enable Enables the TEST channel only in CPU mode. In CTU trigger/control mode the enable is provided directly by the CTU. This field must be set before starting normal conversion and should not be changed while the conversion is in process. This field should only be reset after end of conversion of the last self-test channel has been received. 0b - OFF 1b - ON
6-5 —	Reserved
4 FMA_WDSERR	Fault mapping for watchdog sequence error By default, a failure on the Watchdog Sequence is mapped to drive the NCF line. 0b - NCF mapping 1b - CF mapping
3 FMA_WDTERR	Fault mapping for watchdog timer error By default, a failure on the Watchdog Timer is mapped to drive the NCF line. 0b - NCF mapping 1b - CF mapping
2 FMA_C	Fault mapping for algorithm C By default, a failure during Algorithm C is mapped to drive the CF fault line. 0b - NCF mapping 1b - CF mapping
1 —	Reserved
0 FMA_S	Fault mapping for BGAP algorithm By default, a failure during the supply algorithm is mapped to drive the Critical Fault (CF) line. 0b - Non-Critical Fault (NCF) mapping 1b - Critical Fault (CF) mapping

58.7.44 Self-Test Configuration Register 3 (STCR3)



Offset

Register	Offset
STCR3	348h

Function

This register defines ADC self-testing capabilities in CPU mode (CTU disabled ≥ MCR[CTUEN] = 0). The contents of this register should be programmed before starting the conversion, and should not be changed while conversion is in process.

Diagram

Fields

Field	Function
31-10 —	Reserved
9-8 ALG	• One-Shot Operation mode algorithm scheduling: 00b - Algorithm S (single step=MSTEP) 01b - Reserved 10b - Algorithm C (single step=MSTEP) 11b - Algorithm S (default) For test/debug purposes. • Scan Operation mode algorithm scheduling: 00b - Algorithm S 01b - Reserved 10b - Algorithm C 11b - Algorithm S + Algorithm C (default): The execution baud rate of the selected algorithm is defined by STBRR configuration.
7-5 —	Reserved
4-0 MSTEP	For One-Shot Operation mode: Current step for Algorithm S//C.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• MSTEP = 0 to NUM_SUPPLY_STEPS - 1 for Algorithm S • MSTEP = 0 to NUM_C_STEPS - 1 for Algorithm C The unused codes are RESERVED (should not be used). This field is not used in Scan Operation mode as single-step execution (interleaved mode) is always performed. It should be programmed to zero in Scan Operation mode.

Fields

Field	Function
31-28 —	Reserved
27 WDSERR	Watchdog sequence errors Watchdog sequence errors of the ADC subsystem (check for algorithm step sequence). If a failure occurs, an interrupt will be generated if enabled (STCR2[MSKWDSERR] = 1). It provides the fault indication to the FCCU, asserting a CF or NCF according to the STCR2[FMA_WDSERR] configuration. 0b - No failure 1b - Failure occurred
26 —	Reserved
25 WDTERR	Watchdog timer error Watchdog timer error of the ADC subsystem (algorithm check for completion within safe time). If a failure occurs, an interrupt will be generated if enabled (STCR2[MSKWDTERR] = 1). It provides the fault indication to the FCCU, asserting a CF or NCF according to the STCR2[FMA_WDTERR] configuration. 0b - No failure 1b - Failure occurred
24 OVERWR	Overwrite error Used to notify when STSR1[ERR*x*] is overwritten by a new error. The new error status is written or discarded according to the MCR[OWREN] value. To avoid Overwrite Error indication, STSR1[ERR*x*] must be cleared by software. 0b - No overwrite error 1b - Overwrite error occurred
23 ST_EOC	Self-test EOC This field is set along with EOC bit when end of conversion occurs from the analog SAR_ADC for self-test channel. An interrupt is generated if STCR2[MSKST_EOC] = 1, and IMR[MSKEOC] = 1. Writing 0 has no effect. 0b - Self-test end of conversion is not complete 1b - Self-test end of conversion is complete
22-19 —	Reserved
18 WDG_EOA_C	Indicates that Algorithm C has completed. This field is set after the last STEP of algorithm is executed. An interrupt is generated if STCR2[MSKWDG_EOA_C] = 1. This field will set only if STAW4R[WDTE] = 1. For CTU conversions, this field is significant only for Burst mode of operation. Writing 0 has no effect. 0b - Self-test end of Algorithm C conversion is not complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Self-test end of Algorithm C conversion is complete
17 —	Reserved
16 WDG_EOA_S	Indicates that Algorithm S has been completed. This field is set after the last Step of Algorithm S is executed. An interrupt is generated if STCR2[MSKWDG_EOA_S] = 1. This field is set only if STAW0R[WDTE] = 1. For CTU conversions, this field is significant only for Burst mode of operation. Writing 0 has no effect. 0b - Self-test end of Algorithm S conversion is not complete. 1b - Self-test end of Algorithm S conversion is complete.
15 ERR_C	Algorithm C error STSR1[ERR_C] indicates an error on the self-testing channel (Algorithm C). An interrupt is generated if STCR2[MSKERR_C] = 1. It provides the fault indication to the FCCU, asserting the programmed fault line (STCR2[FMA_*x*]). STSR1[ERR_C] can also be set by software (fault injection) by writing 1 to STCR2[SERR]. In this case, a CF or NCF will be asserted according to the STCR2[FMA_*x*] configuration. Writing 0 has no effect. 0b - No Algorithm C error 1b - Algorithm C error occurred
14 —	Reserved
13 ERR_S2	STSR1[ERR_S2] indicates an error on the self-test channel (Algorithm S (SUPPLY), step2). An interrupt is generated if STCR2[MSKERR_S2] = 1. It provides the fault indication to the FCCU, asserting the programmed fault line (STCR2[FMA_*x*]). STSR1[ERR_S2] can be also set by software (fault injection) by writing 1 to STCR2[SERR]. In this case, a CF or NCF will be asserted according to the STCR2[FMA_*x*] configuration. Writing 0 has no effect. 0b - No error occurred on the sampled signal 1b - Error occurred on the sampled signal
12 ERR_S1	STSR1[ERR_S1] indicates an error on the self-test channel (Algorithm S (SUPPLY), step1). An interrupt is generated if STCR2[MSKERR_S1] = 1. It provides the fault indication to the FCCU, asserting the programmed fault line (STCR2[FMA_*x*]). STSR1[ERR_S1] can be also set by software (fault injection) by writing 1 to STCR2[SERR]. In this case, a CF or NCF will be asserted according to the STCR2[FMA_*x*] configuration. Writing 0 has no effect. 0b - No VDD ERROR 1b - VDD ERROR occurred
11 ERR_S0	STSR1[ERR_S0] indicates an error on the self-test channel (Algorithm S (SUPPLY), step0). An interrupt is generated if STCR2[MSKERR_S0] = 1. It provides the fault indication to the FCCU, asserting the programmed fault line (STCR2[FMA_*x*]). STSR1[ERR_S0] can be also set by software (fault injection) by

STAW0R	380h

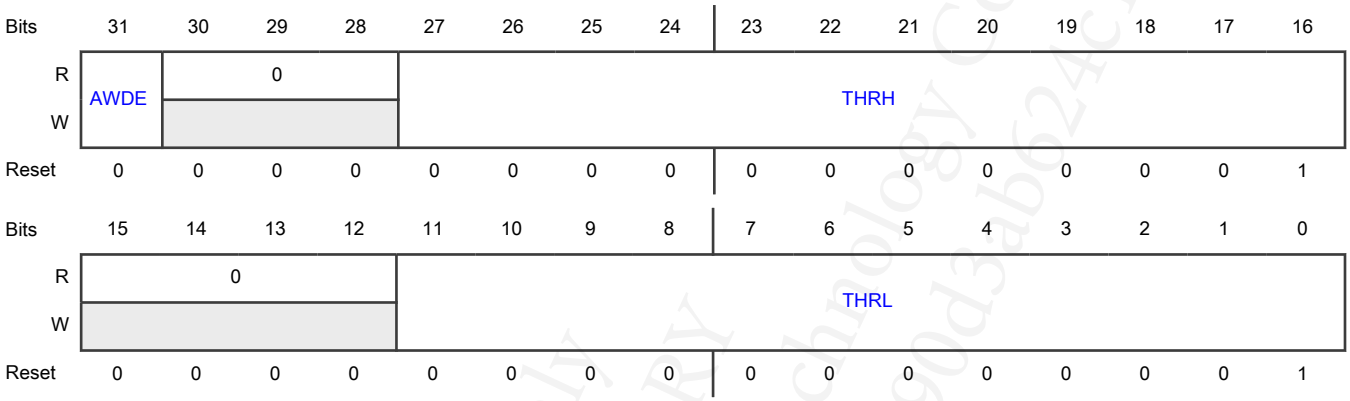
Diagram

Fields

Field	Function
31 AWDE	Enables/disables the comparison of the conversion result from the ADC supply self-test step0 to the thresholds contained in this register (THRH and THRL). 0b - Disabled 1b - Enabled
30 WDTE	Watchdog timer enable (related to the Algorithm S) Enables/disables the watchdog timer monitoring function for all ADC supply self-test steps.

Table continues on the next page...

Table continued from the previous page...



Field	Function
	The watchdog timer verifies: • Correct sequence of the algorithm (step sequence) • Execution of the algorithm within the safe time period as defined by STBRR[WDT] As soon as the watchdog timer is enabled the algorithm execution must be detected within the safe time period. The watchdog timer is reset each time the algorithm restarts. Set this field only in Scan mode. 0b - Disabled 1b - Enabled
29-28 —	Reserved
27-16 THRH	High threshold value for Algorithm S step0 If the analog watchdog is enabled, STSR1[ERR_*x*] is set to 1 if STDR1[TCDATA] > THRH. The reset value of this field is calculated based on a bandgap voltage of 1.2 V. Program the value 2912d (or B60h) for a bandgap voltage of 1.15 V. The formula for calculating the higher threshold is (Bandgap_Voltage_Maximum)*4095/(Reference_Voltage_Minimum). **NOTE** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
15-12 —	Reserved
11-0 THRL	Low threshold value for Algorithm S step0 If the analog watchdog is enabled, STSR1[ERR_*x*] is set to 1 if STDR1[TCDATA] < THRL. The reset value of this field is calculated based on a bandgap voltage of 1.2 V. Program the value 2367d (or 93Fh) for a bandgap voltage of 1.15 V. The formula for calculating the lower threshold is (Bandgap_Voltage_Minimum)*4095/(Reference_Voltage_Maximum). **NOTE** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). This value may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

Chapter 59
Thermal Monitoring Unit (TMU)

59.1 Chip-specific TMU information

59.1.1 Local temperature sensor placements

There are three remote sensors. The table below provides the local temperature sensor placements.

Table 532. Sensor placement

Temperature sensor ID	Placement
0	Between the DDR Sub-System and the internal RAM
1	Near A53 Cluster 0
2	Near LLCE/HSE_H and the Temp Diode

59.1.2 Recommended TCMCFG register settings

The Central Module Configuration Register (TCMCFG) enables you to control accuracy-enhancing features in the TMU, such as offset cancellation mode, dynamic element matching, or dynamic power management, among several others.

It is recommended to make full use of these features to get the most accurate temperature reading possible.

Use the following settings:

- OCS = 0
- OCM = 1
- DEMA = 1
- DFD = 3
- RCTC = 4
- CLKDIV = 4

The combined effect of these settings should leverage the module's ability to increase the number of samples taken from each sensor and fine-tune some of the analog circuitry for optimal performance. The RCTC and CLKDIV settings specifically control the duration of each analog conversion. These settings deliver a stable reading and quick conversion times. See the register description for further details.

59.1.3 Calibration table

To obtain valid temperature results from the TMU in monitoring mode, first initialize the TMU's calibration table.

The contents of the table below have been characterized by NXP and highly recommended. Please do diverge from these settings.

Table 533. Calibration table

TTCFGR[CAL_PNT]	TTRCR[TEMP(K)]	TSCFGR[SENSOR]
0	0x0E9	0x02C
1	0x0E6	0x026
2	0x0F2	0x03D
3	0x10A	0x06B

Table continues on the next page...

Table 533. Calibration table (continued)

TTCFGR[CAL_PNT]	TTRCR[TEMP(K)]	TSCFGR[SENSOR]
4	0x123	0x09B
5	0x13B	0x0C9
6	0x153	0x0F7
7	0x161	0x112 + TMU_CFG_DAC_TRIM_0[4:0]
8	0x16B	0x125 + TMU_CFG_DAC_TRIM_0[4:0]
9	0x184	0x155 + TMU_CFG_DAC_TRIM_0[4:0]
10	0x190	0x16C + TMU_CFG_DAC_TRIM_0[4:0]
11	0x193	0x172 + TMU_CFG_DAC_TRIM_0[4:0]

The table's values should be written to the proper bitfields in the TTCFGR, TTRCR, and TSCFGR registers, as shown. These are generic registers, and their contents will be lost after POR or shutdown events. Always initialize the table before engaging the TMU's monitoring mode.

The last five entries of the table are meant to be used together with a hot temperature trim, which will vary from part to part. This value must be read from the TMU_CFG_DAC_TRIM_0[4:0] fuses, and the end user's software must offset the last five entries of the calibration table with it.

This is not automated. Therefore, the end user's software must fetch the fuse value, add it to the last five entries of the generic table above, and program each part with the newly computed values.

59.2 Introduction

TMU has access to multiple remote temperature measurement sites, which are strategically located on the chip. The module monitors these sites and reports the temperature from one or more of them. You can access the data related to the current and average temperature, which the module constantly captures, for each site. The module can also signal an alarm if a programmed event occurs.

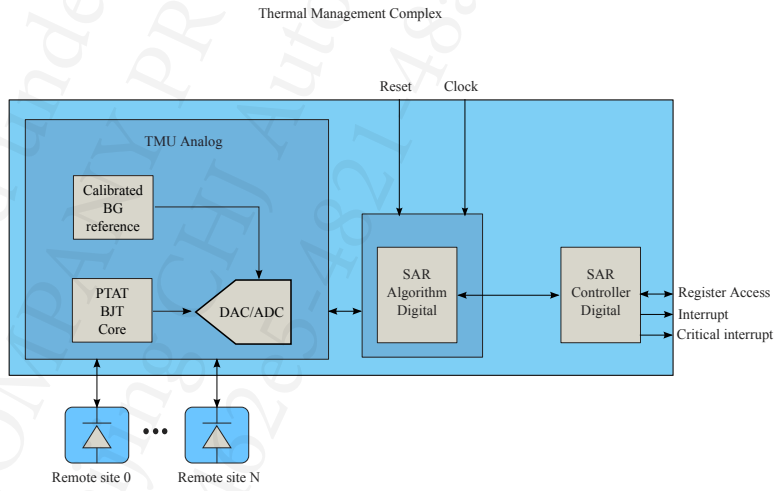

Figure 543. TMU block diagram

59.2.1 Features

TMU includes the following features:

- Temperature measurement ranges from 233 K to 398 K (-40 °C to + 125 °C)
- Configuration
  - TMU software configuration loads and initializes the calibration data
- Monitoring
  - Single- or multi-site monitoring
  - Programmable monitoring interval
  - Out-of-range indication
  - High/low temperature range monitoring
  - Temperature rate change monitoring
  - Immediate and average temperature monitoring
  - Average temperature monitoring based on programmable low-pass filtering
  - Programmable monitoring of high/low temperature thresholds for triggering normal and/or critical alarms
  - Programmable monitoring of the rate of rising/falling temperatures for triggering critical alarms
- Reporting
  - Immediate and average temperature reporting for all monitor sites

59.2.2 Modes of operation

The TMU has the following modes of operation as defined by TMR[MODE]:

- TMU disabled; low-power mode
- Monitoring

59.3 TMU register descriptions

The table below shows the memory map for management of the TMU resources.

59.3.1 TMU memory map

TMU base address: 400A_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Mode (TMR)	32	RW	0000_0000h

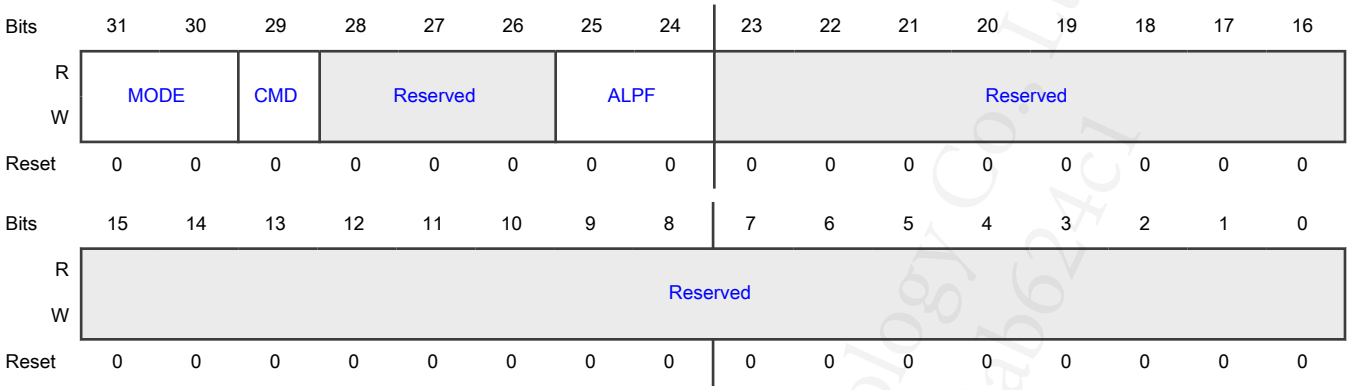
59.3.2 Mode (TMR)



Offset

Register	Offset
TMR	0h

Function

This register allows the software to control the thermal monitoring operation. You must wait for at least 500 µs before changing modes.

Diagram

Fields

Field	Function
31-30 MODE	Mode Before you enable the TMU for monitoring, you must first configure it; see Initialization information. Failure to properly initialize the configuration table may result in undefined behavior. 00b - Idle; low-power mode 01b - Reserved 10b - Monitoring of sites as defined by TMSR[SITE] 11b - Reserved
29 CMD	Central module disable Before disabling the central module, you must first deassert the MODE field and verify that the TMU is idle. You must then enable the circuit during normal operation by writing an appropriate non-zero value in the MODE field. This field allows for statically disabling the centralized circuit and the associated digital logic to reduce power. If the central circuit is re-enabled, TMU must wait before operations can continue as defined by TCMCFG[CMET]. 0b - Enabled 1b - Disabled
28-26 —	Reserved
25-24 ALPF	Average low pass filter setting The average temperature is calculated using this formula: ALPF x Current_Temp + (1 - ALPF) x Average_Temp. If no previous (average) temperature is valid, then the module uses the current temperature for Average_Temp in this calculation. For proper operation, you must change this field only when monitoring is disabled.

Diagram

Fields

Field	Function
31-3 —	Reserved
2-0 SITE	Monitoring site select 2-0 When you set the select bit for a temperature sensor site, it is enabled and included in all monitoring functions. For proper operation, you should only change this field when monitoring is disabled. Multiple sites can be enabled at the same time. SITE[x] controls monitoring of site x, such as: • SITE[0] - controls monitoring site 0 — SITE[0]==0: Disables site 0 — SITE[0]==1: Enables site 0 • SITE[1] - controls monitoring site 1 — SITE[1]==0: Disables site 1 — SITE[1]==1: Enables site 1 • SITE[2] - controls monitoring site 2 — SITE[2]==0: Disables site 2 — SITE[2]==1: Enables site 2

59.3.5 Monitor Temperature Measurement Interval (TMTMIR)

Offset

Register	Offset
TMTMIR	Ch

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

Function

This register allows you to control at what frequency the module reads the temperature sensors. The module reads all enabled monitored sites once in this time interval. The value of the status field, TSR[MIE], is 1 if the temperature measument takes longer than the set interval. The software should consider increasing the interval or reducing the number of active sites if the interval exceeds the temperature monitoring interval determined by the TMI field value in this register. If you disable the interval, then monitoring is continuous.

NOTE

The time it takes for one temperature measurement depends on the temperatures measured and mode settings; thus, the time for a single temperature measurement is not fixed.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved												TMI			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved
3-0 TMI	Temperature monitoring interval in seconds For proper operation, you should only change this field when monitoring is disabled, that is, when TMR[MODE]=b00. For the TMU frequencies calculation, use the following formula for the field description: • $2^{(23+TMI)}$ × TMU clock period in seconds For the monitoring interval calculation, use the following formula: • 0b – 1110b: Interval(s) = $2^{(23+TMI)}$ × TMU clock period in seconds • 1111b: Continuous monitoring mode

59.3.6 Interrupt Enable (TIER)

Offset

Register	Offset
TIER	20h

Function

This register determines if a detected status condition should cause a system interrupt. A system interrupt occurs if the value of any field in this register is 1 and the corresponding field in Interrupt Detect (TIDR) is 1. To clear the interrupt, you write a 1 to Interrupt Detect (TIDR). The following table provides the details of TMU interrupts.

Table 534. TMU interrupts

Interrupt description	Enable field	Reported as	
		Interrupt	Critical interrupt
Immediate high temperature threshold interrupt enable	IHTTIE	Y	—
Immediate low temperature threshold interrupt enable	ILTTIE	Y	—
Average high temperature threshold interrupt enable	AHTTIE	Y	—
Average low temperature threshold interrupt enable	ALTTIE	Y	—
Average high temperature critical threshold interrupt enable	AHTCTIE	—	Y

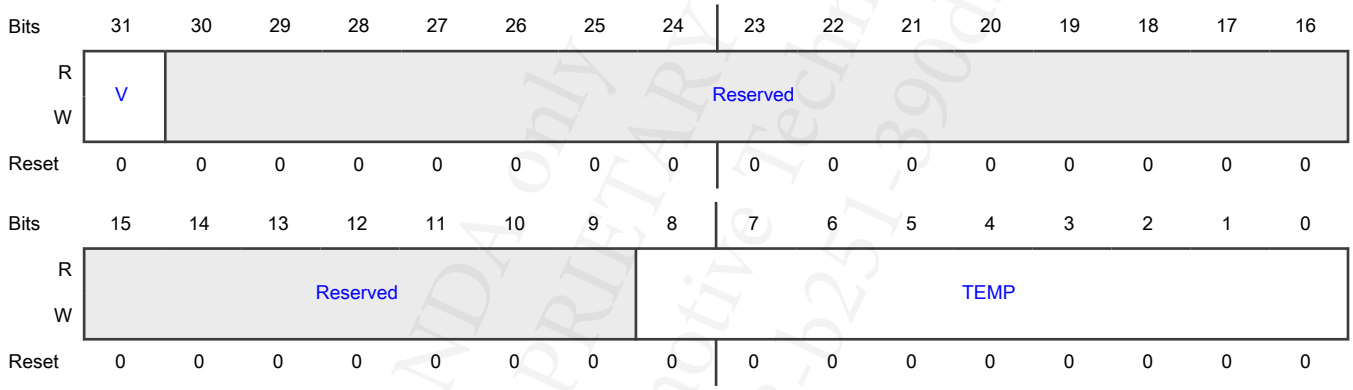
59.3.28 Temperature Range Control a (TTRCR0 - TTRCR15)

Offset

For a = 0 to 15:

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c42e-4821-48a8-b251-390d3ab624c1

Register	Offset
TTRCRa	F10h + (a × 4h)



Function

These registers allow you to define the calibration points used to cover the temperature sensor range. TTRCR0 defines the start of the temperature range which, along with TTRCR1, must always be valid to account for at least two calibration points. We provide selected calibration points to account for any non-linear behavior in the sensor as a function of temperature. A perfectly linear sensor reading requires only two calibration points to find the temperature based on linear interpolation. You must enable the calibration points sequentially, starting with TTRCR0 through TTRCR15.

NOTE

The circuit is designed and calibrated for measuring temperatures in the range of 233 K to 398 K (-40 °C to +125 °C). Without prior circuit knowledge, it is not recommended to go beyond this range when setting up the calibration points. We cannot guarantee the margin of error outside these limits.

30-9 —	Reserved
8-0 TEMP	Temperature in Kelvin for the calibration point In the case of TTRCR0, this is the starting temperature for the range.

59.4 Functional description

The following sections describe the functionality of the TMU in detail.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co.,Ltd.
cc4625-4821-48a8-b251-390d3ab624c1

59.4.1 Monitoring

Monitoring is the process of reading on-chip temperature sensor sites at regular intervals and taking appropriate actions, such as alarming the user when the temperature exceeds a programmed temperature threshold. The monitoring process only applies to those sites that are enabled.

During this process, TMU periodically measures all enabled temperature sensor sites for temperature, starting with site 0 and ending with site 2. In Monitor Temperature Measurement Interval (TMTMIR), you can set the interval at which TMU reads the sensors, and the setting should reflect the maximum interval time required to accurately capture temperature changes. If the measurement interval has not expired after the last active site is read, the sensor logic may enter the low-power mode. If the interval expires before the module reads the last active site, the module sets TSR[MIE] to 1 and reads the next active site immediately. If the interval has been exceeded, you may opt to reduce the number of sites monitored by TMU, or increase the interval, if possible. This is especially critical for capturing temperature rate change events accurately.

TMU records the current and average temperature for each site. It calculates the average temperature based on the low-pass filter function in the TMU mode register. If the module triggers any of the enabled threshold or rate event registers, it sets the corresponding interrupt detect field in Interrupt Detect (TIDR). You enable interrupts through Interrupt Enable (TIER).

The procedure to enable the monitoring mode is as follows:

1. Clear the interrupt detect register, Interrupt Detect (TIDR).
2. Clear the interrupt capture registers: Interrupt Immediate Site Capture (TIISCR), Interrupt Average Site Capture (TIAS CR), and Interrupt Critical Site Capture (TICSCR).
3. Enable interrupt handling by writing 1 to the appropriate fields in the interrupt enable register, Interrupt Enable (TIER).
4. Write the appropriate values to the following temperature threshold registers:
   - Monitor High Temperature Immediate Threshold (TMHTITR)
   - Monitor Low Temperature Immediate Threshold (TMLTITR)
   - Monitor High Temperature Average Threshold (TMHTATR)
   - Monitor Low Temperature Average Threshold (TMLTATR)
   - Monitor High Temperature Average Critical Threshold (TMHTACTR)
   - Monitor Low Temperature Average Critical Threshold (TMLTACTR)
5. Write the appropriate values to thsee temperature rate change registers: Monitor Rising Temperature Rate Critical Threshold (TMRTRCTR) and Monitor Falling Temperature Rate Critical Threshold (TMFTRCTR).
6. Write the appropriate value to the monitoring interval register, Monitor Temperature Measurement Interval (TMTMIR).
7. Enable the monitor mode by setting TMR[MODE] to b10. You control the monitored sites by writing an appropriate value to TMSR[SITE]. You need to enable at least one active site, and set the other mode control fields as needed.
8. If the monitoring interval is too short, as indicated by TSR[MIE], you may need to increase the interval or reduce the number of sites.

59.4.2 Reporting

The TMU can directly report the current and average temperature for a particular temperature sensor site during the monitoring mode by reading one of the site report registers. The report uses the last measurement from the monitoring process, and requires a site to be actively monitored to obtain an accurate reading. Reading a site, which last measured an invalid temperature outside the sensor range of 233 K to 398 K, will have the valid bit cleared.

If you disable monitoring, the last temperature measurement for the site(s) that the TMU previously monitored is retained by the module, and you can still read the report registers, with the knowledge that the temperature(s) reported is (are) no longer accurate. This method can be used to capture the temperatures at multiple sites in time, but does not allow for continuous monitoring.

The temperature capture registers (Monitor High Temperature Capture (TMHTCR) and Monitor Low Temperature Capture (TMLT CR)) record the history of the highest and lowest temperatures that they measure within the valid sensor range. The temperature rate change capture registers (Monitor Rising Temperature Rate Capture (TMRTRCR) and Monitor Falling Temperature

Rate Capture (TMFTRCR)) record how quickly the temperature rises or falls, and you can use this information to determine programmable values for the rate change threshold registers in real applications.

You can read out-of-range indications from Status (TSR). You write 1 to clear these indications during active monitoring.

59.4.3 Using temperature thresholds

The main purpose of the TMU is to autonomously measure temperature at select sites and report to the core when a potentially dangerous operating temperature is about to be reached. This may be to protect a circuit from overheating and causing permanent damage or affecting reliability.

The TMU has a two-level (normal/critical) threshold and interrupt scheme. This allows the software to take preventive actions at a first temperature threshold and additional drastic measures at a second critical threshold. For high temperatures, these measures may include:

- Downgrading the performance of a function or core to reduce power consumption (preventive)
- Reducing the voltage or frequency to a function or core

When TMU detects a high temperature (through interrupt), the software could enable a low or normal threshold to detect when to restore functions to normal. Similarly, preventive actions taken for low temperatures could enable a high or normal temperature to restore functions.

For proper operation, you must set the temperatures in the high threshold registers to be higher than those you set in the low threshold registers.

The rising and falling temperature rate threshold registers (Monitor Rising Temperature Rate Critical Threshold (TMRTRCTR) and Monitor Falling Temperature Rate Critical Threshold (TMFTRCTR)) trigger critical interrupts. A quickly rising temperature because of heatsink separation or cooling fan issues may occur sooner than a critically high temperature. For example, immediate preventive measures can be taken to protect the chip. You could determine a nominal value for the rising threshold value by using the Monitor Rising Temperature Rate Capture (TMRTRCR) or from lab simulations. A quickly falling temperature is less common but you could use this to warn the chip about stress caused by drastic changes in temperature that may lead to cracking.

59.5 Initialization information

TMU calculates temperature by reading one of the on-chip temperature sensor sites. The module calculates the temperature using a table of calibration points that you must program using the procedure outlined below.

You can manually program the sensor translation table by supplying the sensor readings for all temperature points as defined by the TMU temperature range control registers. Failure to initialize all the temperature/sensor configuration table entries correctly may lead to an undefined behavior. The TMU temperature range control registers, Temperature Range Control a (TTRCR0 - TTRCR15), define the starting temperature, the ending temperature, and a number of intervening calibration points. The number of configuration points used depends on the linearity of the sensor. If a sensor reading falls between two configuration points, TMU reports the temperature based on linear interpolation between the nearest upper/lower two points in the table.

Following is the procedure to program the TMU calibration table:

NOTE

For the last four calibration points (12-15), there are per-part trims that you need to apply. You must read these OCOTP fields (in the appropriate shadow register): CFG_DAC_TRIM_0, CFG_DAC_TRIM_1, CFG_DAC_TRIM_2, and CFG_DAC_TRIM_3.

1. Disable monitoring mode, TMR[MODE]=0 (default).
2. Perform a Read-Modified-Write on register Central Module Configuration (TCMCFG) to write 1 to TCMCFG[OCM] and TCMCFG[DEMA]. Do not modify the other fields in this register.
3. Write the temperature configuration register with TTCFGR[CAL_PT]=*n* (where *n* is the calibration point from the table).
4. Write to the TMU configuration register, Sensor Configuration (TSCFGR), with the sensor value for the first calibration point *n*.
5. Write to the TMU temperature range control registers (TTRCR*n*) associated with calibration point *n*.

You need to repeat steps 3—5 for all calibration points from the provided calibration table. You must write 1 to the DEMA and OCM fields of Central Module Configuration (TCMCFG) for the proper operation of TMU.

The values for TTCFGR and TTRCR are chip-specific. See the "Chip-specific TMU section" for details.

Chapter 60
Security

60.1 Introduction

The Hardware Security Engine (HSE_H) is a subsystem that implements the security functions for the device. It provides cryptographic services to host CPUs and the network accelerators, targeting current security specifications. For example, Secure Hardware Extension (SHE), Hardware Security Module (HSM), and E-safety Vehicle Intrusion Protected Application (EVITA) Full. The HSE_H subsystem is responsible for establishing the root of trust on the device during the boot process and includes the following features:

- Secure boot of customer code using asymmetric or symmetric keys
- Highly featured symmetric and asymmetric accelerators
- Support for the following cryptographic functions in hardware:
  - AES (up to 256)
  - SHA-1 and SHA-2
  - Wide support of Elliptic curves (ECC)
  - RSA (up to 4096).
- Arm Cortex-M7 CPU
- True Random Number Generator (TRNG)
- Pseudo Random Number Generator (PRNG)
- Side channel physical protection
- Glitch attack countermeasures
- Firmware Over-the-Air (FOTA) support.

Following is a simplified block diagram of the HSE_H:

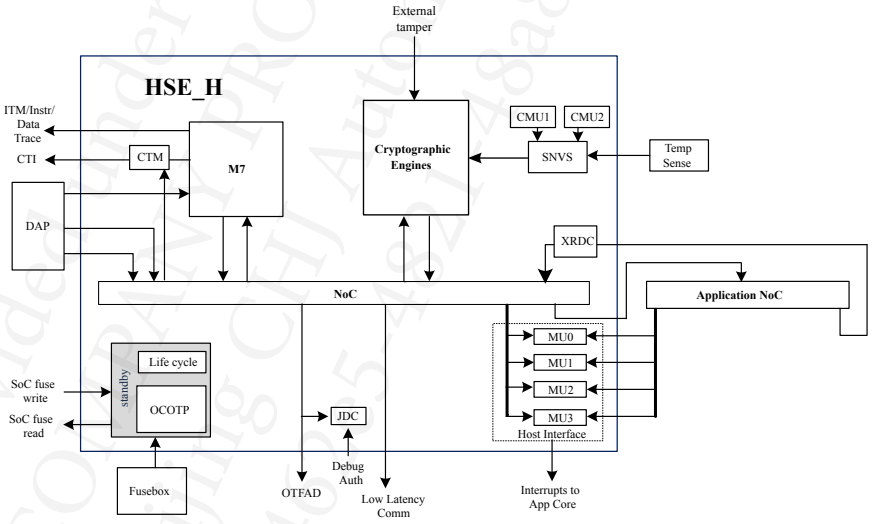

Figure 544. HSE_H simplified block diagram

NOTE

1. Factory-supplied firmware controls HSE_H function. See the documents in the following table for details.[11]
2. No confidentiality is supported for customer application code in devices subject to export controls.

Document Number	Document Title	Description
HSEFWRM	HSE Firmware Reference Manual	Contains architecture details of security firmware
HSESIRM	HSE Service Interface Reference Manual	Security firmware API reference

60.1.1 Detection and response to parametric intrusion attempts

Software and hardware designs incorporate known industry standard measures to prevent leakage of secrets and exposure to other exploitable vulnerabilities. The Security subsystem is designed to be resistant against certain fault and glitch attacks.

60.1.2 Secure software updates

To avoid costly and time consuming service bay updates, over the air (OTA) update is supported for situations where the vehicle MCU software must be refreshed. Updates may be needed to fix known problems or to provide additional features to the vehicle. The Security subsystem supports secure OTA updates for software that is executed on the device, such as HSE code, application code, operating systems and drivers, but not the Boot Loader in ROM.

60.1.3 Secure vehicle network and messaging

Communication between ECUs within a vehicle is necessary for safe and proper operation. Messages between ECUs must be guaranteed authentic and free of error. Attacks on the network can be through a direct connection to the network wires or indirectly through an alternative communication port. The Security subsystem supports both secret key (symmetric) and public key (asymmetric) authentication protocols. Because of the large number of network nodes, data rates and message sizes, a symmetric key protocol is the prevalent authentication choice.

60.1.4 Secure boot

The image stored in external memory may be encrypted and require authentication. The choices are selected by configuration values stored in IVT present in external flash. Authentication with CMAC, HMAC, RSA-2048, ECC-256, and ECC-384 is supported. For details, refer to the Boot chapter.

60.2 Security subsystem registers

60.2.1 Security subsystem register descriptions

The security subsystem registers are detailed in this section.

NOTE

1. Only word accesses are supported for these registers.
2. Any access made to address offsets Ch-1Bh will not generate a transfer error.

60.2.1.1 SEC memory map

Security_CC base address: 4007_C900h

Chapter 61
Messaging Unit (MU)

61.1 Chip-specific MU information

This device includes four MU module instances:

- MU0
- MU1
- MU2
- MU3

Each instance has two sets of registers: MUA and MUB.

Table 535. Register sets of each MU instance

Register set	Mapped to	Accessible only by	Use
MUA	HSE module's internal address space	HSE's Cortex-M7 processor core	Information included for reference only
MUB	Host address space	Application processor core	Functions as the host interface

61.2 Overview

The Messaging Unit module enables two processors within the SoC to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts.

Because the MU manages the messaging between processors potentially using different clocks, the MU must synchronize the accesses from one side to the other. The MU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

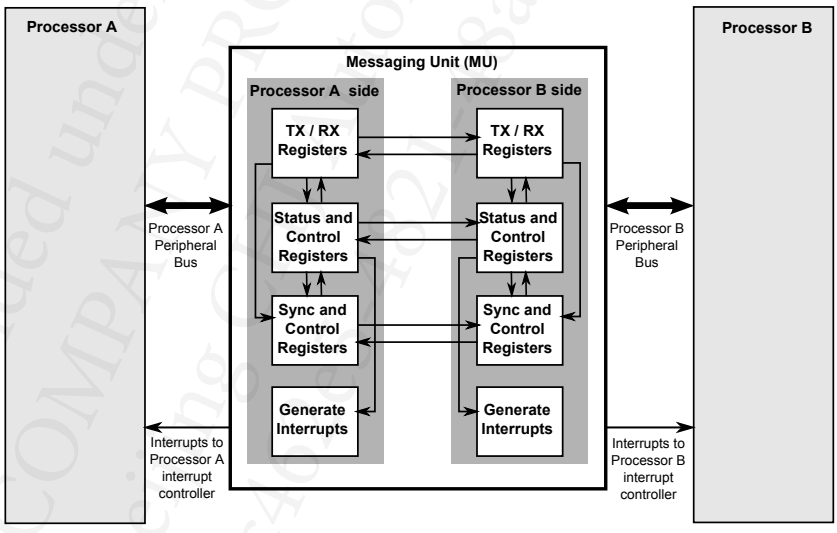

Figure 545. MU Block Diagram

Provided under NDA only
COMPANY PROPRIETARY
Beijing Chuangxin Technology Co., Ltd.
c8c4e4f42f8a8-2251-390a3ab624c1

61.2.1 Features

The MU includes the following features:

- Memory-Mapped Registers
  - The MU is connected as a peripheral under the Peripheral bus on Processor A-side and Processor B-side.
- Synchronized Message Transfers between Cores
  - For sending data or messages from one MU-side to the other MU-side, the MUA provides 16 transmit registers and 16 receive registers, the MUB provides 16 transmit registers and 16 receive registers.
  - The transfer of data messages between cores uses transmit empty and receive full flags provided on both sides of the MU.
  - The update of these transmit and receive flags is accomplished using a synchronization mechanism. There is inherent latency between updating the flag on one side and reflecting its status on other side.
  - The MU has a 32 bit Flag Data Register, which can be used to send flag data between two MU sides.
- Interprocessor Interrupts
  - The MU has 64 interrupt sources on each side (Processor A-side, Processor B-side) that are used for signaling the other processor. The interrupts can be used for notification of RX/TX events and general-purpose signaling between the processors. There are 32 general-purpose interrupt requests available and 32 RX/TX interrupt sources.
  - Processor A can initiate a Non-Maskable Interrupt to Processor B
  - Processor B can initiate a Non-Maskable Interrupt to Processor A
- MU Reset
  - Each Processor can issue a reset to the entire MU, using a control bit (MUR) in each Processor's Control Register (CR).
  - The MUR bit is a self-clearing bit.

61.3 Register Definition

The MU provides transmit and receive data registers (xTR0-n, xRR0-n) for the communication between Processor A and Processor B. Some control and status registers (xCR, xSR) to the Processor A and Processor B sides for control operations (such as interrupts and reset), and for status checking of the other MU-side. Figure 546 shows the MU registers schematic.

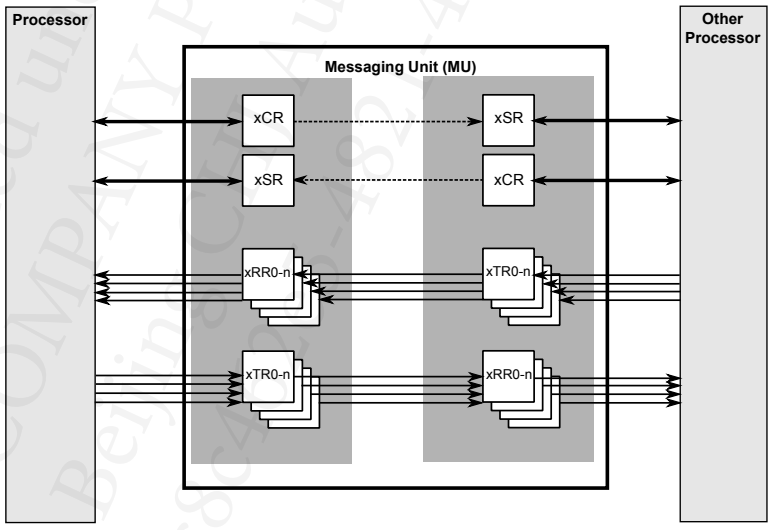

Figure 546. MU Registers

The detailed MU Register Definition can be found below.

61.3.1 MUA register descriptions

This section contains the detailed register descriptions for the MUA registers.

NOTE

A read/write access to any illegal location and a write to a read-only register on the Processor A-side or Processor B-side of the MU will generate a module transfer error acknowledge to the Processor A or Processor B. The only exception to this is at address offsets 0x1C and 0x14 - no transfer error will occur when accessing these locations.

61.3.1.1 MUA memory map

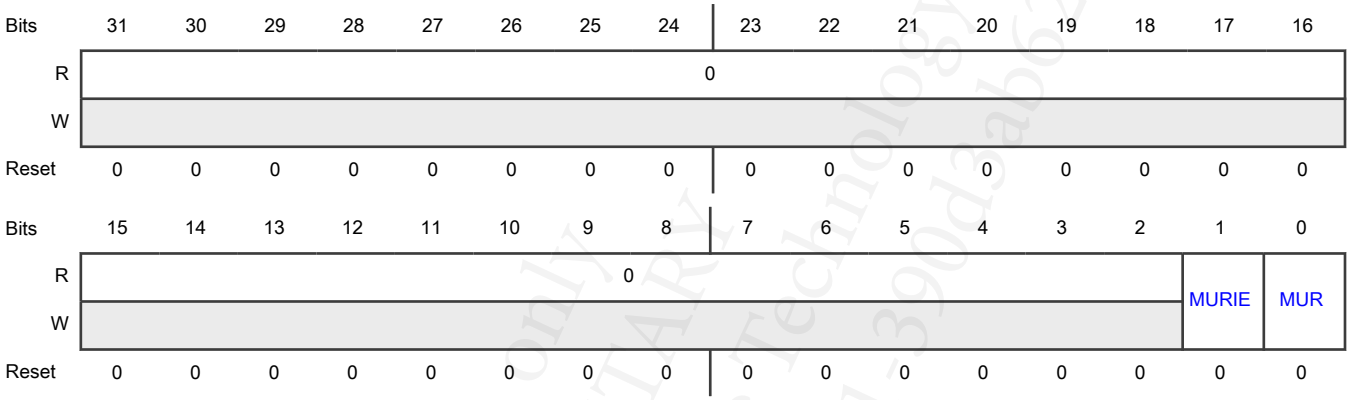
61.3.1.4 Control Register (CR)



Offset

Register	Offset
CR	8h

Function

The CR register controls the MU reset and MU reset interrupt enable.

Diagram

Fields

Field	Function
31-2 —	Reserved
1 MURIE	MUA Reset Interrupt Enable • If MURIE bit is set to "1", then MU reset interrupt request is issued to the Processor A when the MUA_SR[MURIP] bit is set to "1". • If MURIE is cleared, then the value of the MURIP bit is ignored and no MU reset interrupt request will be issued. • Only system reset can reset MURIE, MU reset(MUR) cannot reset this bit. 0b - Disables Processor A-side MU Reset Interrupt request due to MU reset issued by MUB. 1b - Enables Processor A-side MU Reset Interrupt request due to MU reset issued by MUB.
0 MUR	MU Reset • Setting MUR bit to "1" resets both the MUA-side and MUB-side, forcing all control and status registers to return to their default values (except in MUA/B_CCR0 registers, MURIE in MUA/B_CR registers, MURIP bit and MURS bit in MUA/B_SR registers), and all internal states to be cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Before setting the MUR bit to "1", it is advisable to interrupt the Processor B, because setting the MUR bit may affect the ongoing Processor B program. • After setting the MUR bit, monitor the value of the MUA_SR[MURS] bit to know when the reset sequence on the Processor B-side has ended. • MUR bit is always read as "0". • MUR bit is cleared during the MU reset sequence. 0b - Self clearing bit. 1b - Asserts the MU reset.

61.3.1.5 Status Register (SR)

Offset

Register	Offset
SR	Ch

Function

The SR register shows the status of MU resets and the status of pending events/requests described below.

Diagram

c8c462e5-4824-48a8-b251-390d3ab624c1

Table continued from the previous page...

Field	Function
—	
6 RFP	MUA Receive Full Pending Flag • RFP bit is set to "1" when any TRn register is written by MUB to send data to MUA. • After the RFP bit is set to "1", checking the RSR[RFn] bit to decide the data in which RRn register is ready to be read by the MUA. • RFP bit is cleared when all MUA RRn registers are read, or when the MU is reset. 0b - No TRn register is written by MUB. 1b - Any TRn register is written by MUB.
5 TEP	MUA Transmit Empty Pending • TEP bit is set to "1" when TCR[TIEn] bit is set and the corresponding RRn register is read by MUB. • After the TEP bit is set to "1", checking the TSR[TEn] bit to decide the data in which TRn register is ready to be written by the MUA. • TEP bit is cleared when all MUA TRn register are written. • TEP bit is set to "0" when the MU resets. 0b - RRn register is not read by MUB. 1b - Any RRn register is read by MUB.
4 GIRP	MUA General Interrupt Pending • GIRP bit is set to "1" when any general interrupt request is sent from the MUB side to the MUA side. Reading the GSR[GIPn] bit can know which general interrupt request is received. • GIRP bit is cleared when all GIPn bits in MUA_GSR register are cleared. • GIRP bit is cleared when the MU resets. 0b - No general interrupt request is sent from MUB. 1b - Any general interrupt request is sent from MUB.
3 FUP	MUA Flags Update Pending • FUP bit is set to "1" when the MUA side sends a Flags Update request to the MUB side. • A Flags Update request is generated when there is a change to the Fn[31:0] bits of the MUA_FCR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[31:0] bits of the MUA_FCR register, while the FUP bit is set to "1", will not generate a Flags Update event, and the Fn[31:0] bits will stay unchanged. • Writing the FCR register doesn't set FUP bit immediately if there is any event pending(SR[EP] is "1"). • FUP bit is cleared when this Flags Update request is internally acknowledged (the flag is updated) from the MUB side, or during MU reset. 0b - No pending update flags(initiated by MUA) are in process 1b - Pending update flags(initiated by MUA) are in process

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 EP	MUA Side Event Pending • An "event" is any hardware message that is reflected in the status register on the MUB side (for example, "transmit register 0 written"). During normal operations, the update mechanism for the EP bit works automatically. • EP bit is set to "1" when the MUA side sends an event update request to the MUB side. • EP bit is cleared by hardware automatically when the event update acknowledge is received. • To ensure events have been posted to MUB, verify that the EP bit is cleared. If EP bit is set to "1", wait and continue to poll the EP bit. • The EP bit is cleared when the MU resets. 0b - The MUA side event is not pending. 1b - The MUA side event is pending.
1 MURIP	MU Reset Interrupt Pending • MURIP bit signals Processor A that Processor B initiated a MU reset by setting the MUB_CR[MUR] bit. • MURIP bit is set to "1" after Processor B initiated a MU reset. If the interrupt is enabled by the MURIE bit, the Processor A MU reset interrupt request is issued when the Processor B set MUR bit in MUB_CR. • Writing "1" to clear the MURIP bit, which also clears MU reset interrupt request. • Only system reset can reset MURIP. MU reset cannot reset this bit. 0b - Processor B did not issue MU reset. 1b - Processor B issued MU reset.
0 MURS	MUA and MUB Reset State • The MURS bit is set to "1" during any system reset or any MU reset from MUA-side or MUB-side. • The MURS bit is cleared when the reset sequence on both MUA and MUB side ends. After issuing any of the reset events mentioned previously, **verify that the MURS bit is cleared before starting any access.** 0b - MUA and MUB are out of reset. 1b - MUA or MUB is in reset state.

61.3.1.6 Core Control Register 0 (CCR0)

Fields

Field	Function
31-0 Fn	MUB to MUA Side Flag n • n = 0 to 31

Table continues on the next page...

Field	Function
	• Fn bit is the MUA side flag that reflects the values written to the Fn bit in the MUB_FCR register. • Every time that the Fn bit in the MUB_FCR register is written, the Fn bit in the MUB FCR register write event updates the Fn bit in the MUA_FSR register after the event update latency. • If a 0 is read from an Fn bit - Fn bit in the MUB_FCR is 0. • If a 1 is read from an Fn bit - Fn bit in the MUB_FCR is 1. 0b - Fn bit in the MUB FCR register is written 0. 1b - Fn bit in the MUB FCR register is written 1.

61.3.1.10 General Interrupt Enable Register (GIER)

Offset

Register	Offset
GIER	110h

Function

The GIER register contains the MUA general purpose interrupt enables.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 GIEn	MUA General Purpose Interrupt Enable n • There are 32 General Purpose Interrupts (n = 0 to 31) • If a GIEn bit is set to "1", then a General Interrupt n request is issued to Processor A when the GIPn bit in the MUA GSR register is set to "1".

Table continues on the next page...

Field	Function
	• If GIEn is cleared, then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0b - Disables MUA General Interrupt n. 1b - Enables MUA General Interrupt n.

61.3.1.11 General Control Register (GCR)

Offset

Register	Offset
GCR	114h

Function

The GCR register contains the MUA general purpose interrupt requests.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 GIRn	MUA General Purpose Interrupt Request n • There are 32 General Purpose Interrupts (n = 0 to 31) • Writing "1" to the GIRn bit sets the MUB_GSR[GIPn] bit on the MUB-side. If the MUB_GIER[GIEn] bit is set to "1" on the MUB-side, a General Purpose Interrupt n request is triggered to Processor B. • The GIRn bit is cleared if the MUB_GSR[GIPn] bit is cleared by writing "1", thereby signalling the MUA that the interrupt was accepted (cleared by the software). • Writing "0" to the GIRn bit is ignored.

Table continues on the next page...

Field	Function
	• To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0b - MUA General Interrupt n is not requested to the MUB. 1b - MUA General Interrupt n is requested to the MUB.

61.3.1.12 General Status Register (GSR)

Offset

Register	Offset
GSR	118h

Function

The GSR register contains the status of the MUA general interrupt pending requests.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

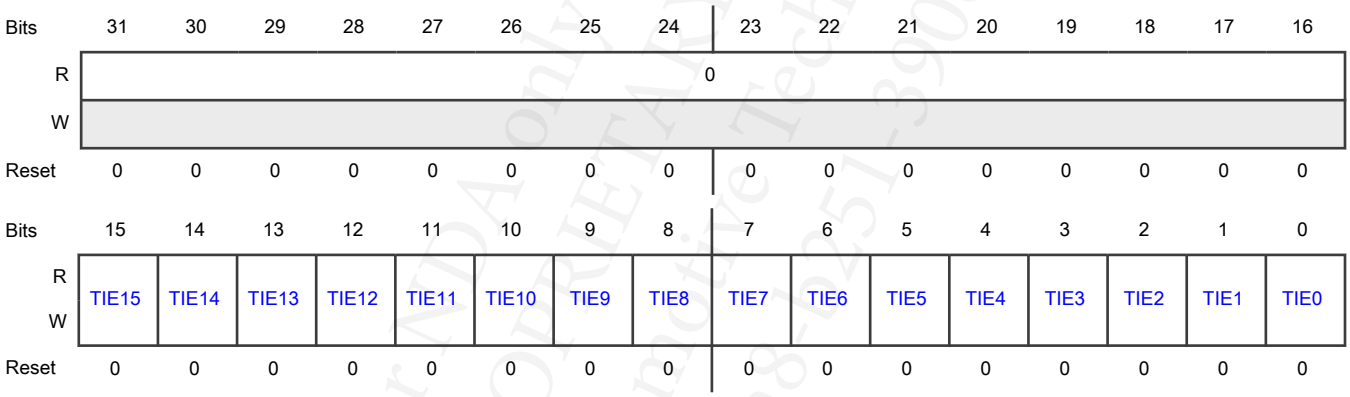
Fields

Field	Function
31-0 GIPn	MUA General Interrupt Request Pending n • There are 32 General Purpose Interrupts (n = 0 to 31) • GIPn bit signals the MUA that the MUB_GCR[GIRn] bit was set from "0" to "1". If the MUA_GIER[GIEn] bit is set to "1", a General Interrupt n request is issued to Processor A. • The GIPn bit is cleared by writing "1". Writing "0" is ignored. • GIPn bit is cleared when the MU resets. • After GIPn bit is cleared, the General Interrupt n request(if the MUA_GIER[GIEn] bit is set to "1") is cleared on the MUA side.

Table continues on the next page...

Field	Function
	0b - MUA general purpose interrupt n is not pending. 1b - MUA general purpose interrupt n is pending.

61.3.1.13 Transmit Control Register (TCR)



Offset

Register	Offset
TCR	120h

Function

The TCR register contains the MUA transmit interrupt enables.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 TIEn	MUA Transmit Interrupt Enable n • There are 16 Transmit Interrupts (n = 0 to 15) • If TIEn bit is set to "1", then an MUA Transmit Interrupt n request is issued when the MUA_TSR[TEn] bit is set to "1". • If TIEn bit is cleared, then the value of the TEn bit is ignored and no MUA Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0b - Disables MUA Transmit Interrupt n. (default) 1b - Enables MUA Transmit Interrupt n.

61.3.1.14 Transmit Status Register (TSR)

Offset

Register	Offset
TSR	124h

Function

The TSR register shows whether the MUA transmit registers are empty or not.

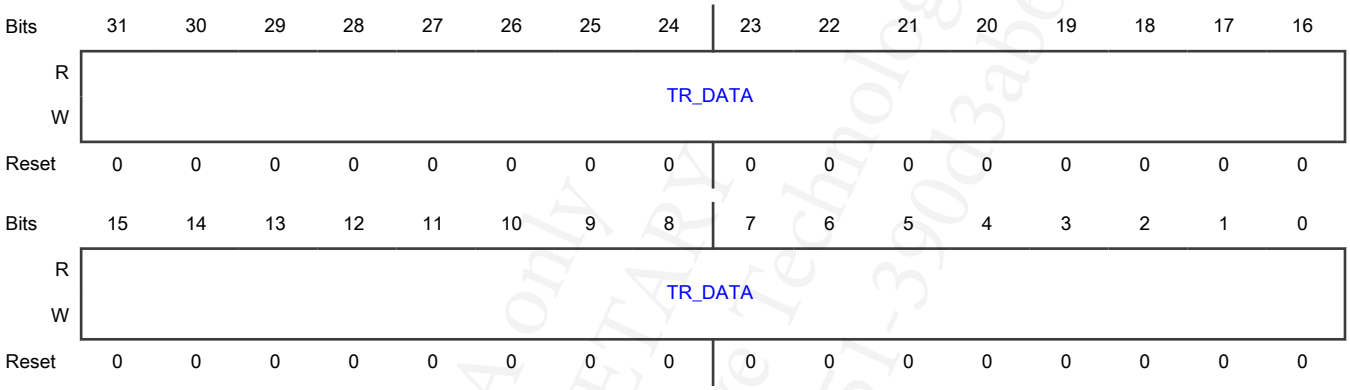
61.3.1.17 Transmit Register (TR0 - TR15)

Offset



For n = 0 to 15:

Register	Offset
TRn	200h + (n × 4h)

Function

MUA Transmit Data.

Diagram

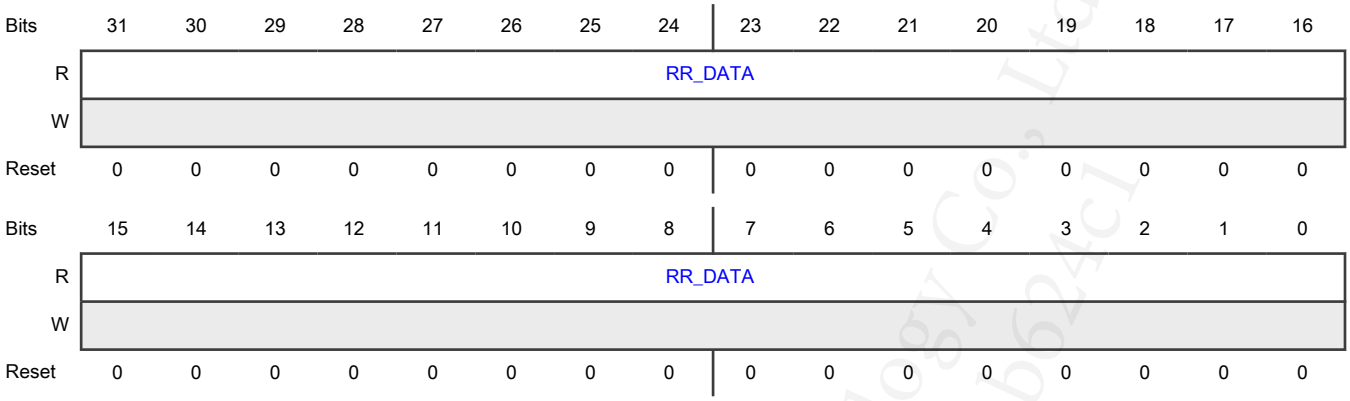
Fields

Field	Function
31-0 TR_DATA	MUA Transmit Data • Data written to the TRn register is reflected in the MUB Receive Register n (RRn). The TRn and RRn registers are not double-buffered, a write to the TRn register overrides the data readable at the RRn register. • A write to the transmit register clears the MUA_TSR[TEn] bit on the transmitter side, and sets the MUB_RSR[RFn] bit on the receiver side. • TRn register can be written only when the MUA_TSR[TEn] bit is set to "1". • Reading the TRn register returns all zeros.

61.3.1.18 Receive Register (RR0 - RR15)

Offset

For n = 0 to 15:



Register	Offset
RRn	280h + (n × 4h)

Preliminary NDA only
COMPANY PROPRIETARY
Beijing C-H Automotive Technology Co., Ltd.
c8c462e5-1a2-4a8-b251-3903ab624c1

Function

MUA Receive Data.

Diagram

Fields

Field	Function
31-0 RR_DATA	MUA Receive Data • Reflects the data written to MUB Transmit Register (TRn). • Reading the RRn register clears the MUA_RSR[RFn] bit on the receiver side, and sets the MUB_TSR[TEn] bit on the transmitter side. • RRn register can be read only when the MUB_RSR[RFn] bit is set to "1". Reading before MUB_RSR[RFn]=1 may result in reading incorrect data. Therefore, polling the MUB_RSR[RFn] bit to confirm it is set to "1" before reading RRn is required. • Writing to the RRn register generates an error response to the MUA.

61.3.2 MUB register descriptions

This section contains the detailed register descriptions for the MUB registers.

NOTE

A read/write access to any illegal location and a write to a read-only register on the Processor A-side or Processor B-side of the MU will generate a module transfer error acknowledge to the Processor A or Processor B. The only exception to this is at address offsets 0x1C and 0x14 - no transfer error will occur when accessing these locations.

Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUB Receive Full Pending Flag • RFP bit is set to "1" when any TRn register is written by MUA to send data to MUB. • After the RFP bit is set to "1", checking the RSR[RFn] bit to decide the data in which RRn register is ready to be read by the MUB. • RFP bit is cleared when all MUB RRn registers are read, or when the MU is reset. 0b - No TRn register is written by MUA. 1b - Any TRn register is written by MUA.
5 TEP	MUB Transmit Empty Pending • TEP bit is set to "1" when TCR[TIEn] bit is set and the corresponding RRn register is read by MUA.

Table continues on the next page...

Table continued from the previous page...

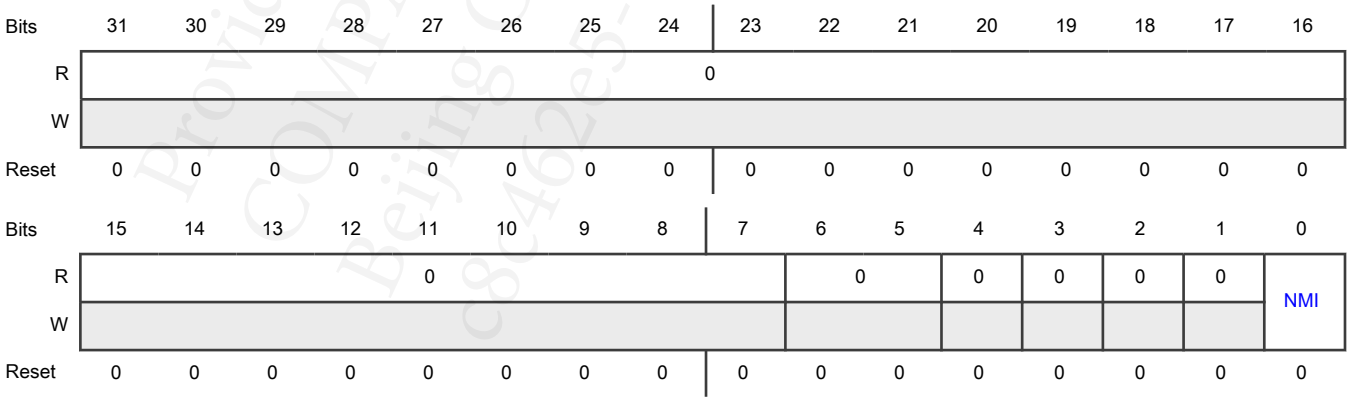
Field	Function
	• After the TEP bit is set to "1", checking the TSR[TEn] bit to decide the data in which TRn register is ready to be written by the MUB. • TEP bit is cleared when all MUB TRn register are written. • TEP bit is set to "0" when the MU resets. 0b - RRn register is not read by MUA. 1b - Any RRn register is read by MUA.
4 GIRP	MUB General Interrupt Pending • GIRP bit is set to "1" when any general interrupt request is sent from the MUA side to the MUB side. Reading the GSR[GIPn] bit can know which general interrupt request is received. • GIRP bit is cleared when all GIPn bits in MUB_GSR register are cleared. • GIRP bit is cleared when the MU resets. 0b - No general interrupt request is sent from MUA. 1b - Any general interrupt request is sent from MUA.
3 FUP	MUB Flags Update Pending • FUP bit is set to "1" when the MUB side sends a Flags Update request to the MUA side. • A Flags Update request is generated when there is a change to the Fn[31:0] bits of the MUB_FCR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[31:0] bits of the MUB_FCR register, while the FUP bit is set to "1", will not generate a Flags Update event, and the Fn[31:0] bits will stay unchanged. • Writing the FCR register doesn't set FUP bit immediately if there is any event pending(SR[EP] is "1"). • FUP bit is cleared when this Flags Update request is internally acknowledged (the flag is updated) from the MUA side, or during MU reset. 0b - No pending update flags(initiated by MUB) are in process 1b - Pending update flags(initiated by MUB) are in process
2 EP	MUB Side Event Pending • An "event" is any hardware message that is reflected in the status register on the MUA side (for example, "transmit register 0 written"). During normal operations, the update mechanism for the EP bit works automatically. • EP bit is set to "1" when the MUB side sends an event update request to the MUA side. • EP bit is cleared by hardware automatically when the event update acknowledge is received. • To ensure events have been posted to MUA, verify that the EP bit is cleared. If EP bit is set to "1", wait and continue to poll the EP bit. • The EP bit is cleared when the MU resets. 0b - The MUB side event is not pending. 1b - The MUB side event is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 MURIP	MU Reset Interrupt Pending • MURIP bit signals Processor B that Processor A initiated a MU reset by setting the MUA_CR[MUR] bit. • MURIP bit is set to "1" after Processor A initiated a MU reset. If the interrupt is enabled by the MURIE bit, the Processor B MU reset interrupt request is issued when the Processor A set MUR bit in MUA_CR. • Writing "1" to clear the MURIP bit, which also clears MU reset interrupt request. • Only system reset can reset MURIP. MU reset cannot reset this bit. 0b - Processor A did not issue MU reset. 1b - Processor A issued MU reset.
0 MURS	MUA and MUB Reset State • The MURS bit is set to "1" during any system reset or any MU reset from MUA-side or MUB-side. • The MURS bit is cleared when the reset sequence on both MUA and MUB side ends. After issuing any of the reset events mentioned previously, **verify that the MURS bit is cleared before starting any access.** 0b - MUA and MUB are out of reset. 1b - MUA or MUB is in reset state.

61.3.2.6 Core Control Register 0 (CCR0)



Offset

Register	Offset
CCR0	10h

Function

The CCR0 enables the MUB to control the Processor on the MUA-side.

Beijing CHJ Automotive Technology Co., Ltd.
cc46e5-4821-48a8-b251-390d8ab624d1

Table continued from the previous page...

Field	Function
	• Writing NMIC bit as "1" signals the MUA to clear the MUA_CCR0[NMI] bit, thus de-asserting the interrupt and enabling the NMI bit to receive another interrupt. • The NMIC bit is always read as "0", therefore NMIC bit cannot be polled. The NMIC bit can only be used as part of the interrupt service routine, in which the NMIC bit should only be written as "1" once. • The NMIC bit is cleared when the MU resets. 0b - Default 1b - Writing "1" clears the MUA_CCR0[NMI] bit.

61.3.2.8 Flag Control Register (FCR)

Offset

Register	Offset
FCR	100h

Function

The FCR register contains read-write flags that reflect the MUA_FSR[Fn] bits.

Diagram

c8c462e5-4821-48a8-b251-39d3ab624c1

Diagram

Fields

Field	Function
31-0 RR_DATA	MUB Receive Data • Reflects the data written to MUA Transmit Register (TRn). • Reading the RRn register clears the MUB_RSR[RFn] bit on the receiver side, and sets the MUA_TSR[TEn] bit on the transmitter side. • RRn register can be read only when the MUA_RSR[RFn] bit is set to "1". Reading before MUA_RSR[RFn]=1 may result in reading incorrect data. Therefore, polling the MUA_RSR[RFn] bit to confirm it is set to "1" before reading RRn is required. • Writing to the RRn register generates an error response to the MUB.

61.4 Functional Description

The Messaging Unit (MU) enables two cores (Processor A or Processor B) to communicate with each other, by passing message/data information to each other, and by enabling one core to wake up the other core using interrupts.

The messaging, control, and status registers of the Processor A and Processor B-side for the MU are mapped to the Processor A and Processor B memory as a regular peripheral. The Peripheral data bus is 32 bits wide inside the MU module.

The messaging logic is used in conjunction with external memory. There are various messaging methods that can be used to implement a messaging protocol. Some of these messages could mean “A message of N words has been written starting at offset X in the memory,” or "The previous data block that was sent has been read." Having the messaging logic independent from the memory array is not restricted to a predefined hardware protocol. On the other hand, the software needed to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the Processor A-side and the Processor B-side. The messaging mechanisms are:

- 16 32-bit transmit registers, which are each reflected in 16 read-only receive registers in the other processor’s side. You can use these registers to transfer 32-bit word messages or frame information of messages written to the shared memory (number of words, initial address, and message type code).
- A write to a transmit register on the transmitter side clears a “transmitter empty” bit in the Status Register on the transmitter side, and sets a “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).

- A read of one of the receive registers at the receiver side clears the “receiver full” bit in the Status Register at the receiver side, and sets the “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).
- 32 general purpose interrupt request flags are reflected in the General Status Register(GSR) on the receiver side.
- 32-bit flag data is transmitted from FCR register to xFSR register with the SR[FUP] indicator bit.

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver will attempt to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a “Transmitter Empty” interrupt, or should poll the “Transmitter Empty” bit in the Transmit Status Register.

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Receive Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter will attempt to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Receive Status Register.

61.4.1 Messaging Examples

The following are some messaging examples:

- **Passing short messages:** Transmit register(s) can be used to pass short messages from one to 16 words in length for Processor A and 16 for Processor B. For example, when a four-word message is desired, only one of the registers needs to have its corresponding interrupt enable bit set at the receiver side; the message’s first three words are written to the registers whose interrupt is masked, and the fourth word is written to the other register (which triggers an interrupt at the receiver side).
- **Passing frame information:** Transmit registers can be used to pass frame information for long messages written to the shared system (for example, SRAM and FLASH). Such frame information normally includes a start address, number of words, and perhaps a message type code.
- **Passing event notices and requests:** Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the general interrupts, such as acknowledging that a long message was read from the shared system memory.
- **Passing fixed length data:** Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general interrupt to signal the other processor that the data is ready.
- **Passing announcements:** The 32 flags can be used by a processor to announce its current program state or other billboard messages to the other processor.

61.4.1.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for n = 0, 1, 2, 3. For n = 0, 1, 2, the interrupts are disabled, therefore no interrupt will go to the other core (although interrupt conditions occur). For n = 3, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence
   - The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
   - When the write to the Transmit Register 3 occurs, the RF3 bit of the xRSR is set after synchronization, and it immediately trigger the Receive Full 3 interrupt to the other Processor.
2. Read Sequence

- The other Processor receives the Receive Full 3 interrupt and starts reading the message transferred from the receive registers.
- After Receive Register 3 is read, the interrupt bit is cleared.

The following table and diagram describe the messaging model using transmit/receive registers and interrupt messaging protocol.

Table 536. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A Data write	A data write to the TRn register by Processor A is immediately reflected in the Processor B RRn register.
2	Clear Tx Empty bit and Set Rx Full bit	The data write to the TRn register • Clears the transmitter empty bit (TEn) in the Processor A Transmit Status Register • Sets the receiver full bit (RFn) in the Processor B Receive Status Register
3	Generate Receive Interrupt request	The setting of the receiver full bit (RFn) in the Receive Status Register generates a Receive Interrupt request to Processor B.
4	Processor B Data read	After receiving the Receive Interrupt request, Processor B performs a data read of the RRn register.
5	Clear Rx Full bit and Set Tx Empty bit	Reading the data out of the RRn register • Clears the receiver full bit (RFn) in the Processor B Receive Status Register • Sets the transmitter empty bit (TEn) in the Processor A Transmit Status Register
6	Generate Transmit Interrupt request	The setting of the transmitter empty bit (TEn) in the Transmit Status Register generates a Transmit Interrupt request to Processor A.

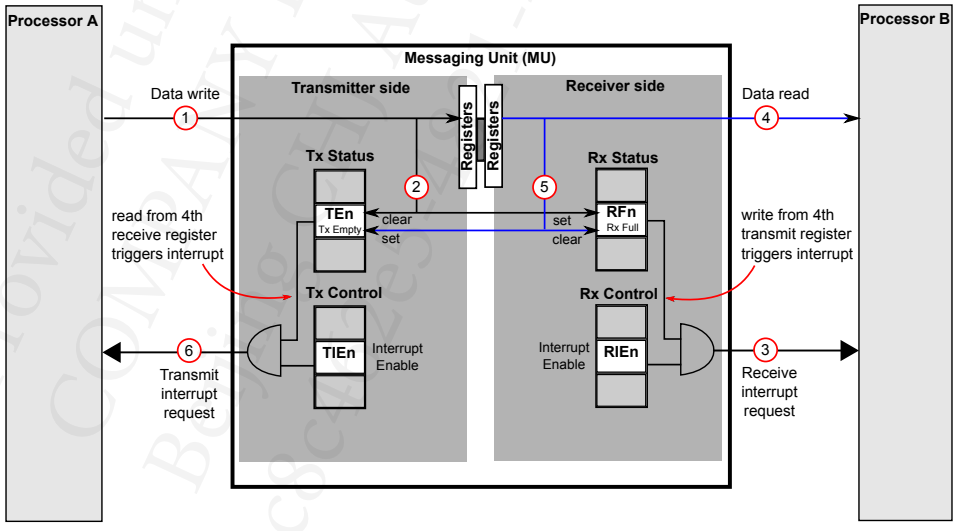

Figure 547. Messaging Model Using Transmit and Receive Registers

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

61.4.1.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The 32 flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

The following table and diagram describe the event sequence when the Processor triggers an interrupt.

Table 537. General Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A sets General Interrupt request bit	Processor A sets its associated General Interrupt request bit (GIRn = 1) in the General Control Register (GCR).
2	General Interrupt Request Pending status bit is set	The General Interrupt Request Pending status bit (GIPn) in the General Status Register (GSR) is set to "1".
3	General Interrupt request to Processor B is generated	Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B).
4	Processor B reads status register	The Processor B reads the GIPn bit in the GSR register.
5	Processor B services the interrupt	-
6	Processor B sets GIPn bit to clear interrupt	The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt.
7	GIRn bit is cleared	Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A General Control Register (GCR).

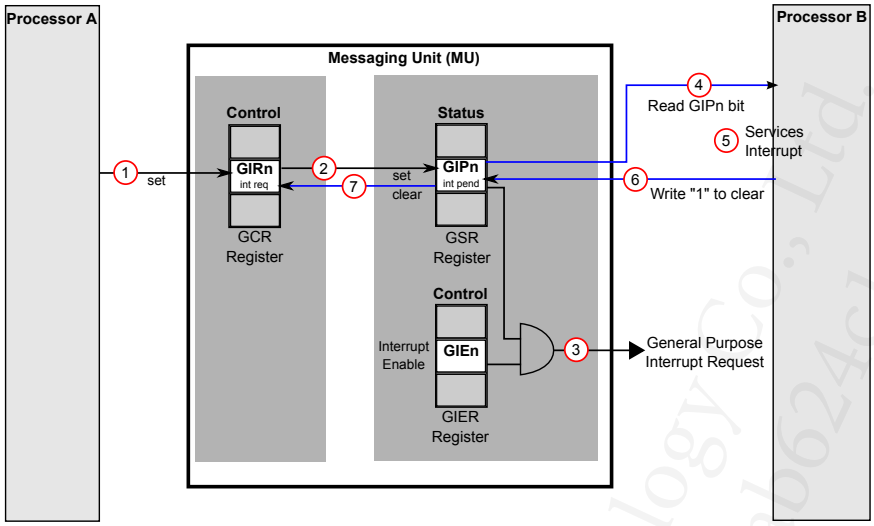

Figure 548. Messaging Model Using a General Purpose Interrupt

61.4.1.3 Exclusive Access to Shared Memory

MU can be used to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIRn bit, RRn register, TRn register) are reserved to support exclusive access to the shared memory protocol.

Table 538. How the Processor A Performs an Exclusive Access to Shared Memory

Sequence	Action	Description
1	Processor A sends GIRn request to Processor B using Processor A control register	When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TRn)	The Processor A will send an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from Processor B	The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding.
4	Processor A accesses shared memory	After receiving a dedicated interrupt from the Processor B, Processor A proceeds.

Table 539. How the Processor B Scans for Transaction Information

Sequence	Action	Description
1	Processor B receives an interrupt from a receive data register (RRn)	-
2	Processor B reads the receive data register (RRn)	-
3	Processor B scans the receive data register contents	For transaction information (whether Processor A has requested an exclusive-access).

Table 540. How the Processor B Accepts Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B triggers a dedicated interrupt	Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A.
2	Processor B sends a code message to Processor A	Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (TRn). The message informs the Processor A that it can exclusively access the shared memory.

Table 541. How the Processor B Rejects Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B ignores Processor A request for exclusive access	If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request.

61.4.1.4 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

Table 542. Packet Data Transfer Sequence

Action	Sequence	Description
Processor B requests DMA	1	The Processor B sends a DMA request to initiate the packet data transfer.
DMA data transfer	2	DMA acknowledges.
	3	DMA starts transferring data from the specified Processor B location to the specified shared memory
	4	DMA interrupts the Processor B to signal that the packet transfer has finished.

Table continues on the next page...

Table 542. Packet Data Transfer Sequence (continued)

Action	Sequence	Description
Processor B informs Processor A that data is in shared memory	5	Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory. The message contains the command, location, and length of packet data information.
Processor A receives interrupt	6	The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory.
Processor A reads data, writes data	7	The Processor A reads or processes packet data from shared memory.
	8	The Processor A writes the result from packet processing to a separate buffer.
Processor A informs Processor B that transfer is finished	9	After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn).
Processor A sends interrupt to Processor B (request for more data)	10	The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data.

61.4.1.5 Free the Processor from Deadlock

During normal operations, one processor may conclude that the other processor is not working or is deadlocked. Using the SR register, the following methods are available for the processor to use to identify and correct the problem.

Table 543. How to Free the Processor A/B from Deadlock

Processor Mode	Technique	Description
-	Processor issues an interrupt	The other Processor can interrupt the Processor by issuing any one of the 64 (general purpose, receive, and transmit) interrupts
Normal	Processor issues a non-maskable interrupt	If the Processor is in Normal mode, the other Processor can issue an Non-Maskable Interrupt (NMI). The NMI routine can be made to execute a diagnostic routine that is predefined for such an event.
-	Processor issues a hardware reset	If the above is not helpful, the Processor can issue a hardware reset strobe to the other Processor.

61.4.2 Event Update Timing

Each processor's MU messaging side (Processor A or Processor B) has a hardware mechanism to send "event update requests" to the other processor's side. An "event" is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is “1 clock of the sending side” + “2 1/2 clocks of the receiving side”. The minimum case is if there is no event pending when the new event occurs.
- The maximum event latency is “6 clocks of the sending side” + “6 1/2 clocks of the receiving side.” The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency will vary between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

61.4.3 Interrupts

The MU controls one processor interrupt requests to the other processor. This section describes all the interrupts that the module generates.

Below interrupt sources can be generated individually from the MU to the Processors.

- 16 receive interrupts (asserted when the Processors receive full bits are set and enabled in the xRCR register) for each of the receive registers
- 16 transmit interrupts (asserted when the Processor transmit empty bits are set and enabled in the xTCR register) for each of the transmit registers
- 32 general purpose interrupts (asserted when the GIP bits are set and enabled in the xGIER register)
- One non-maskable interrupt(asserted when the NMI bit is set in the CCR0 register)
- Core Reset Assertion interrupts(asserted when Processor goes into of Reset state and enabled in RAIE register bit)
- MU Software/Hardware Reset assertion(asserted when MUR and HR bit are written and enabled in MURIE and HRIE register bit)

All the interrupts except NMI are maskable in the Processor Control Register (xTCR, xRCR, xGIER, xCR and xCIER). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

Triggering any enabled interrupt will "wake up" the Processor before servicing the interrupt.

The General Purpose Interrupt Pending GIPn bits should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

The non-maskable interrupt should also be cleared by the software, by writing the NIMC bit in the CSSR0 register (as a part of the interrupt service routine) in order to de-assert the non-maskable interrupt request.

When a Processor writes to the General Interrupt bit (GIRn), the write event is synchronized to the other Processor to set the general interrupt request pending bit (GIPn). When the GIPn bit is set, and if the general purpose interrupt is enabled on the receiving Processor side (GIEn bit is set), then the transmitting Processor general purpose interrupt is issued to the receiving Processor. The receiving Processor clears this interrupt by writing a “1” on the GIPn bit. The interrupt is de-asserted as soon as the GIPn bit is written. The write event of the GIPn bit is synchronized to the other Processor. The synchronized signal clears the GIR bit. The software should not write the GIRn bit again until the GIRn bit is cleared.

Before setting a GIRn bit, you must verify that the GIRn bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIRn bit while the bit has been set to “1” will be ignored, but in some cases it may issue a second interrupt.

61.4.4 Resets

The MU has below reset sources, and each reset has a different function from the MU or system perspective.

- Asynchronous system reset:
  - The asynchronous system reset on one MU-side returns all registers on this MU side to their default state.
  - When the asynchronous system reset on any MU-side is asserted, the MURS bit in CR register is set to "1" until the asynchronous system reset ends. Check MURS bit is cleared before starting any access to MU.
- MU software reset:

— Writing the CR[MUR] bit to "1" causes most of control and status registers to return to their default values and all internal states to be cleared.

— The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register will remain with the reset value. You should monitor the value of the SR[MURS] bit to know when the reset sequence on both processors has ended. After the reset sequence on both processors has ended, you can attemp a write to MU registers.

NOTE

MUR bit assertion is a delicate operation because it affects the other side's registers asynchronously. MUR bit assertion may cause unpredictable behavior if, for example, the other Processor is concurrently testing an MU register bit (TE bit in the other Processor TSR register). Before asserting the MUR bit, you should verify that the other Processor is not presently engaged in an MU signalling activity.

Chapter 62
On-Chip One Time Programmable (OCOTP) Controller

62.1 Introduction

The OCOTP controller is the primary interface with the on-chip fuses. You can use these fuses for several purposes, including:

- Unique chip identifiers
- Mask revision numbers
- Cryptographic keys
- Boot configurations
- Various control signals requiring permanent non-volatility

In this document, the terms "eFuse" and "OTP" (one-time programmable) are interchangeable. OCOTP refers to the hardware block itself.

62.2 Features

The OCOTP controller provides the following features:

- Shadow cache of eFuse loaded at reset prior to system boot
- Ability to read and override fuse values in shadow cache (does not affect fuse element)
- Ability to read fuses directly (ignoring shadow cache)
- Ability to write (program) fuses by the software
- Using eFuses to enable or disable program protection and read protection
- Using eFuses to enable or disable the overriding and read protection of shadow registers
- CRC (Polynomial CRC-32/MPEG-2) test for read-lock fuse content
- Redundancy and ECC protection of each fuse

62.3 Block diagram

The figure below shows the OCOTP system-level diagram.

Provided under NDA
COMPANY PROPRIETARY

c8c462e5-4821-48a8-b251-590d3ab624c1

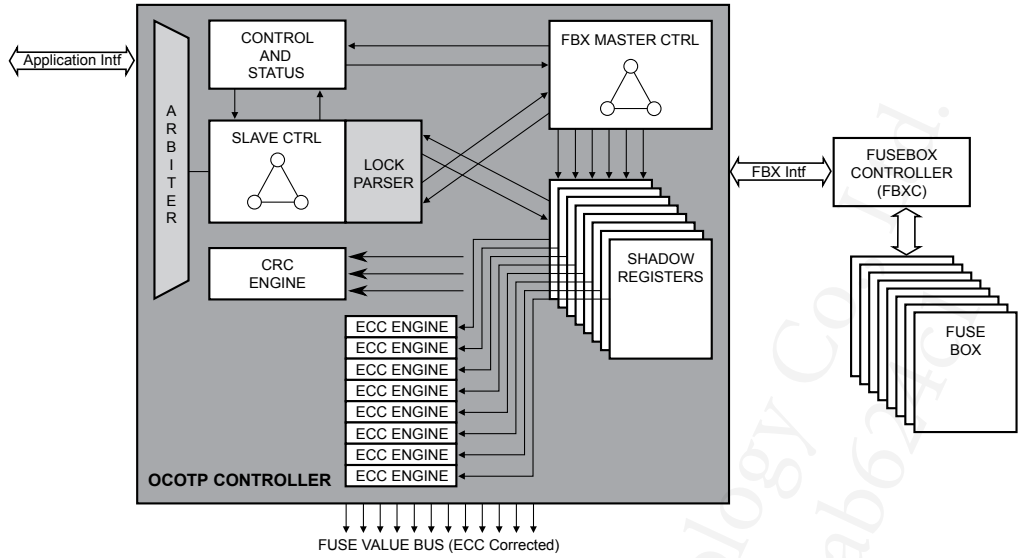

Figure 549. OCOTP system-level diagram

62.4 Operation

The OCOTP provides the following functions:

- Programming and reading of 32-bit eFuse word via the register interface
- ECC-corrected read of shadow registers
- Override of shadow register's value without programming of eFuses
- Calculation of CRC (Polynomial CRC-32/MPEG-2) on eFuse words
- 32-bit read and write accesses to eFuse and shadow registers

An eFuse word comprises 32 bits. Each bit in an eFuse is 0 by default.

The OCOTP reads all 32 bits of an eFuse at a time.

The OCOTP programs an eFuse one bit at a time. After the OCOTP programs an eFuse bit to 1, that bit permanently acquires a value of 1.

The OCOTP includes several groups of registers with slightly-different names, but identical functions. For brevity, the rest of this chapter uses the suffix _x to notate these groups. So, for example, CTRL_x refers to CTRL_SYS .

62.4.1 Shadow register reload

The OCOTP shadows the value of all eFuse words. Therefore, eFuse information is available through memory-mapped shadow registers. If you subsequently program the fuses, you must reload the shadow registers to keep them coherent with the eFuses.

The following operations reload the shadow registers:

- After the MC_RGM triggers a destructive reset

62.4.2 Fuse values

After the chip deasserts its reset, the OCOTP reads and stores all eFuse values in its shadow registers.

You can read eFuse values through shadow registers or by initiating a read sequence on the fuse location, if not read-protected.

All shadow register read accesses are single-error correction and double-error detection (SECDED) protected, if ECC check is enabled.

You can write or override the shadow register values depending on the protection that the corresponding fuse locks enable for those values.

62.4.3 Fuse protection and overrides

Typically the first few words of the eFuses define the eFuse word locks. These locks define the property of the eFuses they are associated with.

The OCOTP allows you to restrict access to eFuse words and shadow registers. You do this by programming the corresponding eFuse's lock bit, if applicable. See the attached chip fuse-map spreadsheet for details.

The type of locks and its effect on the associated fuse word are defined in the following table.

NOTE

eFuse word can have any number of these locks, and can also have no locks as mentioned in the chip fuse map.

NOTE

eFuse/shadow protection is chip-specific implementation dependent. See the chip fuse map for the protection specific to this chip.

Table 544. eFuse/shadow protection

Protection	Access	eFuse-word	Shadow register
Read Protect (RP)	Read	Prohibited *sets STATUS_x[ERROR]*	Prohibited *Reads back 0xBADABADA*
	Write	Allowed	Allowed
Write Protect (WP)	Read	Allowed	Allowed
	Write	Prohibited *sets STATUS_x[ERROR]*	Allowed
Override Protect (OP)	Read	Allowed	Allowed
	Write	Allowed	Prohibited *Will generate transaction error on the peripheral bus*

62.4.4 eFuse and shadow register read

All shadow registers are always readable except when read-protected. The read-protect lock corresponding to a eFuse word also applies read protection to the corresponding shadow register. Any attempt to read from a read-protected eFuse word returns 0xBADABADA. Before initiating any new access of fuse word or shadow register, you must write a 0 to STATUS_x[ERROR].

The shadow registers are memory-mapped. See Shadow (SHADOWS0 - SHADOWS127) for details.

To read a fuse word directly and correctly from the fusebox, complete the following steps:

1. Check that STATUS_x[BUSY] and STATUS_x[ERROR] are 0. You must do this because the OCOTP does not support overlapping access requests. It must complete any pending write, or read request before you can request a new read access.
2. Write the eFuse address to ADDR_x[ADDR].
3. Write the authorization code into CTRL_x[AUTH_KEY]. The OCOTP reads the data and transfers it to RDATA_x[DATA].
4. Write 0001b to CTRL_x[RD_WR]

5. Wait for the read request to finish. If the request finishes successfully, the OCOTP writes a 0 to STATUS_x[BUSY]. If the request was for a read-protected eFuse word or other master region, the OCOTP writes a 1 to STATUS_x[ERROR] and does not write anything to STATUS_x[BUSY].
6. Read RDATA_x[DATA] to get the eFuse word value.

62.4.5 eFuse and shadow register writes

Your software can override shadow register bits unless the bits are protected against overrides.

The shadow registers are memory-mapped. See Shadow (SHADOWS0 - SHADOWS127) for details.

NOTE

You cannot write to the ECC shadow registers.

Here are recommended best practices for you to perform before you program the eFuses:

1. Program the shadow register with the intended eFuse value.
2. Examine how step 1 affected the chip's functionality. If the functionality is as expected, then proceed to the next step.
3. Program the eFuse with the value from step 1.
4. Program the eFuses lock so that eFuses are protected from any spurious writes. If there are other eFuse words with same lock, then the fuse lock should be programmed after the last word.
5. Program the calculated ECC in the ECC eFuse.
6. Program the ECC eFuse enable as 1.

CAUTION

You cannot change the ECC eFuses after performing step 6.

Perform these steps to program the fuse bank correctly::

1. Check that STATUS_*x*[BUSY] and STATUS_*x*[ERROR] are 0. You must do this because the OCOTP does not support overlapping access requests. It must complete any pending write,or read request before you can request a new read access.
2. Write the requested fuse address to ADDR_*x*[ADDR].
3. Write the data to WRDATA_*x*[DATA].
4. Write the following value to CTRL_x[RD_WR], depending on your need:
   - 0010b
5. Write the authorization code to CTRL_x[AUTH_KEY]. You must do this step to avoid rogue code performing erroneus writes to eFuses.

NOTE

Step 4 and 5 must be performed together. You must write to both the register fields on a single write.

After you complete these steps, the OCOTP checks whether your request is to a protected or locked region. If it is, the OCOTP does not perform any eFuse access and writes a 1 to STATUS_x[ERROR]. Your software must then clear this error before submitting any new write request. If the OCOTP determines that it can fulfill your request, it does the following:

1. The OCOTP initiates the write sequence.
2. The OCOTP writes a 1 to STATUS_x[BUSY].
3. The OCOTP programs the eFuse as described in Operation. During the programming, the OCOTP shifts WRDATA_*x*[DATA] to the right with zero fill. This shifting is required to program the eFuse serially.
4. During the write operation, the OCOTP prohibits you from modifying WRDATA_x[DATA] and ADDR_x[ADDR].

5. After the operation completes, the OCOTP writes a 0 to STATUS_x[BUSY].

NOTE

If the ECC also has a lock, you must first program the ECC and only then program the lock register. The ECC must be calculated with assumption that the lock bit has a value of 1.

CAUTION

eFuse write can occur anytime the chip operates within specified operating conditions. However, if eFuse write occurs when the chip's operating conditions are outside of specifications (for example, when losing power), or if something interrupted the eFuse write (for example, a transaction or a chip reset), the update to the eFuse is not guaranteed. The best-practice recommendation is for your software to read the eFuse value after any eFuse write operation to verify the update has occurred as expected.

62.4.6 eFuse powerdown

Your software can powerdown the eFuse by writing 1 to CTRL_FBX[FBX_PD].

Following are the steps that you must perform before powering down eFuses.

1. Write 1 to CTRL_FBX[IPG_STOP].
2. Wait until OCOTP writes 1 to CTRL_FBX[IPG_STOP_ACK].
3. Powerdown eFuse by writing 1 to CTRL_FBX[FBX_PD].

CAUTION

You must not powerdown the eFuses while they are being accessed. This can corrupt the eFuses.

62.4.7 Write postamble

Because of internal electrical characteristics of the eFuse during writes, all eFuse operations following a write must :

- Be separated by a minimum duration defined in the chip data sheet
- Occur after STATUS_x[BUSY] becomes 0

This guarantees that the on-chip programming voltages reach a steady state after the OCOTP finishes a write sequence. A recommended software sequence, to meet the least time required between two subsequent writes, is as follows:

1. Request the writing of data.
2. Wait until STATUS_x[BUSY] becomes 0.
3. Wait for the defined duration.
4. Perform the next eFuse operation.

62.5 Behavior during reset

The OCOTP is always active, post destructive reset. The shadow registers automatically load the appropriate OTP contents after he chip deasserts its reset. During this loading time, the OCOTP keeps STATUS_x[BUSY]=1.

Fuses can support a finite number of reload cycles. See the chip data sheet.

62.6 Power control of OTP memory

Your software is responsible for shutting off power to OTP memory in idle status to save power.

After system power-up, your software must write a 1 to CTRL_FBX[FBX_PD] to shut off power to the eFuses and FBXC if none of the masters requested a fuse operation.

After completing eFuse programming or reading, your software must write a 1 to CTRL_FBX[FBX_PD] to shut off power to eFuses if none of the masters requested a eFuse operation.

Your software must wake up the OTP after power-down by writing a 0 to CTRL_FBX[FBX_PD]. You must meet the OTP access constraint after wakeup. See the chip data sheet.

The OCOTP and its shadow registers are available even after CTRL_FBX[FBX_PD]=1.

62.7 CRC (Polynomial CRC-32/MPEG-2) test

You can use the CRC test feature to validate read-protected eFuse content, though it's not restricted to only read-protected eFuses. A few eFuses are dedicated to store the CRC value of pre-defined eFuse section. See the chip fuse map for details.

When a master executes CRC tests by writing a 1 to CTRL_*x*[CRC_TEST], the OCOTP:

- Automatically calculates the CRC value of the user-defined fuse region
- Compares it to the value in the specified CRC eFuse word

Here is the procedure of the CRC test flow:

1. Program the CRC value calculated by software code into one of the CRC fuse words.
2. Program the CRC test region's start address in CRC_RGN_*x*[STRT_ADDR].
3. Program the CRC test region's end address in CRC_RGN_*x*[END_ADDR].
4. Program the eFuse address of pre-programmed CRC value in CRC_ADDR_*x*[ADDR]. The OCOTP uses this address to compare the calculated CRC for the region defined in steps 2 and 3.
5. Write a 1 to CTRL_*x*[CRC_TEST] to start the CRC check.
6. Check that STATUS_*x*[BUSY] and STATUS_*x*[ERROR] are 0. You must do this because the OCOTP sets STATUS_*x*[BUSY] = 1 until the OCOTP calculates and compares CRC for the eFuses.
7. Check the STATUS_*x*[CRC_FAIL] value. if STATUS_*x*[CRC_FAIL]=0 then the CRC test passed. STATUS_*x*[CRC_FAIL] must be read in an independent read after the STATUS_*x*[BUSY] is 0.

62.8 Fuse ECC

Some of the eFuses are protected with SECDED ECC. See the chip fuse map for details. The OCOTP applies ECC protection to the shadow registers's value.

The OCOTP implements 7-bit ECC for every 32-bit ECC-protected eFuse word.

The eight bit after every 7-bit ECC is the ECC efuse enable.

See Figure 550 for the ECC equation and Table 545 for the terms used in that equation. In Figure 550, the ^ denotes an XOR operation.

$$ECC[i] = \hat{} \left(\text{Fuse Word}[31:0] \,\&\, G[i] \right)$$

Figure 550. Equation for ECC

Table 545. G[i] values

i	G[i]

Fields

Field	Function
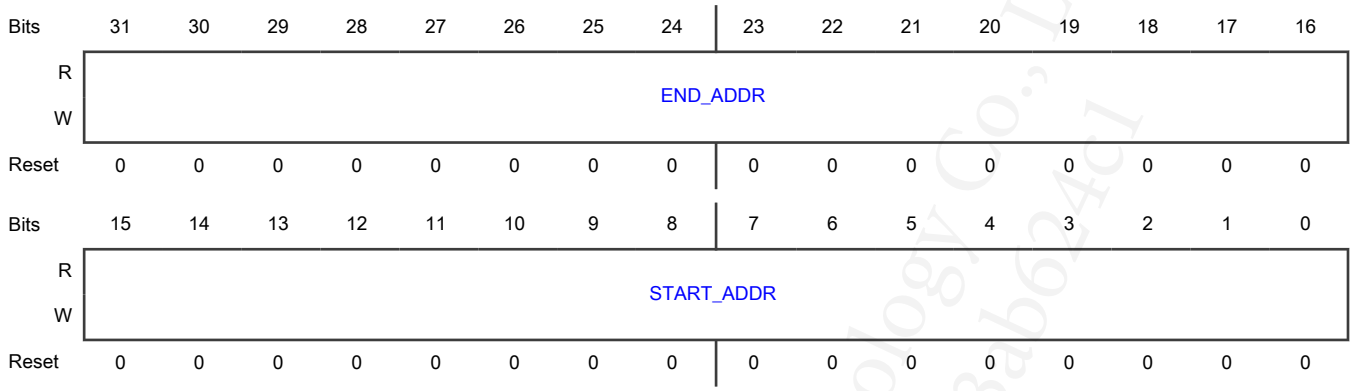
31-19 —	Reserved
18 IPG_STOP_ACK	Low-power mode acknowledgment OCOTP acknowledges that no transaction is underway for eFuse, and OCOTP can be put into low-power mode. OCOTP then writes a 0 to CTRL_FBX[IPG_STOP].
17 IPG_STOP	Low Power entry Indicates that the Fusebox will be put in Low power mode.
16 FBX_PD	Fusebox Power Down After you write a 1 to this field, the FBXC drives the fusebox power-down signal to active-high state. If your chip is accessing the eFuse, the chip must not power down the fusebox during the access to avoid any data loss. See the chip data sheet for the required setup time (between power-down and fusebox access). You must respect this constraint. No accesses are possible to FBXC and eFuse during this time. You must ensure that you have used the CTRL_FBX[IPG_STOP] and CTRL_FBX[IPG_STOP_ACK] handshake mechanism to ensure all the pending transaction of FBXC are complete. See eFuse powerdown for the steps to powerdown eFuses. 1b - Enable fusebox power down mode
15-9 —	Reserved
8 SEC_MODE	Indicates that the FBXC is in Secure mode. If a write error occurs in this mode, OCOTP flags the error as an irrepairable error, even if repairs are available. 1b - FBXC is in secure mode
7-1 —	Reserved
0 —	Reserved

62.9.1.7 eFuse region for CRC validation (CRC_RGN_SYS)



Offset

Register	Offset
CRC_RGN_SYS	34h

Function

Program the CRC (Polynomial CRC-32/MPEG-2) test region's start and end address in this register. A master must address only its own region. Otherwise, OCOTP generates a peripheral bus error. You must write to this register only when STATUS_SYS[BUSY]=0.

Diagram

Fields

Field	Function
31-16 END_ADDR	End eFuse address for CRC calculation
15-0 START_ADDR	Start eFuse address for CRC calculation

62.9.1.8 Pre-calculated CRC eFuse address for comparision (CRC_ADDR_SYS)

Offset

Register	Offset
CRC_ADDR_SYS	38h

Function

Pre-calculated CRC value's (Polynomial CRC-32/MPEG-2) eFuse address used for comparing with OCOTP computed CRC value. Used in conjunction with CTRL_SYS[CRC_TEST]. You must write to this register only when STATUS_SYS[BUSY]=0.

Provided under NDA only

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d8ab624c1

Function

This register provides you with OCOTP and eFuse status. The OCOTP updates this register two OCOTP clock cycles after you write to CTRL_SYS.

Diagram

Fields

Field	Function
31-3 —	Reserved
2 ERROR	Error status flag The OCOTP writes a 1 to this field whenever the OCOTP detects an illegal access. This occurs under the following circumstances: • You wrote an incorrect key to CTRL_SYS[AUTH_KEY] • You attempted to write to write-protected eFuse words • You attempted to read from read-protected eFuse words • The FBXC signaled a peripheral bus error during an access • The FBXC signaled a repair error after the OCOTP tried to program a fuse word • You attempted an access when the OCOTP already signaled a peripheral bus error You must clear this error by writing a 1 to this field before attempting any further access.
1 CRC_FAIL	CRC compare status Indicates that the OCOTP-computed CRC value did not match the CRC eFuse word at CRC_FUSE_ADDR_SYS[ADDR]. You must read CRC_FAIL only when STATUS_SYS[BUSY]=0.
0 BUSY	OCOTP busy indication The OCOTP writes a 1 to this field when any of the following eFuse accesses are in progress: • Write to eFuse • Read from eFuse

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• CRC test You must not initiate any eFuse access when this field is 1. The OCOTP writes a 0 to this field after the OCOTP completes access.

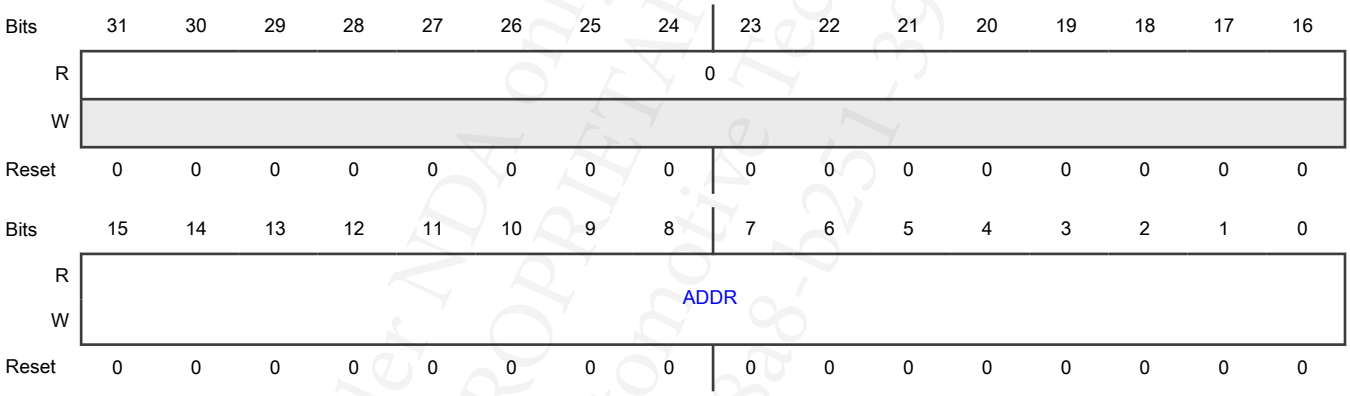
62.9.1.21 ECC error injector (ERR_INJCTR)



Offset

Register	Offset
ERR_INJCTR	F0h

Function

Injects an ECC error at a bit in the shadow register that you specify.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 ADDR	The address of the bit in the shadow register where you want to inject the single-bit ECC error. The OCOTP inverts that bit. ADDR has the following structure: • Bits 15:5 represent the shadow register number minus one. Thus, ADDR[15:5]=0 represents shadow register 1, ADDR[15:5]=1 represents shadow register 2, and so on. • Bits 4:0 represent the shadow-register bit that you want to invert. Thus, ADDR[4:0]=0 represents bit 0 in the shadow register, ADDR[4:0]=1 represents bit 1 in the shadow register, and so on.

Table continued from the previous page...

Field	Function
	ECC error is not introduced when you attempt to inject error on a shadow register that has override protection. OCOTP generates SEC/DED based on the inverted value and on the ECC calculation for ECC-enabled fuse-words.

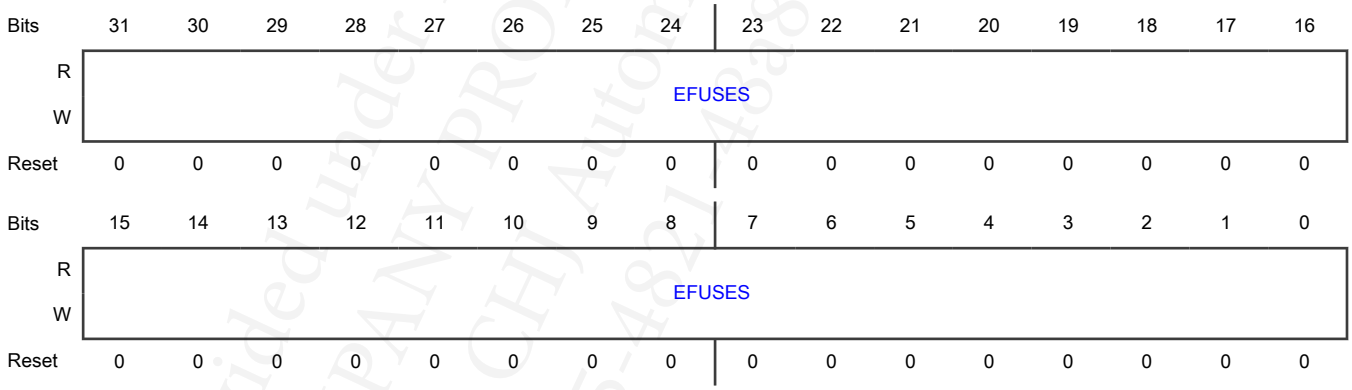
62.9.1.22 Shadow (SHADOWS0 - SHADOWS127)

Offset

For a = 0 to 127:

Register	Offset
SHADOWSa	200h + (a × 4h)

Function



The accesses to shadow register is governed by the access lock as defined in the chip fuse map.

If you write 0000_0000h to this region, the OCOTP disallows it and generates a peripheral bus error. This safeguards against unintended writes.

NOTE

You cannot write to the ECC shadow registers.

Diagram

31-0 EFUSES	OTP data

Chapter 63
Fusebox Controller (FBXC)

63.1 Introduction

The FBXC (fusebox solution) is designed to serve all the applications that require electrically programmable fuses (eFuses). The eFuse controller can be accessed by any master.

The FBXC gasket is aimed to be placed between the eFuse block and a block with a peripheral interface. This way, it provides normal read/write access and controls the eFuse block access to the peripheral interface master block.

63.1.1 Overview

The FBXC gasket supports the peripheral interface and fusebox-specific control signals. The data sheet describes the third-party eFuse macros. The fusebox solution is illustrated in the following block diagram.

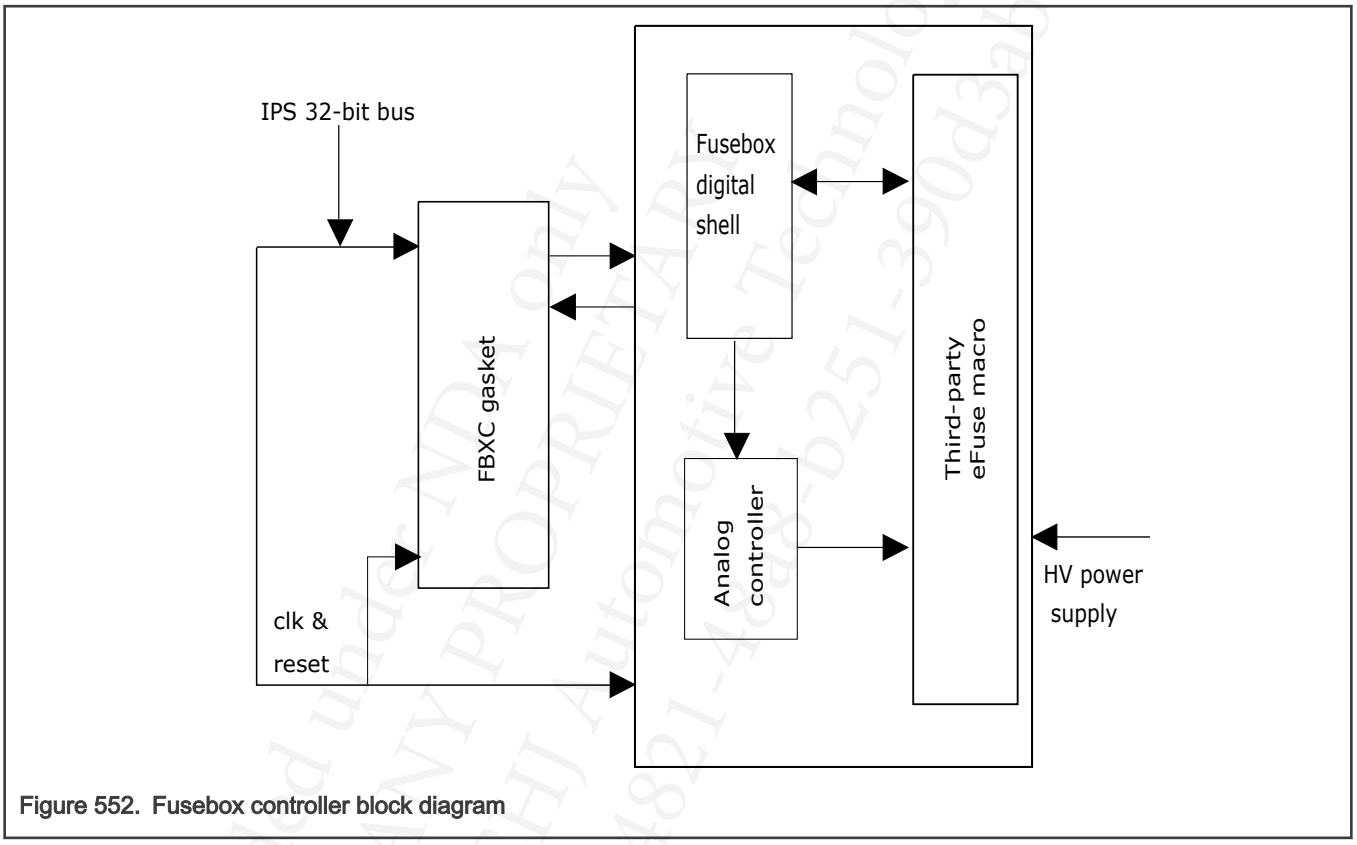

Figure 552. Fusebox controller block diagram

63.1.2 Features

This FBXC gasket includes the following features:

- Synchronous access to one-time electrically programmable fuses (eFuses) with a 32-bit-wide databus
- Synchronous access to all hard macro input/output ports
- Control signals to the eFuse block can be driven by the platform VDD-level control signals (unlike the third-party macros)
- Read / write control signals to the eFuse block that control all the analog eFuse block timing requirements
- Complete control or view of the eFuse block by control/status registers

Chapter 64
Safety

64.1 Introduction

This chip family is developed according to ISO 26262 and has an integrated safety concept targeting safety-related systems requiring high-safety integrity levels. The following documents support integration of this chip into safety-related systems:

- Reference Manual - Describes chip functionality
- Data Sheet - Describes chip operating conditions
- Safety Manual - Describes safety concept, possible safety mechanisms, and measures to reduce dependent failures
- Failure Modes Effects and Diagnostic Analysis (FMEDA) - Inductive analysis enabling customization of system-level safety mechanisms, including the resulting safety metrics for the given ISO standard
- FMEDA Report - Describes the FMEDA methodology and safety mechanisms supported in the FMEDA, including source of failure rates, failure modes, and assumptions made during the analysis
- The Dynamic FMEDA and FMEDA reports are available on request.

This device is a SafeAssure solution. For further information, see www.nxp.com/safeassure.

Chapter 65
Error Reporting Module (ERM)

65.1 Chip-specific ERM information

65.1.1 Instances and numbers of channels

The number of supported channels varies by ERM instance. The following table lists and describes the ERM instances and identifies the number of channels for each instance.

Table 547. ERM instances and numbers of channels

Instance	Reports errors for...	Number of used memory channels
ERM_PER	Memories for: • FlexRay and FlexCAN peripherals • QuadSPI RX and TX • SRAMC	9
ERM_eDMA0	eDMA0	1
ERM_eDMA1	eDMA1	1
ERM_CPU0	• Cortex-M7 core 0 DTCM • data tag RAM • data cache data RAM • instruction tag RAM • instruction cache data RAM	6
ERM_CPU1		6
ERM_CPU2		6

65.1.2 Memory error event sources and captured information

Each ERM instance channel *n* corresponds to a source of potential memory error events. For each instance channel, the following table shows:

- The corresponding memory
- What event information is captured

Table 548. ERM instance channel event sources and captured information

Instance	Channel	Memory event source	Single-bit errors	Multi-bit errors	Address details event				Syndrome(bit position) (SYN*n*)
					Event address (EAR*n*)	Start address (Hex)	End address (Hex)	Address alignment	
ERM PER	0	FlexRay_0 LRAM	No	Yes	Yes	402F8800	402F88AC	Absolute	No

Table continues on the next page...

NOTE

The non-correctable error interrupt of each of the ERM instance is covered in the respective FCCU NCF. They are not controlled by the interrupt controller. See the FCCU NCF sheet for details.

65.1.3 Over-reported single-bit ECC errors for QuadSPI accesses

The ECC errors are generated based on the number of words available in the Tx buffer. Since the QuadSPI module writes data on the flash, it prefetches the data from Tx buffer. Up to 8 words are prefetched.

65.2 ERM_PFE, ERM_LLCE, and ERM_Standby_RAM instances

65.2.1 Instances and numbers of channels

The number of supported channels varies by ERM instance. The following table lists and describes the ERM instances and identifies the number of channels for each instance.

Beijing Qualitative Technology Co., Ltd.
c8c46e54-2e2-48a8-b251-390d3ab624c1

Table 549. ERM instances and numbers of channels

Instance	Reports errors for	Number of channels
ERM_PFE0	egpix_rxf_rd, egpix_txf_rd, etgpix_rxf_rd,hgpi1_txf_rd, hgpi1_txf_rd	11
ERM_PFE1	emac2_iq_class_entry, emac2_iq_lru_count, emac2_iq_lmem*_rd	13
ERM_PFE2	pe0_iram, pe0_dram*	17
ERM_PFE3	pe1_iram, pe1_dram*	17
ERM_PFE4	pe2_iram, pe2_dram*	17
ERM_PFE5	pe3_iram, pe3_dram*	17
ERM_PFE6	pe4_iram, pe4_dram*	17
ERM_PFE7	pe5_iram, pe5_dram*	17
ERM_PFE8	pe6_iram, pe6_dram*	17
ERM_PFE9	pe7_iram, pe7_dram*	17
ERM_PFE10	pe_lmem*, mac_hash*, vlan_hash*, smem2arb_mem_rd*, ro_buf, lmem, class_inq_mem	13
ERM_PFE11	tlite_cntx*, teq_qfifo*, reclaim_buf_rd, bmu2, bcnt2, tlite_inq_rd, bmu, bcnt	24
ERM_PFE12	hif1*	17

ERM_PFE14	emac0*	13
ERM_PFE15	emac1*	13
ERM_LLCE	LLCE Data RAM_A, LLCE Data RAM_B, LLCE FRPE RAM, LLCE TxPPE RAM, LLCE RxPPE RAM, LLCE DTE RAM	9
ERM_STDBY_SRAM	only used to count single bit errors from standby SRAMC	1

65.2.2 Memory error event sources and captured information

Each ERM instance's channel *n* corresponds to a source of potential memory error events. For each instance channel, the following table shows:

- The corresponding memory
- For the corresponding memory's error events, whether the ERM captures single-bit errors, multi-bit errors, the error event's address, event syndrome information, or a combination of this information.

NOTE

For ERM to work properly, follow the sequence below:

1. Initialize all memories inside PFE after power on.
2. Inject a software reset.

Table 550. ERM instance channel event sources and captured information

Instance	Instance channel *n*	Memory *n* event source	Single-bit errors	Multi-bit errors	Address details			Event syndrome (bit position) (SYN*n*)

65.3 Introduction

65.3.1 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If memory supports ECC then ERM syndrome and error address information is captured along with error event. ERM does not receive this information in case of cache or memory with parity along with error event.

65.3.2 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

65.4 ERM_CPU0 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

65.4.1 ERM_CPU0 memory map

ERM_CPU0 base address: 4031_8000h

65.4.2 ERM Configuration Register 0 (CR0)

Offset

Register	Offset
CR0	0h

Function

This 32-bit control register configures the interrupt notification capability for:

- Channel 0
- Channel 1
- Channel 2
- Channel 3
- Channel 4
- Channel 5

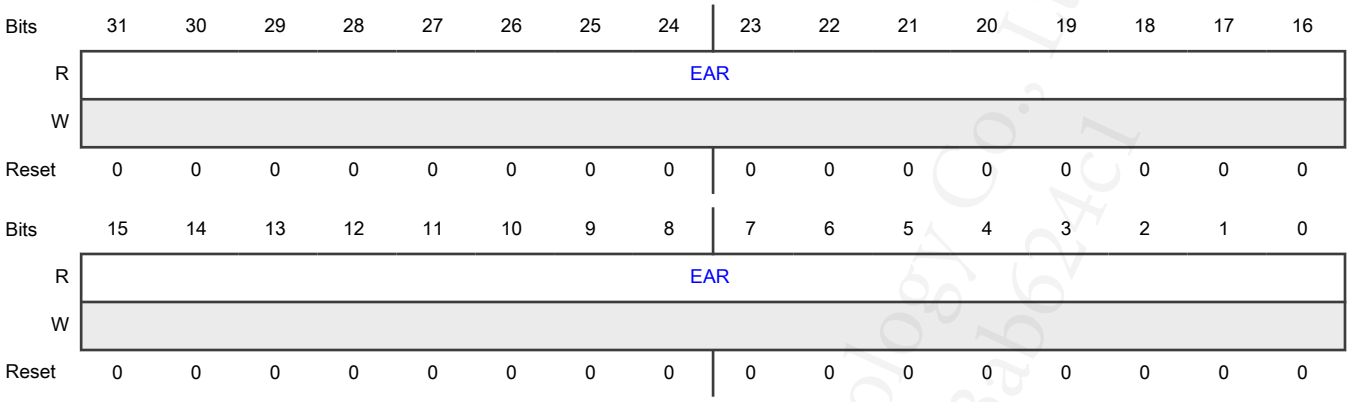
65.4.4 ERM Memory a Error Address Register (EAR0 - EAR1)



Offset

Register	Offset
EAR0	100h
EAR1	110h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

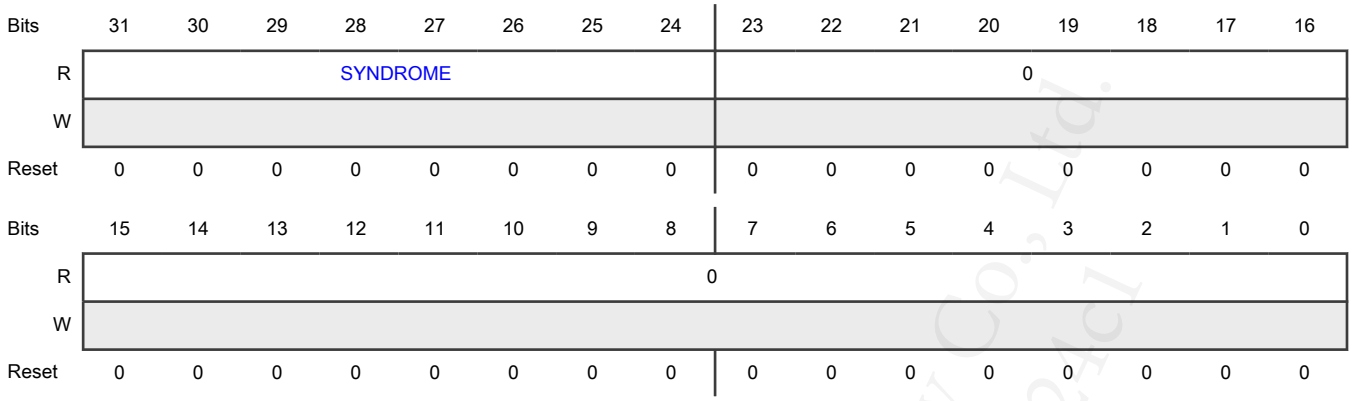
Diagram

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.4.5 ERM Memory a Syndrome Register (SYN0 - SYN1)

Offset



Register	Offset
SYN0	104h
SYN1	114h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

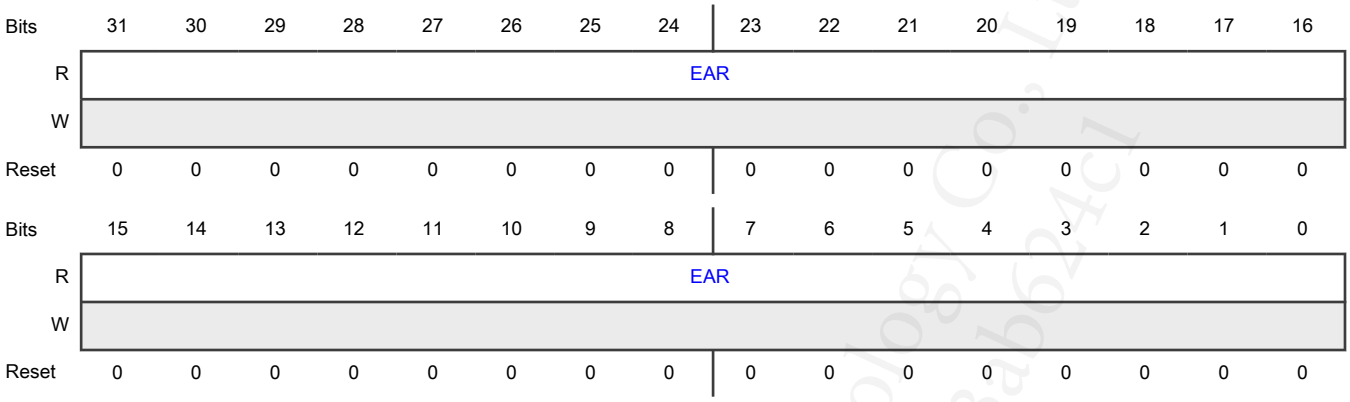
65.6.4 ERM Memory a Error Address Register (EAR0 - EAR1)



Offset

Register	Offset
EAR0	100h
EAR1	110h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

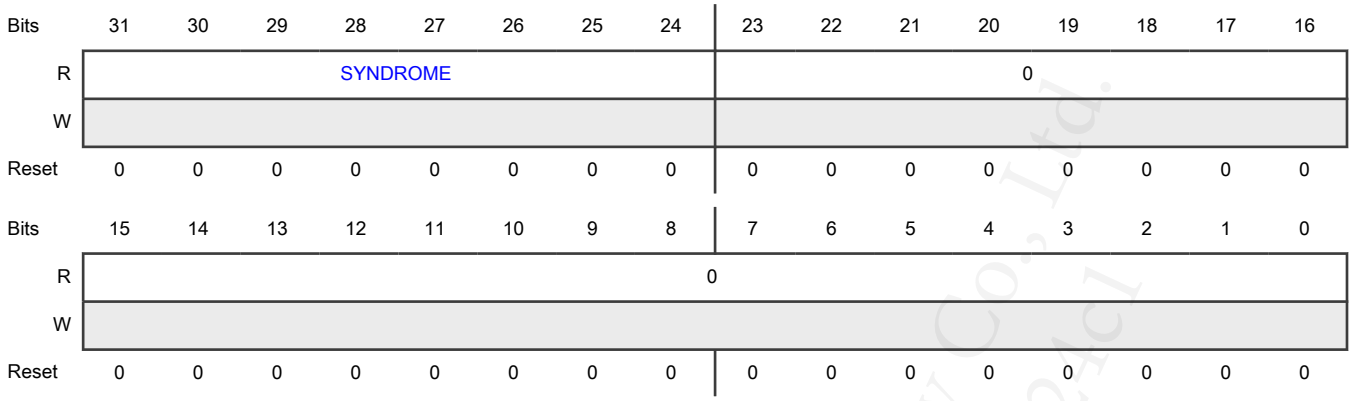
Diagram

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.6.5 ERM Memory a Syndrome Register (SYN0 - SYN1)

Offset



Register	Offset
SYN0	104h
SYN1	114h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

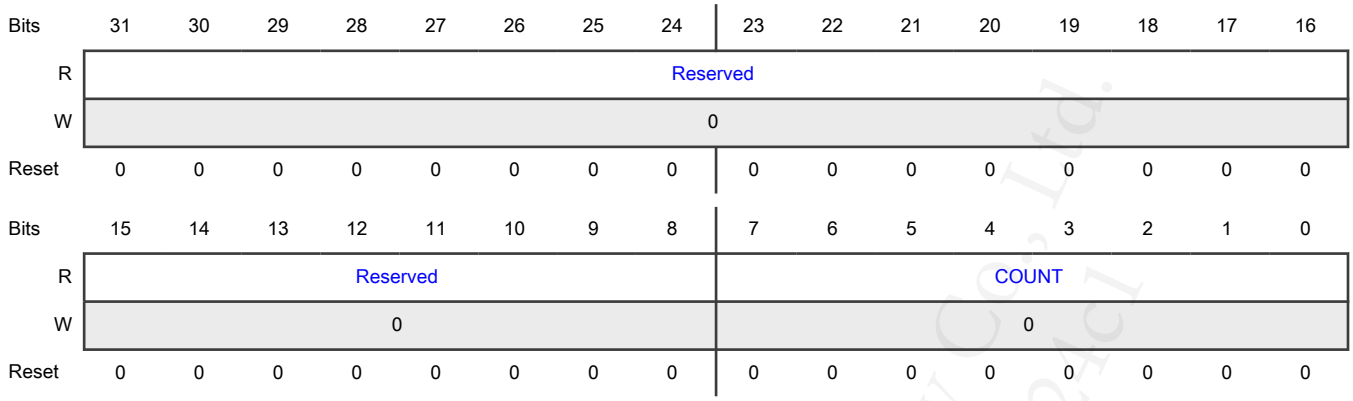
65.6.6 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT5)

Offset



Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.7 ERM_PER register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

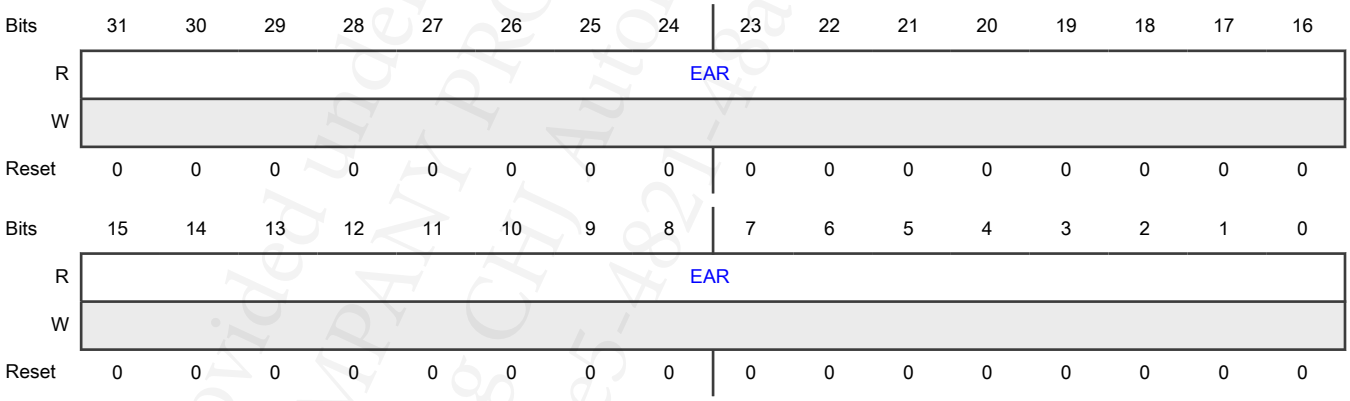
65.7.6 ERM Memory a Error Address Register (EAR0 - EAR9)



Offset

Register	Offset
EAR0	100h
EAR1	110h
EAR2	120h
EAR3	130h
EAR4	140h
EAR5	150h
EAR8	180h
EAR9	190h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

Provided under NDA only
COMPANY PROPRIETARY

65.7.7 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT9)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.7.8 ERM Memory a Syndrome Register (SYN8 - SYN9)

Offset

Register	Offset
SYN8	184h
SYN9	194h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

65.8 ERM_PFE0 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

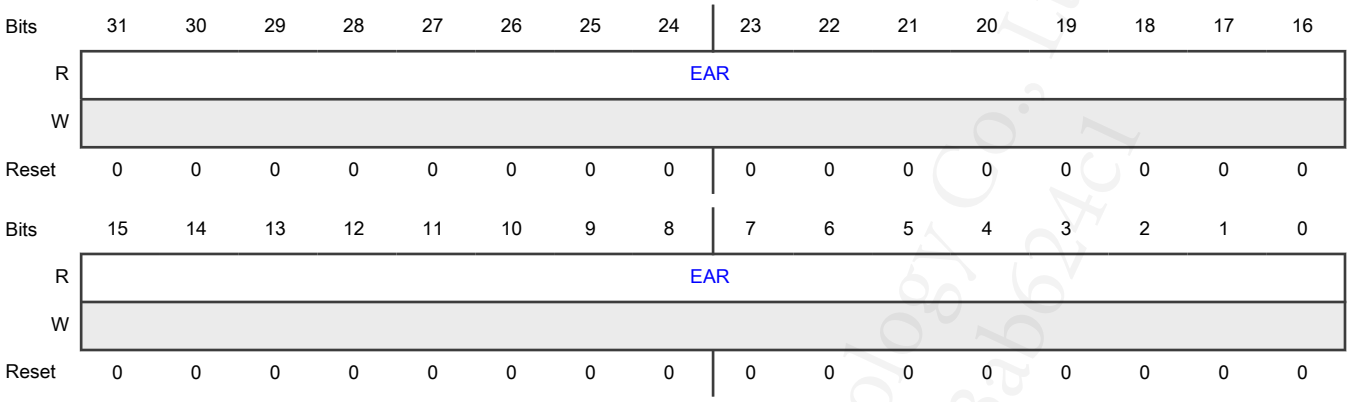
65.8.6 ERM Memory a Error Address Register (EAR0 - EAR10)

Offset

For a = 0 to 10:



Register	Offset
EARa	100h + (a × 10h)

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-1821-48a8-b251-390d3ab624c1

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

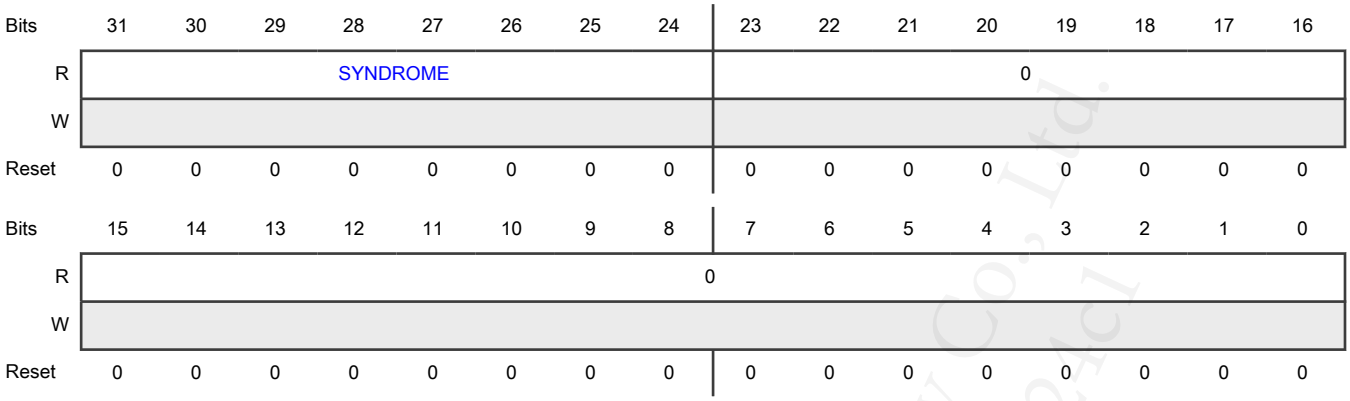
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.8.7 ERM Memory a Syndrome Register (SYN0 - SYN10)

Offset

For a = 0 to 10:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Provided under NDA only

CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h
CORR_ERR_CNT10	1A8h

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.9 ERM_PFE1 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

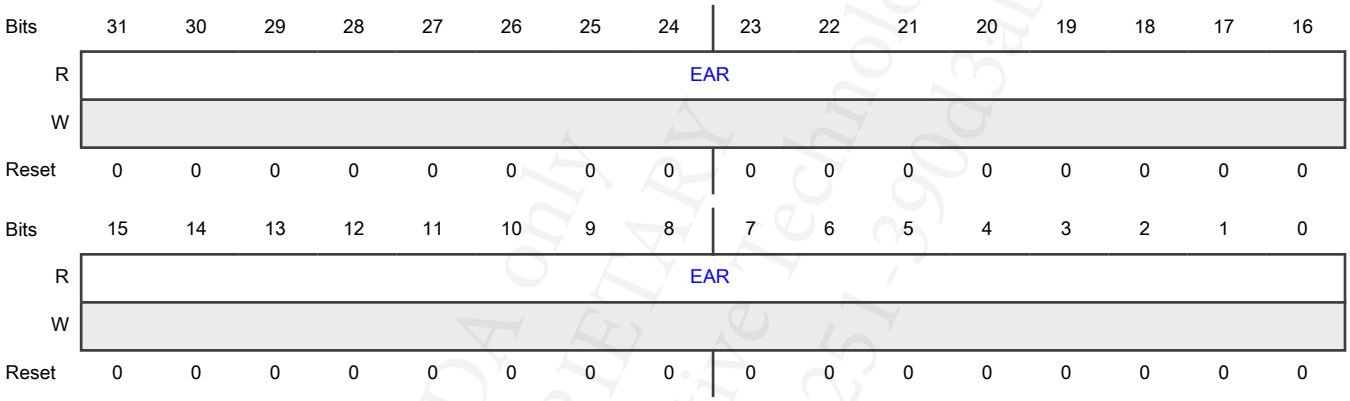
65.9.6 ERM Memory a Error Address Register (EAR0 - EAR12)

Offset



For a = 0 to 12:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

Fields

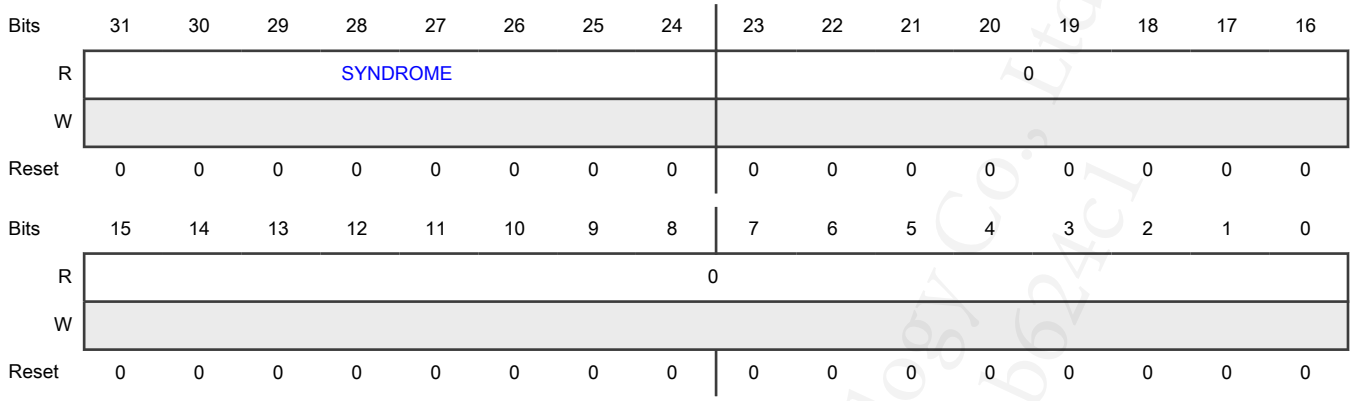
Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.9.7 ERM Memory a Syndrome Register (SYN0 - SYN12)

Offset

For a = 0 to 12:

Register	Offset
SYNa	104h + (a × 10h)



Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-421-48a8-b251-590a3b624c1

position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.

65.9.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h

Table continues on the next page...

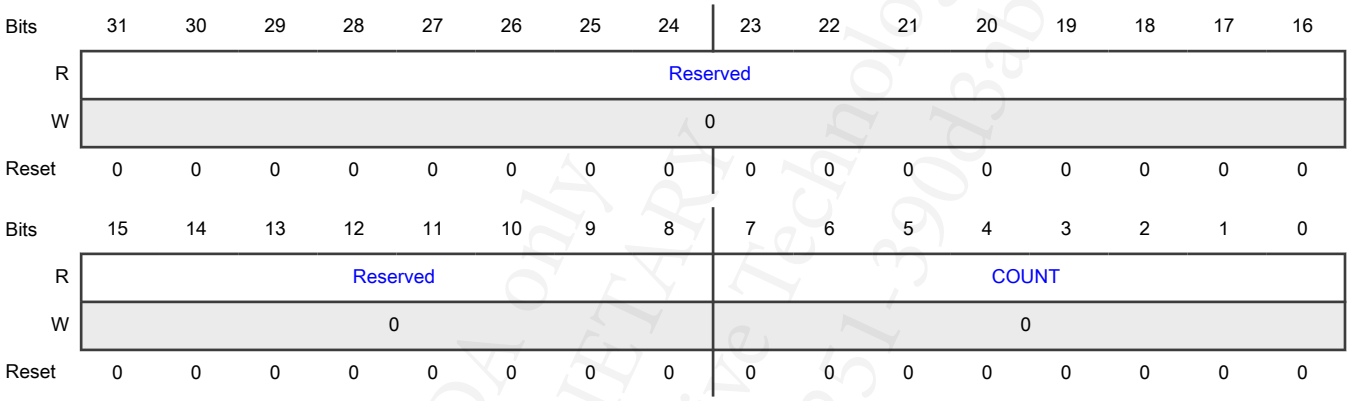

Table continued from the previous page...

Register	Offset
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.10 ERM_PFE10 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode

- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

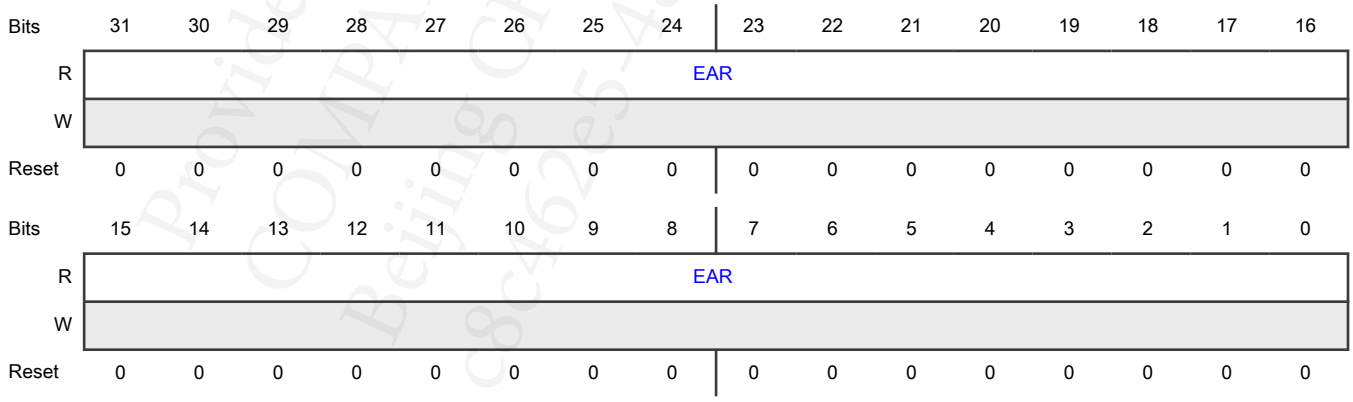
65.10.6 ERM Memory a Error Address Register (EAR0 - EAR12)

Offset



For a = 0 to 12:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

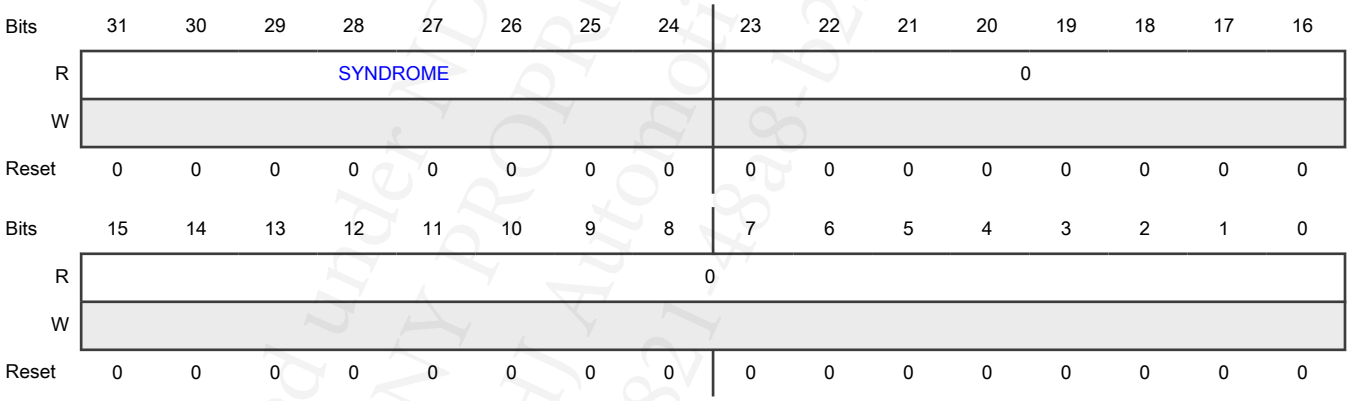
Diagram

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.10.7 ERM Memory a Syndrome Register (SYN0 - SYN12)

Offset



For a = 0 to 12:

Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.
23-0 —	Reserved

65.10.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.11 ERM_PFE11 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

Offset

Register	Offset
CR0	0h

Function

This 32-bit control register configures the interrupt notification capability for:

- Channel 0
- Channel 1
- Channel 2
- Channel 3
- Channel 4
- Channel 5
- Channel 6
- Channel 7

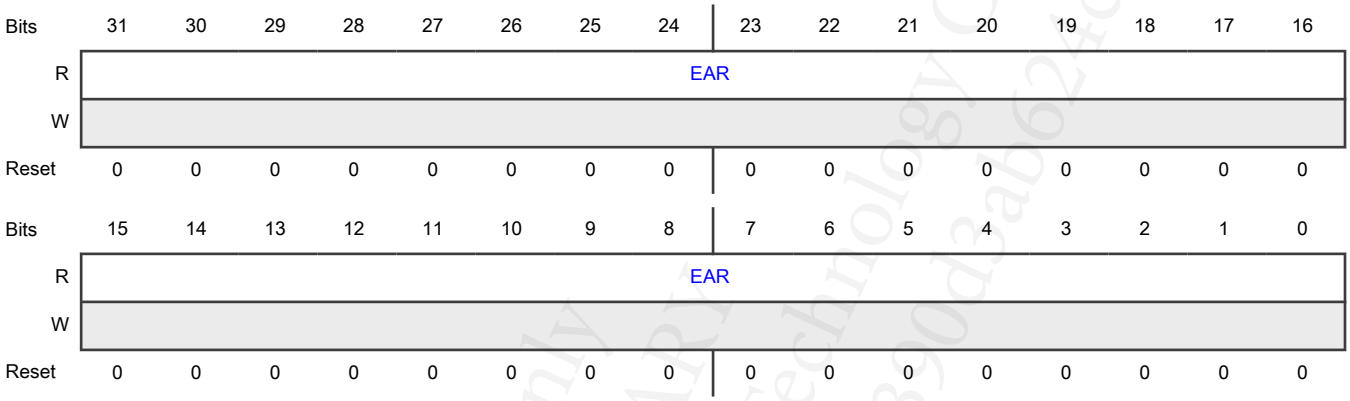
65.11.8 ERM Memory a Error Address Register (EAR0 - EAR23)

Offset

For a = 0 to 23:



Provided under NDA only
COMPANY PROPRIETARY
Beijing ChiUtoInfotive Technology Co., Ltd.
c8c462e5-4821-48a3-b251-390d3ab624c1

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

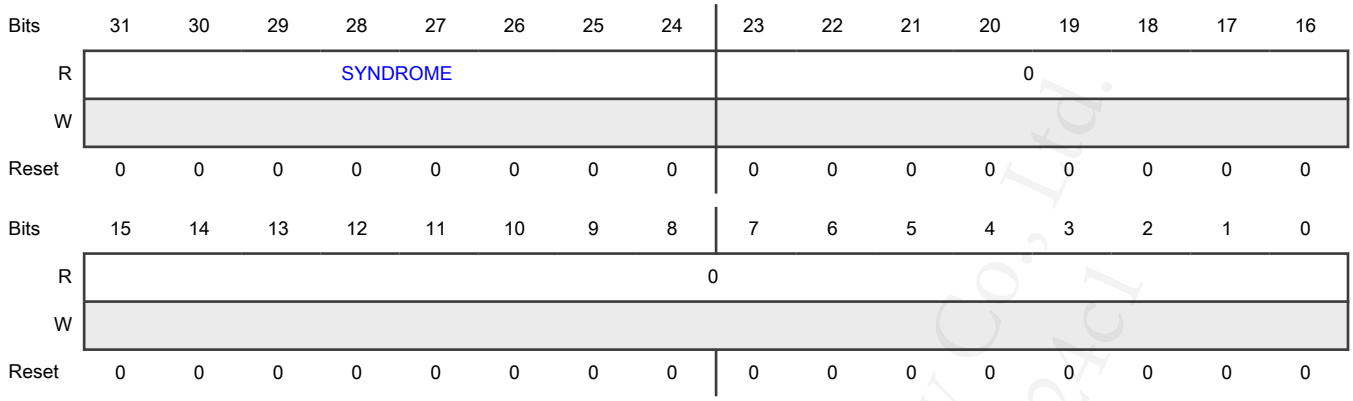
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.11.9 ERM Memory a Syndrome Register (SYN0 - SYN23)

Offset

For a = 0 to 23:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

CORR_ERR_CNT20	248h
CORR_ERR_CNT21	258h
CORR_ERR_CNT22	268h
CORR_ERR_CNT23	278h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.12 ERM_PFE12 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

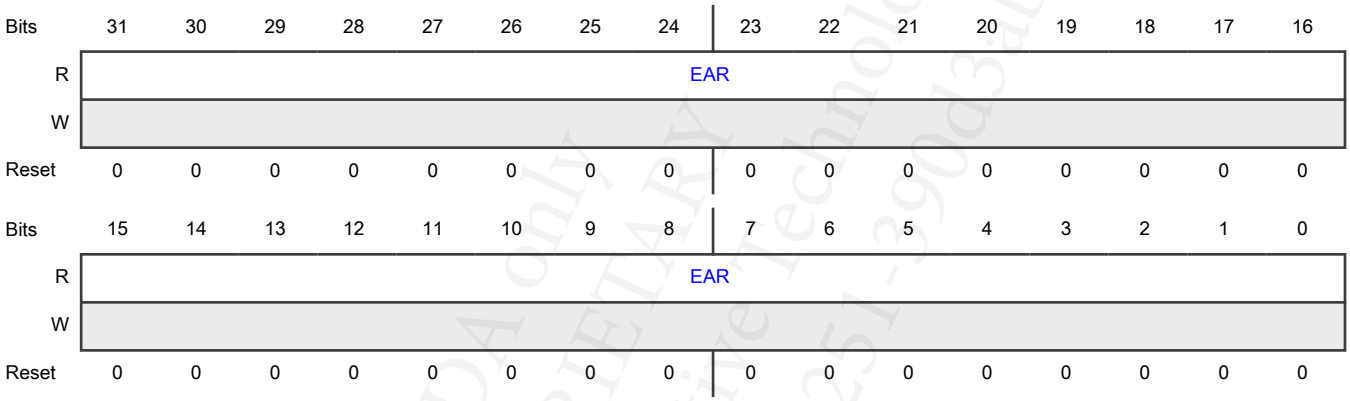
65.12.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset



For a = 0 to 16:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

Fields

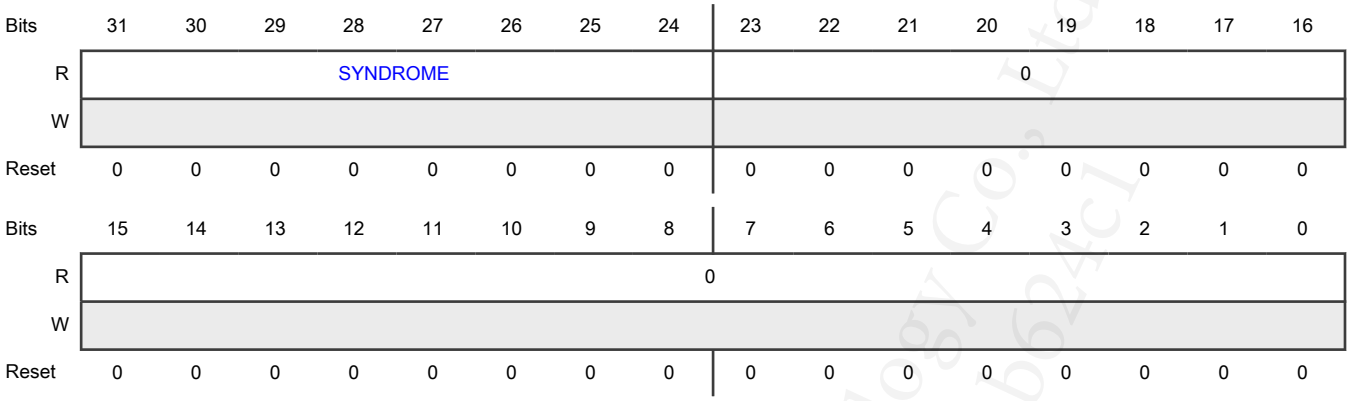
Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.12.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:

Register	Offset
SYNa	104h + (a × 10h)



Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-4d21-48a8-b251-590d3b624c1

position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.

CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT16	208h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.13 ERM_PFE13 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

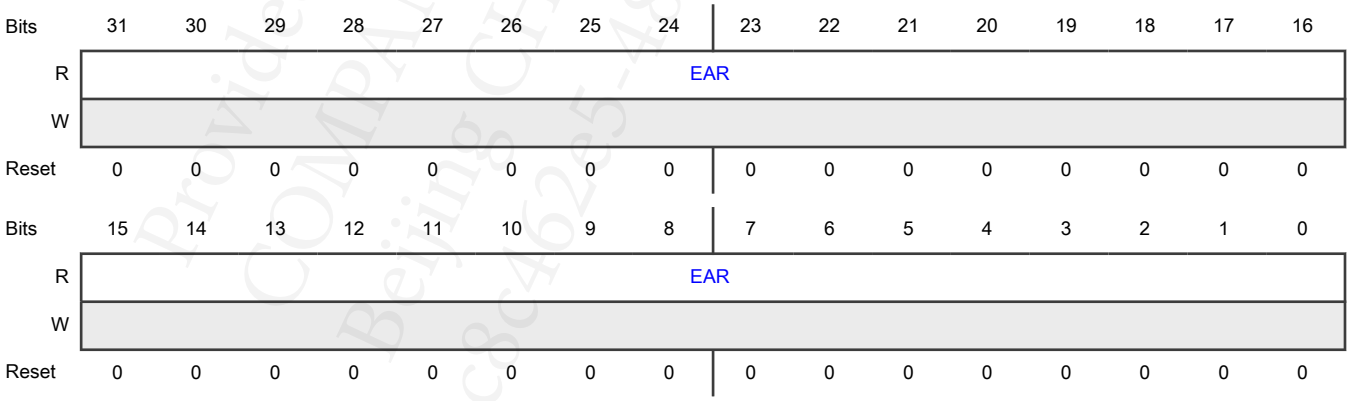
65.13.8 ERM Memory a Error Address Register (EAR0 - EAR17)

Offset



For a = 0 to 17:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

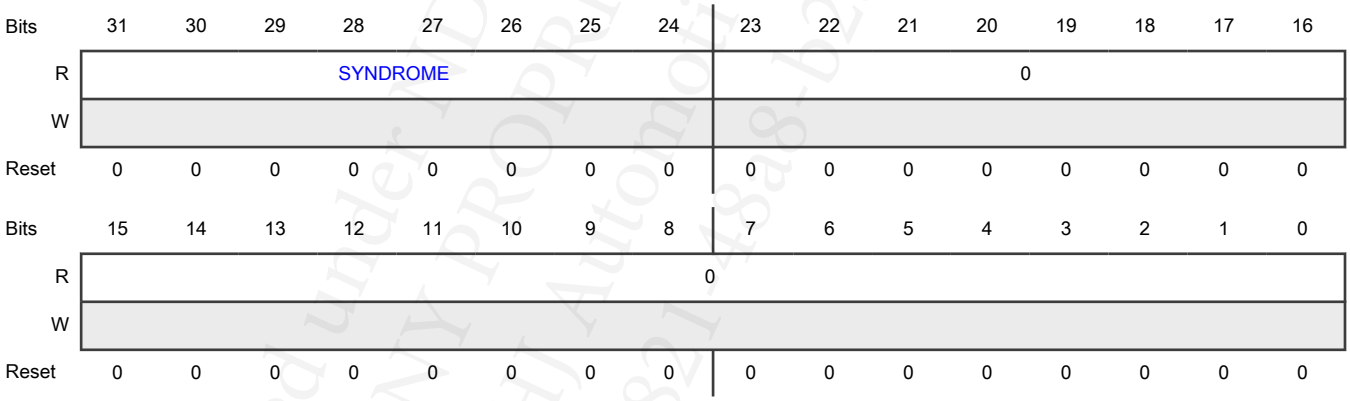
Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c46255-4821-48a8-b251-390d3ab624c1

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.13.9 ERM Memory a Syndrome Register (SYN0 - SYN17)

Offset



For a = 0 to 17:

Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.
23-0 —	Reserved

65.13.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT 17)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.14 ERM_PFE14 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

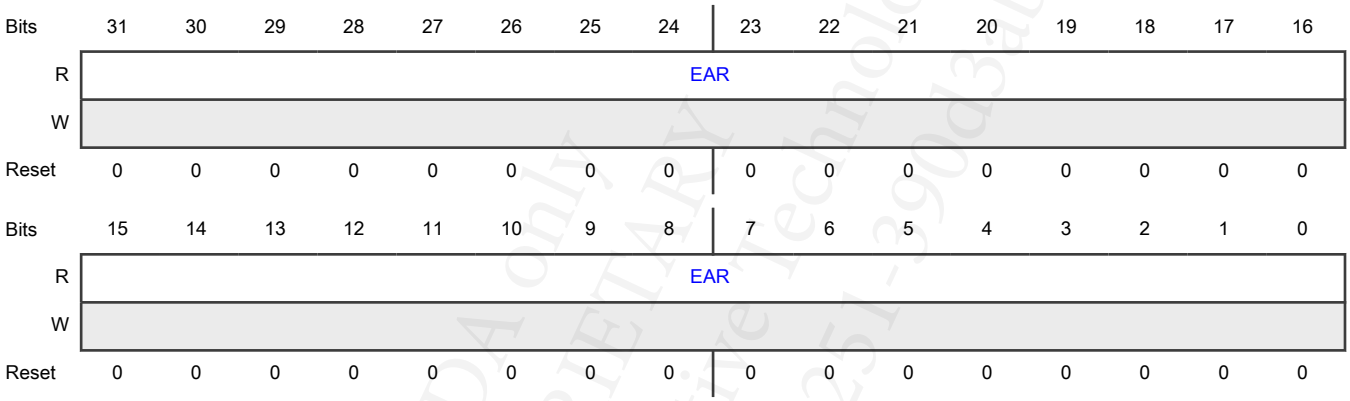
65.14.6 ERM Memory a Error Address Register (EAR0 - EAR12)

Offset



For a = 0 to 12:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

Fields

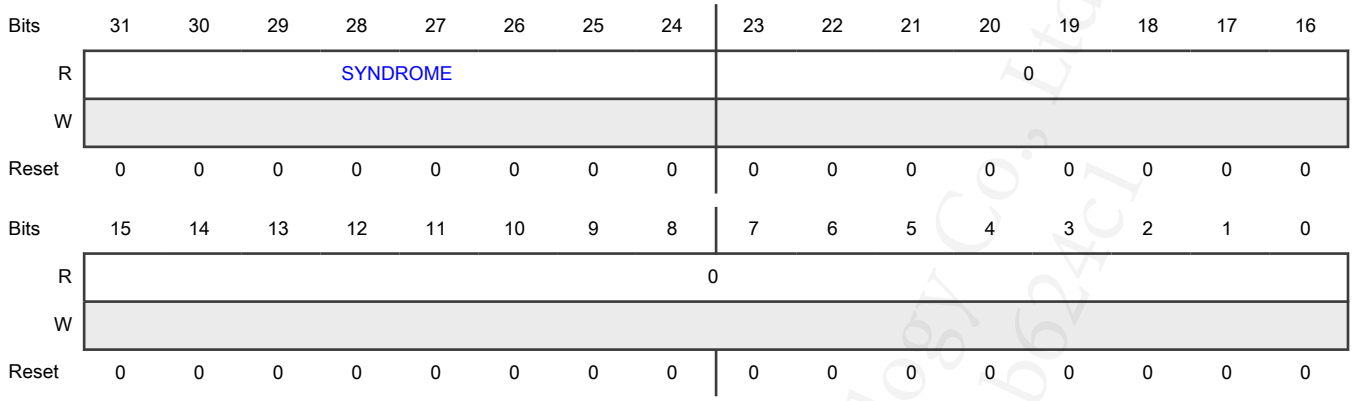
Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.14.7 ERM Memory a Syndrome Register (SYN0 - SYN12)

Offset

For a = 0 to 12:

Register	Offset
SYNa	104h + (a × 10h)



Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-4d21-48a8-b251-590d3b624c1

position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.
23-0 —	Reserved

65.14.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h

Table continues on the next page...

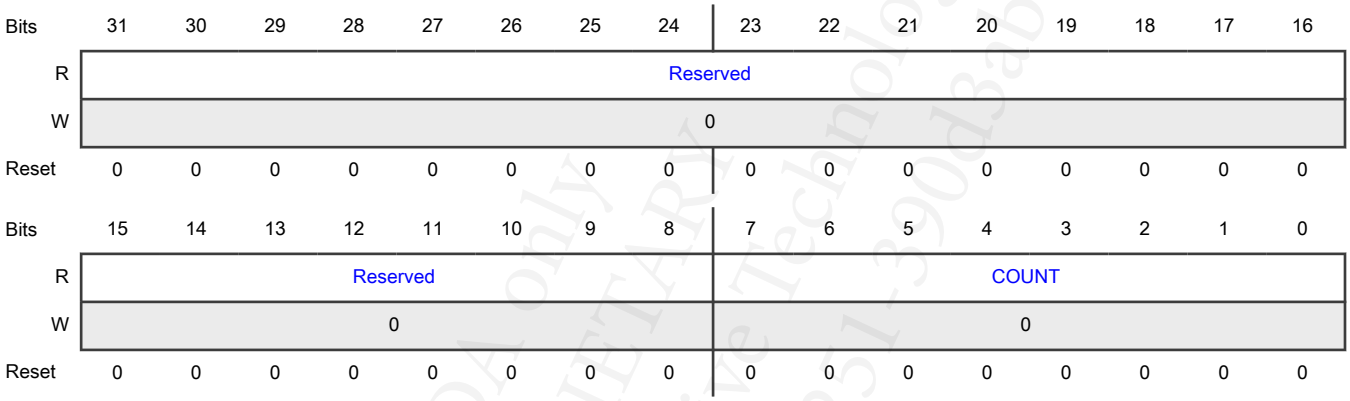


Table continued from the previous page...

Register	Offset
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.15 ERM_PFE15 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode

- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

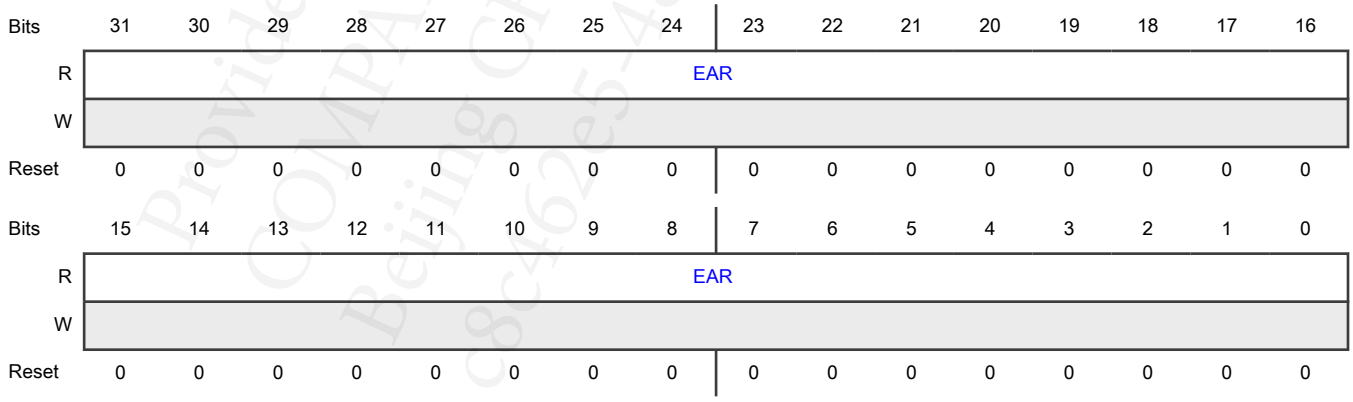
65.15.6 ERM Memory a Error Address Register (EAR0 - EAR12)

Offset



For a = 0 to 12:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

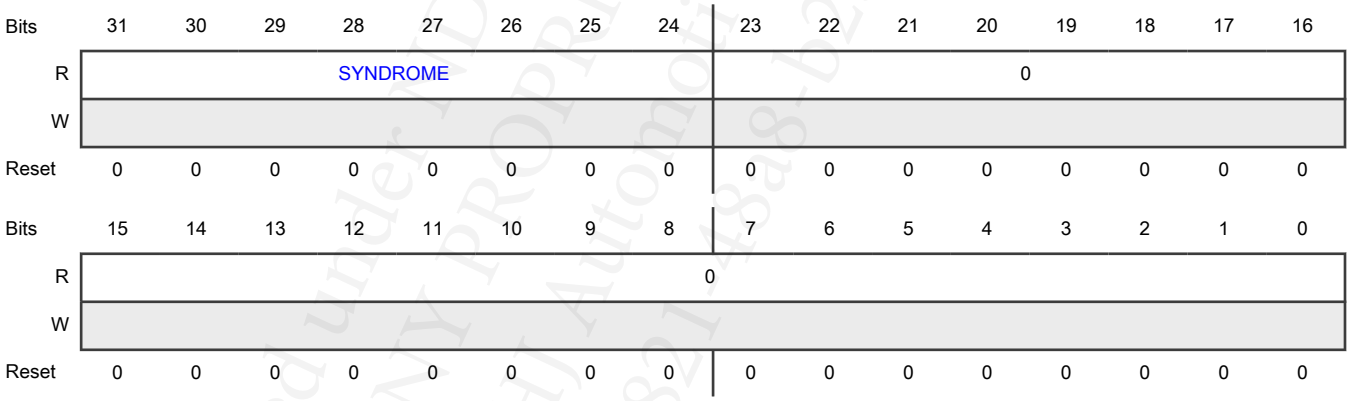
Diagram

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.15.7 ERM Memory a Syndrome Register (SYN0 - SYN12)

Offset



For a = 0 to 12:

Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.
23-0 —	Reserved

65.15.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT12)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Table continued from the previous page...

Field	Function
—	
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.16 ERM_PFE2 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

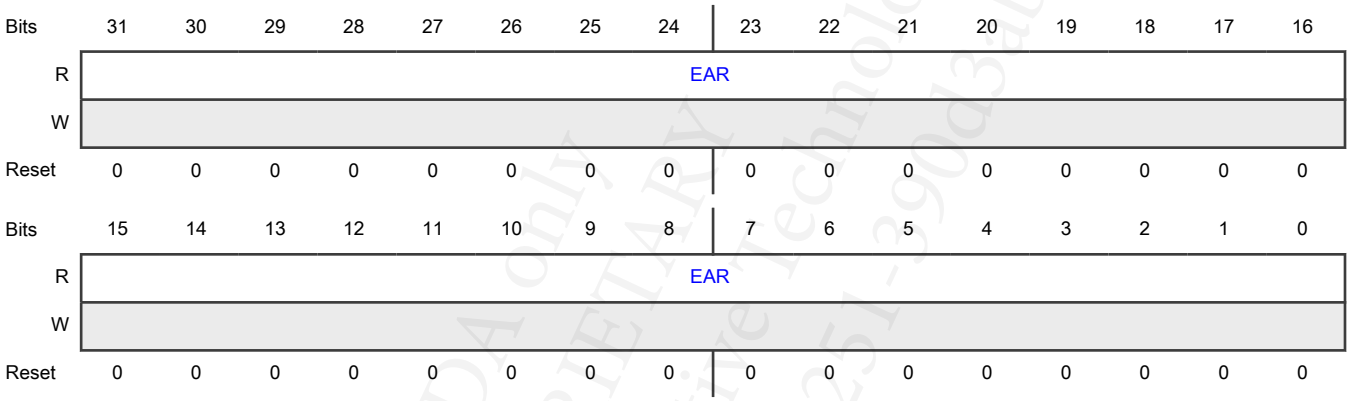
65.16.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset



For a = 0 to 16:

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

Fields

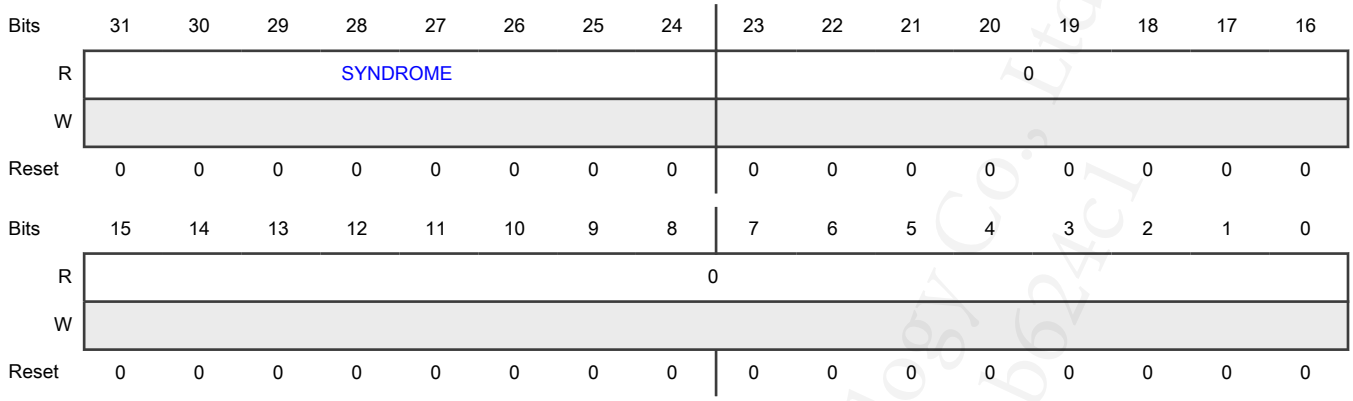
Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.16.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:

Register	Offset
SYNa	104h + (a × 10h)



Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
8c462e5-4021-48a8-b251-590a3b624c1

position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram

Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.

CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT16	208h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.17 ERM_PFE3 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

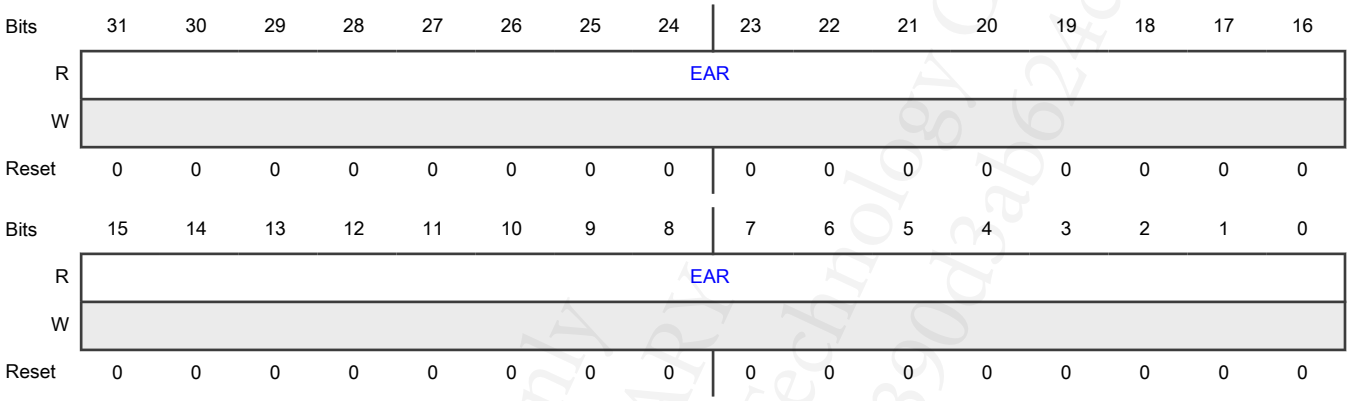
65.17.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset

For a = 0 to 16:



Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c462e5-4821-48a8-b251-390d3ab624c1

Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram

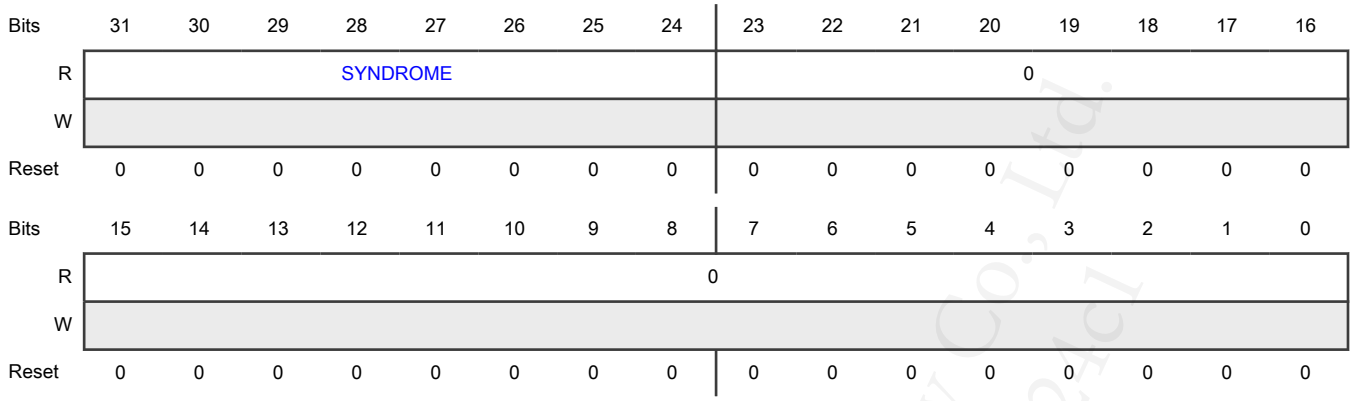
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.17.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Provided under NDA only

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.18 ERM_PFE4 register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

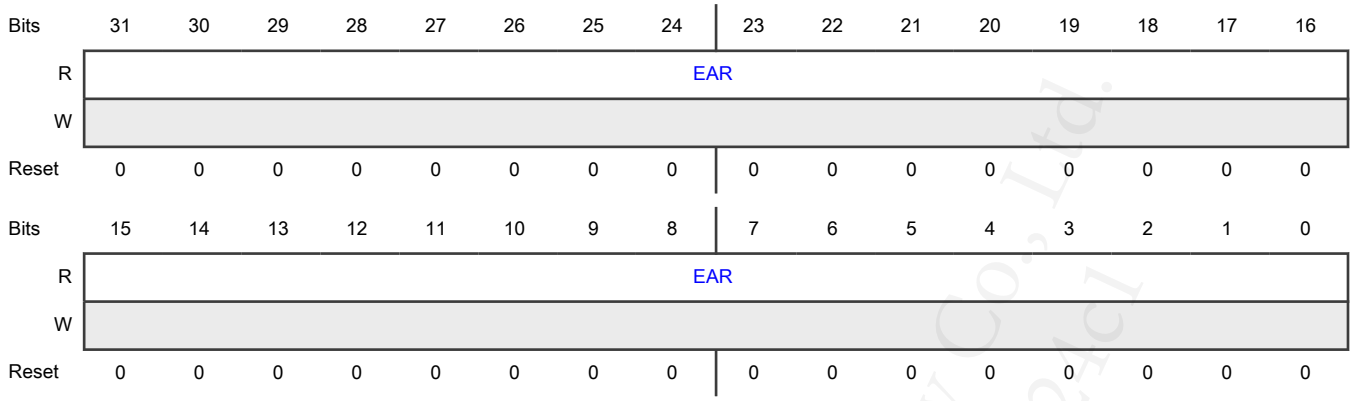
65.18.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset

For a = 0 to 16:



Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

Diagram

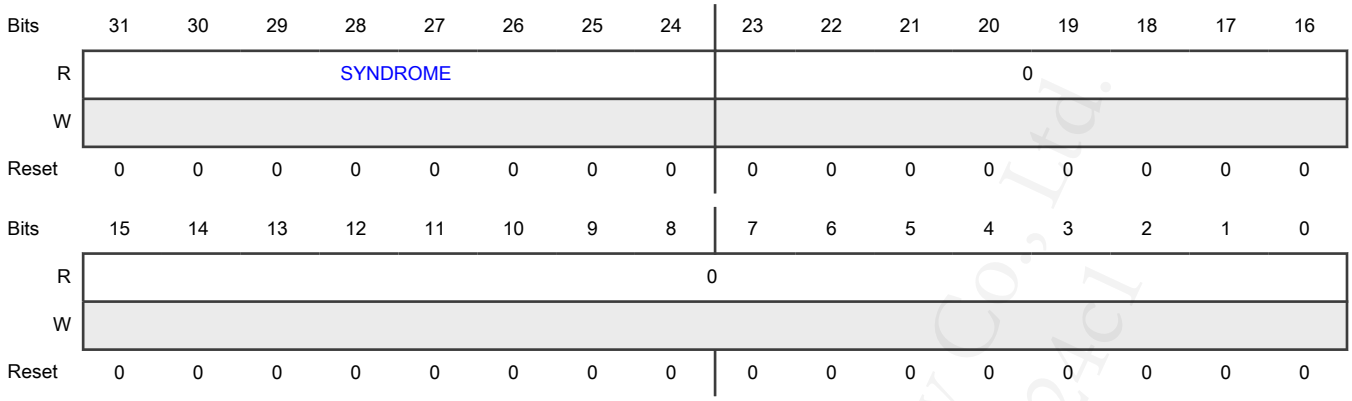
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.18.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT16	208h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.19 ERM_PFE5 register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

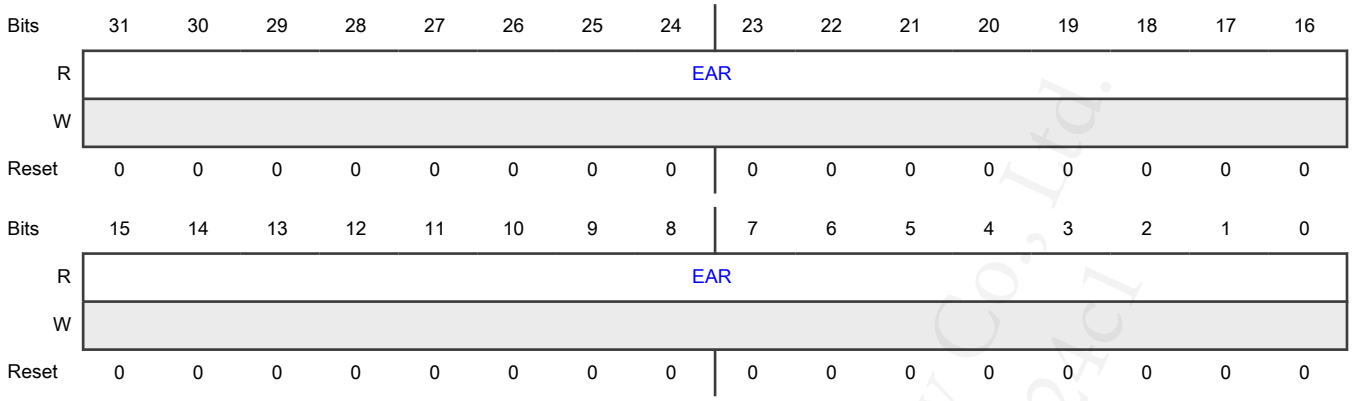
65.19.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset

For a = 0 to 16:



Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

Diagram

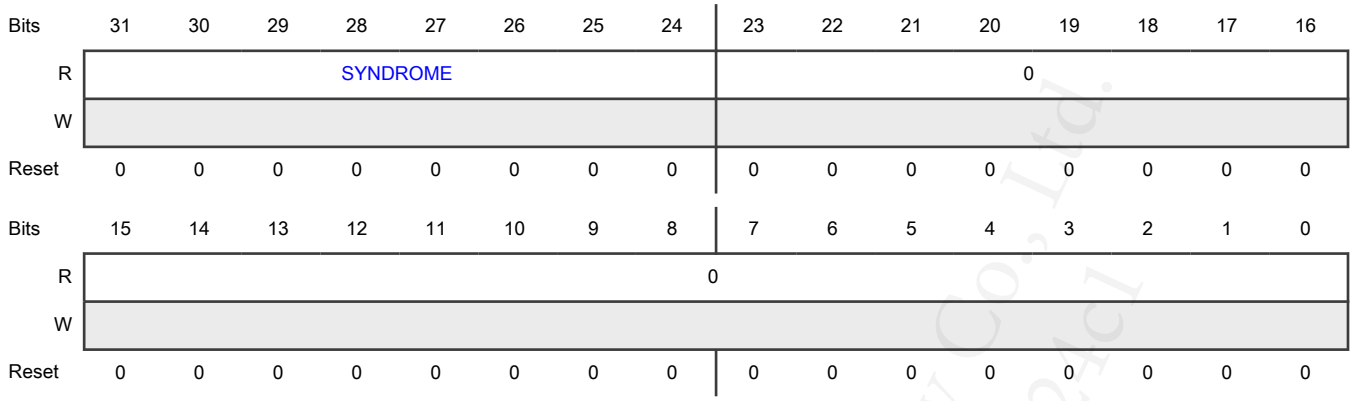
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.19.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.20 ERM_PFE6 register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

65.20.2 ERM Configuration Register 0 (CR0)

Offset

Register	Offset
CR0	0h

Function

This 32-bit control register configures the interrupt notification capability for:

- Channel 0
- Channel 1
- Channel 2
- Channel 3
- Channel 4
- Channel 5
- Channel 6
- Channel 7

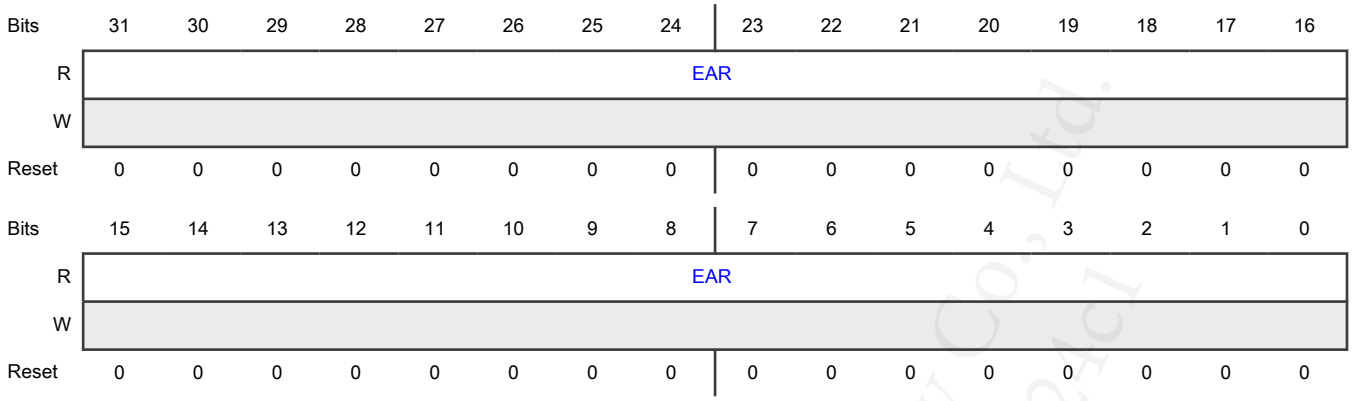
65.20.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset

For a = 0 to 16:



Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.

Diagram

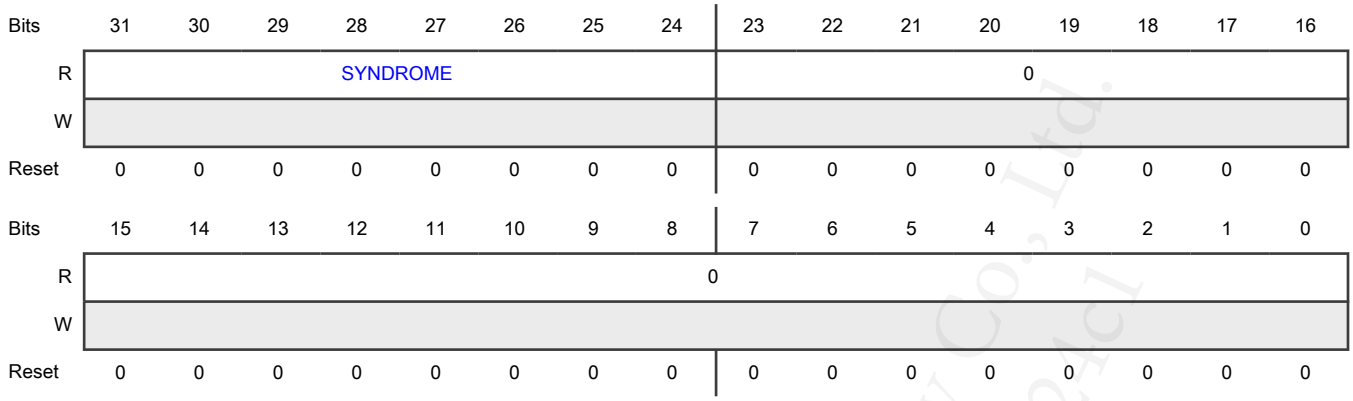
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.20.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.21 ERM_PFE7 register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

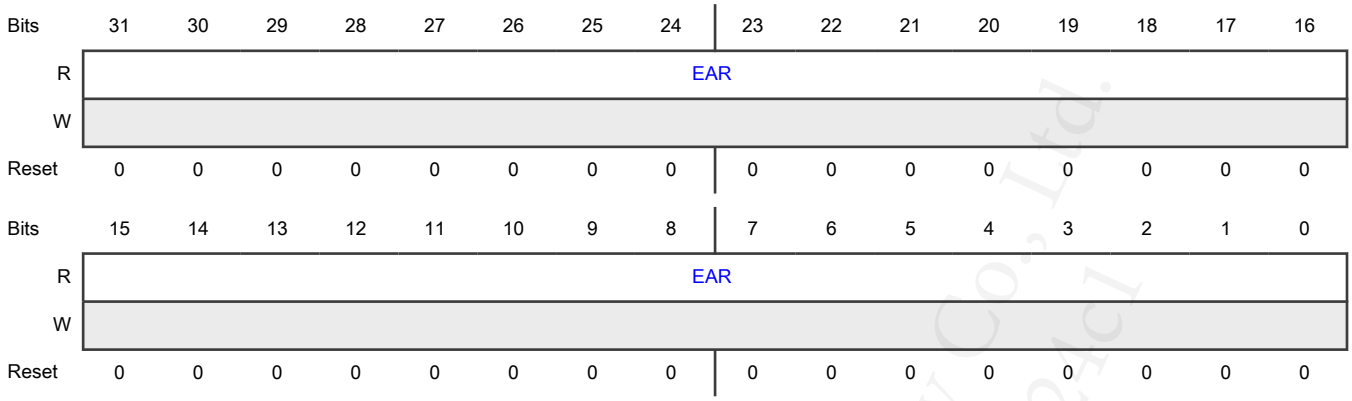
65.21.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset

For a = 0 to 16:



Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Provided under NDA only

Diagram

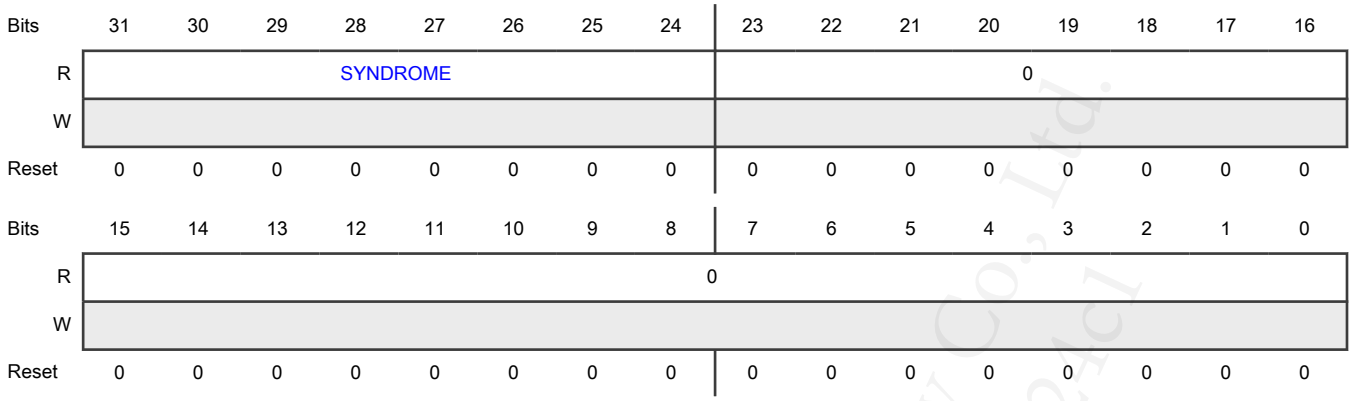
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.21.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.22 ERM_PFE8 register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

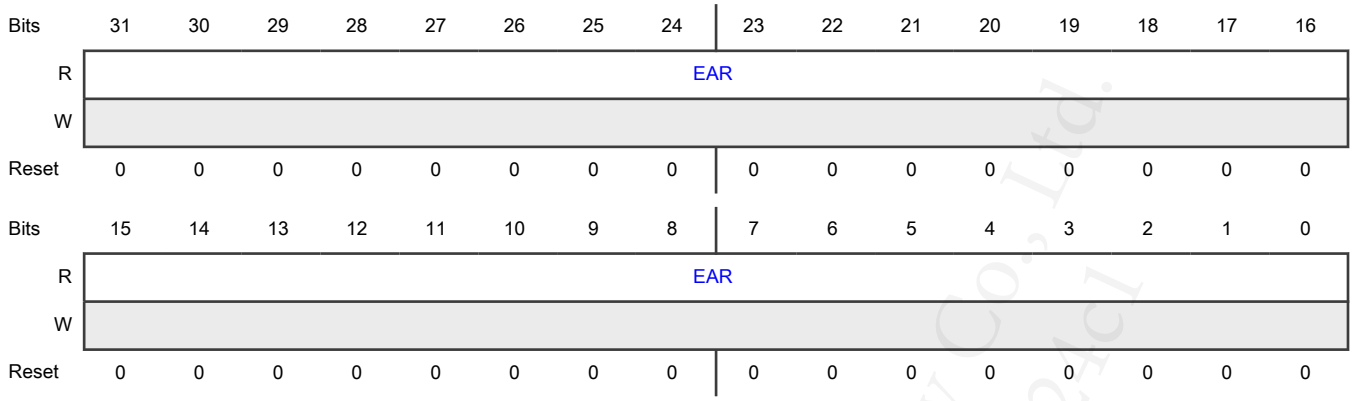
65.22.8 ERM Memory a Error Address Register (EAR0 - EAR16)

Offset

For a = 0 to 16:



Register	Offset
EARa	100h + (a × 10h)

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHJ Automotive Technology Co., Ltd.
c8c4625-4821-48a8-b251-390d3ab624c1

Diagram

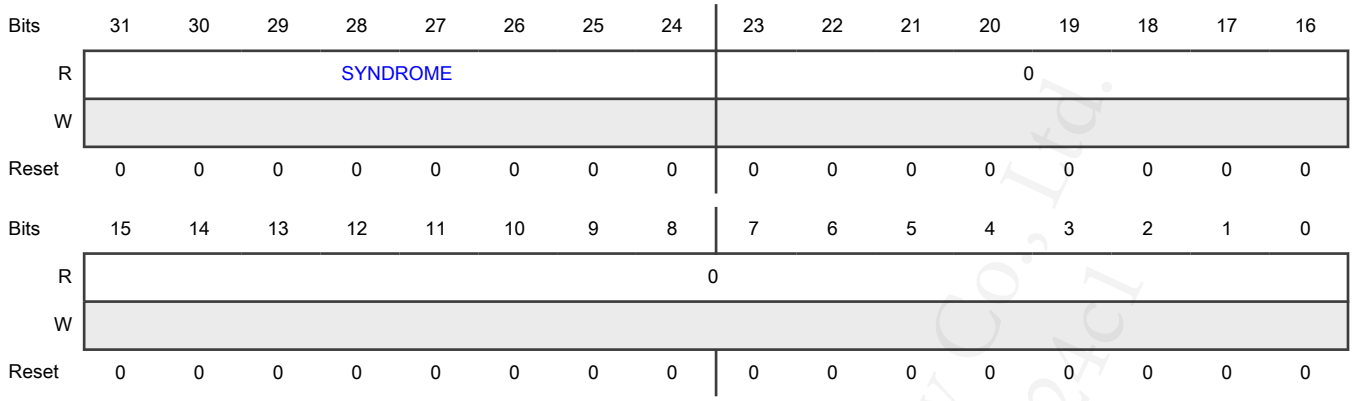
Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.22.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT16	208h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.23 ERM_PFE9 register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

Field	Function
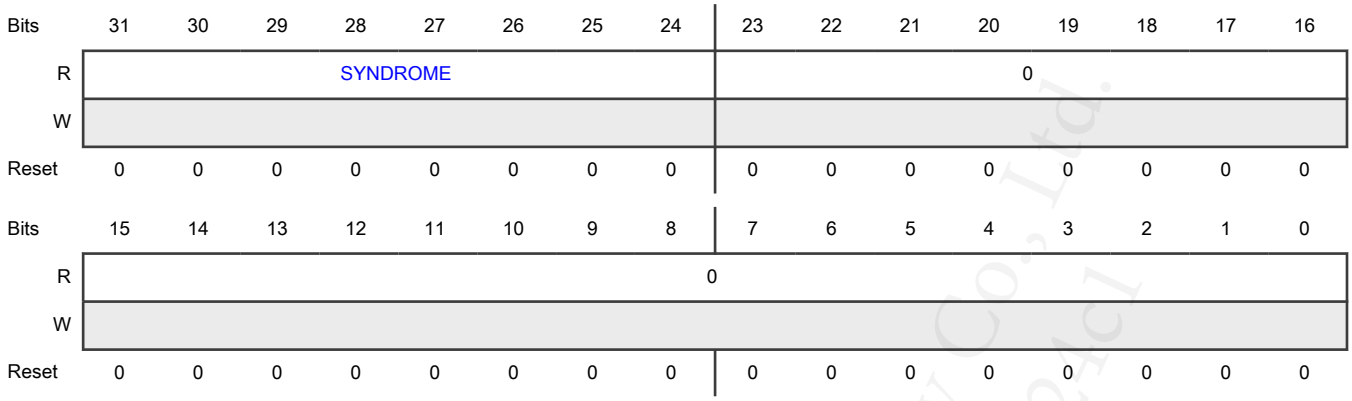
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.23.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

For a = 0 to 16:



Register	Offset
SYNa	104h + (a × 10h)

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

CORR_ERR_CNT16	208h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.24 ERM_STDBY_SRAM register descriptions

You can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

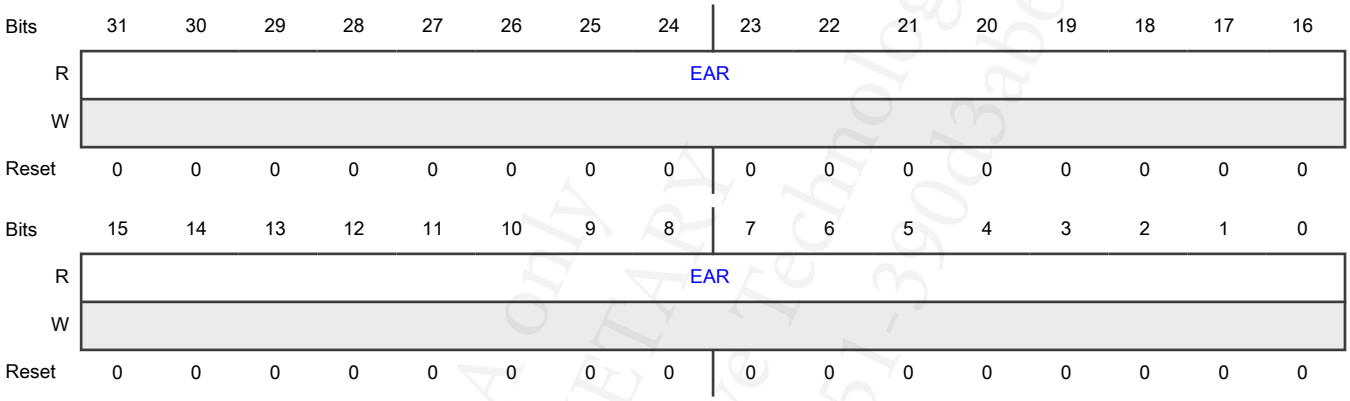
65.26.4 ERM Memory 0 Error Address Register (EAR0)



Offset

Register	Offset
EAR0	100h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

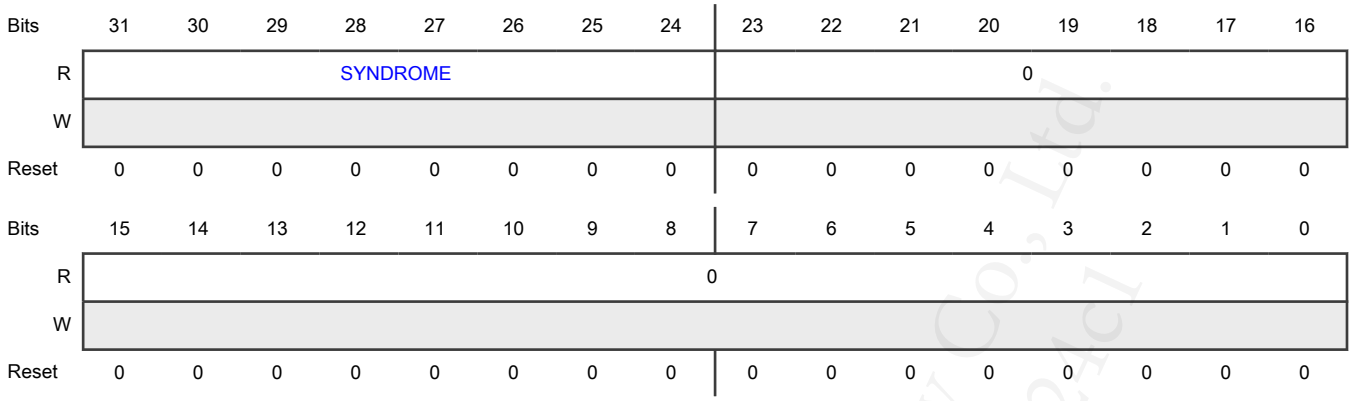
Diagram

Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.26.5 ERM Memory 0 Syndrome Register (SYN0)

Offset



Register	Offset
SYN0	104h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

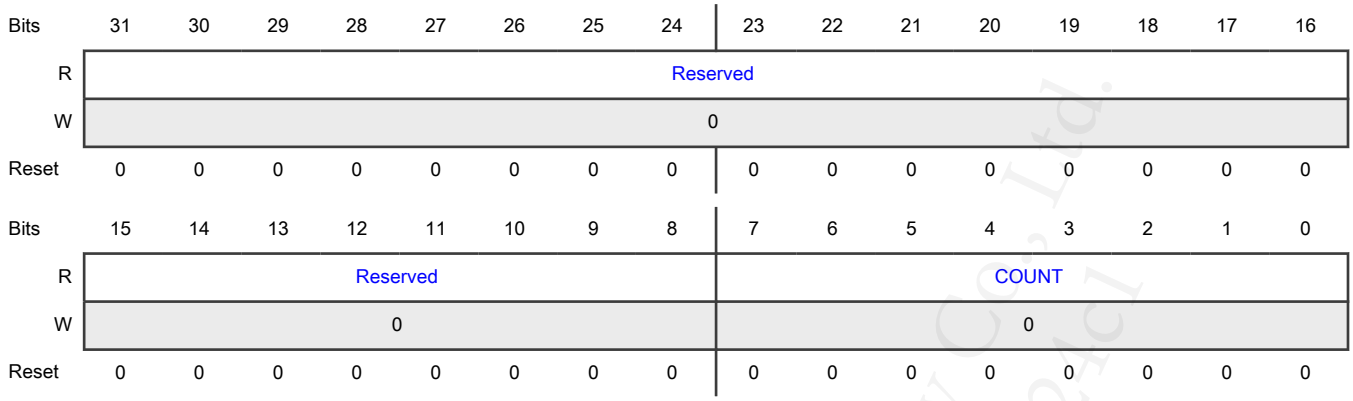
65.26.6 ERM Memory 0 Correctable Error Count Register (CORR_ERR_CNT0)

Offset



Register	Offset
CORR_ERR_CNT0	108h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Provided under NDA only
COMPANY PROPRIETARY
Beijing CHT Automotive Technology Co., Ltd.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.27 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

Fields

Field	Function
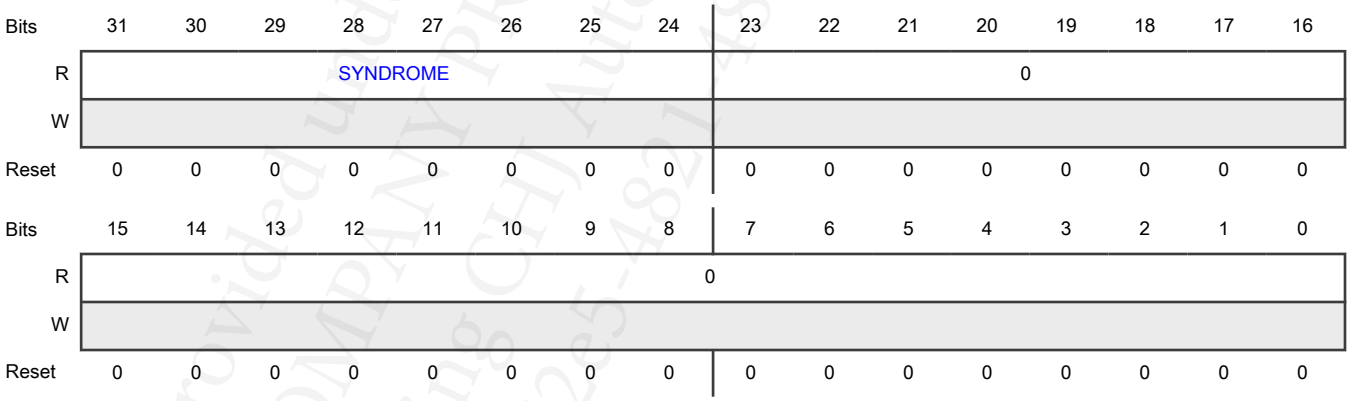
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

65.27.7 ERM Memory a Syndrome Register (SYN0 - SYN6)



Offset

Register	Offset
SYN0	104h
SYN1	114h
SYN3	134h
SYN4	144h
SYN5	154h
SYN6	164h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

65.28 Functional description

65.28.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. This sequence describes how to use the option:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

65.28.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).

- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. This sequence describes how to use the option:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event and address and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

65.29 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

65.30 Glossary

ECC	Error correction code

Chapter 66
Fault Collection and Control Unit (FCCU)

66.1 Chip-specific FCCU information

66.1.1 Chip-boundary FCCU signals

The EOUT0 and EOUT1 signal are used to notify the internal MCU state to the system.

FCCU signal	Chip signal
EOUT0	FCCU_F0
EOUT1	FCCU_F1

66.1.2 Fault mapping

All the FCCU faults support set or clear injection by FCCU. See the Fault map file attached to this document.

66.1.3 Clock frequency

The FCCU SAFECLK is the RC oscillator. The RC oscillator clock is used to have an independent clock source. The RC oscillator clock frequency is 48 MHz.

66.1.4 FOSU timer interval

The FCCU Output Supervision Unit (FOSU) module timer interval is determined by the value of FOSU_COUNT. On this chip, FOSU_COUNT is 0x69780.

66.1.5 CFG register event bit values by source (C)

For each bit in the FCCU_CFG register, this table specifies the value of *C*, a chip-specific value provided by the bit's associated constant inside the module.

Bit	C
31	0
30	0
29	0
28	0
27	0

66.1.6 Supported internal chip reactions

The short functional reset mentioned in this chapter is equivalent to the chip functional reset that is mentioned throughout this document.

66.1.7 Supported FCCU EOUT fault output modes (protocols)

This chip supports only the Bistable fault-output mode of FCCU EOUT. Other EOUT fault-output modes and protocols mentioned in this chapter are not supported on this chip.

66.1.8 Recommended reaction for the fault NCF[21] NoC Mission_Fault_0

The NCF reaction for NoC Mission_Fault_0 should be configured as alarm interrupt only and never as functional reset, and then a software destructive reset inside the interrupt sub-routine must be configured to clean up the chip out of fault state.

66.1.9 NCFs reaction restriction

The fault reaction for the NCFs 47, 48, 49, 59, 60, 61, 62 and 63 should not be configured as functional reset. It should be either alarm interrupt or NMI. In interrupt sub-routine, further reaction to create the necessary destructive reset or PoR or software clearing can be performed to clear up the NCF source.

66.1.10 Clearing FCCU faults

Below are the steps to clear an FCCU fault:

1. NCFx is asserted(through source / fake fault).
2. NCFx status gets set in FCCU.
3. After proper reaction from FCCU, FCCU tries to clear the status. Due to addition of pipes, the NCF takes 2-3 cycles to get deasserted.
4. By writing twice to the NCF status register, the fault is cleared.

66.2 Introduction

The FCCU provides a hardware interface to collect faults and to place the device into a safe state when a failure is detected in the device. No CPU intervention is requested for collection and control operations. FCCU offers a systematic approach to fault collection and control.

66.3 Features

The key features of the FCCU module are these:

- Management of non-critical faults
- HW or SW fault recovery management
- Fault collection from safety relevant modules on the device
- Fault injection (fake faults)
- Collection of test results
- Lockable configuration
  - Changes are only possible after entering the CONFIG state
  - Supports a transient and a permanent lock
  - Configuration changes observed by a watchdog timer
- Configurable fault control

- External reaction (FAULT state): EOUT signaling. Error indication via the pin(s) is controlled by FCCU.
- Internal chip reactions (ALARM state): interrupt request
- Configurable internal chip reactions for each NCF (FAULT state):
  - Short functional reset request pulse
  - NMI
  - No reaction
  - IRQ
- In Bi-Stable operational mode, one of the EOUT signals is high to indicate an OK operational state of FCCU.
