WHAT STARTS HERE CHANGES THE WORLD

Controlled Inputs x_1, x_2, \dots

Uncontrolled but observed Inputs u_1, u_2, \dots

Uncontrolled and unobserved Inputs v_1, v_2, \dots

Process

Outputs y_1, y_2, \dots

Nuisance inputs: inputs we don't care about, but that affect the outputs

Modeling (characterization): How do inputs affect the output?

Optimization: What input values produce the desired outputs (both mean and variance)?

Control: How do we adjust controlled inputs to maximize control of the outputs?

WHAT STARTS HERE CHANGES THE WORLD

Dealing with the Three Types of Inputs

- Controlled Inputs (x)
 - Variation + repeats/replication:** vary the inputs and repeat the experiments in a systematic way
- Uncontrolled but Observed Inputs (u)
 - Blocking:** group experiments into blocks, each block having a fixed value of u
 - Analysis of covariance:** Model the impact of u , then subtract it out from the model
- Uncontrolled and Unobserved Inputs (v)
 - Randomization:** for sufficiently large sample sizes, let impact of v average out to zero

WHAT STARTS HERE CHANGES THE WORLD

What is Experimental Design?

- We design our experiments to get the most information from the least data (that is, minimize time and cost)
- Experiment:** the deliberate variation of one or more process variables while observing the effect on one or more response variables
- Design of Experiments (DOE):** a procedure for planning experiments to efficiently provide valid conclusions
 - Does the experiment have enough statistical power to answer the research questions?

WHAT STARTS HERE CHANGES THE WORLD

Uses of Design of Experiments

- DOE can be used for **exploratory work**
 - Choosing between alternatives (comparison)
 - Selecting the key factors that affect a response (screening)
- DOE can be used to **optimize** a given process (response surface modeling)
 - Hitting and controlling a target response with minimum variability
 - Maximize or minimize a response or goal
 - Increase process robustness
- DOE can be used for **regression/modelling**

WHAT STARTS HERE CHANGES THE WORLD

DOE for Regression

- For a given n (number of data points), pick values of the predictor variables in the experiment to produce some desired statistical behavior
 - The smallest standard errors of the coefficients
 - The smallest standard errors of the predictions
 - Others
- Called **Optimal Design**
 - In general, this requires a numerical search

WHAT STARTS HERE CHANGES THE WORLD.

DOE for Simple Linear Regression

- Example: optimize for the smallest standard errors of the coefficients
- Consider a straight line model with one predictor variable

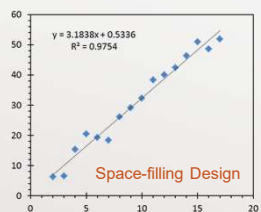

$$s_{b1}^2 = \frac{s_\varepsilon^2}{\sum_{i=1}^n (x_i - \bar{x})^2} \quad s_{b0}^2 = \frac{s_\varepsilon^2}{n} + s_{b1}^2 \bar{x}^2$$
- The lowest $SE(b_1)$ is obtained by picking half of the data points to be at the lowest x-value, and half of the data points to be at the highest data value (dumbbell design)
 - We should space the x-values more evenly only if we wish to check whether the model is correct

DOE for Simple Linear Regression

Space-filling Design

$SE(b_1) = 0.135$

Dumbbell Design

$SE(b_1) = 0.080$

WHAT STARTS HERE CHANGES THE WORLD.

DOE for Regression

- For a straight line model with one predictor
 - Dumbbell Design:** $SE(b_1) = \frac{\sigma_\varepsilon}{\sqrt{n}(x_{max} - x_{min})/2}$
(1/2 at each extreme)
 - Space-filling Design:** $SE(b_1) = SE_{dumbbell} \sqrt{3 \left(\frac{n-1}{n+1} \right)}$
(data spaced evenly apart)
 - Quadratic Design:** $SE(b_1) = S_{dumbbell} \sqrt{3/2}$
(1/3 at each end, 1/3 in middle)

Experimental Design Leverage

- An important goal of Design of Experiments (DoE) is to equalize the **leverage** of every point during multiple regression
 - We want to make $h_{ii} = \bar{h}_{ii} = \frac{p}{n}$ for every i
- For the case of only one predictor variable,

$$h_{ii} = \frac{1}{n} + \frac{(x_i - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{2}{n}$$

We want: $(x_i - \bar{x})^2 = \text{same for each } i$

WHAT STARTS HERE CHANGES THE WORLD.

Six Principles for Regression Design

(NIST/SEMATECH e-Handbook of Statistical Methods, section 4.3.3)

- Capacity for the primary model
- Capacity for the alternate model
- Minimum variance of estimated coefficients or predicted values
 - Except for simple cases, must search for optimal design
- Sample where the variation is
- Repeats and replication
 - To compute a model-independent estimate of the process standard deviation
- Randomization and blocking
 - Allows the detection of drift, reduces influence of known/unknown but unimportant variations

WHAT STARTS HERE CHANGES THE WORLD.

Lecture 64: What have we learned?

- Name the three types of inputs to a process
- Define design of experiments
- What are the three uses of experimental design?
- For regression to a straight line, what is the most efficient design?
- For regression to a straight line, what design produces uniform leverage?
